Abbreviations: Acute MI: Acute Myocardial Infarction, CKD: Chronic Kidney Disease, ESRD: End-Stage Renal Disease, GLP-1: glucagon-like peptide-1 agonists, LN: Lupus Nephritis, RR: Relative Risk, SGLT 2: sodium-glucose cotransporter-2 inhibitors, 95% CI: 95% Confidence Interval ; a- Propensity matched cohorts based on baseline demographics, comorbidities, and medication use. ; b- All patients with outcomes that occurred prior to the time window were excluded from our cohorts.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

aimed to evaluate the effect of GLP-1 (glucagon-like peptide-1) agonists compared to SGLT2 (sodium-glucose cotransporter-2) inhibitors on the outcomes in patients with Lupus Nephritis using the TriNetX database which included electronic healthcare records from over 142 global collaborative healthcare organizations.

Methods: The study utilized patients 18 years or older with a diagnosis of LN (Lupus Nephritis) using the International Classification of Diseases, Tenth Revision (ICD-10) codes. Two different cohorts were created: the first cohort consisted of patient with LN who were on SGLT2 inhibitors, and the second cohort consisted of patients with LN who were on GLP-1 agonists. The index event in study was defined as the initial diagnosis of LN, later followed by three years of exposure to either SGLT-2 inhibitors or GLP-1 agonists. Propensity matching was used for the age at index, gender, race/ethnicity, comorbidities (hypertension, obesity, diabetes, tobacco use), and medications (DMARDS, steroids, biologics, statins, aspirin).

Results: A total of 1,375 patients with LN on SGLT2 inhibitors, and 1,034 patients with LN on GLP-1 agonists were reviewed. Before propensity matching was performed, patients on SGLT2 inhibitors were older (mean age of 51.9 vs. 48.2), consisted of more females (1,043 vs. 884), had more patients with hypertension (1,170 vs. 837), and consisted of mostly Black/African American patients when compared to the GLP-1 agonist group which consisted of mostly White patients. After propensity matching, 1,021patients were excluded, and a total of 694 patients remained in each group. Results showed that the group of patients with LN who were on GLP-1 agonists had reduced progression of chronic kidney disease (RR: 1.526, 95% CI: 1.179-1.976, p= 0.0014), decreased mortality (RR: 2, 95% CI: 1.239-3.227, p=0.0037), and a decreased risk of acute myocardial infarctions (RR: 2.248, 95% CI: 1.294-3.904, p=0.0030).

Conclusion: The findings suggest that patients with Lupus Nephritis taking GLP-1 receptor agonists have a reduced risk of mortality, acute myocardial infarctions, and a decreased progression of CKD compared to patients taking SGLT-2 inhibitors. Further research should be conducted with larger groups, and with longer follow up time to confirm and possibly explain any potential explanations or contributing factors.

Abstract Number: 0842

Association of Urinary Biomarkers with Histological Features in Diagnostic and Per-protocol Repeat Kidney Biopsies in Lupus Nephritis

Andrea Fava[1], CHEN-YU LEE[1], Carla Guthridge[2], Dionysis Nikolopoulos[3], Julius Lindblom[4], Farah Tamirou[5], Michelle Petri[6], Joel Guthridge[2], Frederic Houssiau[7] and Ioannis Parodis[8], [1]Johns Hopkins University, Baltimore, MD, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Cliniques universitaires Saint-Luc, Brussels, Belgium, [6]Johns Hopkins University School of Medicine, Timonium, MD, [7]CUSL, BRUSSELS, Belgium, [8]Karolinska Institutet and Karolinska University Hospital, Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden

SESSION INFORMATION

Session Date: Sunday, October 26, 2025

Session Title: Abstracts: Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes I: Advances in Nephritis (0837–0842)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Persistent intrarenal inflammation despite immunosuppression drives kidney damage and functional decline in lupus nephritis (LN). Yet, current guidelines do not recommend repeat biopsy to assess treatment response, relying instead on proteinuria, which does not reflect histological activity in >50% of cases. Urinary biomarkers are emerging

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. *NA: Non-available

as a promising alternative to assess histological activity and predict long-term renal outcomes. We evaluated candidate biomarkers previously linked to histological activity and risk of renal function loss in LN patients undergoing per-protocol repeat kidney biopsies one year after treatment initiation.

Methods: Twenty LN patients enrolled in Belgium and Sweden underwenta diagnostic and a per-protocol kidney biopsy one year after diagnosis. Treatment was discretionary. Urine samples were collected at time of diagnosis and one-year repeat biopsy, and profiled using Olink Explore HT (5416 proteins). Four candidate biomarkers were selected based on prior associations with histological activity (IL16, soluble CD163), renal function loss (Tenascin C), or B cell activity (BAFF).

Results: At baseline, 18/20 (90%) had ISN/RPS class III or IV +/- V LN and 2/20 (10%) pure class V (**Table 1**). Paired biopsies at one year were available for 18 patients (16 proliferative): one biopsy was unsuccessful, and one patient declined repeat biopsy. After one year of treatment, only 6/16 (37%) patients transitioned from proliferative to non-proliferative

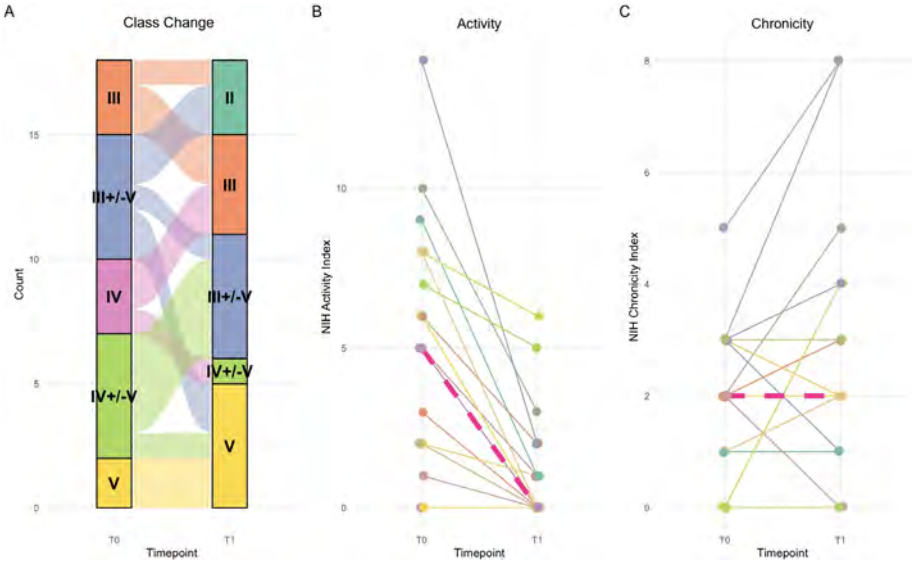

Figure 1. Transition of lupus nephritis (LN) class and histologic indices from baseline to one-year repeat biopsy. (A) Alluvial plot shows individual transitions in ISN/RPS class from T0 to T1, highlighting class change from proliferative to non-proliferative LN. (B) Individual paired trajectories of NIH activity index, showing reduction at T1 for all patients with Activity Index >0 at baseline. (C) Chronicity index at T0 and T1. The medians of the NIH Activity and Chronicity Indices at T0 and T1 are shown by the pink dashed line. Only patients with paired biopsies included (n=18)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Correlation between urinary biomarkers and histologic activity at baseline (T0) and follow-up (T1). (A) All patients. (B) Subset with proliferative lupus nephritis. Proteins are expressed as normalized protein expression (NPX) and normalized by plate-controls. Correlation with NIH Activity Index was assessed using Spearman's rank correlation. P.adjust indicates the p value after adjusting for urine creatinine (linear model). For BAFF, most of the variability contributing to the correlation was in the lower range and not well visualized on the scale shown; the scale was kept unchanged for consistency across plots. UPCR: urine protein-to-creatinine ratio.

classes, but the NIH Activity Index declined in all proliferative LN patients (**Figure 1**). Although the NIH Chronicity Index increased in several patients, the median value remained unchanged because of improved scores in a subset. At one year, 10/16 (62%) patients still had persistent proliferative LN but only 6/16 (37%) had an activity index $\geq$2.

Proteinuria did not correlate with histological activity at baseline or at one year (**Figure 2**). At baseline, urinary IL-16 and sCD163 correlated with histological activity, especially in proliferative LN, but these associations diminished at follow-up. In contrast, urinary Tenascin C (a marker of myofibroblast activation) and BAFF were associated with histological activity at one year .

Conclusion: Urinary IL16 and sCD163 correlated with histological activity at diagnosis, whereas Tenascin C and BAFF associated with histological activity at one year, suggesting a potential temporal shift in dominant inflammatory pathways—from macrophage-driven inflammation to stromal activation and B cell persistence. Notably, urinary sCD163 at one year has been shown to predict future renal function loss but it was not correlated with one-year histological activity, highlighting a disconnect between histological and urinary predictors of outcome. This underscores the value of urinary biomarkers as complementary tools that may capture molecular activity missed by biopsy. Given the limited sample

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. size, these findings require validation in larger cohorts. Together, these results support urinary biomarkers as a noninvasive strategy to complement histologic and clinical assessment, offering insight into disease activity not always reflected by traditional measures.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical I (0843–0848)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: BMS-986353 (CC-97540) is an investigational CD19-directed T-cell therapy expressing the chimeric antigen receptor (CAR) used in globally-approved lisocabtagene maraleucel; it is manufactured via the NEX-T™ process to shorten manufacturing time and optimize phenotypic attributes. Early data from Breakfree-1 trial (NCT05869955) in severe, refractory autoimmune diseases (ADs) showed promising efficacy and manageable safety with BMS-986353.[1] Here, we report updated data on BMS-986353 in the SSc cohort.

986353 at 10×10^6 (dose level [DL] 1) or 25×10^6 (DL2) CAR+ T cells after lymphodepletion. Primary endpoint was safety.

Results: As of April 7, 2025, 14 pts with SSc were enrolled; 9 pts received BMS-986353 (DL1, n = 8; DL2, n = 1), with a median follow-up of 115.5 days (range 42–295) for DL1 and 168 days for DL2. Median age: 54.5 years for DL1, 41 years for DL2. Prior therapies: median 2 (range 1–5) for DL1 and 3 for DL2. At baseline, DL1 pts had a median modified Rodnan skin score (mRSS) of 18.0 and Physician's Global Assessment (PGA) score of 7.0; scores for the DL2 pt were 7.0 and 4.0, respectively. ILD was present in 6 pts. Eight pts were efficacy evaluable (7 DL1, 1 DL2).

All inflammatory AEs (iAE) reported were low grade. In DL1, 50.0% of pts had cytokine release syndrome (CRS; 3 grade 1, 1 grade 2) with a median duration of 2.0 days; 1 pt had grade 1 immune effector cell-associated neurotoxicity syndrome (ICANS) that resolved in 3 days (**Table**). There were 4 transient, self-resolving grade ≥ 3 hematologic TEAEs in DL1 pts; none in DL2. There were no prolonged grade ≥ 3 cytopenias, dose-limiting toxicities, or treatment-related infections.

In DL1, median increase from baseline in absolute forced vital capacity in all patients was 3.0% on day 85 (n = 3) and 7.0% at day 169 (n = 3). In DL1, median reduction in mRSS across all pts with diffuse cutaneous SSc regardless of baseline mRSS was 14.0 points at day 85 (n = 3) and 11.5 at day 169 (n = 2) (**Figure 1**). Median reduction in PGA from baseline was 3.0 points on day 85 (DL1 n = 4; DL2 n = 1) and 4.5 on day 169 (DL1 n = 2). Improvement from baseline in revised Composite Response Index in Systemic Sclerosis was achieved in 3/3 pts at day 85 and day 169. All pts had robust CAR T cell expansion and achieved complete peripheral B-cell depletion (**Figure 2**).

Conclusion: BMS-986353 showed an acceptable safety profile and preliminary meaningful improvement in skin thickening and lung function in pts with severe, refractory SSc. iAEs were grade 1/2 and resolved quickly. Updated safety, efficacy, and translational data will be presented.

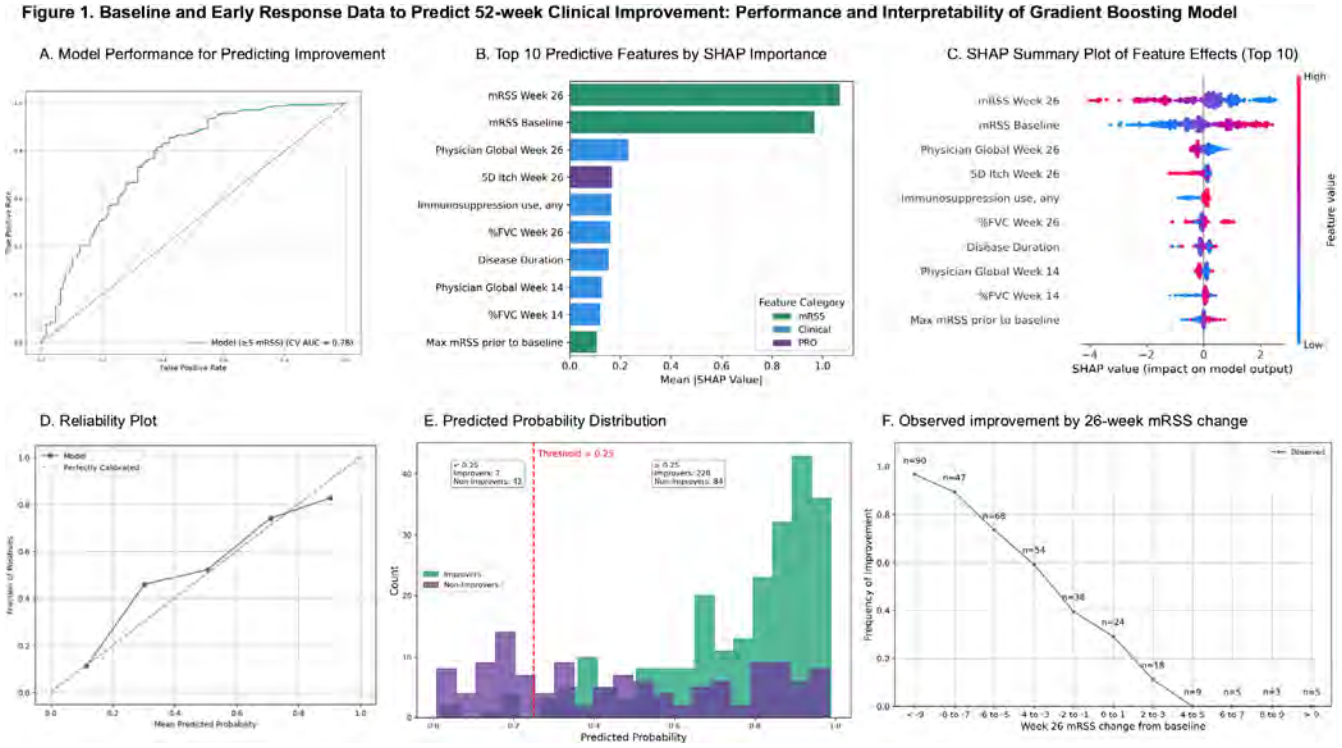

Figure 1. Baseline and early response data to predict 52-week clinical improvement among individuals with diffuse cutaneous systemic sclerosis: Performance and interpretability of gradient boosting model. A. Receiver Operating Characteristic Curve for machine learning model to predict 52-week clinical improvement (at least 5-point modified Rodnan skin score (mRSS) improvement at week 52) with cross-validated area under the curve (AUC) of 0.78. B. Top 10 features ranked by mean SHAP importance. (C) SHAP summary plot illustrates individual feature effects on model predictions. Each dot represents a single patient; red represents high values; blue represents low values. Positive SHAP values contribute to higher probability of clinical improvement, while negative SHAP values contribute to lower probability. D. Reliability plot indicating good agreement between predicted and observed outcomes. E. Histogram of predicted probabilities for 52-week improvers and non-improvers with threshold of 0.25 shown. F. Frequency of 52-week improvement according to baseline to 26-week mRSS change.

of this study is to develop a model for predicting 52-week cutaneous improvement in dcSSc using clinical data collected at baseline, 14, and 26 weeks.

Methods: Clinical data were analyzed from 361 individuals enrolled in RESOLVE-1 (Lenabasum Phase III trial). Cutaneous improvement was defined as ≥5-point decrease in modified Rodnan skin score (mRSS) from baseline to 52 weeks. Characteristics were compared between improvers and non-improvers using Fisher's exact or Wilcoxon rank-sum, as appropriate. A gradient boosting, supervised machine learning model was developed for predicting improvement. 43 candidate predictors were selected by expert opinion and included baseline, 14-, and 26-week data. Model discrimination for classifying improvement status was assessed using area under the receiver operating characteristic curve (AUROC) with five-fold cross-validation. To enhance interpretability, the Shapley Additive exPlanations (SHAP) method was used to visualize the magnitude and directionality of features' individual impact on predictions. A reliability plot was generated to compare predictions to observed outcomes. Observed 52-week improvement was plotted by baseline to 26-week mRSS change.

Results: Of 361 patients with dcSSc, 235 (65%) improved. Immunosuppression (any) and mycophenolate mofetil use were more common among improvers vs. non-improvers **(Table 1)**. By 26-weeks, 52-week improvers had lower physician global ($p< 0.001$), 5D-Itch ($p=0.012$), and Scleroderma Skin Patient Reported Outcome (total score) ($p=0.028$) vs. non-improvers. By both week 14 and 26, 52-week improvers had significantly lower mRSS vs. non-improvers (17 vs. 18, $p=0.025$; 15 vs. 18, $p< 0.001$).

The model accurately predicted 52-week cutaneous improvement with a cross-validated AUROC of 0.78 (**Fig. 1A)** and good reliability (**Fig. 1D**). The top 10 predictive features by mean SHAP value are shown in **Fig. 1B**, with mRSS at week

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

26 and baseline as the two most important features. Higher week-26 mRSS contributed to lower improvement prediction, whereas higher baseline mRSS contributed to higher improvement prediction **(Fig. 1C)**. Predicted probabilities for improvers and non-improvers are shown in **Fig. 1E**. Applying a probability threshold of 0.25 identifies improvers with a sensitivity of 97% (i.e., only 3% of improvers below 0.25 threshold at 26 weeks) and a negative predictive value of 0.86 (i.e., of those predicted to be non-improvers, 86% did not improve). 52-week improvement was uncommon among those who had not experienced any mRSS decline by week 26 (**Fig. 1F**).

Conclusion: Improvement in mRSS at 52 weeks can be reliably predicted using baseline and early follow-up data, identifying those unlikely to improve on current therapy. This model may inform personalized clinical decision making as well as adaptive trial designs with early exit strategies for those highly unlikely to improve.

SESSION INFORMATION
Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical I (0843–0848)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Systemic Sclerosis (SSc) is a clinically and molecularly heterogeneous autoimmune disease. We identified five intrinsic molecular subtypes in SSc by applying semi-supervised machine learning methods to multiple transcriptomic cohorts. A supervised single-sample classifier was developed for subtype predictions. Here, this predictive classifier is validated in multiple independent datasets and is used to comprehensively assess the association between molecular heterogeneity of SSc and key clinical features, extending our previous SSc subtyping research.

Methods: We trained a stacked-ensemble model for intrinsic subtype prediction using GSVA enrichment scores in an integrated discovery cohort of 137 SSc and 37 Healthy participants (GSE9285, GSE32413, and GSE59787). Base learners were binary one-vs-all logistic regression models whose predicted probabilities were then combined by a Random Forest meta-learner. This model was applied to external DNA microarray and RNA-seq cohorts for assessment and validation. We tested associations between predicted subtypes and clinical features, such as FVC, DLCO, MRSS, ILD-risk, and autoantibody status. Discrete variables were compared with Odds Ratios (OR) test; continuous variables were tested using Wilcoxon rank-sum tests.

Results: We identified 5 intrinsic molecular subtypes of SSc through semi-supervised clustering and comparison to original publications. We identified an inflammatory-fibroproliferative group and an intermediate group between inflammatory and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Identification and prediction of SSc intrinsic subtypes using semi-supervised and supervised machine learning approaches. (A) Semi-supervised constrained k-means clustering in the integrated discovery cohort (MPH, n = 174) defines five intrinsic subtypes and refines the "mixed" group into "inflammatory-fibroproliferative" and "intermediate" (between normal-like and inflammatory) subtypes. Principal component analysis (PCA) of all discovery samples colored by the final three broad subtype calls (inflammatory, normal-like, fibroproliferative) demonstrates clear separation. (B) Heatmap showing the up- and down-regulated pathways for the identified subtype. (C) Receiver operating characteristic (ROC) curves for one-vs-rest classifiers on a 20% hold-out set yield AUROC = 0.94 (inflammatory), 0.90 (normal-like), and 0.85 (fibroproliferative). (D) Concordance of predicted subtypes in independent validation cohorts (DNA microarray) versus discovery labels, shown as confusion matrices and similarity metrics. (E) Concordance of predicted subtypes in ASSET RNA-seq cohort versus discovery reference samples.

normal-like, which may represent a transitional subtype (Fig. 1A). Gene sets were identified that were most predictive for each subtype (Fig. 1B). We used the three broad subtype labels for classification due to small sample numbers. The best models showed AUROC of 0.94, 0.90, and 0.85 for inflammatory, normal-like, and fibroproliferative subtypes, respectively (Fig. 1C). The final, three-class model is able to predict SSc subtypes in independent DNA microarray and RNA-seq cohorts with strong concordance to the discovery set (Fig. 1D-E).

Inflammatory patients were enriched for dcSSc ($p < 0.001$), had shorter disease duration ($p < 0.001$), and the highest MRSS ($p < 0.001$), exhibited increased ILD risk ($p< 0.01$) with reduced FVC/DLCO ($p < 0.01$), and were most likely to have RNA-polymerase III autoantibodies ($p < 0.01$)(Fig. 2). In contrast, Normal-like patients were enriched for lcSSc (OR ≈3.0, p<

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Clinical feature associations of intrinsic SSc molecular subtypes in MPH discovery set. (A) Disease duration (months) by subtype, shown as boxplots with Wilcoxon rank-sum p-values above each pairwise comparison. (B) Forest plot of odds ratios (95% CI) for diffuse cutaneous versus limited cutaneous SSc (dcSSc vs. lcSSc) for each subtype, relative to Normal-like (dashed vertical line at OR=1). (C) Modified Rodnan skin score (MRSS) by subtype, with p-values from Wilcoxon tests. (D–G) Forest plots of odds ratios (95% CI) for serologic and pulmonary categorical features: (D) RNA-polymerase III autoantibody, (E) anti-centromere autoantibody, (F) ANA positivity, and (G) interstitial lung disease (ILD) presence. (H–J) Pulmonary function measures (% predicted) by subtype—(H) FEV_1, (I) FVC, and (J) total lung capacity (TLC)—shown as boxplots with Wilcoxon test p-values. Subtype colors are fibroproliferative (red), inflammatory (purple), normal-like (green), and intermediate (yellow).

0.001), late-stage disease ($p < 0.01$), longer disease duration ($p < 0.001$), lowest MRSS ($p < 0.001$), showed reduced ILD risk ($p < 0.01$) and preserved lung function ($p < 0.01$), and were most likely to carry ACA ($p < 0.01$)(Fig. 2). An intermediate MRSS and pulmonary impairment were observed in Fibroproliferative patients ($p < 0.05$). These subtype-clinical patterns were largely recapitulated in 4 additional, independent cohorts (Hinchcliff 8 plex, PRESS, GENISOS, ASSET) (Fig. 3).

Conclusion: Our second-generation classifier robustly predicts intrinsic SSc subtypes across studies and platforms. Each subtype shows consistent, biologically meaningful associations with disease phenotypes, severity, and autoantibody profiles.

SESSION INFORMATION

Session Date: Sunday, October 26, 2025
Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical I (0843–0848)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Mycophenolate Mofetil (MMF) is the most commonly prescribed immunosuppressive treatment for patients diagnosed with diffuse cutaneous systemic sclerosis (dcSSc). Here, we analyzed skin gene expression data for the largest longitudinal scleroderma cohort treated with MMF. By applying intrinsic molecular subtype classification to these skin gene expression data, we evaluated longitudinal changes in skin and other clinical outcomes during treatment, demonstrating an association between SSc molecular intrinsic subtypes and disease course during MMF treatment.

Methods: We analyzed longitudinal gene expression of 761 skin biopsies from a cohort of 201 scleroderma patients (based on ACR/EULAR 2013 criteria) with clinically active disease (in the treating physician's opinion) and 57 healthy participants. Biopsies were obtained from lesional and non-lesional skin at baseline and at 6, 12, 24, and 36 months after start of MMF treatment initiation (Fig 1A). Clinical metadata including age, sex, ethnicity, autoantibodies, disease duration/stage, and

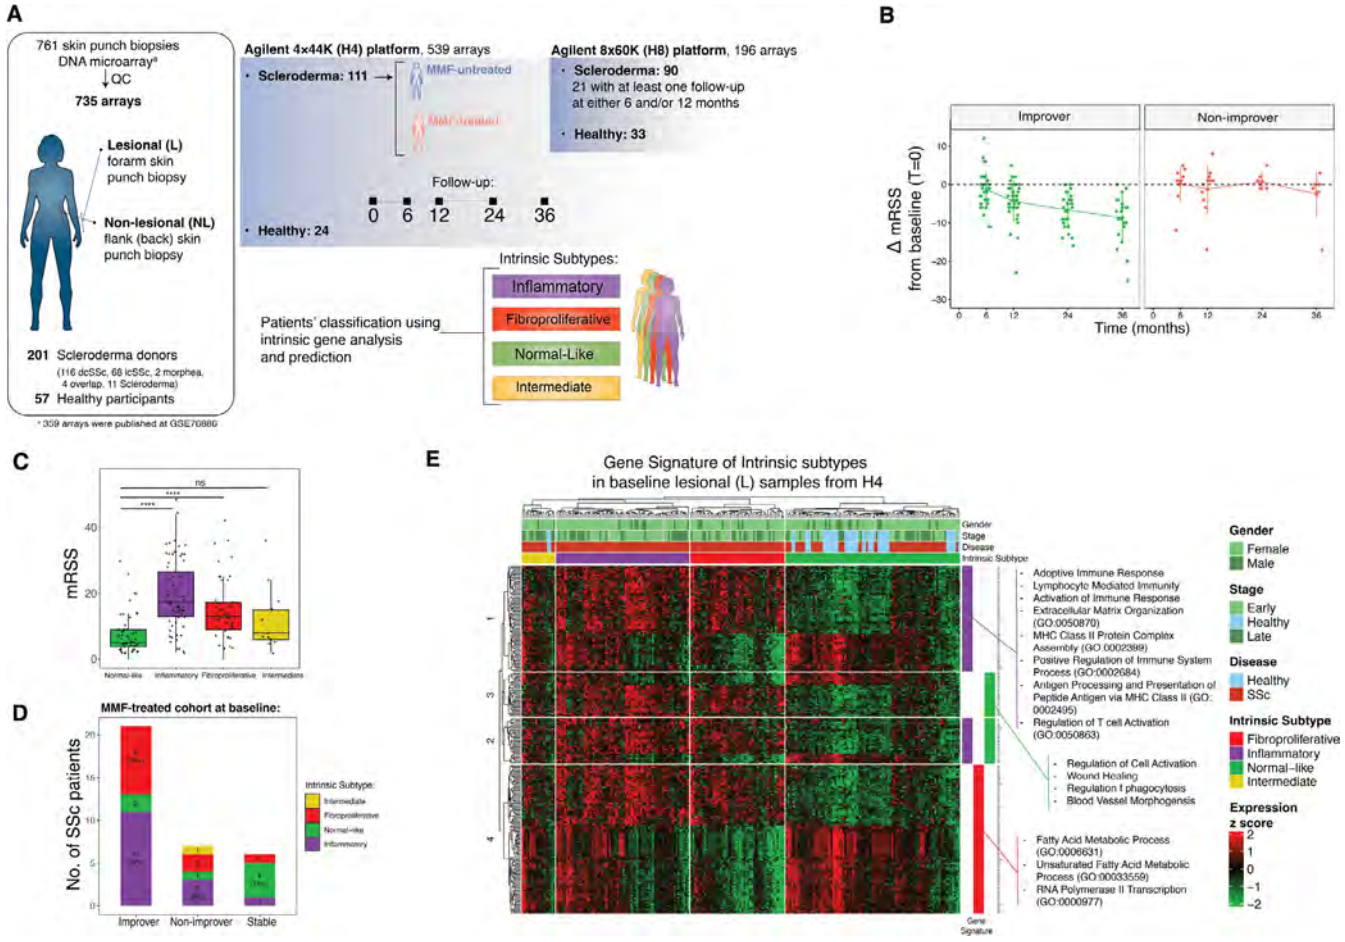

Figure 1. A) The schematic of the skin punch biopsy gene expression data set from lesional (forearm) and non-lesional (flank) of scleroderma and healthy donors that were processed in two DNA microarray platforms: Agilent 4x44K (H4) and Agilent 8x60K (H8). Intrinsic subtypes – inflammatory, fibroproliferative, normal-like and intermediate – were predicted for each skin sample. B) Change in mRSS from baseline for improvers in green and non-improvers in red. C) The mRSS levels for each intrinsic subtype for all patients at baseline. D) Distribution of subtypes for improvers, non-improvers, and stable patients who were treated with MMF. E) Heatmap showing intrinsic subtype gene signatures in baseline lesional skin samples from H4. The color bar on the right indicates gene expression levels associated with each intrinsic subtype signature. Representative Gene Ontology biological pathways enriched in each signature are shown next to the heatmap. dcSSc, diffuse cutaneous systemic sclerosis; lcSSc, limited cutaneous systemic sclerosis; MMF, Mycophenolate Mofetil; mRSS, modified Rodnan skin score.

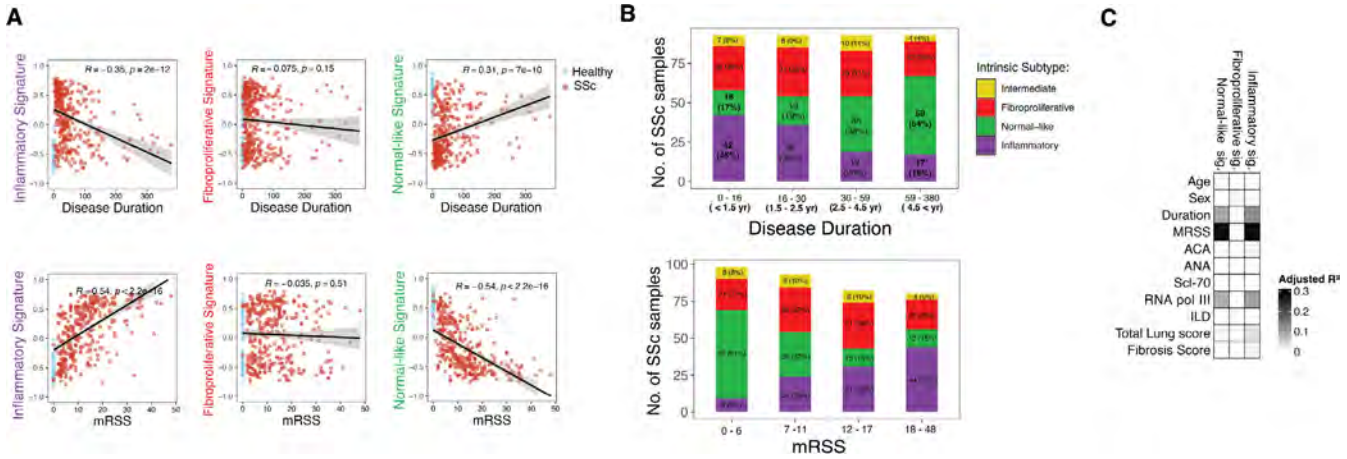

Figure 2. A) The scatter plots and Pearson correlations of the inflammatory, fibroproliferative, and normal-like signatures over disease duration and mRSS for all SSc (red) and healthy (blue) samples. R-squared and p-values of Pearson correlations are depicted in the graph. (Disease duration was identified as the time of the biopsy to the onset of the disease, which was marked as first non-Raynaud's symptom.) B) Distribution of SSc intrinsic subtypes across disease duration and mRSS. Both disease duration and mRSS values were categorized into four bins. The plot shows the number of patients in each subtype within these bins. C) Heatmap showing significant association between the intrinsic gene signatures and the clinical characteristics and manifestations.

modified Rodnan skin score (mRSS) were obtained. The intrinsic subtype of each sample was predicted using a machine learning classifier, distinct gene signatures were identified, and subtype enrichment was calculated.

Results: We identified improvers and non-improvers during MMF using 12-month mRSS post-treatment (Fig 1B). The inflammatory subtype had the highest mean mRSS, followed by the fibroproliferative and normal-like subtypes (Fig 1C). Within the MMF-treated cohort, most improvers (11 out of 21 improvers; 52%) were inflammatory. The majority of patients classified as non-improvers or stable were predicted to be normal-like (Fig 1D). The inflammatory subtype gene signature was enriched for immune cell activation pathways, whereas normal-like and fibroproliferative signatures were characterized by fatty acid metabolism, cell cycle, and other metabolic pathways (Fig 1E). The inflammatory enrichment scores correlate with markers of disease severity; negatively with disease duration and positively with mRSS, whereas the normal-like signature shows the opposite pattern (Fig. 2A). Early-stage patients (< 1.5 years after disease onset) were shown to have a 46% likelihood of being classified as inflammatory, whereas patients with disease duration > 4.5 years had a 54% likelihood of being classified as normal-like. Patients with high mRSS were more likely to be classified as inflammatory (55%), while those with low mRSS were more likely classified as normal-like (Fig 2B). Lastly, the association between subtype and the clinical manifestations showed that both inflammatory and normal-like signatures were associated with disease phenotypes (Fig 2C). The fibroproliferative subtype remained stable over the course of disease progression in this cohort.

Conclusion: These analyses suggest a link between disease severity and the intrinsic molecular subtype signatures. Inflammatory patients were more active, had higher mRSS, and showed more improvement during MMF. These data suggest that the inflammatory and normal-like subtypes represent opposite phenotypic states and disease activity.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical I (0843–0848)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Systemic Sclerosis (SSc) is a heterogeneous autoimmune disease characterized by vascular damage, immune dysregulation, and fibrosis. It is typically classified into limited cutaneous (lcSSc) and diffuse cutaneous (dcSSc) subsets, each associated with distinct clinical complications. dcSSc is generally linked to more severe organ involvement and higher mortality, and given the higher disease activity is the cutaneous subset most targetetd in clinical trials. Two independent studies have recently demonstrated the value of serum IFN score activity in stratifying patients for severe outcome (1,2). This study aims to evaluate the prognostic value of serum Type I IFN activity in a "basket" observational cohort of lcSSc and dcSSc patients, tested against a time to clinically significant event endpoint.

Methods: A retrospective, longitudinal cohort of patients fulfilling the 2013 ACR/EULAR SSc classification criteria was identified within the STRIKE national, multicentre observational cohort. The combined morbi-mortality endpoint from the MINIMISE trial was used as the clinical outcome in a time-to-event analysis starting from the time of serum analysis. The IFN score was calculated as previously described, derived from the serum concentration of CCL2, CCL8, CCL19, CXCL9, CXCL10, and CXCL11 (Myriad RBM). Patients were characterized according to the EUSTAR MEDS dataset. Time to endpoint was analysed using Kaplan-Meier curves, Log-rank test, and Cox Proportional Hazard regression models.

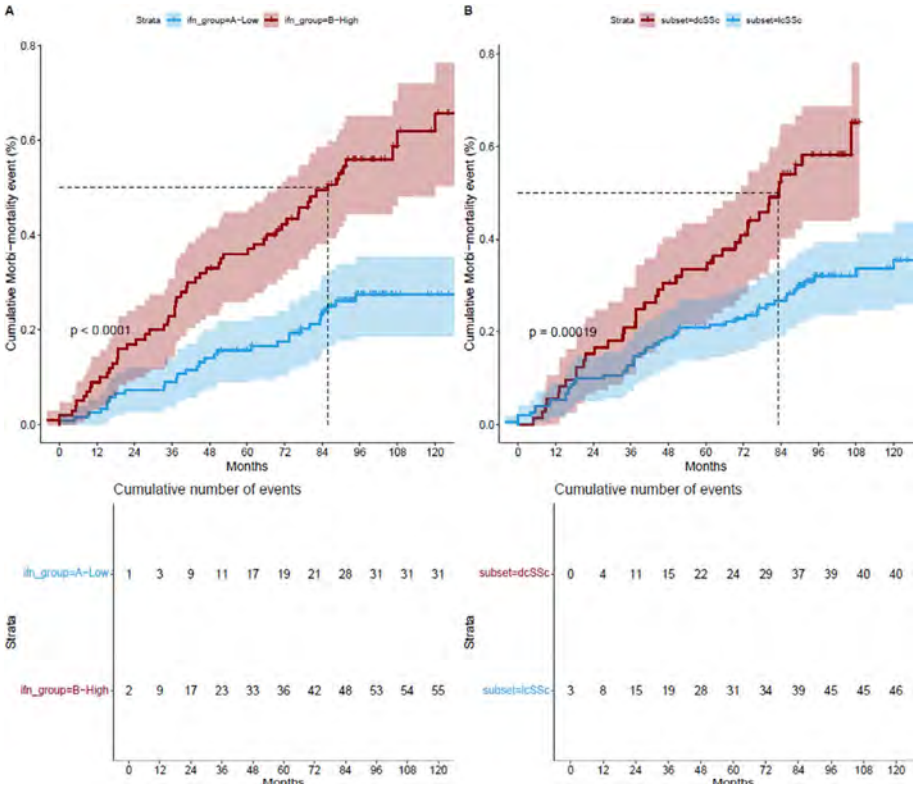

Figure 1. Kaplan-Meier curves for cumulative morbi-mortality events in SSc patients. A: Cumulative incidence of morbi-mortality events stratified by IFN score, with patients classified as IFN-low (blue) and IFN-high (red). B: Cumulative incidence of morbi-mortality events stratified by LeRoy subset, with patients classified as limited cutaneous SSc (blue) and diffuse cutaneous SSc (red).

Multivariable Cox regression models were adjusted for prognostic factors identified in univariate analyses, including age, sex, disease duration, Leroy subset, interstitial lung disease, modified Rodnan skin score (mRSS), digital ulcers (DU), and Pulmonary Arterial Hypertension (PAH).

Results: 221 SSc patients (67% lcSSc and 33% dcSSc) were included in the analysis (87% female, mean [SD] age 57 [16] years). Median (IQR) disease duration was 6 (10) years. 100 (45%) patients had a "high" IFN score (above 2 standard deviations from the Healthy Control [HC] mean), while 121 (55%) were classified as "low" IFN. Kaplan-Meier time to event analysis indicated a significantly lower event-free survival in IFN "high" compared to "low" patients ($p< 0.001$), as well as in diffuse SSc patients compared to limited SSc ($p< 0.001$). Multivariable Cox proportional hazard models confirmed that a high IFN score was associated with a Hazard Ratio (HR) of 2.57 (95% C.I. 1.64 – 4.03, $p< 0.001$) compared to IFN low, independent of subset. When used as a continuous variable, the IFN score maintained an HR of 1.60 (95% C.I. 1.18 - 2.16, $p=0.002$). Importantly, no significant interaction was detected between IFN score and disease subset ($p=0.42$) in the multivariable model including IFN score, indicating that the prognostic value of IFN score is independent of the cutaneous subset of SSc.

Conclusion: Serum assessment of Type I IFN activity is a valuable prognostic and stratification tool in SSc, providing enrichment for progressive disease independently of cutaneous subset. This approach supports the use of IFN score as a universal biomarker for risk stratification in clinical practice and trial design.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical I (0843–0848)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Assessing skin involvement in systemic sclerosis (SSc) is complex, with no single method capturing all pathological changes. The modified Rodnan Skin Score (mRSS) is subjective, requires experienced assessors, and has notable inter-observer variability. Our initial studies showed that Spatial Frequency Domain Imaging (SFDI), an objective,

Figure 1. Overview of study design, cohort demographics, and histologic features. (A) Diagram depicting the SFDI technology and clinical assessments. (B) Demographic and clinical summary of enrolled patients. (C) Histology assessments in systemic sclerosis (SSc) and healthy controls. Collagen score was based on visual grading (0–3) of overall collagen fiber thickening on H&E-stained sections. ASMA – Alpha smooth muscle actin. ASMA score was assessed using a 0–3 visual analog scale (VAS), excluding adnexal and vascular structures. Trichrome staining was quantified via ImageJ color deconvolution (M = millions). Data are shown as median (Q1, Q3) or n (%). p<0.05, p<0.01, p<0.001.

Table 1. Correlation between optical SFDI biomarkers and clinical/histologic measures of skin involvement. Spearman correlation coefficients (r_s) and p-values are shown for reduced scattering (μs′), absorption (Rd), and mRSS with respect to clinical assessments (ultrasound, durometry) and histologic markers (collagen score, ASMA, trichrome). Collagen score was graded 0–3 based on dermal fiber thickening using the method developed by Dr. Jeff Browning at BUMC. ASMA was quantified on a 0–3 VAS scale based on α-SMA–positive fibroblasts, excluding adnexal/vascular structures. Trichrome intensity was quantified using ImageJ with color deconvolution. p<0.05 considered significant.

	Clinical						*Histology*			
	Ultrasound		Durometry		Collagen Score		ASMA		Trichrome	
	r_s	p	r_s	p	r_s	p	r_s	p	r_s	p
R_d	-0.52	0.004	-0.41	0.046	-0.39	0.012	-0.52	<0.001	-0.42	0.005
μs′	-0.43	0.024	-0.36	0.040	-0.43	0.006	-0.48	<0.001	-0.53	<0.001
mRSS	0.45	0.022	0.60	0.001	0.58	<0.001	0.47	0.003	0.60	<0.001

noninvasive optical imaging modality, correlates with mRSS and has higher inter-rater reliability. However, the specific aspects of skin pathology measured by this technique remain unclear, as does its ability to track longitudinal changes. In this study, we systematically compare SFDI to mRSS, histology (gold-standard), ultrasound (for thickness), and durometry (for stiffness), and evaluate its longitudinal changes against changes in mRSS.

Methods: SSc patients and controls where enrolled under an IRB approved protocol. SFDI parameters (μ_s' and R_d at 0.2 mm^{-1} and 851 nm) were recorded at six sites: fingers, hands, and forearms. High-frequency ultrasound, durometry, and skin biopsies were done at the dorsal forearm. Two dermatopathologists evaluated histological sections for dermal thickness, alpha smooth muscle actin(ASMA)-positive fibroblast scoring, and other features. Collagen fiber score and trichrome quantification via ImageJ were also assessed. All measurements were performed blinded to clinical data. SFDI values were analyzed and compared across mRSS-defined groups using linear mixed models; clinical and histologic measurements were compared using one-way ANOVA with post-hoc Tukey tests, and correlations were assessed by Spearman's method.

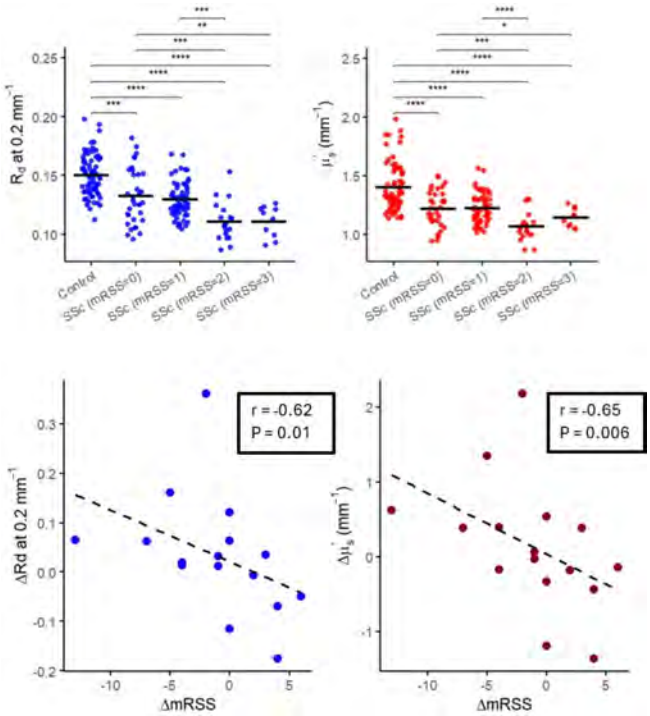

Figure 2. (A) Baseline diffuse reflectance (Rd, left) and reduced scattering coefficient (μs′, right) significantly decreased with increasing modified Rodnan skin score (mRSS), with notable differences observed even between controls and patients with clinically uninvolved skin (mRSS = 0). Each dot represents an individual skin site (forearm, hand, or finger); black bars denote group medians. Asterisks indicate statistical significance based on Tukey's post hoc test. (B) Longitudinal changes in Rd and μs′ were inversely correlated with changes in mRSS (ΔmRSS), indicating that optical properties increase in parallel with clinical improvement. Spearman correlation coefficients and p-values are shown.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: 37 SSc patients and 18 controls who had skin biopsies along with SFDI measurements were included in the study. Longitudinal measurements were taken in 16 patients. Histology showed similar dermal and epidermal thickness between groups, while SSc patients had more dermal fibrosis, pigment incontinence, higher collagen and ASMA scores (Figure 1). SFDI parameters (μ_s' and R_d) showed significant correlations with histology - including trichrome, ASMA, and collagen fiber scores - that closely matched those of mRSS. For clinical measures, SFDI correlated with ultrasound to a similar degree as mRSS, but did not perform as well as mRSS for durometry, though associations remained significant (Table 1). Additionally, SFDI measurements were significantly lower in SSc patients with mRSS = 0 compared to controls and declined further with increasing mRSS. Analysis of longitudinal changes revealed a strong correlation between changes in SFDI (ΔR_d and $\Delta \mu_s'$) and changes in mRSS (ΔmRSS) in Figure 2.

Conclusion: Our study shows that SFDI parameters exhibit face, content, and criterion validity comparable to mRSS when benchmarked against skin biopsy and other clinical metrics, supporting its use as a noninvasive, objective tool. SFDI also tracks longitudinal skin changes in SSc patients, making it versatile for monitoring disease progression and treatment response. Given its objectivity and minimal training requirements, SFDI is promising as a practical clinical tool, but further validation in longitudinal and multicenter studies is needed.

Abstract Number: 0849

Mortality and Major Adverse Cardiac Events (MACE) with GLP-1 Receptor Agonists in Psoriatic Arthritis

Nanuka Tsibadze[1], Irakli Tskhakaia[1] and Irene Tan[2], [1]Jefferson Health - Einstein, Philadelphia, PA, [2]Einstein Healthcare Network Philadelphia - Jefferson Health, Bala Cynwyd, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Plenary II (0849–0854)
Session Type: Plenary Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Glucagon-like-peptide-1 receptor agonists (GLP-1 RAs) are the novel drug class that has gained widespread attention for its cardiovascular, renal and weight loss benefits in patients with type 2 diabetes mellitus. Available evidence has illustrated that weight loss, through surgical or behavioral modification, is associated with improvements in disease activity in patients with obesity and RA, PsA, or psoriasis.

Methods: This is a nationwide, retrospective study. We used the global, multicenter research network (TrinetX) database from 83 large healthcare organizations across multiple countries. We included patients older than 18 years old with a diagnosis of psoriatic arthritis, for the last 10 years (between January 2015 and December 2024), using the International Classification of Disease-10 codes. We compared psoriatic arthritis patients on GLP-1 RAs (Semaglutide, Liraglutide, Exenatide, Lixisenatide), with psoriatic arthritis patients not on GLP-1 RAs. We used 1:1 propensity score matching that accounted for demographics variables, diagnoses, and medication use. Index event was defined as simultaneous appearance of psoriatic arthritis and GLP-1 RA use in patients' charts. Outcome of interest was the incidence of major adverse cardiovascular effects and overall mortality. Patients displaying these outcomes before the index event were excluded from the analysis.

The exposure for the outcome was any time after the diagnosis of psoriatic arthritis during the time window. Risk ratios with 95% confidence intervals were calculated for each outcome. A two-sided p-value less than 0.05 was considered statistically significant.

Results: We identified 4,104 psoriatic arthritis patients taking GLP-1 receptor agonists (GLP-1 RAs) and 86,432 psoriatic arthritis patients not taking GLP-1 RAs. At baseline, the mean age at diagnosis was 55.4 ± 11.5 years for those on GLP-1 RAs and 52.6 ± 15.1 years for those not on GLP-1 RAs. Female patients were more prevalent in GLP-1 RA group, on the contrary male patients were predominant in no GLP-1 RAs. White patients made up the largest racial group in both subgroups (80.9% for GLP-1 RA users and 73.5% for non-users). After propensity score matching, patients on GLP-1 RAs showed lower risk of developing major cardiovascular adverse events and had reduced mortality compared to those not using GLP-1 RAs (Table 2).

Conclusion: Psoriatic arthritis patients receiving GLP-1 receptor agonists have lower risk of developing major adverse cardiac events, and have reduced mortality compared to psoriatic arthritis patients not taking GLP-1 receptor agonists. GLP-1 receptor agonists may be a promising adjunct in the management of patients with inflammatory arthritis, who have comorbidities including obesity and/or type 2 diabetes mellitus. Further research is warranted to better understand the mechanisms underlying these outcomes and to confirm the long-term benefits of GLP-1 RAs.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Plenary II (0849–0854)

Session Type: Plenary Session

Session Time: 8:00AM–9:30AM

Background/Purpose: CD4$^+$ T cells play a central role in the pathogenesis of human rheumatoid arthritis (RA). However, therapies targeting CD4$^+$ T cell-derived humoral factors, including IL-17, have shown limited clinical efficacy. This suggests that the key CD4$^+$ T cell subsets and associated effector molecules driving synovial inflammation in RA remain incompletely understood. To address this, we performed a comprehensive single-cell transcriptomic analysis of synovial CD4$^+$ T cells from RA patients.

Methods: Single-cell RNA sequencing (scRNA-seq) was performed on CD4$^+$ T cells in the synovial tissue and synovial fluid of 11 seropositive RA patients (all female, mean age 65.6 years, mean DAS28-ESR 4.21). The function of an inflammatory factor identified in the analysis was assessed through in vitro experiments including CRISPR-Cas9. Serum levels of this factor were investigated in 30 control participants and 30 RA patients.

Results: scRNA-seq identified CD4$^+$ T cell clusters, including PD-1$^+$CXCL13$^+$ peripheral helper T (Tph), regulatory T (Treg), cytotoxic T, and Th17 cells. The frequency of Tph cells showed a significant correlation with disease activity, whereas the frequency of Treg and Th17 cells did not. We further identified a humoral factor, pathogenic helper inflammatory factor (PHIF, tentative gene name), with whose expression correlated with disease severity. PHIF was specifically expressed by human CD4$^+$ T cells, predominantly within Tph cells. In vitro experiments showed that PHIF promoted CXCL13 production in Tph cells. In addition, PHIF activated NF-κB signaling in monocytes and induced gene signatures associated with pathogenic macrophages from RA synovial tissue, including CXCL10 and CXCL9. Consistently, CRISPR/Cas9-knockout of PHIF in patient-derived synovial Tph cells suppressed the activation of CXCL10 and IFN signature in co-cultured monocytes (Figure 1). Notably, serum PHIF protein levels significantly correlated with RA disease severity and effectively discriminated RA patients, comparable to established biomarkers such as anti-citrullinated antibodies (Figure 2).

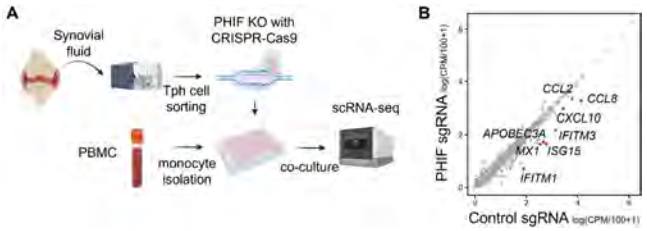

Figure 1. Effects of PHIF knockout in Tph cells on monocyte gene expression. (A) Tph cells sorted from synovial CD4+ T cells were treated with PHIF knockout using CRISPR-Cas9 and were co-cultured with PBMC monocytes, followed by scRNA-seq analysis. (B) A scatter plot comparing RNA expression of control sgRNA and PHIF sgRNA in co-cultured monocytes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

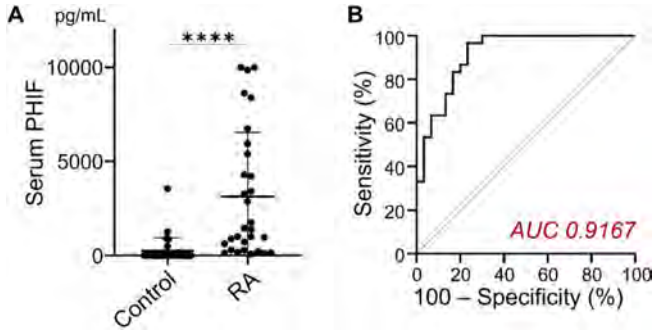

Figure 2. Clinical assessment of PHIF in RA. (A) Blood PHIF protein levels between control (n = 30) and RA (n = 30). (B) ROC curve of blood PHIF levels for RA determination with the AUC value. The means ± SD are shown in (A). ****p < 0.0001; Mann-Whitney U tests (A). ROC, receiver operating characteristic; AUC, area under the curve.

Conclusion: These findings highlight the substantial involvement of PHIF in RA pathogenesis, emphasizing how human Tph cells exert pleiotropic regulation of local immune responses via PHIF in addition to promoting antibody production via CXCL13. Thus, PHIF can be a potential biomarker and therapeutic target for RA.

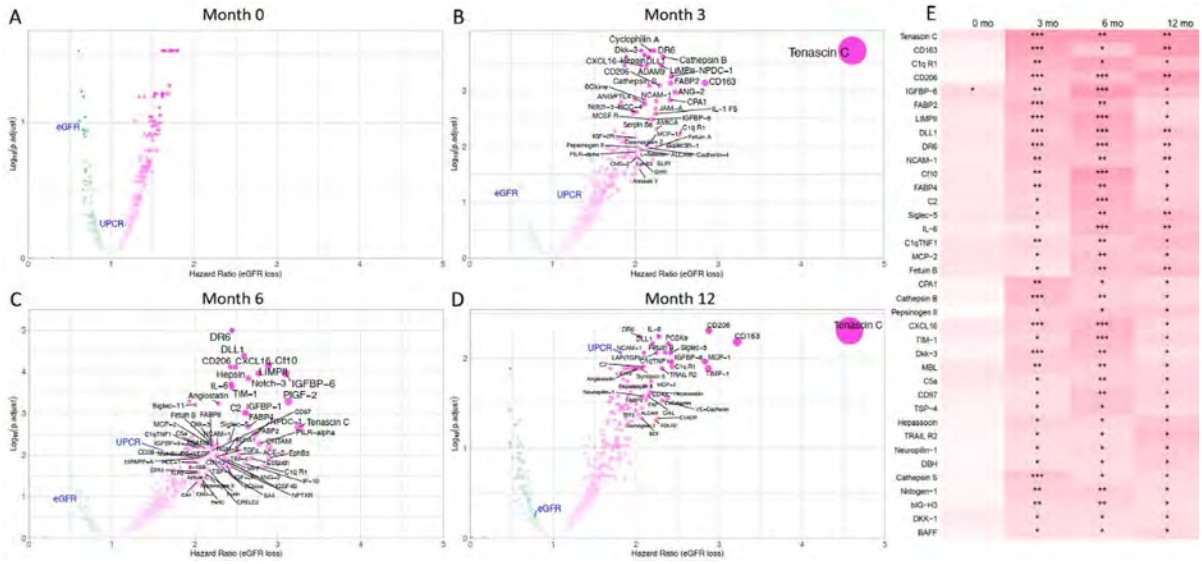

Figure 1. Proteomics signatures of increased risk of eGFR loss over time. Cox regression results at month 0, 3, 6, 12 (A-D). Only proteins with a significant hazard ratio greater than 2 are labeled on the four volcano plots. eGFR and UPCR are labeled in blue. (E) Heatmap summarizing urinary proteins significantly associated with eGFR loss from month 3 onward. Color intensity indicates the hazard ratio (HR) for eGFR loss, with white representing HR = 1 and deeper red shades indicating higher HR values. *: adjusted $p < 0.05$; **: adjusted $p < 0.01$; ***: adjusted $p < 0.001$. eGFR: estimated Glomerular Filtration Rate; UPCR: urine protein-to-creatinine ratio.

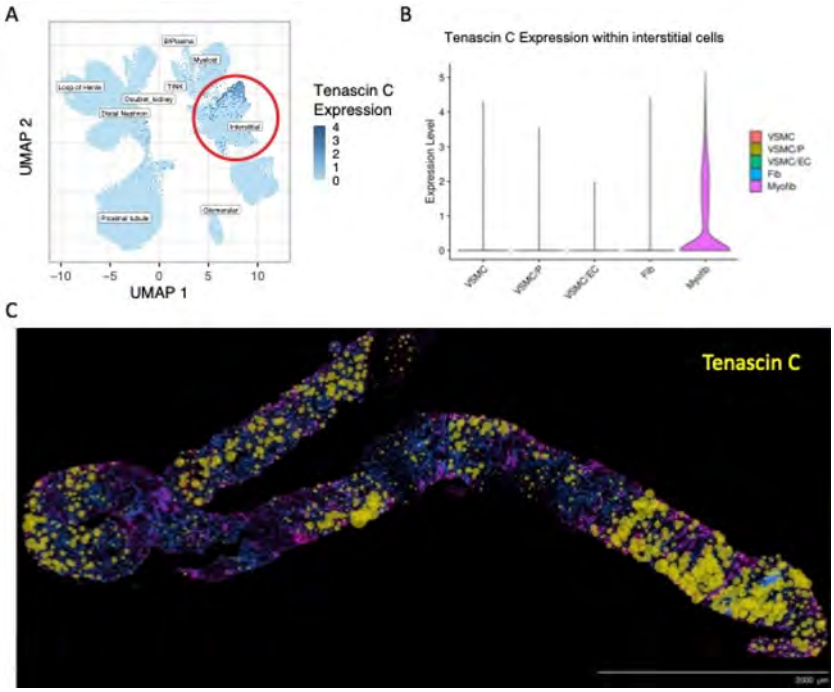

Figure 2. Tenascin C is broadly expressed in LN by myofibroblasts. (A) UMAP projection of ~ 500k cells from 16 kidney biopsies profiled using Xenium and scFFPE RNA sequencing from the AMPAIM cohort. Each cluster is labeled by its inferred cell type, and cells are colored by log-normalized expression of Tenascin C (TNC). The interstitial stromal cluster is highlighted in the red circle. (B) Violin plots of TNC expression across interstitial subpopulations): vascular smooth muscle cells (VSMC, n=3,854), VSMC/pericytes (VSMC/P, n=5,458), VSMC/endothelial cells (VSMC/EC, n=2,933), fibroblasts (Fib, n=3,584), and myofibroblasts (Myofib, n=1,220). Myofibroblasts show the highest TNC levels, indicating this cell type as the primary source. Data generated from the AMP RA/SLE cohort (n=200) using 10X Genomics scRNA-seq technology on disaggregated kidney biopsies. (C) Spatial transcriptomic map (10× Xenium) of a representative LN kidney section: yellow circles mark TNC transcript density, demonstrating broad expression within interstitial regions (scale bar = 2000 μm).

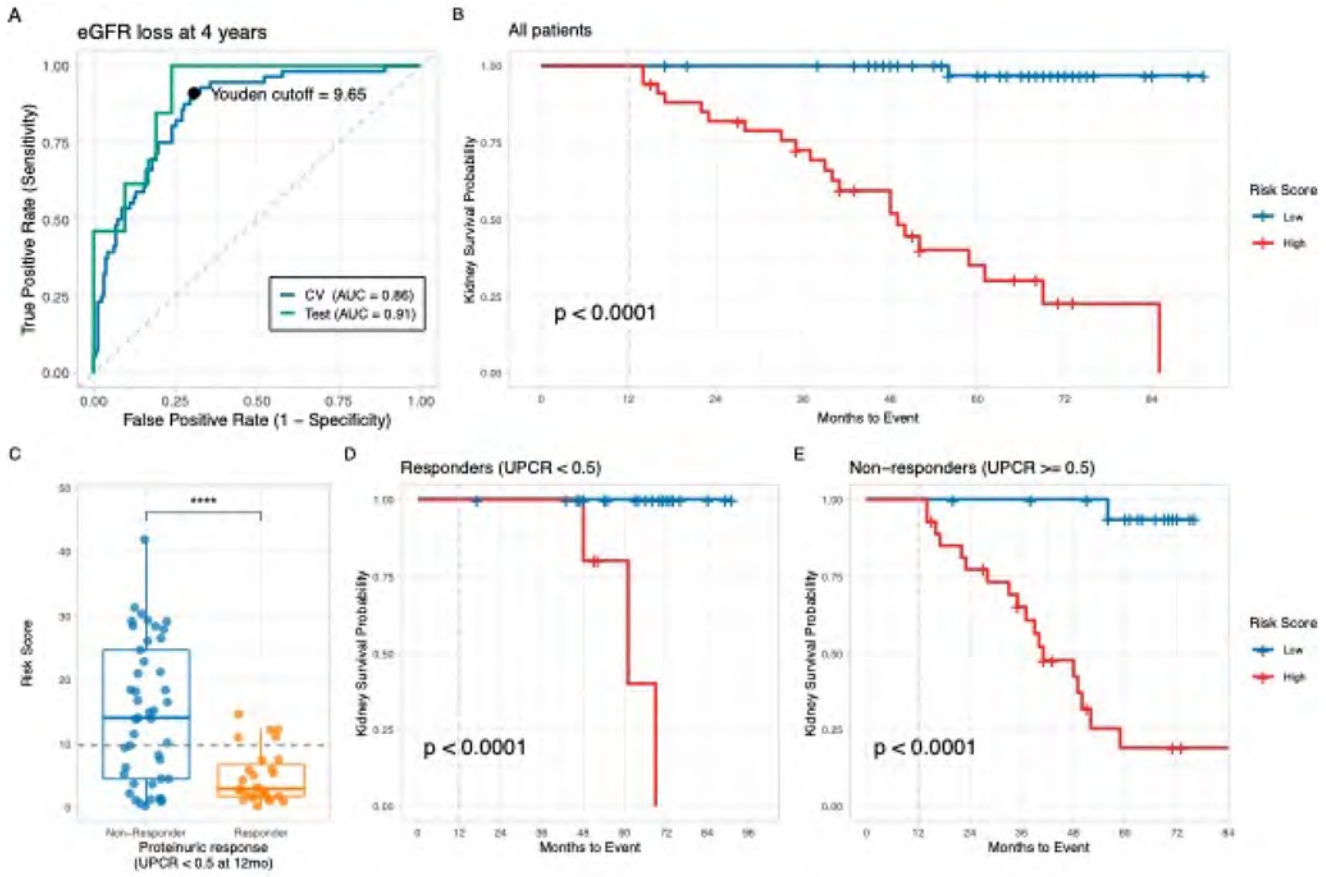

Figure 3. Urinary proteomics-based risk score predicts renal function loss and stratifies patients by treatment response. (A) Time-dependent ROC curve at 48 months demonstrates predictive performance of the risk score, with an optimal Youden cutoff of 9.65 separating high- and low-risk groups for eGFR decline. An 80:20 data split was used for model development, with 80% of patients in the training set and 20% held out for independent testing. Cross-validation within the training set optimized model hyperparameters. All follow-up visits were used to train the model to predict future eGFR loss. To prevent data leakage and overfitting, patients were split at the subject level, ensuring that all visits from a given patient remained in either the training or test set. (B) Kaplan-Meier kidney survival analysis for all patients, stratified by risk score at month 12. Patients with scores ≥9.65 were classified as high risk; those <9.65 as low risk. (C) Distribution of risk scores by treatment response at month 12. (D-E) Kidney survival stratified by risk score among proteinuric responders (D, UPCR < 0.5) and non-responders (E, UPCR ≥ 0.5).

Background/Purpose: Kidney survival is the ultimate treatment goal in lupus nephritis (LN), but long-term predictors remain understudied due to the need for extensive follow up. Proteinuria at one year is used to establish treatment response, but it is inadequate: repeat biopsy studies showed persistent intrarenal activity in ~50% of proteinuric responders with up to 30% progressing to renal insufficiency. Our objective was to identify urinary biomarkers that predict kidney function loss.

Methods: We followed 170 LN patients from the Accelerating Medicines Partnership (AMP) cohort up to 7.8 years (median 4.9). Treatment was discretionary. Estimated Glomerular Filtration Rate (eGFR) loss was defined as a sustained ≥40% decline in eGFR from baseline or development of end-stage kidney disease. We quantified 1200 biomarkers (RayBiotech) in urine samples collected at time of kidney biopsy and month 3, 6, and 12 in LN. Time-to-event models were used to evaluate associations between urinary protein levels and risk of future eGFR loss. Kidney single-cell RNA-seq and spatial transcriptomics (Xenium) were used to identify the renal cellular source of biomarkers. A Random Survival Forest model was trained to predict eGFR loss at any time after baseline and validated on a 20% hold-out test set.

Results: During follow-up, 53/170 (31%) patients developed eGFR loss. At month 3, Tenascin C emerged as the strongest predictor of eGFR loss (HR 4.6) and remained elevated through month 12 (Figure 1). Several inflammatory and fibrosis-associated markers (i.e., CD163, CD206, FABP4, IL6, IGFBP-6) were persistently associated with increased risk. Single-cell and spatial transcriptomics localized Tenascin C expression to interstitial myofibroblasts in LN kidneys, suggesting a

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

pathologic role in progressive fibrosis (Figure 2). To maximize clinical applicability, we developed a urinary protein-based classifier to predict future eGFR loss at any time point after baseline. The model (11-proteins, including tenascin C) achieved excellent predictive performance (AUC = 0.91 at 48 months) stratifying patients into high- and low-risk groups (Figure 3A). For example, at month 12, the risk score was significantly associated with eGFR preservation ($p < 0.001$, Figure 3B), and revealed heterogeneity within proteinuric response groups: some responders (UPCR < 0.5) had high risk scores, while some non-responders had low scores (Figure 3C). The classifier accurately predicted eGFR loss in both groups underscoring the limitations of proteinuria and the added utility of biomarker-based risk prediction (Figure 3D-E).

Conclusion: Urinary Tenascin C, a marker of myofibroblast activation, emerged as a robust predictor of kidney function loss in LN. Elevated CD163 and CD206 levels in high-risk patients point to ongoing M2 macrophage–driven profibrotic signaling and incomplete resolution of intrarenal inflammation, even among proteinuric responders. A proteomics-based risk score outperformed proteinuria, accurately stratifying high-risk individuals regardless of response. These findings offer mechanistic insight and support early biomarker-guided strategies to personalize treatment, refine clinical trials, and prevent irreversible kidney damage.

Abstract Number: 0852

LEVI-04 Significantly Reduces Bone Marrow Lesions and Symptoms in Knee Osteoarthritis: Results from a Phase II RCT

Simon Westbrook[1], Ali Guermazi[2] and Philip Conaghan[3], [1]Levicept Ltd, Sandwich, United Kingdom, [2]Boston University, West Roxbury, MA, [3]University of Leeds, Leeds, United Kingdom

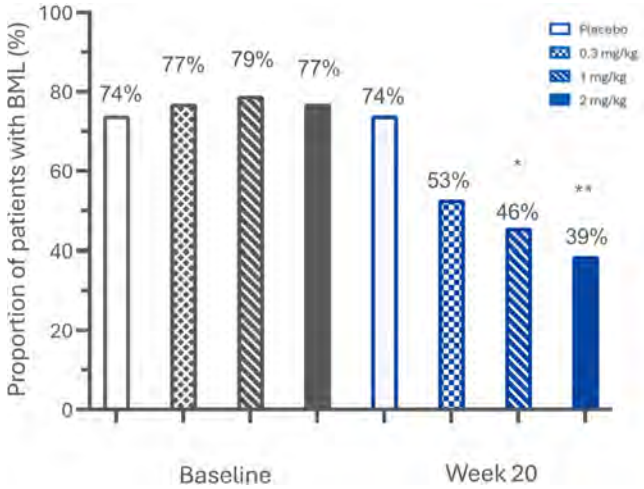
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Plenary II (0849–0854)
Session Type: Plenary Session
Session Time: 8:00AM–9:30AM

Background/Purpose: Bone marrow lesions (BMLs), detectable on MRI as areas of ill-defined high signal intensity on fluid-sensitive sequences, are a common feature of osteoarthritis (OA), representing areas of increased bone turnover, oedema, and fibrosis. BMLs are prevalent in ~80% of symptomatic knee OA patients, correlate with radiographic severity (Kellgren-Lawrence [KL] grade) and fluctuate with knee pain. LEVI-04, a first-in-class p75NTR-Fc fusion protein demonstrated significant and clinically meaningful improvements versus placebo for WOMAC pain, function and stiffness, patient global assessment (PGA) and pain on movement (StEPP).[1] LEVI-04 was well tolerated, with no increased incidence of joint pathologies compared to placebo.[1]

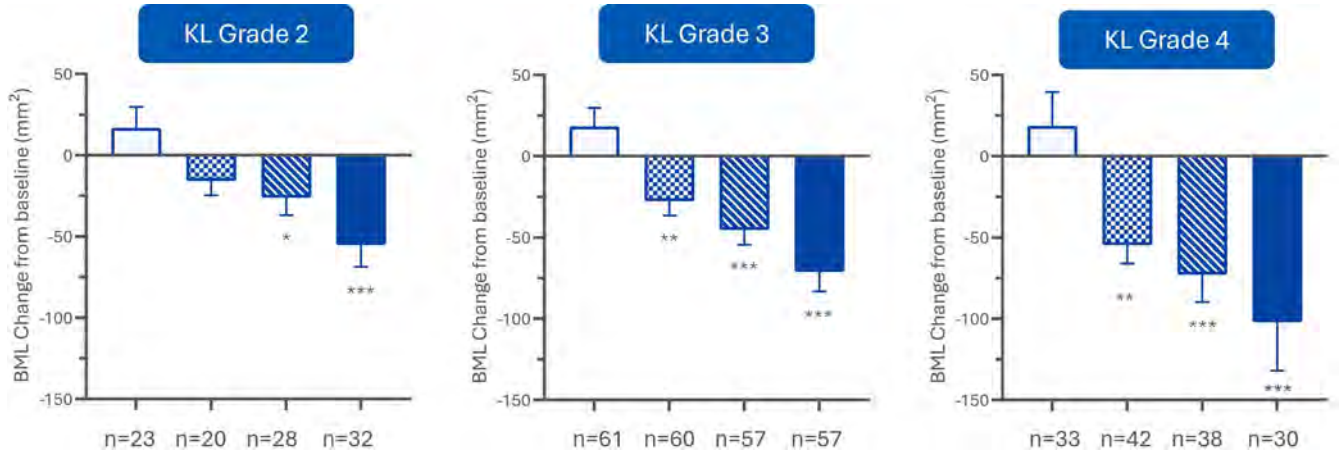
This analysis investigated LEVI-04's effects on BMLs and the relationship with OA symptoms.

Methods: 518 participants with symptomatic knee OA (WOMAC pain ≥ 4/10, KL grade ≥ 2) were enrolled in a Phase II multicentre randomized double-blinded placebo-controlled trial. Participants received placebo or LEVI-04 (0.3, 1, or 2 mg/kg) every 4 weeks through week 16. BML area (mm^2) was measured in a blinded fashion from coronal proton density-weighted fat-suppressed (PD-FS) sequences (slice thickness 3 mm, TE/TR 35/3000 ms) of the target knee at baseline and week 20. For each participant, BML area was determined as the largest area within the MRI sequence of ill-defined high signal intensity of the subchondral bone marrow, and without presence of a fracture line. The perimeter of each BML was highlighted and the area measured electronically using IAG Dynamika™ Software. For BML presence, participants were categorized as



Proportion of participants with bone marrow lesions at baseline and week 20. *P<0.05; **P<0.01 vs placebo at 20 weeks

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Change from baseline in bone marrow lesion area (mm2) in placebo or LEVI-04 0.3, 1 or 2 mg/kg groups at week 20. *P<0.05, **P<0.01; ***P<0.001 vs placebo

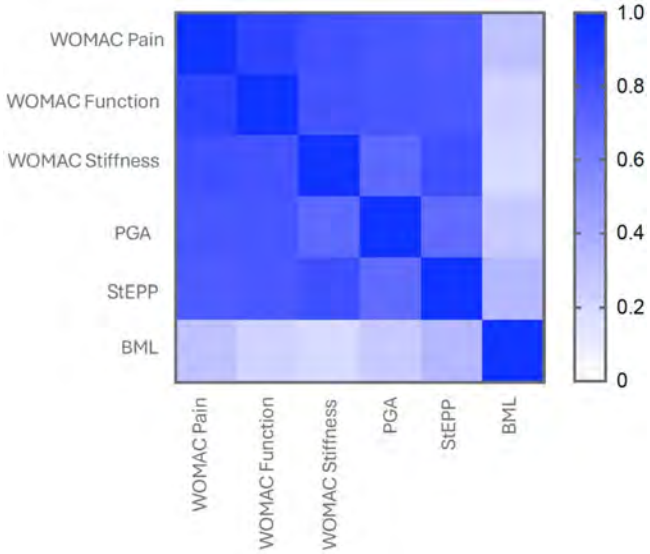


FIGURE 3: Spearman's Rho correlations between change from baseline in BML area and OA symptoms.

BML positive if ≥1 lesion was identified in the target knee. Presence and change from baseline in BML area were assessed in response to LEVI-04. Spearman's Rho correlation was used to assess the relationship between changes in BML area and changes in clinical outcomes.

Results: Presence of BMLs at baseline was similar across LEVI-04 and placebo groups (74-79%). At week 20, there was a significant, dose-dependent reduction in the proportion of participants with BMLs (figure 1) and in mean BML area from baseline (0.3 mg/kg p< 0.01; 1 mg/kg and 2 mg/kg p< 0.001) compared to placebo. A greater absolute reduction in BML area was seen in patients with higher baseline KL grades (figure 2). Comparison between change from baseline in BML area and clinical symptoms for all LEVI-04 groups showed modest yet statistically significant positive correlations (p< 0.001) for WOMAC pain (Rho=0.21), function (Rho=0.22) and stiffness (Rho=0.19), PGA (Rho=0.20), and StEPP (Rho=0.25) (figure 3).

Conclusion: A significant, dose-dependent reduction in BML presence and area across all KL grades was observed for LEVI-04 compared with placebo. Changes in BML area significantly correlated with changes in patient-reported symptoms. LEVI-04 supplements endogenous soluble p75NTR, which is present in the extracellular matrix of OA tissue including BMLs. These findings suggest that LEVI-04 holds promise as a therapy to provide contemporaneous modification of structure (BMLs) and symptoms of OA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Plenary II (0849–0854)

Session Type: Plenary Session

Session Time: 8:00AM–9:30AM

Background/Purpose: Fetal atrioventricular block (fAVB) is presumed dependent on the transplacental passage of SSA/Ro52/60kD autoantibodies that bind to apoptotic fetal cardiomyocytes, triggering macrophage activation and cardiac fibrosis. While anti-Ro is necessary for fAVB, titers alone are insufficient for prediction which challenges preconception counseling, surveillance, and trial design. Thus, identification of additional permissive factors for injury would yield greater understanding of pathogenesis and more precise biomarkers of significant clinical utility. The biobanks generated from the STOP BLOQ and PATCH trials represent a rare opportunity to evaluate sera collected during pregnancy but prior to fAVB occurrence. Accordingly, this study leveraged these samples and Olink proteomics to identify additional predictive serum proteins for fAVB in high titer anti-Ro pregnant subjects.

Methods: Sera from 12 fAVB affected pregnancies were matched to 13 high titer anti-Ro exposed healthy pregnancies. To eliminate factors conferring a change in serum proteins and/or fAVB risk, samples were matched on race/ethnicity, maternal rheumatologic diagnosis, anti-Ro52 and 60 titers (ELISA in our research lab), and hydroxychloroquine dose. All samples were

Table 1: Clinical characteristics of fAVB and Anti-Ro+ non fAVB pregnancies. Data are represented as median (IQR) or N (%). fAVB: fetal atrioventricular block, SLE: Systemic Lupus Erythematosus, SjD: Sjögren's Disease, UAS: Undifferentiated Autoimmune Syndrome

Clinical Characteristic	Anti-Ro+ fAVB N=12	Anti-Ro+ non-fAVB Healthy N=13
Age	28 (28-32)	34 (32-36)
Race		
Asian	1 (8.3%)	1 (7.6%)
Black	1 (8.3%)	1 (7.6%)
White	10 (83.3%)	11 (84.6%)
Ethnicity		
Hispanic	1 (8.3%)	0 (0%)
Non-Hispanic	11 (91.6%)	13 (100%)
Previous Child With fAVB	0 (0%)	0 (0%)
Maternal Diagnosis		
Asymptomatic/UAS	6 (50.0%)	5 (38.5%)
SLE	1 (8.3%)	1 (7.6%)
SjD	4 (33.3%)	7 (53.8%)
SjD/SLE	1 (8.3%)	0 (0%)
Any dose Hydroxychloroquine	11 (91.6%)	13 (100%)
400 mg Hydroxychloroquine	6 (50.0%)	7 (53.8%)
Ro52 titer (ELISA Units/mL)	12621 (10136-20732)	18536 (8975-20420)
Ro60 titer (ELISA Units/mL)	32772 (14536-37775)	31890 (18005-42395)

collected prospectively between weeks 10-19 during enrollment in STOP BLOQ or PATCH and, for affected pregnancies, before the development of fAVB. Samples from five anti-Ro negative healthy pregnant women were also tested. Serum proteins (>5400) were assessed by the Olink Explore HT assay. Principal component analysis (PCA) was performed and a t-test was

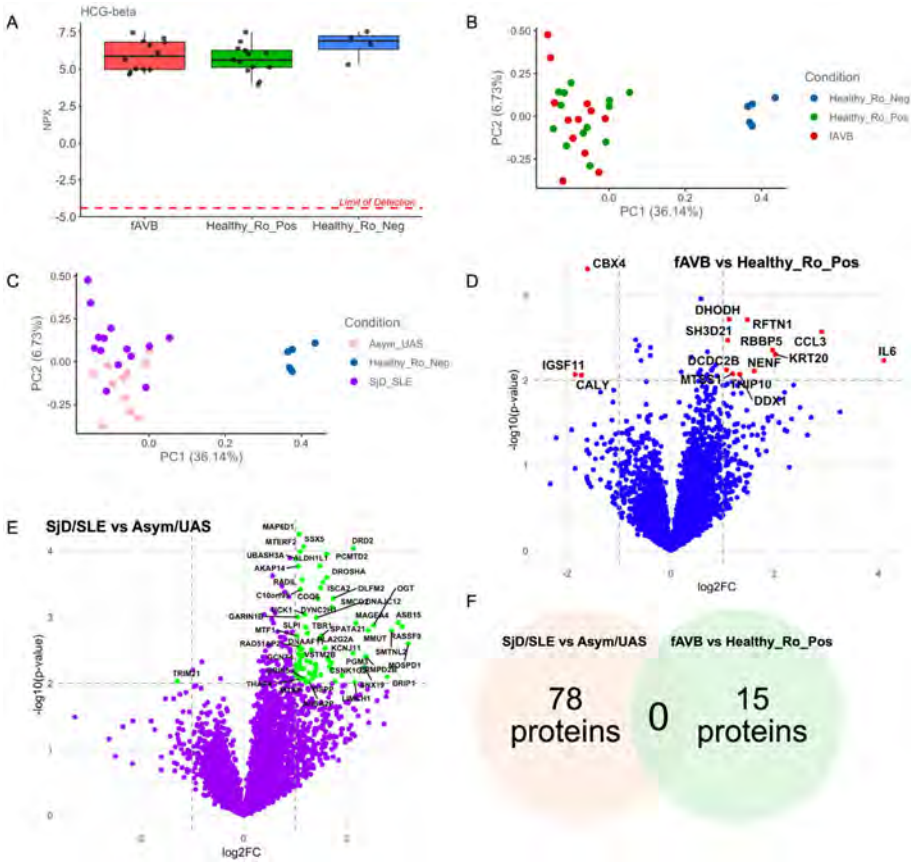

Figure 1: A) Boxplots showing the levels of HCG-beta detected among the fAVB, anti-Ro+ healthy, and anti-Ro- healthy pregnancies. Note that one healthy anti-Ro negative control is not represented due to a QC failure for the HCG-beta assay. The horizontal red dashed line represents the technical lower limit of detection for HCG-beta provided by Olink. B) PCA visualization of the fAVB, anti-Ro+ healthy, and anti-Ro- healthy pregnancies. C) PCA visualization of the Asym/UAS, SjD/SLE, and anti-Ro- healthy pregnancies. D) Volcano plot showing the 15 differentially abundant proteins between fAVB and anti-Ro+ healthy subjects. E) Volcano plot showing the 78 differentially abundant proteins between SjD/SLE and Asym/UAS subjects. F) Venn diagram showing that none of the 78 differentially abundant proteins between SjD/SLE and Asym/UAS subjects overlap with the 15 differentially abundant proteins between fAVB and anti-Ro+ healthy subjects.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Boxplots showing the levels of the 15 significantly different proteins with p<0.01 and log2FC < -1 or > 1 between fAVB and anti-Ro+ healthy subjects.

employed to compare fAVB to anti-Ro exposed healthy pregnancies. Candidate proteins had a p< 0.01 and log2FC |1|.

Results: The 12 fAVB pregnancies and 13 anti-Ro+ non-fAVB pregnancies were well matched on clinical variables (Table 1). As a validation, high levels of HCG-beta were detected (Fig 1A). The PCA effectively distinguished anti-Ro+ from anti-Ro- pregnancies and asymptomatic or undifferentiated autoimmune syndrome (Asym/UAS) from SjD/SLE, but did not separate fAVB from non-fAVB cases (Fig 1B & 1C). While 78 proteins separated Asym/UAS from SjD/SLE, there were 15 other differentially abundant proteins between fAVB vs anti-Ro+ non-fAVB pregnancies (Fig 1D & 2). That these 15 proteins did not differ between UAS and SjD/SLE pregnancies supports prior observations that maternal diagnosis does not influence fAVB risk (Fig 1E & 1F). Two macrophage related proteins, IL6 (log2FC = 4.1) and CCL3 (log2FC = 3.9), showed the greatest difference between fAVB and non-fAVB subjects (Fig 2), and were highly correlated (r=0.84, p< 0.0001). Neither were correlated with either anti-Ro52 or 60 levels.

Conclusion: This high-throughput evaluation of prospective samples collected early in pregnancy provides insights into novel proteins that predict the development of fAVB in anti-Ro exposed pregnancies. Given the low molecular weight of these novel pro-inflammatory candidates, passive transport across the placenta supports an additional maternal contribution (not related to maternal disease status which was separated by other proteins) to the pathogenesis by amplifying anti Ro-mediated fetal cardiac injury.

Background/Purpose: The 2009 ASAS classification criteria had sensitivity (Sn) of 83% and specificity (Sp) of 84% for a rheumatologist diagnosis of axial spondyloarthritis (axSpA). Given the high prevalence of back pain, greater specificity would be desirable. The global Classification in Axial Spondyloarthritis Inception Cohort (CLASSIC) study was established as a combined initiative of ASAS and SPARTAN to validate the performance of the 2009 criteria according to prespecified Sn/Sp targets of ≥75%/≥90%.

Methods: CLASSIC recruited consecutive patients referred to a rheumatologist with current undiagnosed back pain of ≥3 months duration with onset ≤45 years of age. Diagnostic evaluations for axSpA were performed at 5 stages: Stage 5 provided all diagnostic information including centralized imaging review by two primary readers and an adjudicator, and served as reference standard. The cohort data were randomly divided into testing and validation datasets (50:50). The testing dataset was used to develop candidate criteria, while the validation dataset evaluated whether criteria achieved the Sn/Sp targets, using the stage 5 global diagnosis as the reference standard. Regression techniques (least absolute shrinkage and selection operator (LASSO), multivariable logistic regression (MLR)) were used to identify which SpA variables were independently associated with stage 5 diagnosis and for estimating the strength of this association according to LASSO coefficients. Final selection of SpA variables and their weighting was determined by expert consensus and the final proposal was selected by a vote of the combined ASAS and SPARTAN membership.

Results: CLASSIC included 1015 patients from 61 centers in 27 countries of whom 370 (36.5%) were diagnosed with axSpA per stage 5 global. The 2009 ASAS classification criteria did not meet the prespecified targets (Sn 82.4%, Sp 77.1%)[1], indicating the need for revised criteria. MRI of the SIJ indicative of axSpA by global assessment of both active and structural lesions had the highest independent association with stage 5 diagnosis of axSpA followed by radiographic sacroiliitis. Selected clinical variables were HLA-B27, inflammatory back pain, inflammatory bowel disease, acute anterior uveitis, heel enthesitis, and dactylitis. Expert consensus led to the inclusion of psoriasis and replacement of dactylitis by elevated CRP. Two high-performing proposals in the testing dataset achieved the Sn/Sp targets in the validation dataset (Figures 1 and 2). The final proposal selected by the ASAS-SPARTAN vote (158 vs 151, 9 abstained) assigned weights for the selected SpA variables based on LASSO coefficients and achieved Sn of 79.5% and Sp of 90.4% in the validation dataset (Table).

Conclusion: The ASAS-SPARTAN revised classification criteria for axSpA achieved prespecified performance targets of ≥75% sensitivity and ≥90% specificity, emphasizing the central role of imaging and incorporating a more focused set of clinical variables compared to the 2009 ASAS criteria.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Antiphospholipid Syndrome (0855–0860)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: The IMPACT trial (NCT03152058) showed that certolizumab appears effective in preventing placenta-mediated adverse pregnancy outcome (APO) in high-risk antiphospholipid syndrome (APS) patients. We have continued recruitment to this trial and herein summarize our findings.

Methods: We assessed treatment with certolizumab in pregnant patients with APS and LA, administered gestational weeks 8 through 28, in addition to standard treatment with low molecular weight heparin and low dose aspirin. The primary APO was a composite of fetal death >10 weeks' gestation or preeclampsia with severe features or placental insufficiency requiring delivery < 34 weeks' gestation. The target sample size for the IMPACT trial was 45 with expected APO rate of 20% with certolizumab versus 40%, the assumed APO rate under the null hypothesis which was considered to be conservative by the study team given the observed APO rate of 44% among IMPACT-eligible patients (ie, with APS and LA) in the PROMISSE Study (N=61). Published results of the IMPACT Trial (Branch et al., Ann Rheum Dis, ePub ahead of print 2025) include data for 45 completed pregnancies. Ongoing recruitment has enrolled 5 additional patients.

Table 1: Demographic and Clinical Characteristics of IMPACT Patients	Modified Intention-to-Treat (N=50)
Age, years, median (range)	32 (20–40)
Body mass index, kg/m^2, median (range)	25.7 (18.7–44.9)
<25, N (%)	23 (46)
25–30, N (%)	15 (30)
>30, N (%)	12 (24)
Ethnicity	
Hispanic/Latina, N (%)	10 (20)
Race	
White, N (%)	39 (78)
Asian, N (%)	4 (8)
Black, N (%)	1 (2)
>1 Race, N (%)	2 (4)
Other/Not Reported, N (%)	4 (8)
Lupus anticoagulant (LA), N (%)	50 (100)
Anticardiolipin (aCL) and LA, N (%)	28 (56)
IgG positive[4]	26 (52)
IgM only positive[4]	2 (4)
Anti-beta-2 glycoprotein-1 (aB2GP1) and LA, N (%)	25 (50)
IgG positive[4]	23 (46)
IgM only positive[4]	2 (4)
aCL or aB2GP1 and LA, N (%)	34 (68)
IgG positive	31 (62)
IgM only positive	3 (6)
aCL and aB2GP1 and LA positive, N (%)	19 (38)
IgG positive	18 (36)
IgM only positive	1 (2)
LA positive only, N (%)	16 (32)
Systemic lupus erythematosus, N (%)	8 (16)
With renal involvement, N (%)	1 (2)
History of thrombotic features of APS, N (%)	34[2] (68)
Venous thromboembolism, N (%)	29 (58)
Arterial thromboembolism, N (%)	6 (12)
Stroke, N (%)	4 (8)
Other,[3] N (%)	2 (4)
History of obstetric features of APS, N (%)	43 (86)
History of thrombotic and obstetric features of APS, N (%)	27 (54)
History of immune thrombocytopenia, N (%)	5 (10)
Medications at enrollment	
Low molecular weight heparin, N (%)	50 (100)
Thromboprophylactic, N (%)	23 (46)
Therapeutic, N (%)	27 (54)
Low dose aspirin, N (%)	50 (100)
Hydroxychloroquine, N (%)	31 (62)
Azathioprine, N (%)	2 (4)
Prednisone,[4] N (%)	1 (2)
Other,[5] N (%)	2 (4)

[1] Defined as > 40 standard units in most recent assay result
[2] One patient had a history of both arterial and venous thrombosis
[3] Includes 2 patients with amaurosis fugax
[4] Prednisone <10 mg daily
[5] Includes 1 patient on tacrolimus and 1 patient on labetalol and nifedipine

Table 2: Obstetric History of IMPACT Modified Intention-to-Treat Patients (N=50)			
Individual Patients (N=47)[1]			
Gravidity excluding study pregnancy, median (range)	2 (1-9)		
History of ≥3 consecutive early losses (<10 weeks' gestation)[2], N (%)	3 (6)		
History of fetal death(s) ≥ 10 weeks' gestation, N (%)	35 (74)		
History of preeclampsia or placental insufficiency requiring delivery <34 weeks' gestation, N (%)	35 (74)		
History of a prior IMPACT adverse pregnancy outcome[3], N (%)	41 (87)		
History of live birth surviving to hospital discharge, N (%)	17 (36)		
Prior Pregnancy Outcomes			
	All prior pregnancies	LDA and LMWH[4] treated prior pregnancies	LDA, LMWH[4] and HCQ treated prior pregnancies
Total Pregnancies, N	118[5]	53[6]	16[7]
Pregnancies beyond 10 weeks' gestation, N	74	36	12
Fetal death > 10 weeks gestation, N (% of pregnancies beyond 10 weeks' gestation)	48 (65)	20 (56)	8 (67)
Preeclampsia or placental insufficiency requiring delivery <34 weeks' gestation, N (% of pregnancies beyond 10 weeks' gestation)	43 (58)	23 (64)	9 (75)
IMPACT adverse pregnancy outcome[3], N (% of pregnancies beyond 10 weeks' gestation)	56 (76)	26 (72)	9 (75)
Live birth surviving to hospital discharge, N (% of pregnancies beyond 10 weeks' gestation)	22 (30)	13 (36)	3 (25)

[1] Three patients had no prior pregnancies
[2] In 2 of the 3 patients, thus was the only obstetric criterion for APS
[3] Otherwise unexplained fetal death and/or preeclampsia or placental insufficiency requiring delivery <34 weeks
[4] Defined as low dose aspirin and heparin agent started in 1st trimester of pregnancy
[5] Total number of pregnancies among 47 modified intention-to-treat patients with prior pregnancies
[6] Total number of pregnancies among 26 patients treated with LDA and LMWH
[7] Total number of pregnancies among 8 patients treated with LDA, LMWH and HCQ, 4 of whom had SLE

Table 3: IMPACT Outcomes	Modified Intention-to-Treat
Primary Outcome	**N = 50**
Otherwise Unexplained Fetal Death ≥10 Weeks' Gestation	3
Preeclampsia or Placental Insufficiency Requiring Delivery <34 Weeks' Gestation	7
Composite primary outcome N (%)	9[1] (18.0)
Infant survival	**N = 50**
Live births	47 (94)
Live births surviving to hospital discharge	47 (94)
Non-obstetric Secondary Outcomes	**N = 50**
Maternal thrombosis N(%)	1 (2)
Known adverse reaction to certolizumab	0
Obstetric Secondary Outcomes	**N = 47**[2]
Gestational age at delivery	
With primary outcome, median (range)	31 (27-33)
Without primary outcome, median (range)	37 (32-39)
Preterm live births (<37 weeks' gestation)	
With primary outcome, N (%)	6 (13)
Without primary outcome, N (%)	15 (32)[3]
Preeclampsia or placental insufficiency not requiring delivery <34 weeks' gestation, N (%)	3 (6)[4]
Small-for-for gestational age birthweight (<10th percentile)	
With primary outcome, N (%)	3 (6)
Without primary outcome, N (%)	6 (13)
Neonatal death due to preterm birth for preeclampsia or placental insufficiency, N (%)	0

[1] One participant met both outcomes: intrauterine fetal death at 21 weeks and preeclampsia with severe features
[2] Obstetric secondary outcomes are only applicable to live births
[3] Includes 1 case each of preterm labor at 32 weeks' gestation; maternal pulmonary hypertension at 35 weeks' gestation, flare of polychondritis at 35 weeks' gestation, and suspected fetal growth restriction at 36 weeks' gestation; 2 cases of preterm premature rupture of the membranes, 3 cases of fetal growth restriction (2 at 34 weeks' and 1 at 36 weeks' gestation), 2 cases of cholestasis of pregnancy at 36 weeks' gestation; and 4 cases of patient-physician shared-decision elective preterm delivery at 35 or 36 weeks' gestation.
[4] Diagnosed with fetal growth restriction/placental insufficiency and were delivered of small-for-gestational age infants in the absence of preeclampsia.

Results: In the now completed IMPACT Trial, the pre-determined criteria for efficacy of certolizumab were met. The primary APO rate in the original trial was 20% (9/45 in the modified intention-to-treat population) compared to 40% in historic controls from the PROMISSE Study. With ongoing recruitment, 57 patients have now been enrolled and 56 patients have completed their participation in the trial. Of those enrolled with a prior pregnancy, 87% had a history of an IMPACT primary APO. Baseline characteristics are included in Table 1. Outcomes of prior pregnancies in IMPACT participants are included in Table 2: of 39 previous pregnancies treated with LMWH and LDA that progressed beyond 10 weeks' gestation 27, (69%) resulted in an IMPACT APO, and only 15 (38%) were liveborn and survived to hospital discharge. Excluding 6 patients that

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

had a pregnancy loss < 10 weeks' gestation or fetal loss due to genetic abnormalities, outcomes from the certolizumab-treated pregnancy of 50 modified intention-to-treat participants are described below (Table 3). Nine had a primary APO (18.0%; 95% CI: 8.6% - 31.4%), meeting the predetermined criteria for efficacy of certolizumab and significantly lower rates than in historical controls. There were 47 (94%) liveborn infants and all survived to hospital discharge. Median gestational age at delivery was 37 weeks for patients without the primary outcome and 31 weeks for those with the primary outcome. Three patients delivered prematurely (after 34 but before 37 weeks' gestation) because of placental insufficiency and thus met a secondary outcome. In the trial, there were no serious infections, no substantial increases in antiphospholipid antibodies or other autoantibody levels, and no new cases or severe flares of lupus.

Conclusion: Results of our ongoing enrollment indicate that certolizumab appears effective in preventing placenta-mediated adverse outcomes in high-risk APS patients.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Antiphospholipid Syndrome (0855–0860)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: To elucidate the molecular and cellular mechanisms underlying antiphospholipid antibody (aPL) nephropathy using integrated single-cell and spatial transcriptomic (SP) profiling of kidney tissues.

Methods: Renal biopsy specimens from five patients diagnosed with chronic aPL nephropathy were analyzed. Single-cell RNA sequencing (scRNA-seq) was performed on three samples using the Singleron platform. SP was conducted on two samples using the 10x Genomics Visium platform. Control kidney datasets from three healthy donors were curated from GEO datasets generated using the same platform (GSE171458 and GSE171314). Data processing included dimensionality reduction, unsupervised clustering, differential expressed genes (DEGs) analysis, pathway enrichment, correlation analysis, subclustering analysis.

Results: We profiled 34,253 kidney cells from aPL nephropathy patients (n=3) and healthy controls (n=3). Integration of single-cell clustering data with SP profiles revealed three cell populations within the pathognomonic vascular lesion regions: endothelial cells (ECs), stromal cells (Stroma) and mononuclear phagocytes (MNPs). To molecularly characterize these populations,DEGs analysis was conducted, identifying upregulation of mesenchymal cell markers, CCN2, SOX18, JUN and JUNB, in ECs. ECs from aPL nephropathy samples exhibited marked inflammatory pathway activation, suggesting an inflammatory vascular microenvironment. In parallel, ECs and Stroma showed enrichment of fibrotic and proliferative

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Integrated single-cell and spatial transcriptomic analysis reveals distinct cellular signatures of endothelial and Stroma in aPL nephropathy. (A) Schematic overview of the experimental design for the study. Kidney biopsy sample from aPL nephropathy (APSN) patients underwent single-cell RNA sequencing (scRNA-seq) (n = 3) and spatial transcriptomics profiling (n = 2). scRNA-seq datasets from 3 healthy controls(HCs) were obtained from GEO database (GSE171458 and GSE171314). (B) UMAP of 34,253 cells in an integrated human kidney scRNA-seq data generated in this study. Annotated cell types are indicated on the plot. (C) Spatial location of identified cell types using Visium. Left, haematoxylin and eosin (H&E)-stained tissue. Right, Celltrek cell-type imputations of the Visium spatial data annotations showing the location of different cell types in the kidney biopsy sample of APSN patient. (D) Volcano plot of DEGs in both ECs(left) and Stroma(right) of APSN patients compared with HCs. (E) Enriched KEGG enrichment analysis utilizing intersect DEGs in both ECs(left) and Stroma(right) of HC and APSN patients. (F) Violin plot showing estimated IFNA scores (top left), IFNG scores (top right), complement scores (bottom left) and ECM scores (bottom right) in ECs and stromal cell clusters calculated by UCELL. (G) Dot plot illustrating the expression pattern of all complement genes in various cell types annotated in the single cell transcriptome data. PT, proximal tubule cells; LOH, Loop of Henle cells; IC, intercalated cells; DT, distal tubule cells; PC, principal cells; Pod, podocytes; EC, endothelial cells; Stroma, stromal cells; TNK, T and NK cells; B, B cells; Plasma, plasma cells; MNP, mononuclear phagocytes; Mast, mast cells; Neu, neutrophils; Cyc imm, cycling immune cells.

pathways along with upregulation of complement and coagulation cascades, and ECM score, indicating the potential activation of endothelial-to- mesenchymal transition (EndoMT) in ECs. Further complement gene analysis identified MNPs as the primary renal complement source **(Figure 1)**.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Complement Pathway Activation in Endothelial Subtypes Associates with Endothelial-Mesenchymal Transition (A)UMAP projection of 2,027 endothelial and stromal cells showing twelve transcriptionally distinct subclusters. (B) UMAP visualizing the predicted ECs and Stroma lineage trajectory using scvelo. (C) Dot plot displaying average expression (color) and proportion of cells (size) for representative marker genes across endothelial and stromal subclusters. (D) UMAP depicting the estimated gene set signatures of arteries (left), capillaries (middle), and veins (right) calculated using UCELL. (E) Correlation plot between each geneset score calculated by UCELL. (F)Violin plot showing estimated ECM scores (top) and complement scores (bottom) in ECs and stromal cell subclusters calculated by UCELL. (G) Correlation between CCN2 expression and complement scores (bottom) geneset scores from each endothelial subcluster. (H) AEA and VSMC, ECM and complement gene-expression score in the SP datasets using Visium. H&E sections shown on the left of the figure show individual tissue histology of our Visium sections. AEA, afferent/ efferent arteriole; AVR, ascending vasa recta; DVR, descending vasa recta; GC, glomerular capillary; PTC1, peritubular capillary type 1; PTC2, peritubular capillary type 2; Mes, mesangial cell; Fib, fibroblast; VSMC, vascular smooth muscle cell.

Subclustering of ECs and Stroma identified 12 distinct subtypes. Pathway scoring indicated dominant complement activation and significantly elevated ECM scores in afferent/ efferent arteriole (AEA), SOX9^{+} ECs and peritubular capillary type 2 (PTC2). Complement-ECM correlation (r=0.49, p< 0.001) and CCN2-complement linkage in AEA (r=0.5, p< 0.01) highlighted complement-driven ECM pathology. Spatial validation confirmed lesion-associated ECs as AEA subtypes **(Figure 2)**.

Conclusion: This study presents an integrated single-cell and SP atlas of aPL nephropathy and uncovers a pathogenic cascade involving endothelial inflammation, MNP-derived complement activation, and ECM organization. Our findings support a model of complement associated EndoMT, offering mechanistic insights and potential therapeutic targets for aPL nephropathy.

CD14-dependent MAP kinase signaling is required for pathogenic neutrophil extracellular trap formation in APS

Thalia Newman[1], NaveenKumar Somanathapura[1], Chao Liu[2], Srilakshmi Yalavarthi[1], Pooja Kapoor[1], Ajay Tambralli[1], Jacqueline Madison[1], Yu (Ray) Zuo[1] and Jason S. Knight[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Superior Charter Twp, MI

SESSION INFORMATION

Session Date: Monday, October 27, 2025

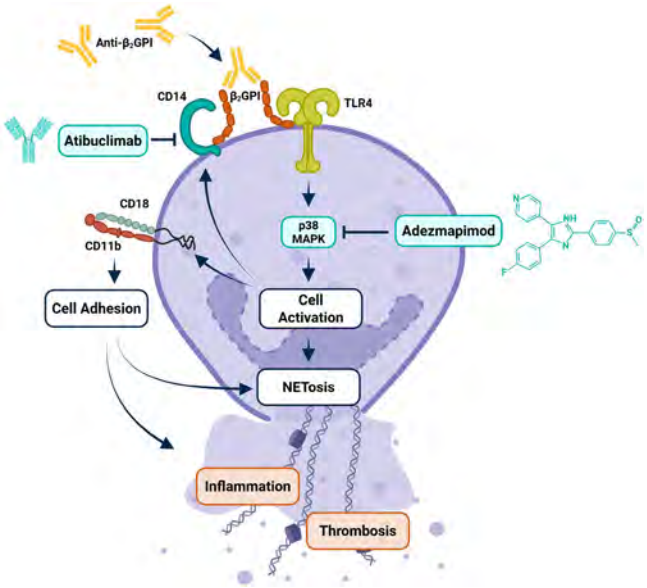
Session Title: Abstracts: Antiphospholipid Syndrome (0855–0860)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Antibodies targeting beta-2-glycoprotein I (**anti-β_2GPI**) promote inflammation and thrombosis in antiphospholipid syndrome (**APS**). It has been shown that anti-β_2GPI activate neutrophils through Toll-like receptor 4 (**TLR4**) to promote the release of pathogenic neutrophil extracellular traps (**NETs**), which promote a thrombo-inflammatory milieu. It is also known that APS patient neutrophils upregulate TLR4-associated genes, including those encoding CD14 and p38 MAP kinase (**MAPK**). Here, we sought to elucidate the potential role of CD14-dependent MAPK signaling in the neutrophil response to anti-β_2GPI.

Methods: For patient profiling, peripheral blood was collected from healthy donors (n=9) or primary APS patients (n=9, meeting the 2023 ACR/EULAR Criteria), and neutrophil expression of CD14 and activation markers was assessed by flow cytometry. For mechanistic studies, affinity-purified anti-β_2GPI IgG (10 μg/mL) was added to isolated primary human neutrophils or whole blood for 1-5 hours (depending on the assay) in the presence or absence of the CD14 blocking antibody atibuclimab (10 μg/mL). CD14 and activation marker expression was assessed by flow cytometry. NETs were visualized by immunofluorescence microscopy, and p38 phosphorylation was quantified by immunoblotting. Lastly, C57BL/6J mice were



Schematic illustration of the proposed roles for CD14 and p38 MAPK in pathogenic anti-β_2GPI antibody-mediated neutrophil activation and NETosis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. pretreated with the p38 inhibitor adezmapimod (25 mg/kg) or an appropriate vehicle control 1 hour prior to inducing thrombosis in the inferior vena cava. At the time of thrombosis induction, mice also received APS or control IgG (500 μg). Thrombi were collected and weighed 24 hours after surgery.

Results: Neutrophil surface CD14 showed a positive association with the activation markers CD11b and CD18 in APS patients (R^2=0.7318, p=0.0033 and R^2=0.4702, p=0.0415) but not in healthy controls (R^2=0.2448, p=0.1757 and R^2=0.2237, p=0.1985). Furthermore, healthy neutrophils treated with anti-β_2GPI displayed increased surface CD14 expression (1.7-fold change, p=0.0078). Given the association between CD14 and APS-associated neutrophil activity, we asked whether CD14 blockade with atibuclimab could mitigate the effects of anti-β_2GPI on neutrophils. Indeed, atibuclimab attenuated anti-β_2GPI-induced neutrophil CD11b expression (0.7-fold change, p=0.0319), p38 phosphorylation (0.5-fold change), and NET formation. Having seen that p38 phosphorylation downstream of anti-β_2GPI was CD14 dependent, we assessed whether p38 inhibition with adezmapimod could modulate APS-associated thrombosis in vivo. In mice, APS IgG potentiated thrombus weight (mean 5.5 mg vs 2.6 mg, p=0.002), which was significantly attenuated with adezmapimod treatment (mean 2.1 mg vs 5.5 mg, p=0.0004).

Conclusion: Neutrophil CD14 appears to be required for the p38 MAPK-mediated neutrophil activation and NETosis reliably triggered by anti-β_2GPI in APS. This work identifies neutrophil surface CD14 and downstream p38 MAPK signaling as novel therapeutic targets with the potential to restrain not only thrombosis, but also the upstream inflammation that underlies APS.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Antiphospholipid Syndrome (0855–0860)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Cardiovascular disease is a major cause of morbidity and mortality in antiphospholipid syndrome **(APS)**, with rates of accelerated atherosclerosis comparable to those seen in diabetes. Although the proatherogenic (and other) effects of IgG antiphospholipid antibodies (**aPL**) have been widely studied, emerging evidence suggests that IgA aPL—particularly IgA anti-β2-glycoprotein I (**aβ2GPI**)—may also contribute significantly to atherogenesis. For example, a population-based study demonstrated a fourfold increased risk of future atherosclerotic cardiovascular events among individuals with IgA aPL but no established autoimmune condition. In the same study, IgA aPL were associated with reduced cholesterol efflux capacity (**CEC**), a critical anti-atherosclerotic function of HDL. However, the mechanisms by which IgA

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: aβ2GPI IgA enhances fatty acid uptake in macrophages and impairs their cholesterol efflux capacity. (A) Macrophage fatty acid uptake was evaluated in real-time after 4hrs pre-treatment with 25 µg/mL of either control IgA or aβ2GPI IgA for 90 minutes. Fluorescent fatty acid analogs were used to assess intracellular uptake. (B) Comparison of % Cholesterol efflux at 4 hours after treatment with 25µg/mL of control or aβ2GPI IgA. Significance, *p<0.05, and ***p<0.001.

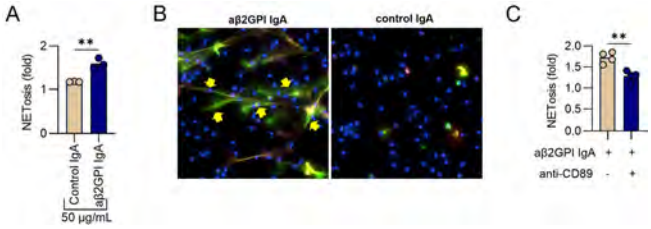

Figure 2: aβ2GPI IgA induces NETosis in neutrophils from healthy donors. (A) Donor neutrophils were treated with aβ2GPI IgA (50 µg/mL) or control IgA (50 µg/mL). NETosis was quantified by SYTOX Green assay. (B) Neutrophils treated with IgA by microscopy (green=neutrophil elastase; red=myeloperoxidase; and blue=DNA; arrows indicate netting neutrophils). (C) Treatment with anti-CD89. Significance, **p<0.01.

aβ2GPI might promote vascular dysfunction and frank atherosclerosis remain poorly defined. Here, we aimed to investigate the role of IgA aβ2GPI in promoting atherosclerosis through effects on myeloid cells, HDL function, and vascular integrity.

Methods: Total IgA was purified from IgA aβ2GPI-positive patients (**aβ2GPI IgA**) and assessed in various *in vitro* and *in vivo* systems. Myeloid cell functional assays assessed CEC, fatty acid uptake, foam cell formation, and NETosis. Aortic endothelial function was tested in mice treated with either aβ2GPI IgA or control IgA. Vascular reactivity was measured by wire myography, and plasma HDL function was evaluated using a CEC assay.

Results: Compared with control IgA, treatment of macrophages with aβ2GPI IgA significantly enhanced fatty acid uptake and promoted foam cell formation—hallmarks of early atherogenesis. aβ2GPI IgA also impaired cholesterol efflux capacity, a critical anti-atherosclerotic function of HDL (**Fig. 1**). Furthermore, aβ2GPI IgA triggered robust NETosis by healthy primary neutrophils, an effect that was markedly reduced by blockade of the IgA receptor CD89 (**Fig. 2**). *In vivo*, mice treated with aβ2GPI IgA exhibited widespread vascular dysfunction. Wire myography demonstrated impaired acetylcholine-mediated relaxation of phenylephrine-contracted aortic rings (i.e., endothelium-dependent relaxation), consistent with endothelial impairment (**Fig. 3A-B**). Plasma from the same mice demonstrated significantly reduced cholesterol efflux capacity compared to controls, suggestive of HDL dysfunction (**Fig. 3C**). Collectively, these findings support a mechanistic model in which aβ2GPI IgA promotes proatherosclerotic vascular injury via three interrelated pathways: (1) induction of lipid-laden, pro-atherogenic macrophages; (2) CD89-dependent NETosis; and (3) systemic impairment of HDL function and endothelial responsiveness.

Conclusion: By driving foam cell formation, inducing CD89-mediated NETosis, and impairing HDL function and endothelial responsiveness, aβ2GPI IgA may have a role as a key mediator of atherogenesis in APS. Targeting IgA-driven mechanisms may offer new therapeutic avenues to mitigate cardiovascular risk in affected patients.

Background/Purpose: Neutrophil extracellular traps (**NETs**) are webs of chromatin and proteases (e.g., neutrophil elastase) that have been implicated in antiphospholipid syndrome (**APS**)-associated thrombosis; however, their contribution to the placental dysfunction inherent to APS remains underexplored. Here, we aimed to investigate the impact of antiphospholipid antibodies (**aPL**) and downstream NET formation on implantation, placental health, and fetal viability in mice.

Methods: Wild-type (WT) mice were injected with 2 mg of IgG pooled from either healthy donors or APS patients on gestational days 0, 3, 6, 9, and 12; placental resorptions were assessed on day 15. *Pad4*-deficient mice, which are known to have reduced NET formation, were evaluated in parallel. Circulating myeloperoxidase (MPO)-DNA complexes were quantified as markers of NETs, and plasma PlGF-2 as a measure of placenta-associated angiogenesis. Placental histopathology was assessed using a semiquantitative scoring system evaluating six parameters—vasculopathy, thrombosis, inflammation, fibrin deposition, villous ischemia, and hemorrhage—each graded from 0 (normal) to 3 (severe). Placental expression of citrullinated-histone H3 was analyzed by immunoblotting. In vitro experiments were performed with HTR-8/SVneo trophoblasts.

Results: Among APS IgG-treated WT mice, 29.6% with a vaginal plug (indicating copulation) had a false pregnancy, compared with 16.0% in the control IgG group. None of the *Pad4*$^{-/-}$ mice treated with APS IgG had a false pregnancy. Mean fetal resorption rates were significantly higher in APS IgG-treated WT mice (15.8% for n=16 mice) compared with control IgG-treated WT mice (5.8% for n=19 mice, p=0.0096). APS IgG-treated *Pad4*$^{-/-}$ mice had an average of 3.6% resorptions (n=10 mice, p=0.0079 compared with APS WT mice). Plasma MPO-DNA complexes were significantly higher in APS WT mice compared with both controls (mean 1.8-fold, p=0.0061) and APS *Pad4*$^{-/-}$ mice (1.9-fold, p=0.0135). In contrast, plasma PlGF-1 levels were reduced by approximately 2-fold in APS WT mice compared with controls (p=0.0100); the APS *Pad4*$^{-/-}$ mice did not differ from controls. Inflammation was the most prominent feature in non-resorbed APS WT placentas (mean score=2.7 versus 1.0 in controls), followed by vasculopathy and hemorrhage; the inflammatory infiltrate was predominantly neutrophilic. Notably, resorbed APS WT placentas had dramatically increased citrullinated-histone H3 expression (a marker of NETs), which was absent in resorbed control placentas. Finally, in vitro, trophoblast proliferation was impaired after 48 hours of exposure to purified NETs (1 μg/mL) compared with vehicle-treated cells (p = 0.0323). The neutrophil elastase inhibitor GW311616A restored proliferation to baseline levels, suggesting a role for elastase's enzyme activity in NET-mediated trophoblast dysfunction.

Conclusion: These findings suggest that APS IgG may contribute to fetal loss and placental alterations by triggering increased NET formation. Significant protection in NET-deficient *Pad4*$^{-/-}$ mice suggests that NET inhibition is an approach worth exploring to improve pregnancy outcomes in the APS clinic.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

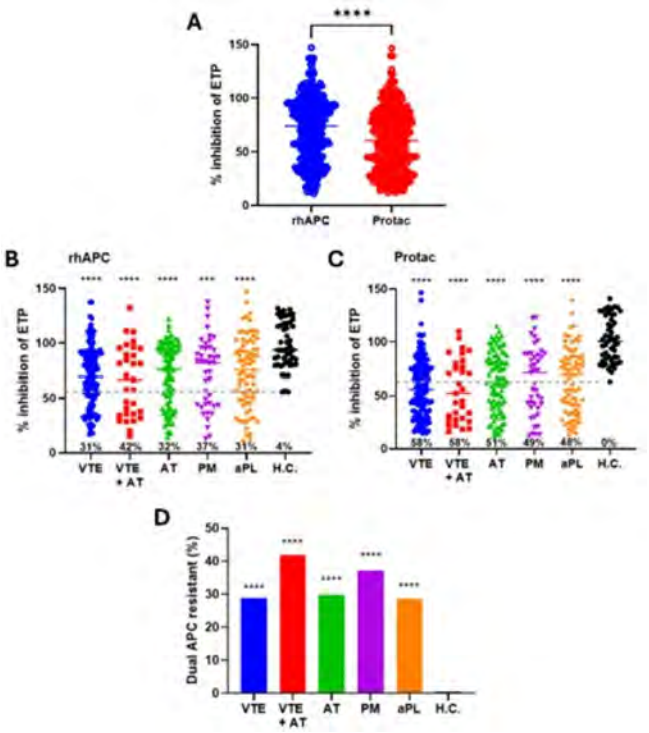
Session Title: Abstracts: Antiphospholipid Syndrome (0855–0860)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Dysregulation in the protein C anticoagulant pathway, more specifically acquired resistance to activated protein C (APCr) and antibodies against protein C (anti-PC), has been proposed as a potential contributing mechanism in the pathophysiology of antiphospholipid syndrome (APS). However, prevalence, clinical significance, and predictive value have not been established.To determine the prevalence of APCr and anti-PC, their associations with antiphospholipid antibody (aPL) profiles and clinical phenotypes, and their predictive value for new thrombotic events.

Methods: Patients with aPL with/without APS classification were identified from the prospective APS ACTION registry (n=283) and University College London Hospital database (n=87). Fifty-one healthy controls were also included. Patients (n=370) were subcategorised by clinical phenotype: aPL only (n=77), pregnancy morbidity (PM) only (n=43), venous thromboembolism (VTE) (+/-PM) (n=132), arterial thrombosis (AT) (+/-PM) (n=87), or VTE+AT (+/-PM) (n=31). Based on baseline samples of different subgroups, APCr was determined using thrombin generation with recombinant human APC (rhAPC)



Activated protein C (APC) resistance in the different aPL cohorts. Thrombin generation was measured using platelet-poor plasma (PPP)in patients with aPL (n=370) with or without antiphospholipid syndrome (APS) and healthy controls (H.C., n=51); A: Paired comparison of % inhibition of ETP by rhAPC and Protac in the patient cohort (n=370). Patients were subcategorised into clinical manifestations of venous thromboembolism (VTE, n=132), arterial thromboembolism (AT, n=87), VTE + AT (n=31), pregnancy morbidity (PM, n=43), carriers of aPL (aPL, n=77) and compared to H.C. (n=51) with rhAPC (B) and Protac (C). Grey dotted lines (56% for rhAPC, 63% for Protac) indicate cut-offs established in HC. (56% for rhAPC, 63% for Protac) are considered APC resistant, with percentages shown. The proportion of each clinical subcategory that were resistant to both rhAPC and Protac are shown (D), compared to H.C. ***p<0.001, ****p<0.0001

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. APC resistance and anti-protein C antibodies. Citrated plasma from APS patients with VTE, n=132, ATE, n=87, VTE + ATE (n=31), PM, n=43, aPL only, n=77 and H.C., n=51 were diluted 1:25 and run on an in-house protein C ELISA to detect anti-protein C (anti-PC) antibodies. Antibody titres of subjects in each group are shown, compared to H.C. (A): Values on or above the grey dotted line (36U/mL) are considered positive for anti-PC antibody, with percentage of each group positive for antibody shown. The proportion of the antibodies detected (VTE n=61, VTE + AT n=14, AT n=31, PM n=23, aPL n=26) that were high avidity were compared to the aPL only cohort. (B): The antibody titres of all high avidity (n=88) and low avidity (n=66) anti-PC were compared. (C): High avidity anti-PC were significantly at higher titres compared to low avidity anti-PC. (D) The proportion of patients with no APC resistance (n=167), recombinant human APC (rhAPC) resistance (n=122), Protac resistance (n=196) and resistance to both rhAPC and Protac (n=115) with anti-protein C antibodies. (E): The proportion of anti-protein C antibodies that were high avidity in each of the APC resistance groups. *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001, ns – not significant, resis. – resistance

or Protac (for endogenous protein C activation). Anti-PC and avidity were detected by in-house ELISA. In a subgroup analysis, based on prospective APS ACTION data, the incidence of new thrombotic events was compared in patients with and without APCr and anti-PC.

Results: All patient subgroups had markedly greater APCr than healthy controls (p< 0.001), most prominent in 'higher risk' patients, i.e., those with VTE+AT or triple aPL-positivity (Figure 1). Forty-two percent (156/370) of patients were positive for anti-PC with the highest prevalence in the PM, VTE and VTE+AT cohorts: 53%, 47%, and 45%, respectively, and lowest prevalence in aPL only patients (34%) (Figure 2A). The VTE+AT group had significantly higher prevalence of high avidity anti-PC (79%) compared to aPL only patients (38%) (p< 0.05, Figure 2B). Most patients with APCr (69.5% [141/370]) had detectable anti-PC. There was a strong association between presence of APCr and anti-PC (Figure 2D) especially in the VTE+AT and the triple aPL positive patient groups. During the follow-up (median 8.3 years) of APS ACTION patients, 25/283 (8.8%) patients had new thrombosis; there was no difference in the number of new thrombotic events in patients with or without APCr or anti-PC (p=0.60). Non-anticoagulated patients with APCr had a higher number of new thrombotic events compared to those without APCr, although this did not reach statistical significance (HR 4.5, 95% CI 0.8-25.9, p=0.14).

Conclusion: Acquired resistance to activated protein C is highly prevalent in persistently aPL-positive patients with the highest prevalence in 'higher risk' APS patients. The lack of an association with thrombosis in these patients may reflect the effectiveness of anticoagulation. The association between greater APCr and thrombosis in non-anticoagulated patients merits exploration as to whether this may provide a basis to guide consideration of initiation of prophylactic antithrombotic treatment in this subset of patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II: Basic & Translational Research (0861–0866)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Myositis-specific autoantibodies (MSAs) play a crucial role in diagnosing and classifying idiopathic inflammatory myopathies (IIMs). However, approximately 30% of seronegative IIM patients may be unrecognized or misdiagnosed due to the absence of reliable biomarkers. This study aims to identify potential autoantibodies in seronegative IIM.

Methods: We enrolled 42 seronegative IIM patients, 149 MSA-positive IIM cases, 83 healthy controls (HCs), and 83 autoimmune disease controls (DCs). Initial high-throughput autoantibody screening was performed using the HuProt^{TM} human proteome microarray in a discovery cohort. Subsequently, candidate antigens were expressed, purified, and validated via western blotting in an expanded cohort. An autoantigen-induced murine model was then utilized to explore immunological properties.

Results: Through systematic screening and validation, anti-hepatoma-derived growth factor-like protein 1(HDGFL1) was identified as a novel autoantibody, detected in 33% (14/42) of seronegative IIM patients but absent in HCs (0/83, $P< 0.0001$). Within the seronegative IIM group, anti-HDGFL1 antibody-positive patients demonstrated significantly higher frequencies of rash (71.4% vs 25.0%, $P=0.004$) and arthritis (28.6% vs 3.6%, $P=0.035$) compared to anti-HDGFL1 antibody-negative patients.

HDGFL1-immunized mice developed specific autoantibodies, alongside elevated levels of serum creatine kinase and aspartate aminotransferase compared to the control group. Histopathological examination revealed pronounced inflammatory cell infiltration in skeletal muscle, characterized by increased CD3+ T cells and CD68+ macrophages. Flow cytometric analysis indicated enhanced splenic T cell proliferation in the HDGFL1-immunized group compared to controls.

Conclusion: Anti-HDGFL1 autoantibody was identified as a novel biomarker for the diagnosis of seronegative IIM, offering new insights into immunopathogenesis.

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II: Basic & Translational Research (0861–0866)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: The aim of this study was to investigate whether in immune-mediated necrotising myopathy (IMNM), anti-HMGCR antibodies interfere with HMGCR activity and have a myopathic effect.

Methods: To obtain polyclonal anti-HMGCR autoantibodies, the 6 peptides identified as the epitopes of anti-HMGCR antibodies were used to immunise a white New Zealand rabbit. Antibodies from a non-immunised animal served as control. Plasma of anti-HMGCR (n=5) and anti-SRP (n=2) IMNM patients were obtained from plasmapheresis eluates. Rabbit and human anti-HMGCR antibodies were purified by affinity chromatography. Inhibition of HMGCR was measured *in vitro* by spectrophotometry in the presence of different concentrations of autoantibodies. Pravastatin was used as a negative control. Human autoantibodies were electroporated into human myotubes: creatine-kinase levels (CK) were measured in the supernatant, and hematoxylin/eosin (H&E) as well as oil red-O stainings were performed.

Thirty-four patients with inflammatory myopathies (IM) according to the EULAR/ACR 2017 criteria, not taking immunomodulators or statins, were included (anti-HMGCR: n=10; other IM: n=24) as well as 3 patients without neuromuscular diseases (no NMD). Histological sections of deltoid muscle taken at the time of diagnosis were immunostained with an anti-human IgG antibody. Oil red-O staining was used to study the accumulation of lipid droplets, quantified (extension score 0-4) by two myopathologists blinded to the diagnosis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Anti-hydroxy-3-methylglutaryl CoA reductase (HMGCR) antibodies inhibit HMGCR activity leading to lipid droplet accumulation in myofibres. a) Maximum (max) *in vitro* HMGCR activity in the presence of rabbit purified polyclonal anti-HMGCR, control antibodies and pravastatin. *: p= 0.04, **: p=0.002, ****: p= 0.0001, ns: not significant (vs. vehicle). b) Maximum *in vitro* HMGCR activity in the presence of plasma and purified autoantibodies from anti-HMGCR immune-mediated necrotising myopathy (IMNM) patients, plasma from anti-SRP IMNM patients and pravastatin. *: p<0.05, **: p<0.01, ns: not significant (vs. vehicle). c) Representative images of oil red-O staining performed 4 days after electroporation of human myotubes exposed to purified human anti-HMGCR antibodies or human control antibodies or pravastatin. Scale bar: 50 µm. Brown arrows point to lipid droplets. d) Representative images of oil red-O-stained deltoid muscle cryosections of untreated patients with inflammatory myopathies (IM). * indicates fibres with lipid droplet accumulation (one example per image). Scale bar: 50 µm. e) Oil red-O staining score in deltoid muscle cryosections of patients with IM. Each dot represents a patient. Scores are expressed as mean ± standard error of the mean. ***: p=0.0001 compared to anti-HMGCR IMNM. #: p=0.0001, ns: not significant compared to non-NMD patients.

Results: To test whether anti-HMGCR antibodies inhibit the function of their target, HMGCR enzymatic activity was assessed *in vitro* in the presence of anti-HMGCR, control antibodies and pravastatin. A dose-dependent inhibition of HMGCR activity was observed in the presence of anti-HMGCR (Figure 1a). Rabbit anti-HMGCR 5 µg/ml and human anti-HMGCR 2 µg/ml had similar effects to that of pravastatin 0.5 µM (Figure 1a, 1b). IgG from the non-immunised rabbit and plasma from anti-SRP patients did not affect HMGCR activity (Figure 1a, 1b).

To test whether anti-HMGCR internalisation in myofibres exerts a myopathic effect, human myotubes were electroporated with human purified anti-HMGCR, control IgG or pravastatin. Antibody presence in the cytoplasm 4 days after electroporation was confirmed. CK levels were 2.4-fold higher in the supernatant of myotubes electroporated with anti-HMGCR compared to those electroporated with control IgG (p=0.0001). H&E staining showed necrotic myotubes after electroporation with purified anti-HMGCR and pravastatin, but not with control IgG. Oil red-O staining revealed a lipid droplet accumulation in myotubes electroporated with purified anti-HMGCR and pravastatin, but not with control IgG (Figure 1c). Lipid droplet accumulation score was 10-fold higher in anti-HMGCR IMNM patients compared to other IM and no NMD (3.2 ± 0.6 vs. 0.3 ± 0.5; vs. 0.3 ± 0.6, respectively, p=0.0001) and a score ≥ 2 was a hallmark of anti-HMGCR IMNM (Figure 1d, 1e).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Together, these data demonstrate that anti-HMGCR antibodies inhibit HMGCR activity, leading to the sarcoplasmic accumulation of lipid droplets and myofibres necrosis. These findings could have implications for both the diagnosis and treatment of IMNM.

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II: Basic & Translational Research (0861–0866)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Although inclusion body myositis (IBM) is an inflammatory myopathy, there are no effective immunomodulating agents, underlying the need for better understanding of its pathogenesis. Previous studies have implicated KLRG1+ TBX21+ CD8+ T cells as drivers of IFNG-mediated inflammation in IBM. Based on previous reports, we hypothesize that myeloid dendritic cells (mDCs) may activate these CD8+ T cells. Here, we sought to identify and characterize mDC subsets in IBM muscle and examine their correlation with transcriptomic markers of disease activity.

Table 1. Patient composition of datasets used in snRNA-seq and RNA-seq analyses. Datasets B, C, and E were publicly available datasets, derived from Wischnewski et al. *Nature Aging* 2024, Nelke et al. *Acta Neuropathol* 2023, and Ikenaga et al. *Ann Neurol* 2022 respectively.

Assay	Dataset	IBM	Other Inflammatory Myopathy (OIM)	CTRL	Total
snRNA-seq	A	4	21 • 9 Dermatomyositis (DM): 4 anti-Mi2, 2 anti-NXP2, 3 anti-TIF1γ • 7 Immune-mediated necrotizing myopathy (IMNM): 4 anti-HMGCR, 3 anti-SRP • 5 Anti-synthetase syndrome (ASyS): 5 anti-Jo1	2	27
	B	8	4 • 4 Immune-mediated necrotizing myopathy (IMNM): 4 anti-SRP	7	19
	C	3	0	3	6
	Total	**15**	**25**	**12**	**52**
RNA-seq	D	53	199 • 82 Dermatomyositis (DM): 22 anti-Mi2, 11 anti-MDA5, 21 anti-NXP2, 28 anti-TiF1γ • 80 Immune-mediated necrotizing myopathy (IMNM): 60 anti-HMGCR, 20 anti-SRP • 37 Anti-synthetase syndrome (ASyS): 37 anti-Jo1	37	289
	E	43	0	9	52
	Total	**96**	**199**	**46**	**341**

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. snRNA-seq Analysis. (A) UMAP clustering of all cells, (B) UMAP clustering of myeloid cells, (C) Representative specific markers of mDC subsets in snRNA-seq data, (D) Relative Proportions of mDC subsets among all cells by group, (E) Expression of *KLRG1* and its ligands (*CDH1*, *CDH2*) and *TBX21* and its activating cytokine, *IL12B*, in each cluster in IBM samples.

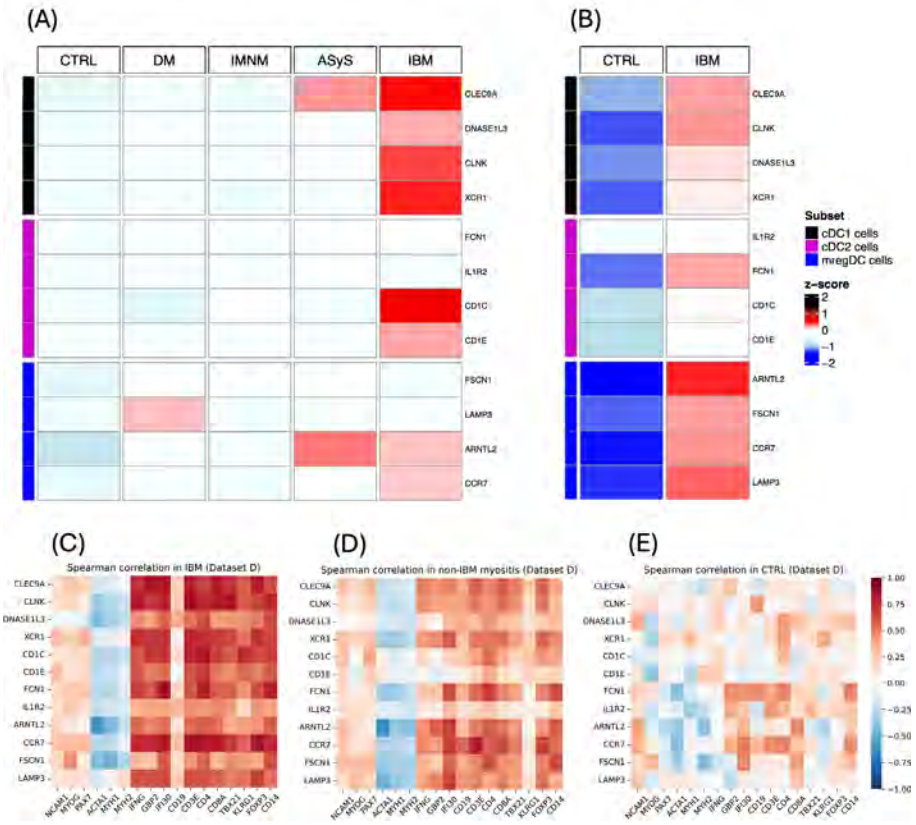
Methods: We analyzed skeletal muscle single nuclei RNA-seq (snRNA-seq) data from three datasets (A-C), including 15 IBM patients, 25 other inflammatory myopathy (OIM) patients, and 12 control (CTRL) patients (Table 1). We also analyzed skeletal muscle bulk RNA-seq data from two datasets (D-E), including 96 IBM patients, 199 OIM patients, and 46 CTRL patients (Table 1).

snRNA-seq data from Datasets A-C was merged and analyzed using Seurat/4.4.0 within R/4.4.1. Data underwent quality control, normalization, integration, UMAP generation, cluster identification to identify mDC subsets, and cluster-specific gene identification (adjusted $p < 0.001$ versus all cells and myeloid cells, $p < 0.05$ versus each cell cluster). RNA-seq data was analyzed separately using R/4.4.1 and Python/3.9.6. Counts underwent normalization using trimmed means of M values. Normalized counts were used to generate heatmaps of median mDC marker expression by myositis group and Spearman correlation heatmaps of mDC markers with transcriptomic markers of disease activity.

Results: Clustering of snRNA-seq data revealed ten main clusters. Unsupervised subclustering of the myeloid cells revealed two distinct mDC subsets: type 1 conventional dendritic (cDC1) cells and mature immunoregulatory dendritic (mregDC) cells. A third mDC subset, type 2 conventional dendritic (cDC2) cells, was identified by manually selecting cells from the main monocyte cluster expressing the cDC2 marker *CD1C* and lacking expression of the specific monocyte marker *C5AR1*. All three mDC subsets expressed subset-specific markers and were relatively increased as a proportion of total cells in IBM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. RNA-seq Analysis. (A-B) Median expression heatmaps of mDC-specific genes by group in Dataset D (A) and E (B); (C-E) Correlation heatmaps of mDC-specific genes versus transcriptomic markers of disease activity in IBM samples (C), OIM samples (D), and CTRL samples (E) from Dataset D. Markers of disease activity shown include markers of muscle regeneration (*NCAM1*, *MYOG*, *PAX7*), mature muscle (*ACTA1*, *MYH1*, *MYH2*), the IFNG pathway (*IFNG*, *GBP2*, *IFI30*), B cells (*CD19*), T cells (*CD3E*, *CD4*, *CD8A*, *TBX21*, *KLRG1*, *FOXP3*), and macrophages (*CD14*).



patients compared to other groups. Notably, cDC1 cells exhibited the highest average expression of the two ligands of KLRG1, *CDH1* and *CDH2*, while both cDC1 and mregDC cells specifically expressed the fate-specifying cytokine subunit for TBX21+ T cells, *IL12B* (Figure 1).

In the RNA-seq data, expression of specific mDC markers for all three subsets appeared higher in IBM samples compared to non-IBM samples across both datasets. In addition, all three subsets appeared strongly correlated with markers of the IFNG pathway and T cell subsets, including *KLRG1* and *TBX21*, in IBM samples to a greater degree than in OIM and CTRL samples (Figure 2).

Conclusion: Three mDC subsets are increased in IBM muscle compared to OIM and CTRL muscle. Markers of these subsets correlate with markers of the IFNG pathway and T cell subsets. We propose that cDC1 cells activate IFN-γ-secreting KLRG1+ TBX21+ CD8+ T cells via specific expression of the ligands of KLRG1, *CDH1* and *CDH2*, and *IL12B*.

Immunophenotyping Reveals Upregulated IL-9R on Circulating T and B Cells in Dermatomyositis

Danica Lee[1], Daniel Reay[2], Timothy Oriss[2], Didem Saygin[3], Dana Ascherman[4] and Daniella Schwartz[4], [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, [3]Rush University Medical Center, Chicago, IL, [4]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II: Basic & Translational Research (0861–0866)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM), or myositis, comprise a group of autoimmune diseases with significant morbidity, yet the pathogenesis of myositis remains incompletely understood. In addition to inflammatory muscle disease, myositis can cause lung, vascular, and skin disease. A previous analysis of subjects with myositis revealed significant elevation of serum IL-9 (p=0.001) relative to healthy volunteers (**Saygin et al., 2024**). Therefore, we questioned whether IL-9 might *directly* promote disease pathology by modulating myocyte or immune cell function. We hypothesized that Th9 cells (IL-9$^+$ secreting CD4$^+$ T cells) infiltrate inflamed muscle tissue to promote inflammatory cell recruitment and autoantibody formation in IIM.

Methods: To determine potential cellular targets of high serum IL-9 in myositis, we first re-analyzed GSE220915 and GSE221091, two publicly available RNA-seq datasets on myositis patient muscle biopsies and dermatomyositis (DM) patient sorted immune cells, respectively. We quantified IL-9 receptor (IL-9R) mRNA levels as well as expression of *SPI1*, the master transcription factor of the Th9 cell lineage. Next, we cultured peripheral blood mononuclear cells (PBMCs) from pre-treatment DM patients and sex and age-matched healthy controls *in vitro*. Spectral flow cytometry was used to quantify IL-9R expression on B cells, T cells, and monocytes.

Results: In DM patients, immunomodulatory treatment, including oral prednisolone, methotrexate, azathioprine, and cyclophosphamide, reduced expression of *SPI1* in CD4$^+$ T cells (**Figure 1A**, GSE221091). *IL9R* was expressed in patient muscle biopsy tissue from many subtypes of IIM (**Figure 1B**, GSE220915). In sorted PBMCs, *IL9R* mRNA levels were higher in B and T cells from myositis patients compared to monocytes (**Figure 1C**, GSE221091). Furthermore, not only was *IL9R* mRNA increased, but IL-9R surface protein expression was significantly increased on circulating B cells, memory T cells, and CD4$^+$ T cells in DM patients compared to healthy controls (**Figure 2**).

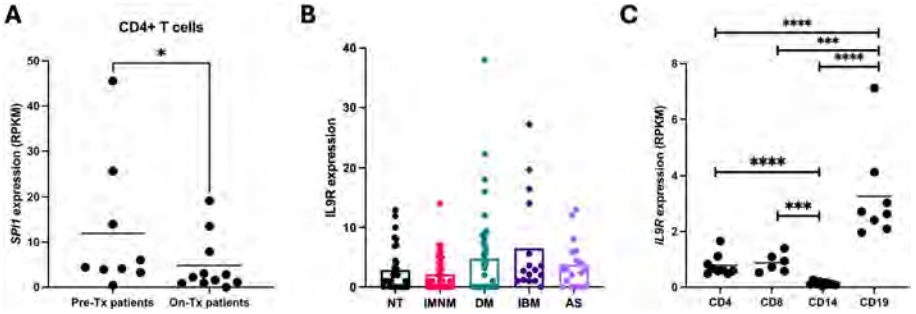

Figure 1. (A) SPI1 expression (RPKM, reads per kilobase per million mapped reads), a marker of Th9 identity, was higher in CD4+ T cells from pre-treatment (Pre-Tx) myositis patients compared to myositis patients currently on medication (On-Tx). (B) IL-9R was expressed in muscle tissue from myositis patients. NT=normal tissue, IMNM=immune-mediated necrotizing myopathy, DM=dermatomyositis, IBM=inclusion-body myositis, AS=anti-synthetase syndrome. (C) IL-9R expression (RPKM) was highest in peripheral blood B cells from myositis patients. *p<0.05, ***p<0.001, ****p<0.0001, Kolmogorov-Smirnov test.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

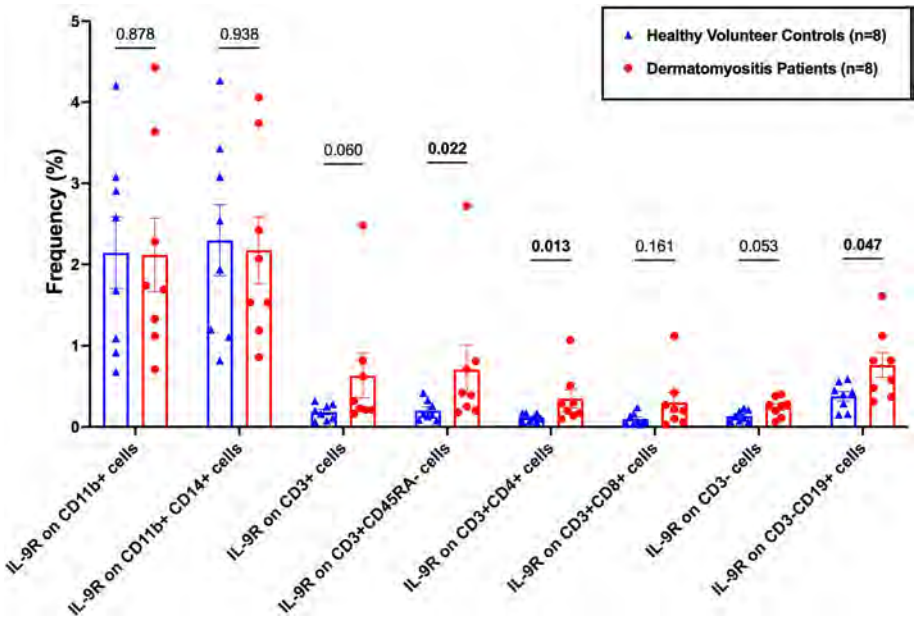

Figure 2. Frequency of IL-9R expression on unstimulated monocytes, B cells, and T cells. p<0.05, Mann-Whitney.

Conclusion: Treatment with immunomodulators reduces *SPI1* expression in CD4+ T cells, suggesting involvement of the Th9/IL-9 axis in IIM. DM is also characterized by increased IL-9R surface expression on circulating T and B cells and within inflamed muscle, suggesting they may be key cellular targets of IL-9 signaling in myositis pathogenesis. Future studies will profile human muscle samples (biopsy/RNAscope and scRNA-seq) for Th9 cells and IL-9R-expressing populations.

Background/Purpose: Calcinosis cutis affects up to 20% of adults with dermatomyositis (DM), causing significant morbidity including recurrent infections, incapacitating pain, and functional impairment. Current management focuses on surgical excision despite the risk of recurrence. To better understand and treat this devastating complication, we must first better understand its pathogenesis, including gene expression profiles and relevant cell types.

Methods: We performed Visium 10X spatial transcriptomics on four calcinosis samples from adult DM patients meeting 2017 ACR/EULAR criteria (positive for anti-MDA5, PM-Scl, Ro, and Jo-1) and three healthy adult control skin biopsies. All DM samples contained active calcinosis defined as new or evolving lesions. Data preprocessing was conducted using cellranger, with downstream analysis conducted in R using the Seurat v5.0.0 package. Pseudo-bulk analysis was conducted using the DESeq2 v. 1.44.0 package, and all other differential expression was conducted using the default FindMarkers command. Spatial annotations were conducted in Loupe Browser 8 by one observer (CP).

Results: Pseudo-bulk analysis (Fig. 1) identified a distinct inflammatory signature with elevated *IL6* RNA expression and upregulation of macrophage markers (*CD68*, *MSR1*) and chemokine *CCL3*. We observed increased transcription of RNA encoding immunoglobulins (*IGKC*, *IGHG1*, *IGHA1*, *JCHAIN*). Extracellular matrix dysregulation was evidenced by decreased keratin expression, elevated *MMPs 1/9/13*, and elevated cartilage/bone-specific collagens. Osteopontin (*SPP1*), which resorbs pathological calcification, was robustly elevated in lesional samples.

UMAP analysis revealed minimal overlap between DM and healthy control samples, prompting us to adopt a spatial-first approach. In the DM samples, spatial transcriptomic spots were categorized based on their distance from the calcinosis lesion into four groups: < 50 μm (C), 50–100 μm (P), 100–150 μm (2P), and 150–200 μm (3P). Differential expression analysis across these groups showed that *SPP1* expression was highest near the calcinosis, while professional antigen-presenting cell (APC) markers, immunoglobulin genes, and complement genes were most enriched 100–150 μm from the lesion. Additionally, a complex interplay of matrix remodeling genes, including *MMPs* and their regulators (*TIMPs*), was observed at varying distances from the calcinosis (Fig. 2).

Conclusion: This study provides the first detailed spatial molecular map of calcinosis in DM, suggesting a complex pathogenic cascade involving macrophage-driven inflammation, enhanced local antibody production, and increased osteopontin expression. Further validation is planned to refine our interpretation and explore cell types and signals driving disease pathogenesis.

Background/Purpose: Most patients with inflammatory myopathies have autoantibodies to intracellular proteins. We previously showed that immunoglobulin colocalizes with its cognate autoantigen in muscle biopsies from myositis patients. Transcriptomic analyses of muscle biopsy specimens revealed that each myositis autoantibody is associated with a unique transcriptomic profile.

We confirmed that these effects are antibody-mediated by using electroporation to internalize antibodies from patients into cultured muscle cells. Cultured muscle cells with internalized immunoglobulin from anti-MDA5+ and anti-Mi2+ patients expressed the same genes (e.g., Mx1 and CAMKV, respectively) as seen in the muscle tissue.

The aims of the current study were to: (i) determine if electroporation of myositis-associated antibodies into human endothelial cells has similar transcriptomic profile as seen in muscle and (ii) to determine if immunoglobulin could passively enter cultured endothelial cells without electroporation.

Methods: Electroporation of purified antibody from Healthy controls, MDA5+, and Mi2 + sera was performed in HUVECS. The cells were incubated for 24hrs at 37 degrees Celsius following electroporation in appropriate growth media. The RNA was extracted from the HUVECs and RNA to CT was performed for comparative, quantitative PCR using Mx1 and CAMKV as probes and an18S as an internal loading control to assess gene expression.

For passive antibody uptake experiments, HUVECs were cultured for 24 hours in growth media with purified healthy control, Mi2 +, and MDA5 + immunoglobin at 6 different concentrations (1:3 titration). RNA was the extracted using RNEAsy kits. Taqman RNA to CT kit was used to perform comparative, quantitative PCR to measure MX1 gene expression relative to an 18S loading control.

Results: Electroporation of MDA5 antibody increased resulted in increased relative MX1 expression as measured by PCR and electroporation of Mi2 antibodies resulted in relatively increased CAMKV compared to MDA5 and Healthy controls, respectively (Figure 1).

Purified concentrated, MDA5 IgG that was passively introduced via a 24-hour incubation resulted in significantly increased relative Mx1 expression compared to healthy control IgG or Mi2 IgG (Figure 2).

Conclusion: These results suggest that autoantibodies are able to enter the cultured endothelial cells both with electroporation and passively, without electroporation. The higher relative MX1 expression with internalization of purified immunoglobulin from MDA5 and Mi2 compared to healthy controls suggests that the antibodies themselves may be contributing to pathogenesis and that endothelial cells may be contributing to disease pathogenesis in some types of idiopathic inflammatory myositis. Additional work is ongoing to elucidate the mechanism for the antibodies passively entering the cells and reaching the antigenic target.

NLRP3 Inflammasome Impairs Fracture Repair in Rheumatoid Arthritis through RhoA/Rac1-IL1β Axis-Mediated Suppression of Osteoblast Differentiation

Wen Sun and Hua Wang, Nanjing Medical University, Nanjing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Rheumatoid Arthritis – Animal Models (0867–0872)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Rheumatoid arthritis (RA) is often characterized by bone loss and fragility fractures and is a frequent comorbidity. The NLRP3 inflammasome, a key mediator of inflammation, drives inflammatory processes that fundamentally accompany the pathogenesis of RA. However, the role of NLRP3 inflammasome in RA fracture healing remains unclear.

Methods: For in vivo analyses, we established tibial fractures in two murine RA models: TNF-transgenic (TNF^{Tg}) mice and collagen-induced arthritis (CIA). To address the contribution of NLRP3 inflammasome to fracture repair in RA, we generated TNF^{Tg};$NLRP3^{KO}$ mice by deleting the NLRP3 gene in TNF^{Tg} mice. The effects of TNFα overexpression on osteogenic differentiation were assessed using mesenchymal progenitor cells (MPCs) with or without MCC950, a potent and specific inhibitor of the NLRP3 inflammasome. The role of MCC950 in RA fracture repair was investigated using CIA mice.

Results: TNF^{Tg} mice exhibited delayed fracture healing, characterized by decreased callus bone volume and reduced bone mechanical strength. The NLRP3 inflammasome was excessively activated in TNF^{Tg} mice, leading to elevated expression of NLRP3, IL-1β, and Caspase-1. Moreover, NLRP3 deficiency in TNF^{Tg} mice significantly mitigated the delayed fracture healing (Fig. 1). Mechanistically, TNFα overexpression suppressed osteogenic differentiation of MPCs through NLRP3 inflammasome activation. This process involves RhoA/Rac1-dependent NF-κB signaling that triggers inflammasome assembly, ultimately leading to IL-1β secretion. Notably, MCC950 administration significantly attenuated these pathological effects. Lastly, in vivo MCC950 treatment rescued the delayed fracture healing by reducing NLRP3 inflammasome activation and promoting bone formation in CIA mice (Fig. 2).

NLRP3 deficiency improves delayed fracture healing in TNFTg RA mice

Conclusion: This study provides novel insights into the mechanisms underlying delayed fracture healing in RA and highlights the potential therapeutic benefits of targeting the NLRP3 inflammasome (Fig. 3).

PD-1 inhibitor unleashes pathogenic CD8+ T cells and induce arthritis in collagen-primed mice

Clement Adedeji[1], Muhammad Hamdan[1], Hong-Jai Park[2], Kelsey Wang[1] and **Sang Kim**[3], [1]Yale University, New Haven, [2]Yale University, New Haven, CT, [3]Yale University, Branford, CT

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Rheumatoid Arthritis – Animal Models (0867–0872)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Background/Purpose: Immune checkpoint inhibitors (ICIs) are associated with immune-related adverse events, including inflammatory arthritis (ICI-arthritis). The pathophysiology of ICI-arthritis, particularly the role of T cells, remains unclear due to the lack of preclinical murine models.

Methods: We immunized 8-12-week-old C57BL/6 mice with type II chicken collagen (CII) Two to three weeks later, we administered a PD-1 inhibitor and measured arthritis scores until the mice were euthanized. Inflamed joints (knees) and CII-draining lymph nodes (dLNs) were harvested for immunologic and histological analyses.

Methods: We immunized 8-12-week-old C57BL/6 mice with type II chicken collagen (CII) Two to three weeks later, we administered a PD-1 inhibitor and measured arthritis scores until the mice were euthanized. Inflamed joints (knees) and CII-draining lymph nodes (dLNs) were harvested for immunologic and histological analyses.

Results: Mice primed with CII but without PD-1 inhibitors (CII_No PD-1i) or mice that did not receive CII but were given PD-1 inhibitors (No CII_PD-1i) did not develop arthritis. In contrast, CII-primed mice began developing arthritis 4-5 days after the initiation of PD-1 inhibitors, recapitulating human PD-1i-induced arthritis. The severity of arthritis at euthanasia was comparable between mice with PD-1i arthritis and conventional collagen-induced arthritis (CIA) mice. Histological analysis of the knee joints showed inflammation and joint destruction in CII_PD-1i mice. The numbers of $CD45^+$ immune cells were increased in the joint and draining lymph nodes (dLN) in CII_PD-1i mice compared to the CII_No PD-1i and No CII_PD-1i groups. Notably, $CD8^+$ T cells were expanded in the inflamed joints and dLNs of CII_PD-1i mice. Furthermore, these

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$CD8^+$ T cells produced inflammatory cytokines including IFNγ and TNFα in response to CII. Levels of pathogenic CII-specific antibodies in CII_PD-1i mice were lower than in CIA, suggesting that the pathogenesis of PD-1i arthritis differs from that of rheumatoid arthritis.

Conclusion: CII-primed mice developed *de novo* arthritis following PD-1 inhibition, suggesting that these mice can serve as a murine model of PD-1i arthritis. Of note $IFNg^+$ $TNFa^+$ $CD8^+$ T cells are expanded in these mice, indicating that PD-1 inhibitor unleashes pathogenic $CD8^+$ T cells in CII-primed mice.

Same Model, Different Results: Vendor and Microbiome Influence Reproducibility in Collagen Induced Arthritis

Brenda Seymour[1], Brendan Allen[2] and Kristine Kuhn[3], [1]University of Colorado School of Medicine, Denver, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]2022 - 2023 / Adult/ University of Colorado, Aurora, CO

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Rheumatoid Arthritis – Animal Models (0867–0872)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Although collagen-induced arthritis (CIA) in mice is a useful tool for studying inflammatory arthritis, it is a highly variable model with inconsistent disease severity and penetrance across studies. Previous studies have shown that CIA severity and penetrance vary by mouse strain, sex, and source of type II collagen. Furthermore, we and others have shown that CIA development is microbiome-dependent. Despite these findings, the extent to which distinct microbiome compositions affect CIA outcomes has not been well studied. As such, microbiome variation between mouse vendors, housing facilities, and even over time has the potential to negatively impact the reproducibility of CIA studies. We therefore performed a head-to-head comparison of CIA in DBA/1 mice obtained from three different vendors and compared CIA outcomes to microbiome composition.

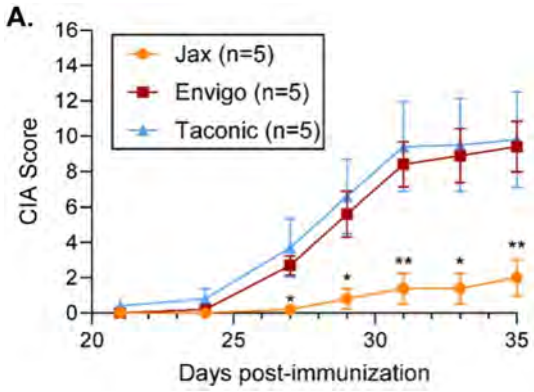

Figure 1. CIA was induced in 7-week old male DBA/1 mice from Envigo, Jax, and Taconic. Arthritis severity was scored every other day starting at day 21. Data shown are represented as mean (symbol) ± SEM (error bars). Two-way ANOVA with Tukey correction for multiple comparisons were performed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

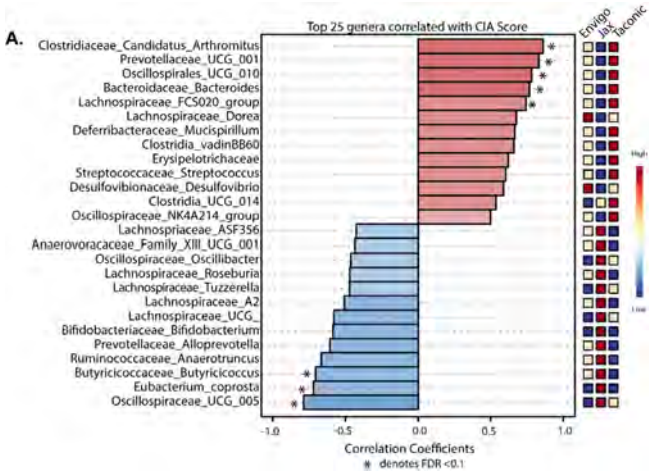

Figure 2. Fecal microbiome on CIA day 35 was assessed by 16S rRNA sequencing. The top 25 genera that correlate (spearman rank) with CIA severity were plotted. Bars represent correlation coefficient, with darker shading representing increased absolute value of the correlation efficient. * denotes FDR < 0.1.

Methods: 7-week-old male DBA/1 mice were purchased from The Jackson Laboratory (Jax), Envigo, or Taconic. Mice from the three vendors simultaneously were injected intradermally at the base of the tail with 200μg bovine CII (Elastin) emulsified in 50μl complete Freund's adjuvant (CFA, Sigma) on days 0 and 21. Disease severity was assessed every other day starting at day 21. Serum and fecal pellets were collected weekly throughout the experiment. Serum cytokines and autoantibodies were measured by ELISA; 16S rRNA sequencing was performed by the CU Anschutz Mucosal Immunobiology Core.

Results: CIA severity was significantly higher in Envigo and Taconic mice compared to Jax mice (Figure 1). While Taconic and Envigo mice had nearly identical mean CIA severity scores, there was a higher degree of score variability within the Taconic mice. Despite significant differences in CIA severity between the Jax, Envigo, and Taconic groups, there were no significant differences in total CII-IgG levels at day 28, nor CII-IgG isotypes (IgG1, IgG2a, IgG2b). We also observed significant differences in microbiome alpha and beta diversity between the three groups. Finally, we identified 7 genera that significantly correlated with CIA score (Figure 2). *Candidatus arthromitus* (also known as segmented filamentous bacteria) had the strongest positive correlation with CIA severity, while butyrate-producing *Butyricoccaceae* had a significant negative correlation with CIA severity.

Conclusion: Our findings reveal that the vendor source of mice significantly impacts CIA severity, independent of systemic autoantibody and cytokine levels. Several bacterial taxa (e.g. *Candidatus arthromitus, Butyrococcaceae)* may play a key role in disease severity differences. This highlights a critical but often overlooked source of variability that may contribute to irreproducibility across preclinical arthritis studies. Moving forward, intentional selection of mouse source—and consideration of microbiota as a key experimental variable—will be essential for enhancing the reproducibility of the CIA model.

Session Title: Abstracts: Rheumatoid Arthritis – Animal Models (0867–0872)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Despite advances in targeted therapeutics, methotrexate (MTX) remains the first-line therapy in the treatment of rheumatoid arthritis (RA) and other inflammatory arthritides. However, more than 50% of patients do not achieve clinically adequate improvement on MTX alone. For decades, investigators have sought to identify determinants of MTX response, and while multiple factors have been implicated (e.g., genetics, environment), the molecular mechanisms underpinning MTX response are incompletely understood. We sought to investigate the extent to which the human gut microbiome contributes to variation in MTX response. We previously showed that among RA patients, the gut microbiome is associated with MTX efficacy. Further, we found microbial communities from RA patients variably depleted MTX *ex vivo*, and that depletion was negatively associated with future MTX efficacy. We also identified multiple representative human gut bacterial strains that directly deplete MTX *in vitro*. Given these clinical associations and supportive *ex vivo* and *in vitro* findings, here we quantify the extent to which the human gut microbiome contributes to MTX pharmacokinetics (PK) *in vivo* and whether this is linked to treatment outcomes in autoimmunity.

Methods: Germ-free mice were variably colonized with human or murine microbiota. We quantified levels of MTX and its metabolites in circulation and stool using LC-MS over an 8- to 24-hour time course. We used stable isotope labeling to identify novel MTX metabolites. We harvested strains from RA patients to test their MTX metabolism abilities *in vitro*. We used specific-pathogen-free (SPF) SKG mice reared in different facilities to test the impact of the gut microbiota on MTX pharmacology and clinical arthritis scores.

Results: MTX PK profiles significantly differed between germ-free and colonized mice *in vivo*. Further, germ-free mice colonized with different patient microbiota significantly differed in MTX plasma profiles. We harvested over 300 bacterial strains from RA patients representing 46 unique species; of these, 12 (26%) metabolized MTX *in vitro*. Stable isotope labeling studies revealed 3 novel MTX metabolites, and one of these novel metabolites was found to be the major product of microbial metabolism. Finally, studying SPF SKG mice reared at two different facilities with differing microbiota, we found that clinical response to MTX differed by facility, that co-housing reduced this difference, and that germ-free mice colonized with these different mouse microbiotas showed significantly different MTX PK profiles, suggesting that microbial MTX metabolism is linked to treatment outcomes *in vivo*.

Conclusion: We provide evidence that the human gut microbiome causally contributes to MTX pharmacology *in vivo* through known and novel mechanisms and raise the possibility that microbial metabolism can be modulated to impact MTX pharmacology and treatment outcomes in patients. These results are a first step towards understanding and manipulating the human gut microbiome in the treatment of autoimmunity and the advancement of precision medicine for millions of patients globally taking MTX for autoimmunity.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Animal Models (0867–0872)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Schnurri-3 (SHN3) is an adaptor protein and a negative regulator of osteoblast (OB) function. Its inhibition prevents bone loss and joint erosion in models of rheumatoid arthritis (RA). TNF enhances osteoclast differentiation while suppressing OB function, promoting bone loss. Previously we reported that TNF induces SHN3 transcription via p65/p50 binding at promoter position +10, while also promoting p65 binding to 2 other sites in the SHN3 promoter. However, the contribution of SHN3 to the regulation of OB differentiation under the influence of TNF is not known.

Methods: Mice were generated with constitutively active (CA) NF-κB signaling in OB lineage cells. IKK-2-CA$^{fl/fl}$ and IKK-2-CA$^{fl/fl}$;Shn3$^{fl/fl}$ mice were crossed with *Prx1-Cre* transgenic mice. This breeding strategy produced two genotypes: IKK-2-CA^{Prx1_Cre} mice, (CA-IKK in OB lineage cells), and Shn3$^{fl/fl}$;IKK-2-CA^{Prx1_Cre} mice (CA IKK in OB lineage-cells with deletion

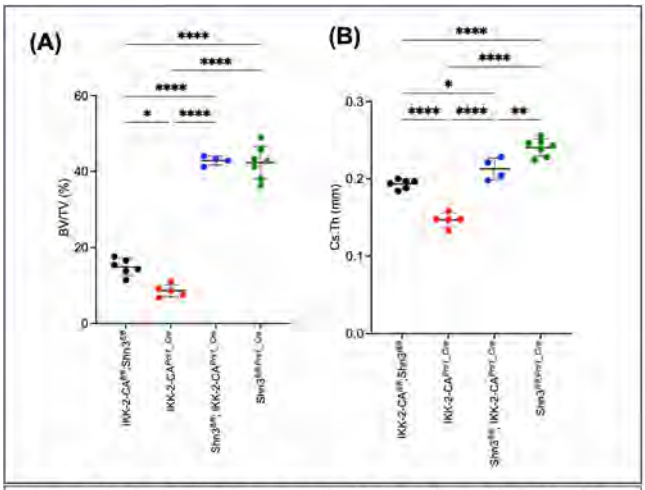

Figure 1: Deletion of Shn3 protects against NF-κB pathway-induced bone loss. MicroCT analysis was performed on 8-week-old mice as follows: IKK-2-CA$^{fl/fl}$;Shn3$^{fl/fl}$ (control) and *Prx-1^{Cre}* transgenic mice were used to generate: IKK-2-CA^{Prx1_Cre} (CA-IKK specifically in OB lineage cells),Shn3$^{fl/fl}$;IKK-2-CA^{Prx1_Cre} (CA-IKK-2 in OB lineage-cells with deletion of SHN3), and Shn3$^{fl/fl;Prx1_Cre}$ (OB lineage-cells with deletion of SHN3). Relative quantification of the femur bone parameters by microCT: **(A)** BV/TV (bone volume/tissue volume of trabecular bone), **(B)** Cs.Th (cortical bone thickness). Data are presented as mean ± SD; **P < 0.01, ***P < 0.001, ****P < 0.0001 (one-way ANOVA between groups). (n=4-6 mice).

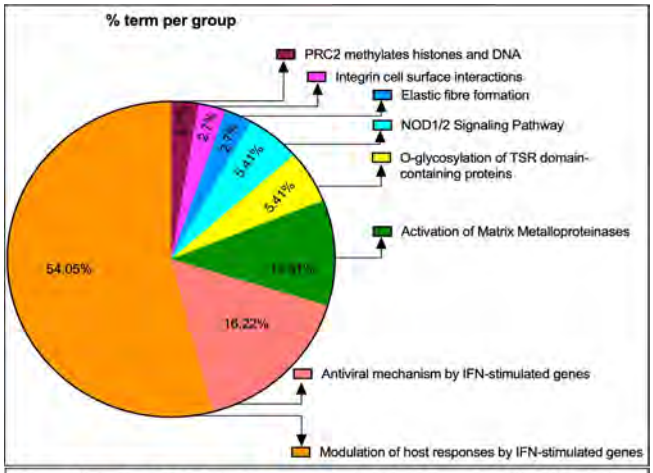

Figure 2: A ClueGO pie chart showing enriched pathways in Shn3KO+TNF vs. WT+TNF. (TNF-treated_p≤0.01)

of SHN3). Shn3$^{fl/fl;Prx1_Cre}$ served as a positive control known to promote OB formation. To determine the impact of SHN3 on OB differentiation during TNF-mediated inflammation, BMSCs from Shn3WT and Shn3KO (globally deficient) mice were differentiated into OBs and treated with TNF (2 ng/mL) from days 4-18. Alkaline phosphatase staining was performed to assess OB differentiation, and RNA was harvested for bulk RNA sequencing. Data analysis was conducted using Qlucore Omics Explorer. Functional enrichment of differentially expressed genes (DEGs) in KO+TNF vs. WT+TNF cells was performed using ClueGO in Cytoscape, and selected genes were validated by qRT-PCR.

Results: Mice with constitutive activation of NF-κB in OB-lineage cells (IKK-2-CA^{Prx1_Cre}) had reduced femoral and cortical bone volume compared with control IKK-2-CA$^{fl/fl}$;Shn3$^{fl/fl}$ mice. Shn3 deletion in OB-lineage cells (Shn3$^{fl/fl}$;IKK-2-CA^{Prx1_Cre}) rescued this loss, and demonstrated bone mass similar to Shn3$^{fl/fl;Prx1_Cre}$ mice (Fig.1). *In vitro*, SHN3 deletion reversed TNF-induced suppression of OB differentiation, indicating that SHN3 deficiency mitigates TNF-driven suppression of OB function. RNA-seq analysis identified 211 significantly DEGs (p ≤ 0.01) between TNF-treated BMSCs from WT/KO groups. Reactome

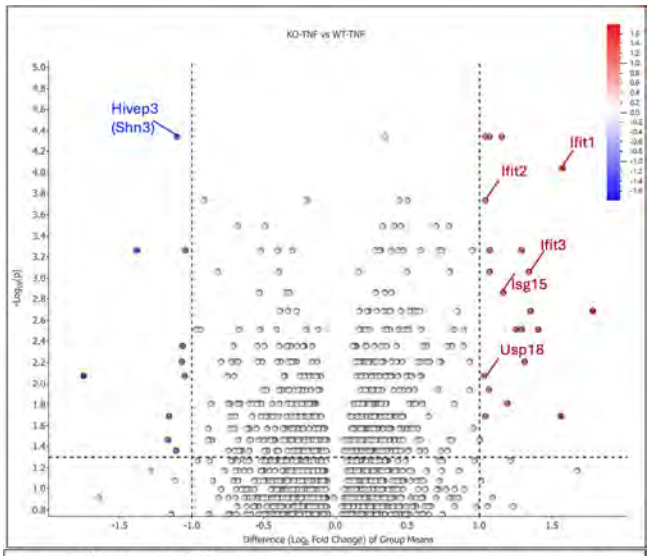

Figure 3: Volcano plot of RNA-seq analysis of differentially expressed genes using the mRNAs isolated from the WT and KO TNF treated groups with significance (p≤0.01).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. and GSEA analysis showed enrichment of type I IFN pathways in KO+TNF (Fig. 2). Notably, ISGs including *Isg15*, *Usp18*, and *Ifit1/2/3* were also upregulated in KO+TNF compared with WT+TNF (Fig. 3), validated by qRT-PCR.

Conclusion: Shn3 silencing in OB-lineage cells prevents NF-κB-driven bone loss and promotes bone formation under inflammatory conditions, establishing SHN3 as an important effector of NF-κB signaling in bone. *In vitro*, Shn3 deletion restores OB differentiation in the presence of TNF and significantly increases the expression of ISGs, suggesting that SHN3 negatively regulates type I IFN responses in OBs during chronic inflammation. These findings compliment a report in non-inflammatory conditions showing that OB function is modulated by type I IFN and ISGs expression[1]. Together, our data highlight a novel axis in osteoimmunology in which SHN3 mediates TNF-induced inhibition of OB function, potentially through modulation of type I IFN signaling.

Session Time: 10:00AM–11:30AM

Background/Purpose: PsA affects male and female patients equally; however, variations in manifestations and treatment response exist between sexes. Deucravacitinib is an oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor. This post hoc pooled analysis of 2 randomized, placebo (PBO)–controlled, phase 3, pivotal studies (POETYK PsA-1 [NCT04908202] and POETYK PsA-2 [NCT04908189]) assessed proteomic profiles in patients with PsA by sex to identify relevant biological pathways and evaluate the effect of deucravacitinib on disease activity–related proteomic scores.

Methods: Proteomic profiling of plasma samples from POETYK PsA-1 and PsA-2 was conducted using Olink 3072, a multiplex assay that includes ≈ 3000 proteins, and harmonized using 24 bridging samples. Differential expression (DE) analysis was conducted using DREAM. Significant DE proteins were identified for all patients vs demographically matched normal

healthy volunteers (NHVs; fold change [FC] = 1.5; adj $P < 0.05$). The FC threshold was 1.23 (adj $P < 0.05$) for male vs female patient comparisons. Enriched pathways were identified using clusterProfiler based on DE proteins. Disease state protein signatures were derived from baseline DE proteins in all patients vs all NHVs, female patients vs female NHVs, and male patients vs male NHVs. Disease activity protein signatures were independently derived by selecting proteins with > 0.3 repeated measure correlations with clinical endpoints. Protein signature scores were calculated using z score normalization to standardize expression across samples. The geometric mean of the z scores for constituent proteins was calculated to obtain the final signature score via the Gene Set Variation Analysis package.

Results: DE proteins were seen in patients with PsA (n = 1222) vs NHVs (n = 121) in a KEGG pathway analysis (**Figure 1A**). Upregulated proteins (eg, PI3, IL-17, IL-19, beta-defensin, MMP3) were reduced with deucravacitinib vs PBO (**Figure 1B**). Overall, 133 and 177 unique proteins were identified in male and female patients, respectively, vs sex-matched NHVs. Female patients had greater enrichment in neuroactive ligand receptor interaction and hormone metabolism pathways vs male patients. Regardless of whether disease state protein signature scores were derived from all patients, female patients, or male patients, deucravacitinib reduced these scores vs PBO in female and male patients at W16 (**Figure 2**). Deucravacitinib also significantly reduced protein signature scores associated with PsA-relevant disease activity vs PBO in male and female patients.

Conclusion: DE was identified in patients with PsA vs NHVs. Deucravacitinib reduced upregulated proteins in all patients. Unique proteomic profiles were identified in male vs female patients with PsA. Deucravacitinib reduced disease state signature scores in the overall population, male patients, and female patients, which is consistent with improved clinical efficacy in the overall population and by sex. Deucravacitinib also reduced disease activity signature scores in male and female patients. Findings provide insight into sex-specific PsA disease biology and may help personalize disease management.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Therapies (0873–0878)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: The first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor deucravacitinib has an established clinical profile in moderate to severe plaque psoriasis with over 5 years of long-term data[1] and is approved in multiple countries for this indication. Deucravacitinib showed superior efficacy vs placebo (PBO) at W16 across multiple endpoints in patients (pts) with active PsA in the global, randomized, double-blind, PBO-controlled phase 3 POETYK PsA-1 (NCT04908202) and PsA-2 (NCT04908189) studies, with no new safety signals.[2,3] Composite efficacy measures provide a comprehensive assessment of disease activity and response to treatment across several disease domains. We report deucravacitinib efficacy based on composite measures of disease activity in pts from the POETYK PsA studies.

Methods: Pts in the POETYK PsA-1 and PsA-2 studies were randomized to deucravacitinib 6 mg once daily or PBO for 16 weeks (in PsA-2, a group received apremilast as a safety reference arm). This analysis included pts treated with deucravacitinib or PBO to W16. Composite measures of disease activity, including minimal disease activity (MDA), Disease Activity in Psoriatic Arthritis (DAPSA), Psoriatic Arthritis Disease Activity Score (PASDAS), modified Composite Psoriatic Disease Activity Index (mCPDAI), and Psoriatic Arthritis Response Criteria (PsARC), were analyzed using nonresponder imputation for missing binary data and control-based pattern imputation for missing continuous data.

Results: At W16, a significantly higher proportion of pts treated with deucravacitinib vs PBO achieved MDA response (PsA-1, $P = 0.0012$; PsA-2, $P = 0.0007$), DAPSA low disease activity or remission (PsA-1, $P = 0.0001$; PsA-2, $P <$

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Achievement of (A) MDA response, (B) DAPSA low disease activity or remission and disease remission, and (C) PsARC response at week 16 in patients treated in the POETYK PsA-1 and PsA-2 studies

Total number of patients randomized to the deucravacitinib or placebo arms. A composite variable strategy was used for treatment discontinuation prior to week 16 (ICE) to set the patient as a nonresponder. A treatment policy strategy was used for rescue medication therapy prior to week 16. After the ICEs were handled, missing data were imputed as nonresponders. 95% CIs were calculated using the Clopper-Pearson exact method. Risk differences and odds ratios were obtained from stratified contingency tables. *P* values were obtained using a CMH test stratified by TNF inhibitor (yes/no; PsA-2 only), screening hsCRP concentration (< 10 mg/L or ≥ 10 mg/L), and csDMARD use at baseline (yes/no).
CMH, Cochran-Mantel-Haenszel; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DAPSA, Disease Activity in Psoriatic Arthritis; hsCRP, high-sensitivity C-reactive protein; ICE, intercurrent event; MDA, minimal disease activity; PsARC, Psoriatic Arthritis Response Criteria; QD, once daily; TNF, tumor necrosis factor.

0.0001), DAPSA disease remission (PsA-1, $P = 0.0009$; PsA-2, $P = 0.0005$), and PsARC response (PsA-1, $P < 0.0001$; PsA-2, $P < 0.0001$; **Figure 1**). Decrease from baseline in PASDAS and mCPDAI at W16 was significantly greater in pts treated with deucravacitinib vs PBO (PASDAS: PsA-1, $P < 0.0001$; PsA-2, $P < 0.0001$; mCPDAI: PsA-1, $P < 0.0001$; PsA-2, $P < 0.0001$; **Figure 2**). Efficacy was consistently higher with deucravacitinib vs PBO in male and female pts.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

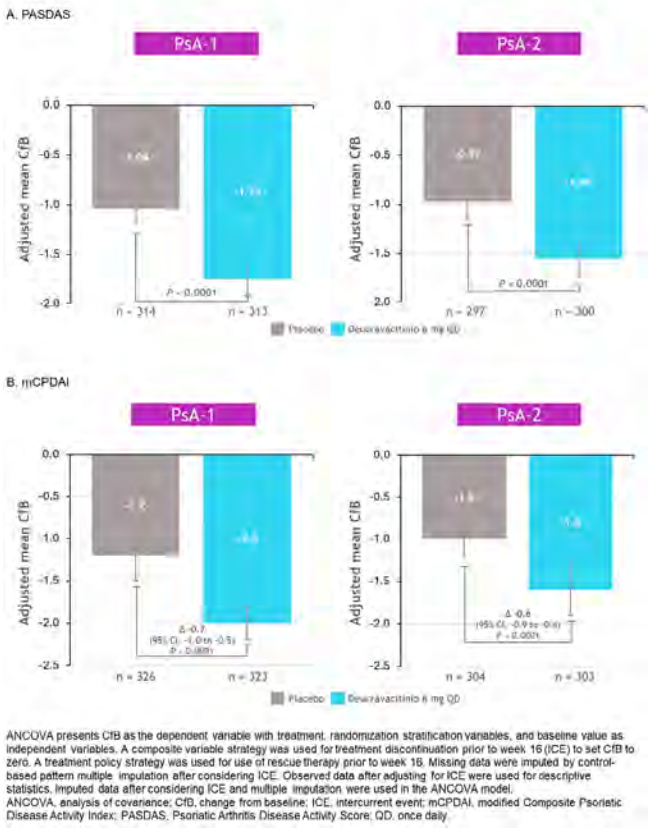

Figure 2. Change from baseline in (A) PASDAS and (B) mCPDAI at week 16 in patients treated in the POETYK PsA-1 and PsA-2 studies

ANCOVA presents CfB as the dependent variable with treatment, randomization stratification variables, and baseline value as independent variables. A composite variable strategy was used for treatment discontinuation prior to week 16 (ICE) to set CfB to zero. A treatment policy strategy was used for use of rescue therapy prior to week 16. Missing data were imputed by control-based pattern multiple imputation after considering ICE. Observed data after adjusting for ICE were used for descriptive statistics. Imputed data after considering ICE and multiple imputation were used in the ANCOVA model.
ANCOVA, analysis of covariance; CfB, change from baseline; ICE, intercurrent event; mCPDAI, modified Composite Psoriatic Disease Activity Index; PASDAS, Psoriatic Arthritis Disease Activity Score; QD, once daily.

Conclusion: In these analyses of the pivotal POETYK PsA-1 and PsA-2 phase 3 studies, deucravacitinib substantially reduced disease activity vs PBO at W16 in several composite measures of disease activity, and a significantly higher proportion of pts reached optimal control of disease activity, which aligns with the results from the primary analyses.[2,3] Given that remission and low disease activity are primary goals of PsA treatment, deucravacitinib may be an efficacious treatment choice for pts with active PsA.

Table. Baseline Demographics, Disease Characteristics, and Previous Treatment Among Adolescents With Moderate-to-Severe Psoriasis

	Placebo (n=22)	Icotrokinra (n=44)	Total (N=66)
Demographics			
Age, years	15.0 (1.5)	15.0 (1.8)	15.0 (1.7)
Sex, Female	64%	52%	56%
Race, Asian/Black/White	23/0/77%	23/4/70%	23/3/73%
Weight, kg	66.4 (23.4)	75.5 (20.9)	72.5 (22.0)
BMI, kg/m^2	24.4 (7.9)	26.0 (7.1)	25.5 (7.4)
Disease Characteristics			
Psoriasis disease duration, years	5.8 (3.4)	4.9 (4.0)	5.2 (3.8)
IGA score			
Severe (4)	18%	30%	26%
Moderate (3)	82%	70%	74%
PASI score (0-72)	18.6 (4.0)	19.8 (8.2)	19.4 (7.1)
BSA (%)	27.1 (14.0)	26.1 (15.6)	26.4 (15.0)
Previous Psoriasis Treatment			
Systemic[a]	50%	52%	52%
Conventional nonbiologic systemic[b]	32%	36%	35%
Biologics[c]	41%	14%	23%
Phototherapy (PUVA or UVB)	14%	23%	20%
Novel nonbiologic systemic[d]	0	2%	2%

Data shown are mean (SD) or %. [a]Includes conventional nonbiologic systemics, novel nonbiologic systemics, 1,25-vitamin D3 and analogues, phototherapy, and biologics. [b]Includes PUVA, methotrexate, cyclosporine, acitretin, azathioprine, and fumarate. [c]Includes etanercept, infliximab, adalimumab, ustekinumab, briakinumab, secukinumab, ixekizumab, brodalumab, guselkumab, risankizumab, tildrakizumab, alefacept, efalizumab, natalizumab, and certolizumab pegol. [d]Includes apremilast, deucravacitinib, and tofacitinib. BMI=body mass index; BSA=body surface area; IGA=Investigator's Global Assessment; PASI=Psoriasis Area and Severity Index; PUVA=psoralen plus ultraviolet A; SD=standard deviation; UVB=ultraviolet B.

Background/Purpose: Icotrokinra (ICO), a novel targeted oral peptide, binds the interleukin (IL)-23 receptor to inhibit IL-23 signaling. ICONIC-LEAD (NCT06095115) is the first Phase 3 study in moderate-to-severe psoriasis to assess the efficacy and safety of a systemic therapy simultaneously in adolescents and adults.

Methods: In ICONIC-LEAD, adolescents (12 to < 18 years) with moderate-to-severe psoriasis (body surface area [BSA] ≥10%, Psoriasis Area and Severity Index [PASI] ≥12, Investigator's Global Assessment [IGA] ≥3) and body weight ≥40 kg were randomized 2:1 to once-daily ICO 200 mg or placebo through Week 16. Placebo patients transitioned to ICO after Week 16. Overall ICONIC-LEAD co-primary endpoints, IGA 0/1 response (IGA score=cleared [0] or minimal [1] and ≥2-grade improvement) and PASI 90 response at Week 16, were assessed in adolescents, as were the efficacy and safety through Week 24.

Results: Adolescents comprised 9.6% (66/684) of the ICONIC-LEAD population. The mean age was 15 years and the mean psoriasis disease duration was 5.2 years (**Table**). Higher proportions of adolescents receiving ICO vs placebo achieved clear/almost clear skin at Week 16 (IGA 0/1: 84.1% vs 27.3%; PASI 90: 70.5% vs 13.6%; nominal p< 0.001). At Week

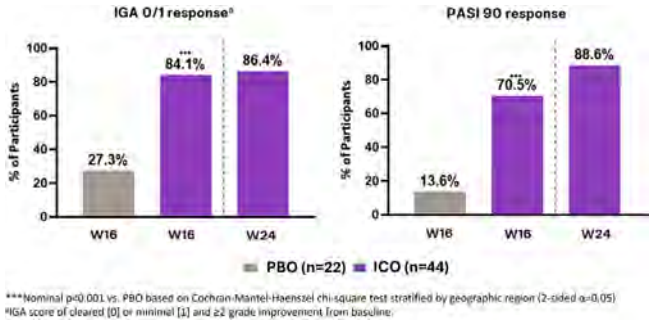

Figure. IGA 0/1 and PASI 90 Response at W16 and W24

24, rates of clear/almost clear skin with ICO were 86.4% (IGA 0/1) and 88.6% (PASI 90; **Figure**). Response patterns were consistent for IGA 0 and PASI 100. At Week 16, 50% of ICO and 73% of placebo adolescents had ≥1 adverse event; no safety signals emerged through Week 24.

Conclusion: In adolescents with moderate-to-severe psoriasis, higher proportions of ICO vs placebo participants achieved clear/almost clear skin at Week 16, with unprecedented response rates at Week 24 and a favorable adverse event profile.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Therapies (0873–0878)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: QX002N is a novel high-affinity monoclonal antibody (mAb) that selectively targets IL-17A.

In the phase II clinical study, QX002N was well tolerated and rapidly reduced symptoms and signs of active radiographic axial spondyloarthritis (r-axSpA) compared with placebo.

We conducted the phase III pivotal study to confirm the efficacy and safety of QX002N in r-axSpA patients. A pre-planned primary analysis was performed after all patients completed week 16. Here, we report the primary analysis results of the study. Results of exploratory radiographic endpoints at 16 weeks are also presented, which are measured by the Spondyloarthritis Research Consortium of Canada (SPARCC) Magnetic Resonance Imaging (MRI) index, an objective and quantifiable variable to assess the post-treatment inflammation changes of the Sacroiliac Joints (SIJ) and the spine.

Methods: This is a multicenter, phase III, randomized, double-blind, placebo-controlled, parallel-group study. Adults with active r-axSpA were randomized 1:1 to receive 160 mg subcutaneous QX002N every 4 weeks (Q4W) or placebo. At week 16, all patients received 160mg QX002N Q4W through week 52. The primary endpoint was the proportion of participants reaching the standard of the Assessment in SpondylArthritis International Society (ASAS) 40 at week 16. The key secondary endpoint was the proportion of participants achieving ASAS20 at week 16. The exploratory endpoints included changes from baseline in SIJ and spinal SPARCC Scores at Week 16 in patients with evaluable MRI at baseline and week 16(MRI completers).

Results: A total of 641 r-axSpA patients were randomized to receive 160mg QX002N Q4W (n=322) and placebo (n = 319). Baseline characteristics were similar between treatment groups (Table 1).

Statistically significant improvements in disease activity, function, quality of life, spinal and SIJ MRI–evident inflammation were observed after 16 weeks of QX002N treatment versus placebo (Figure 1). At week 16, significantly higher proportions of QX002N patients (40.4%; P<0.0001) had achieved an ASAS40 response versus the placebo group (18.9%) (Figure 1A). Similarly, ASAS20 response rate (65.2% vs 41.3%) and other secondary endpoints all favoured QX002N versus placebo at

Table 1. Baseline characteristics.

Characteristics	QX002N N=322	PBO N=319
Age, years	33.2 (8.66)	34.2 (8.30)
Male, n (%)	260 (80.7%)	276 (86.5%)
BMI , kg/m2	24.63 (4.085)	24.73 (4.209)
Age at diagnosis	24.92 (7.446)	24.49 (7.272)
Disease duration (AS)	8.28 (6.357)	9.66 (7.405)
Prior anti-TNF therapy	66 (20.5%)	65 (20.4%)
SIJ SPARCC score¶	18.2 (16.59)	14.8 (15.76)
Spine SPARCC score¶	19.7 (19.43)	19.3 (22.13)

¶ Data were available for the magnetic resonance imaging (MRI) subclean population only. (N = 98 for the placebo group, N = 100 for the QX002N group).
Continuous parameters are presented as mean (+/-SD) unless otherwise noted. Categorical variables are presented as n(%).

week 16 (Figure 1B-D,G). For the MRI sub-study, 30.9% (198/641) and 30.6% (196/641) of the patients had SPARCC SIJ and spine assessments respectively. Rapid reduction from baseline to Week 16 in mean SPARCC SIJ score (QX002N:–6.2 , PBO: –2.3 ; P=0.0262; Figure 1E) and mean SPARCC spine score (QX002N: –8.1, PBO: –1.4; P=0.0005; Figure 1F) were observed.

The overall incidence of Treatment-emergent adverse events (75.8% vs. 71.2%) were comparable in patients receiving QX002N and placebo. Serious adverse events were reported in 2.2% and 0.9% of patients in the QX002N and placebo groups, respectively. The majority of TEAEs were categorized as CTCAE (Version 5.0) Grade 1 or 2 (Table 2).

Conclusion: QX002N provided significant improvements in the symptoms and signs, as well as marked reduction in inflammation of the spinal and SIJ as measured by MRI in r-axSpA patients, when compared to placebo at week 16. The safety of QX002N was tolerable.

Abstract Number: 0877

Therapeutic Approach in Patients with Arthralgia at Risk of Progression to Psoriatic Arthritis.

Rodrigo García Salinas[1], Gisel Reyes-Jara[2], Felicia Almada[3], Juan Arguello[2] and Sebastian Magri[4], [1]Hospital Italiano La Plata, La Plata, Argentina, [2]Hospital Italiano de La Plata, La Plata, Argentina, [3]Hospital Italiano de La Plata, La Plara, Argentina, [4]Hospital Italiano La Plata, Melchor Romero, Argentina

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Therapies (0873–0878)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: The transition from psoriasis (Pso) to psoriatic arthritis (PsA) presents an opportunity for early intervention and preventive strategies in high-risk patients with arthralgia. Objectives: To estimate the frequency of treatment initiation in patients with arthralgia at risk of progression to PsA (ARP-PsA), compare characteristics between treated and untreated groups, and analyze progression to PsA after one year.

Methods: A prospective cohort study included patients >18 years with arthralgia and no prior PsA diagnosis. Baseline assessments included laboratory tests, radiography, ultrasound, and clinical evaluation (reuma-check). Data on demographics, joint count, global VAS, HAQ, Pso, and family history (FH) were collected. ARP-PsA was defined as arthralgia + Pso and/or FH. Treatment initiation with NSAIDs and/or DMARDs was evaluated, as well as progression to PsA after one year, based on our previous published research (1). High-risk factors (Pso >15 years, Pso + FH, ultrasound synovitis/enthesopathy) were assessed. Statistical tests included, descriptive analisis, chi-squared, Fisher's exact, Student's t-test, and Mann-Whitney.

Results: Of 1419 patients with arthralgia, 8.4% (n=119) met ARP-PsA criteria. Among them, 41% initiated treatment: NSAIDs in 22%, DMARDs in 21% (56% methotrexate), and corticosteroids in 4%. Treated patients more frequently had psoriasis (60% vs. 24%, p=0.001), while other demographic, clinical, imaging, and laboratory variables showed no significant differences (Table 1). At one-year follow-up, 29% (n=34) progressed from arthralgia to clinically classified PsA, and 62% of them had received treatment (35% NSAIDs, 26% DMARDs) (Figure 1). Among those meeting at least one high-risk criterion (36% of ARP-PsA), 65% were treated.

Conclusion: In ARP-PsA patients, 41% initiated treatment, with psoriasis being the key differentiating factor. Of those progressing to PsA, 62% were under treatment, highlighting the importance of early therapeutic intervention, particularly in patients with high-risk features.

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Therapies (0873–0878)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Enthesitis is an early event in the course of psoriatic arthritis (PsA) and a hallmark feature of the disease. Currently, much of the understanding of enthesitis relies on clinical assessment and imaging techniques such as MRI and ultrasound, which complicates detailed molecular analysis due to the difficulty in acquiring high-quality entheseal tissues. Previous pre-clinical studies and surgical data indicate that interleukin-17 (IL-17) plays a pivotal role in the pathogenesis of enthesitis, supported by the efficacy of IL-17 blockers in clinical settings. However, molecular insights on how IL-17 blockade affects enthesitis in humans remain limited. This study aims to investigate the immune and non-immune compartments in active enthesitis of PsA patients and their alterations following IL-17A inhibition.

Methods: We performed minimally invasive ultrasound-guided biopsies of the lateral epicondyle on ten biologic-naïve PsA patients with active elbow enthesitis before and after six months of treatment with secukinumab. One patient did not undergo the second biopsy. Tissue samples underwent conventional histological staining, second harmonic generation (SHG) for morphological assessment, Hyperion imaging mass cytometry (IMC) for protein expression, scRNAseq and GeoMx spatial transcriptomic technology for RNA expression analysis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Eleven patients with active psoriatic arthritis (PsA) and lateral epicondyle enthesitis were screened, resulting in ten enrollments, where 40% were female. The mean Disease Activity in Psoriatic Arthritis (DAPSA) score at screening was 22.8 ± 12.6, indicating moderate disease activity, with an average of 9.6 ± 6.8 tender joints and a SPARCC entheseal score of 4.30 ± 2.75. Nine patients had previously failed conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs). Following treatment with secukinumab, PD signals significantly decreased six months later (P = 0.0156), and notable improvements were observed in DAPSA (11.8 ± 10.5; P = 0.0078) and SPARCC scores (1.4 ± 2.5; P = 0.0039). Adverse events were mild and managed well. Total IL-17A+ cell counts decreased substantially, contributing to the therapeutic response as assessed by Imaging mass cytometry. Spatial transcriptomics highlighted a significant shift towards DKK3 and CD200 positive fibroblasts following IL-17A inhibition, indicating a transition to a pro-resolving phenotype in the entheseal tissue. Furthermore, pathways related to osteoblast differentiation were significantly reduced upon treatment with secukinumab, indicating a decreased transcriptional activity associated with osteoblasts post-treatment.

Conclusion: Here we show a full picture of cellular changes in the microarchitecture of inflamed entheses upon anti-IL-17A treatment. Resolving entheseal inflammation is not only associated with reduction of IL-17-producing cells but also with DKK3/CD200+ fibroblast / ILC2 activation and osteoblast control.

Background/Purpose: Interstitial lung disease (ILD) is traditionally associated with the diffuse subset of systemic sclerosis (dcSSc) but may be observed in limited SSc (lcSSc), with features not clearly defined, but antiScl-70. This study aims to characterize risk factors and prognosis of lcSSc-ILD within the EUSTAR cohort.

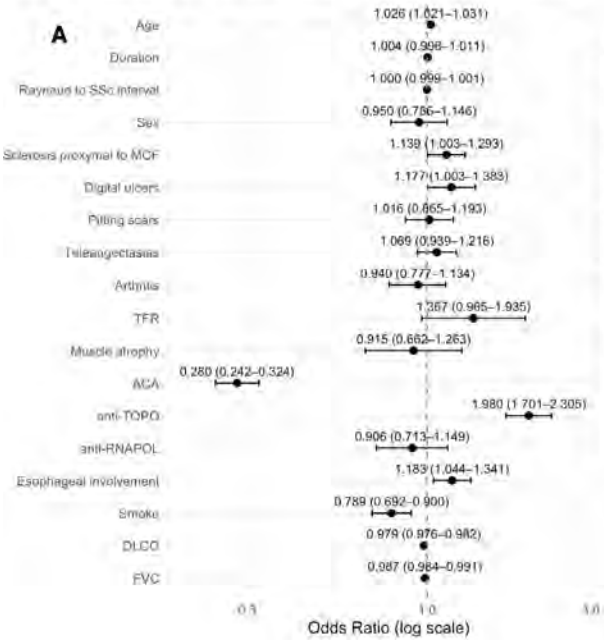
Methods: We performed the CP175 retrospective study including patients in EUSTAR up to February 2025 and arrayed according to skin subset and presence/absence of ILD at chest HRCT at enrollment (baseline). Disease features were analyzed for risk factors and survival of lcSSc patients with: (i) ILD at baseline (multivariable logistic regression), (ii) incident ILD during follow-up (Cox proportional hazards models), and (iii) progressive ILD (Hoffmann-Vold, 2021).

Results: Baseline HRCT was available in 5953/8153 (73%) lcSSc cases (vs 3248/3974 [81%] dcSSc; $p < 0.001$), more frequently with coexisting anti-Scl70 (OR 1.5, CI 1.3–1.8), lower FVC and DLCO (OR 0.99 both), but less frequently with serum ACA (OR 0.7, CI 0.6–0.8).

At baseline (Fig 1A), 36% (2127/5953) lcSSc patients had ILD, in association with older age (OR 1.03, CI 1.02–1.03), digital ulcers (OR 1.18, CI 1.00–1.38), skin thickening proximal to metacarpophalangeal (MCP) joints (OR 1.14, CI 1.01–1.29), esophageal involvement (OR 1.18, CI 1.04–1.34), anti-Scl70 (OR 1.98, CI 1.7–2.3), lower FVC (OR 0.99, CI 0.98–0.99) and lower DLCO (OR 0.98, CI 0.97–0.98). Serum ACA were protective (OR 0.28, CI 0.24–0.32), also in anti-Scl70+ or anti-RNAPOL+ lcSSc (OR 0.3, CI 0.2–0.4). Among ACA+ lcSSc cases, skin fibrosis proximal to MCP (OR 1.3, CI 1.03–1.6) and concurrent anti-Scl70 (OR 2.4, CI 1.7–3.4) were risk factors for ILD. Among anti-Scl70+ lcSSc patients, digital ulcers increased ILD risk (OR 1.5, CI 1.1–2.0). In lcSSc, ILD extension >20% (19% vs 31%) and honeycombing (14% vs 22%) were less frequent with ACA, honeycombing more with anti-Scl70 (23% vs 16%) (Fig 1B).

Among 3826 lcSSc cases without ILD at baseline, 443 developed it during follow-up (incidence rate 6% person-years) and the incidence was highest with anti-Scl70 (14% person-years) and lowest with ACA (4% person-years). Incident ILD was independently associated with age (HR 1.03, CI 1.02–1.04), male sex (HR 1.4, CI 1.1–1.9), anti-Scl70 (HR 1.7, CI 1.3–2.1), lower FVC and DLCO (HR 0.99 for both); telangiectasias (HR 0.6, CI 0.5–0.8) and ACA (HR 0.4, CI 0.4–0.6) were protective (Fig 2).

Figure 1. (A) Risk factors for ILD at baseline in lcSSc. (B) Radiological and functional features of patients with lcSSc and ILD at baseline, according to the autoantibody status.



B

Variable	ACA+	ACA-	p (ACA)	Scl70+	Scl70	p (Scl70)
ILD > 20% at HRCT	36/193 (18.7%)	125/405 (30.9%)	.002	80/264 (30.3%)	86/339 (25.4%)	0.210
Ground glass opacity	241/494 (48.8%)	691/1103 (62.6%)	<.001	478/742 (64.4%)	484/901 (53.7%)	<.001
Honeycombing	45/320 (14.1%)	164/731 (22.4%)	0.002	116/499 (23.2%)	96/586 (16.4%)	0.006
Reticular pattern	177/298 (59.4%)	428/658 (65.0%)	0.108	300/459 (65.4%)	321/521 (61.6%)	0.251
Traction bronchiectasis	22/60 (36.7%)	86/138 (62.3%)	0.002	78/133 (58.6%)	32/74 (43.2%)	0.047
DLCO (%predicted)	63 [50–76] [n=447]	61 [47–75] [n=1064]	0.077	62 [48–77] [n=708]	62 [48–74] [n=833]	0.168
FVC (%predicted)	97.8 (22.8) [n=1628]	85.6 (21.4) [n=1628]	<.001	86 [72–99] [n=757]	92 [75–109] [n=903]	<.001
TLC (%predicted)	96 [84–107] [n=351]	84 [70–99] [n=800]	<.001	86 [71–97] [n=533]	92 [74–104] [n=638]	<.001

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. (A) 10-year incidence of ILD in patients with lcSSc vs dcSSc. (B) Incidence of ILD in lcSSc according to autoantibodies (CTPneg if all ACA, Scl70, and RNAPOL neg); p-value of Log-rank test. (C) Risk factors for incident ILD.

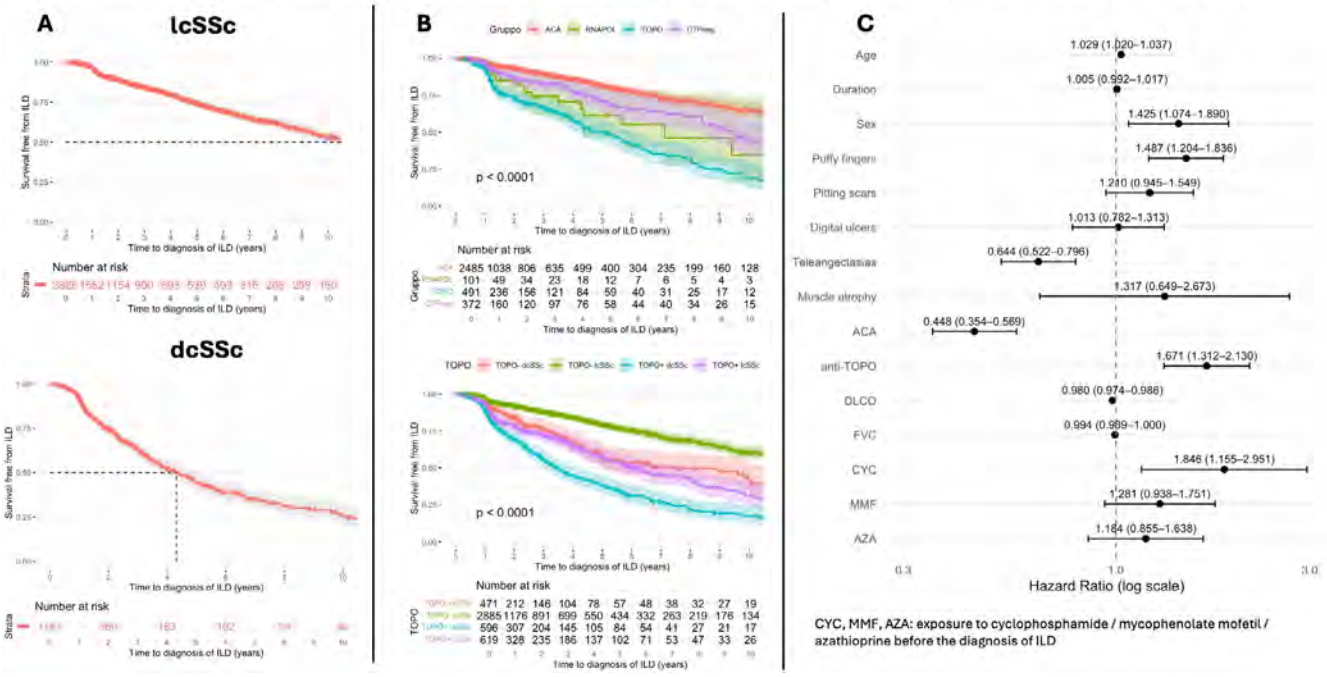


Figure 3. (A) Survival of patients with SSc depending on skin subset and presence of ILD. (B) Survival of patients with lcSSc and ILD, depending on progression vs. non-progression of pulmonary disease, according to the EUSTAR definition (Hoffmann-Vold AM, Ann Rheum Dis, 2021). P-values of Log-rank test are reported.

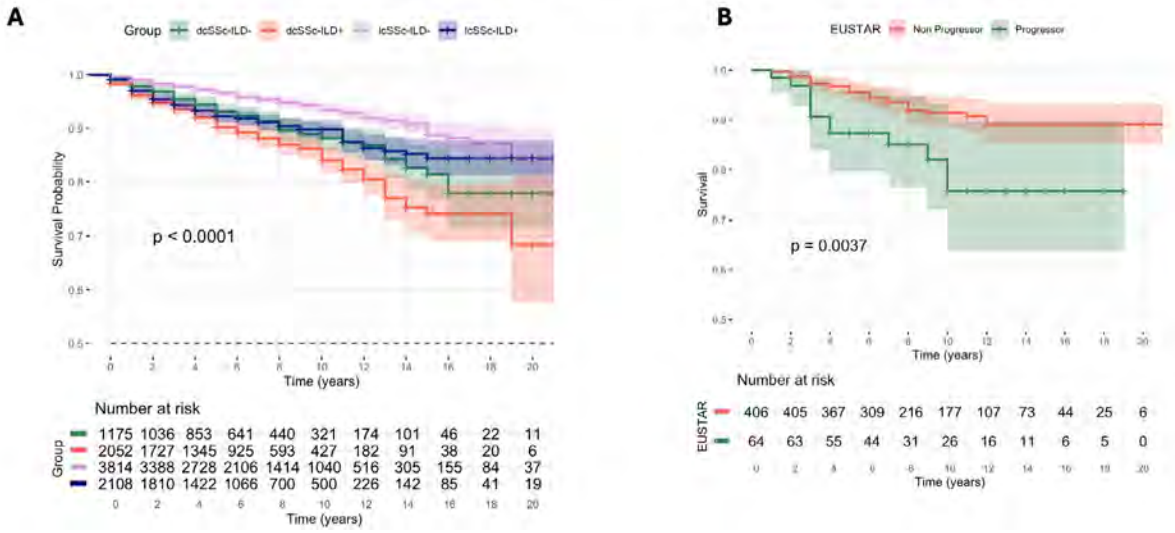

Of 472 ILD patients with available follow-up data, 64 (14%) met the criteria for ILD progression within the first year. ILD significantly reduced survival in lcSSc, though to a lesser extent than in dcSSc. Patients with progressive ILD had significantly worse survival compared to non-progressors (Fig 3).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: ILD is found in 36% of lcSSc patients, with a 6% person-years subsequent incidence rate. ILD in lcSSc carries a poor prognosis and may progress over time. Peculiar risk factors can aid stratify patient risk, and early identification is crucial for establishing proper treatment. This study supports the inclusion of patients with lcSSc-ILD in therapeutic trials and underscores the need for risk-adapted ILD monitoring protocols and multidisciplinary care in this subgroup.

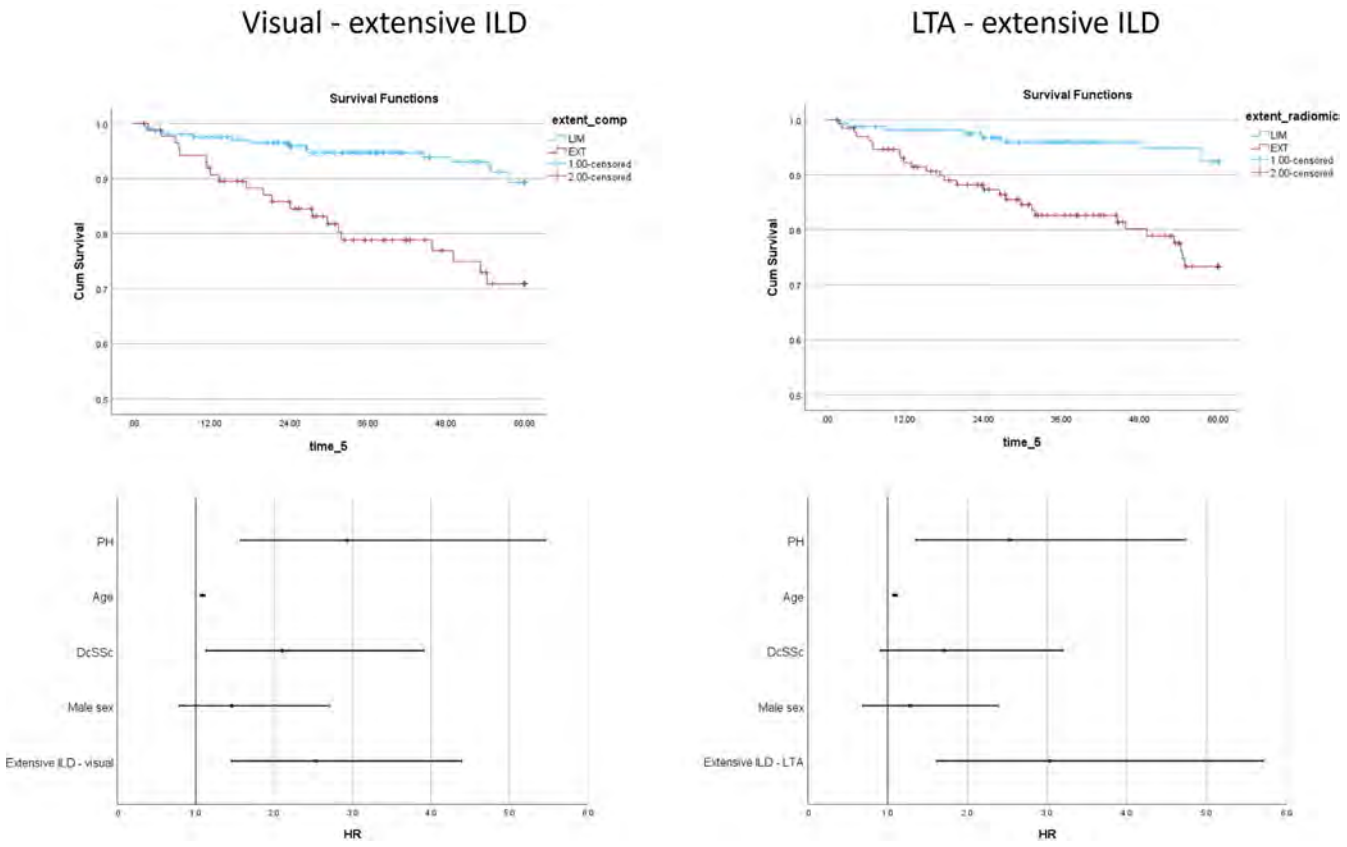

Figure 2. Prediction of mortality for extensive (EXT) versus limited (LIM) interstitial lung disease (ILD) identified through visual assessment vs. lung texture analysis (LTA). EXT: extensive disease; ILD: interstitial lung disease; HR: hazard ratio; LIM: limited disease; LTA: lung texture analysis; PH: pulmonary hypertension.

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of death in patients with systemic sclerosis (SSc), especially in case of extensive disease detected on computed tomography (CT). Automated post-processing analysis software can compute the extent of ILD through lung texture analysis (LTA) of CT images. However, its use in clinical practice is limited by the lack of standardized thresholds.

The aim of our study was to identify and validate optimal thresholds of ILD extent quantified through LTA to detect the presence of ILD and to define extensive ILD in SSc patients.

Methods: SSc patients visiting two SSc referral center between 2005-2021, who underwent chest CT, were included. Technically suitable images (non-contrast, axial inspiratory acquisition, slice thickness and spacing ≤2 mm) were analyzed through LTA (Imbio), quantifying the percentage of lung volume occupied by total ILD (sum of ground glass, reticulation and honeycombing). Two radiologists blinded to the LTA data independently reviewed the CT scans to visually identify the presence of ILD and extensive ILD. The latter was defined as ILD involvement >20% of lung parenchyma or forced vital capacity < 70% predicted in case of indeterminate extent (Goh 2008). Disagreements were resolved by consensus, otherwise through a third reviewer. Patients were randomly split into derivation and validation cohorts using a 2:1 ratio. Receiver operating characteristic (ROC) curves with area under the curve (AUC) were computed to identify the optimal ILD extent threshold for detecting presence of ILD and, in patients with ILD, for identifying extensive disease, using the visual evaluation as the reference standard. Kaplan Meier curves and Cox regression analysis were performed to determine the impact of ILD and extensive disease on both visual and LTA assessments on mortality up to 5 years, the second adjusted for known mortality risk factors (age, sex, diffuse skin subset and pulmonary hypertension).

Results: A total of 664/1118 (58%) SSc patients were eligible for the study (Table 1). Visual analysis identified ILD in 313 (47%) cases, 103 (33%) showing extensive ILD. In the derivation cohort (433 patients, 206 ILD, 38% extensive), ROC analysis identified the optimal total ILD extent threshold for ILD detection at 1% (AUC 0.83) and at 7% for extensive ILD (AUC 0.84). In the validation cohort (231 subjects, 104 ILD, 25% extensive), these thresholds achieved 78% sensitivity / 71% specificity for ILD detection, and 81% sensitivity / 70% specificity for extensive ILD identification. Over median 5 years follow-up, 84 (13%) patients died [37 (12%) in the ILD group]. After adjustment for confounders, both ILD presence (Fig. 1) and extensive disease (Fig. 2) were independent risk factors for mortality, with comparable results by visual and LTA assessments.

Conclusion: Cutoffs for total ILD extent by LTA to detect ILD presence and identify extensive disease were derived and validated, with comparable performance to visual evaluation on negative prognostic impact. Our results lay the foundation for expanding the use of LTA post-processing in SSc-ILD towards automated diagnosis and prognostic stratification.

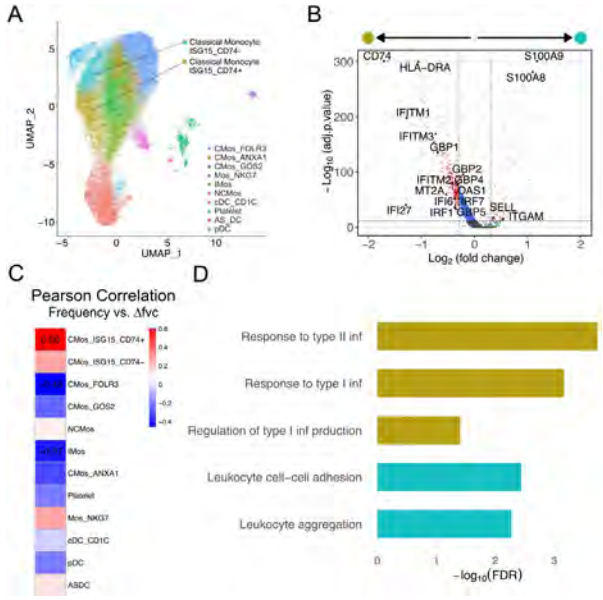

Fig. 1. A. UMAP of myeloid cells showing subclustering of monocyte cluster with type I IFN signature. B. Volcano plot of subcluster markers. C. Correlation of cluster frequencies with change in %fvc from baseline for SSc-ILD patients. D. Pathways for classical monocyte ISG15 subclusters.

Background/Purpose: Circulating monocytes with pro-inflammatory and pro-fibrotic phenotype have been implicated in SSc-ILD pathogenesis, but their potential trajectory to mature cell lineage macrophages driving organ-specific damage is not well defined.Evidence suggests that osteopontin expressing macrophages likely contribute to fibrotic mechanisms in SSc-ILD. We sought to characterize specific myeloid subpopulations associated with SSc-ILD progression and establish potential precursor relationships with lung macrophages.

Methods: Single-cell RNA-seq (scRNA-seq) was performed on peripheral blood obtained from 60 SSc patients meeting 2013 ACR/EULAR criteria. Unsupervised clustering identified two subpopulations of monocytes with type I interferon signatures. Differential expression and subtype correlation analyses against %change in forced vital capacity (FVC, liter) per year from baseline were conducted in subjects with SSc-ILD (n=40). Transcription factor (TF) analysis was conducted for progressive (>10% decrease in FVC) and non-progressive SSc-ILD patients. Reprocessed publicly available scRNA-seq data from SSc-ILD lungs were used to perform trajectory analysis.

Results: Clustering and annotation of myeloid cells identified 11 myeloid cell types and two subclusters ($CD74^+$ and $CD74^-$) of an "ISG15-hi" monocyte population expressing high levels of interferon (IFN)-inducible markers (Fig.1A). The $CD74^+$ subpopulation showed further enrichment for genes involved in "*Response to type I IFN signaling*" (FDR = 6.82×10^{-4}) whilst the $CD74^-$ subpopulation upregulated genes involved in "*Leukocyte cell-to-cell adhesion*" (FDR = 3.61×10^{-3}) (Fig.1B,D). Correlation analysis of cell type proportions against FVC %-change for SSc-ILD patients (Fig.1C) revealed a Pearson correlation

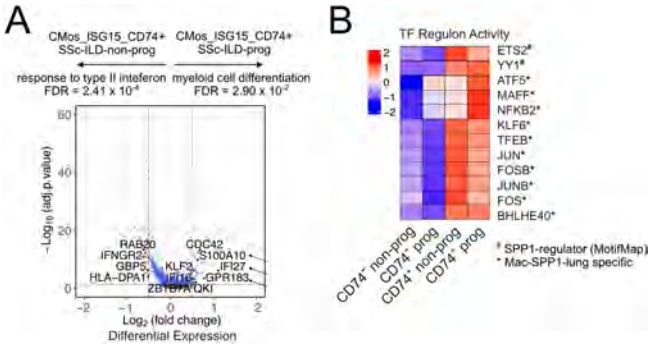

Fig. 2. A. Volcano plot for differential expression of progressive vs non-progressive SSc-ILD in CD74+ subpopulation. B. SCENIC TF analysis of subclusters split by disease progression.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig. 3. A. DotPlot for markers of lung monocytes and osteopontin expressing macrophages. B. UMAP of clusters and trajectory analysis. Ref 1: Ann Rheum Dis. 2019 Aug 12;78(10):1379_1387

of 0.60 ($p=1.9x10^{-4}$) in the $CD74^+$ "ISG15-hi" monocyte population. In the $CD74^+$ subpopulation, progressive SSc-ILD patients upregulated genes involved in "*Myeloid differentiation*" (FDR = 2.90×10^{-2}) (Fig.2A) and further showed increased activity for TFs previously reported as specific regulators in osteopontin expressing lung macrophages (Mac-SPP1-lung) from SSc-ILD patients including ATF5 and MAFF (Fig.2B). A reanalysis of SSc-ILD lung scRNA-seq data identified a population of "ISG15-hi" classical monocytes CMos-ISG15-lung and the previously reported Mac-SPP1-lung (Fig.3A). Trajectory analysis predicted a differentiation trajectory from CMos-ISG15-lung to Mac-SPP1-lung (Fig. 3B).

Conclusion: We identified a novel $CD74^+$ subcluster within ISG15-high circulating monocytes, marked by strong type I IFN-inducible gene expression and significantly negatively associated with progressive SSc-ILD. This population may serve as a precursor to pro-fibrotic, osteopontin-expressing lung macrophages, suggesting a pathogenic role in SSc-ILD.

Comparison of the receiver operating characteristic curve of blood markers for predicting progressive ILD in patients with SSc; ROC curves: %FVC relative change from baseline; %DLCO relative change from baseline; KL-6 relative change from baseline; IL-18BP relative change from baseline; IL-18 relative change from baseline; ESR relative change from baseline; CRP relative change from baseline, AUC area under the curve.

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of morbidity and mortality in systemic sclerosis (SSc). Early detection and continuous monitoring of ILD are critical for timely intervention and improved clinical outcomes. In recent years, serum biomarkers have gained recognition as potential non-invasive tools for evaluating ILD onset, progression, and prognosis. However, their clinical utility in SSc-ILD remains incompletely understood. This study aimed to evaluate the prognostic value of serum biomarkers—KL-6, IL-18, and IL-18 binding protein (IL-18BP)—for assessing ILD progression and mortality in SSc patients.

Methods: This prospective cohort study followed 74 SSc patients for 24 months. Patients were stratified based on the presence or absence of ILD using high-resolution computed tomography (HRCT). Clinical assessments, pulmonary function tests (PFTs), and serum biomarker levels (KL-6, IL-18, and IL-18BP) were measured. ILD progression was defined by changes in forced vital capacity (FVC). Relationships between biomarkers, lung function, and ILD severity were analyzed using Pearson's correlation. Receiver operating characteristic (ROC) curves determined optimal biomarker thresholds, while logistic regression identified predictors of ILD progression and mortality, accounting for potential confounders.

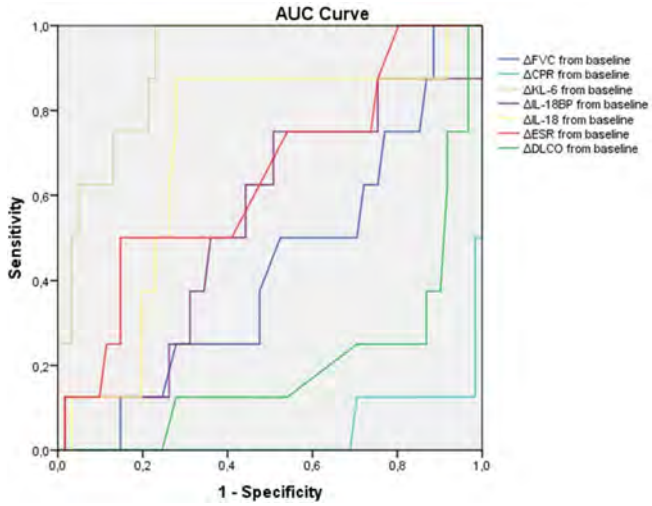

Fig 2. Comparison of the receiver operating characteristic curve of blood markers for predicting mortality in patients with SSc; ROC curves: %FVC relative change from baseline; %DLCO relative change from baseline; KL-6 relative change from baseline; IL-18BP relative change from baseline; IL-18 relative change from baseline; ESR relative change from baseline; CRP relative change from baseline, AUC area under the curve.

Logistic regression analysis for progressive ILD in SSc. FVC forced vital capacity, DLco difusing capacity of the lung for carbon monoxide, KL-6 Krebs von den Lungen-6, CRP C-reactive protein, ESR erythrocyte sedimentation rate, Δ changes from baseline

Results: Among the 74 patients, 38% had ILD at baseline, increasing to 54% over two years. The proportion of patients with lung involvement ≥20% rose from 26% to 43%. Serum KL-6 proved to be a strong biomarker for progressive ILD, with an annual increase of +14.18 serving as the threshold (AUC: 0.803, P = 0.002, sensitivity: 80%, specificity: 64%). For mortality, an annual KL-6 increase of +71.17 showed the highest predictive accuracy (AUC: 0.91, 95% CI: 0.84–0.99, P < 0.0001, sensitivity: 75%, specificity: 85%). DLCO decline (ΔDLCO) also emerged as a mortality predictor, with a -17% annual decrease as the critical threshold (AUC: 0.20, P = 0.006). ΔKL-6 (OR: 3.21, 95% CI: 1.78–4.89, P = 0.03), ΔDLCO (OR: 1.98, 95% CI: 1.12–3.72, P = 0.03), ΔCRP (OR: 1.32, 95% CI: 1.13–3.24, P = 0.04), and anti-Scl70 antibodies (OR: 1.98, 95% CI: 1.04–3.24, P = 0.03) were independent predictors of progressive ILD, while ΔIL-18, ΔIL-18BP and ΔESR exhibited limited predictive utility. Multivariate analysis confirmed that immunosuppressive therapy was protective against ILD progression (OR: 0.27, 95% CI: 0.16–0.92, P = 0.004).

Conclusion: Serum KL-6 is a reliable biomarker for predicting ILD progression and mortality in systemic sclerosis, with well-defined thresholds showing high sensitivity and specificity. ΔDLCO and anti-Scl70 antibodies were also independent predictors of ILD progression, while immunosuppressive therapy demonstrated a protective effect. These findings highlight the potential of KL-6 for non-invasive monitoring and risk stratification in SSc-ILD.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical II (0879–0884)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: The course of interstitial lung disease (ILD) in systemic sclerosis (SSc) is highly variable and difficult to predict using clinical variables alone. Therefore, there is a need for reliable biomarkers to improve prognostication. The Scleroderma Lung Study (SLS) II showed that Krebs von den Lungen 6 (KL-6), CCL18, IFNγ-inducible 10-kDa protein (IP-10), and monokine induced by IFNγ (MIG) were significant predictors of ILD progression. In this study, we aimed to validate these findings and build a multivariable model to predict the course of ILD in SSc based on longitudinal data in a US-based multicenter observational cohort.

Methods: Patients with SSc enrolled in the CONQUER cohort were included in this analysis. Enrollment in CONQUER required fulfillment of the 2013 ACR/European League Against Rheumatism classification criteria and disease duration of less than five years from the onset of the first non-Raynaud's symptom. For the current study, we included only those patients who had interstitial lung disease (ILD) confirmed by high-resolution computed tomography (HRCT) and who were treated with mycophenolate mofetil (MMF) between the baseline and 12-month visits. The study visits were scheduled every 6 months. Blood samples were collected at baseline. Sixty-two proteins were measured as part of a multiplex assay. We used linear mixed-effects models to evaluate the predictive significance of individual cytokines for ILD progression. Follow-up FVC% was the outcome, with baseline cytokine levels, MMF treatment status, baseline FVC%, and time as fixed effects. Random intercepts and slopes accounted for between-patient variability in baseline FVC% and its change over time. A Bayesian regularized linear mixed-effects model was used to develop a prediction model that included clinical variables and serum protein levels.

Results: A total of 122 patients were included, of whom 100 (82%) were female, with a median age of 52 years and a mean disease duration of 2.7 years. Higher baseline levels of IP-10 (b = 0.0020, P = 0.013) and MIG (b = 0.0007, P = 0.023) were associated with higher FVC% over time, indicating a better ILD course. In contrast, higher KL-6 levels (b = –0.0020, P =

0.015) predicted lower FVC% over time. CCL18 was not significantly associated with the FVC% trajectory. In the exploratory analysis, α2-macroglobulin (α2M, b = -3.29, P < 0.001) and serum amyloid P component (SAP, b = -0.49, P = 0.007) also showed predictive significance. In the multivariable Bayesian model, baseline FVC% had the highest estimate among clinical variables (β = 14.03), while α2-macroglobulin had the highest among protein predictors (β = –1.39). The R2 of the model, including clinical predictors and a selected number of serum proteins, was 0.765.

Conclusion: This study confirmed the predictive significance of IP-10, MIG, and KL-6 for the course of SSc-ILD and identified α2M and SAP as potential biomarkers. We also built a multivariable model including clinical and protein variables to predict the SSc-ILD course.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Clinical II (0879–0884)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Systemic sclerosis (SSc) is a rare disease that often leads to severe complications and premature mortality. Recent advancements in the field have led to the emergence of more intensive therapy strategies for refractory or severe SSc patients, including haematopoietic stem cell transplantation (HSCT) and chimeric antigen receptor T-cell (CAR T-cell) therapy. Nevertheless, these therapeutic interventions are associated with considerable risks, including treatment-related mortality (TRM). In order to identify patients who may benefit from such therapies, a reliable mortality risk score is required to allow us to identify patients for whom a high mortality risk justifies the considerable TRM.

Methods: With RESIST (**R**isk score for **E**arly mortality to stratify for **I**ntensive **S**Sc Therapy) we aimed to develop a simple risk score to predict early mortality (< 5 years) in SSc patients eligible for intensive therapies using the EUSTAR cohort. Patients deemed unsuitable for intensive therapies were defined as patients over the age of 65 years, with a history of renal crisis, LVEF < 40%, DLCO < 40%, or FVC < 45% [1]. Only patients with at-least one follow-up visit were included.

The overall survival was estimated by the Kaplan-Meier method. We compared SSc patients who had succumbed during the initial five-year period with those who had survived until the 5th year. Covariates were selected according to expert opinion, univariable models, and evidence from the literature. A multivariable Cox model with adaptive LASSO variable selection

Table 2: Multivariate analysis. The simplified score was utilised to differentiate patients into distinct categories: high (>22), intermediate (1-22), and low (0).

Parameter	HR [95% CI]	p	simplified score
Male	1.41 [0.96-2.08]	0.072	3
dcSSc	1.56 [0.95-2.54]	0.070	4
Age >55 years	1.91 [1.35-2.69]	0.0002	6
CRP elevated	1.96 [1.31-2.93]	0.001	7
DUC (current/previous)	1.6 [1.02-2.5]	0.039	5
mRSS >14	1.81 [1.12-2.93]	0.014	6
LVEF<60%	1.67 [1.16-2.4]	0.005	5
DLCO<60%	2.17 [1.52-3.09]	<0.0001	8

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

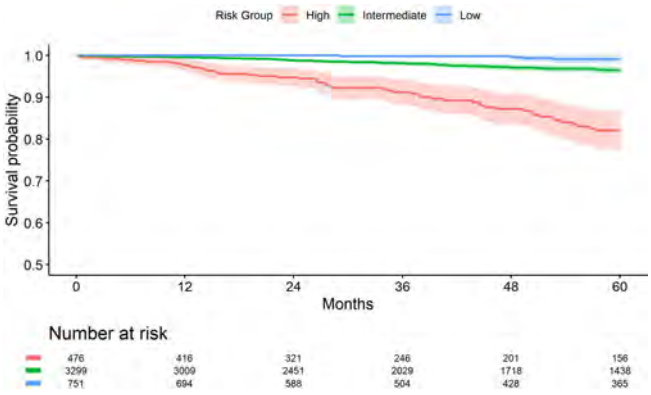

Figure 1: Overall survival according to simplified score. The 5-year survival rate was 99% (95% CI: 98–100) for low-risk patients, 96% (95% CI: 95–97) for intermediate-risk patients, and 82% (95% CI: 78–87) for high-risk patients.

was developed using 20 imputed datasets. Model performance was assessed via C-index, AUC at 3 and 5 years, and calibration. Internal validation by bootstrapping corrected for optimism using the calibration slope

Results: From 22,059 patients who were included in the EUSTAR data base, a total of 4,526 patients were included following the application of exclusion criteria. 3797/4172 met the ACR/EULAR criteria for SSc (354 missing data) Median follow-up was 53 months (95%CI: 51-55 months). The 5-year survival rate was 98% [95%CI: 97.6-98.5]. Baseline characteristics are presented in Table 1.

The RESIST score included the following eight characteristics: male sex, dcSSc, age >55 years, elevated CRP, digital ulcers (current or previous), mRSS >14, LVEF < 60% and DLCO-SB < 60% (Table 2) The AUC was 0.80 and 0.79, respectively for the 3 and 5-year mortality. As demonstrated in Figure 1, the three-cut-off system (low: 0; intermediate: 1-22; high risk: >22 points) enables an effective stratification of patients into different risk categories.

Conclusion: This future mortality risk score has the potential to serve as a valuable tool to stratify patients who could benefit from intensive (cellular) therapies in SSc patients with an acceptable benefit-risk profile. The identification of high-risk patients by clinicians is of paramount importance, as it enables the optimization of treatment plans and the improvement of overall survival.

MAIT cell-mediated immune modulation in lupus: antigen-driven expansion as a protective strategy

Grace Crossland[1], Iennard Ostendorf[2], Vianey Chavez[1], Lindsay Mendyka[1], Deepak Rao[3] and Sladjana Skopelja-Gardner[1], [1]Dartmouth College, Lebanon, NH, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0885–0890)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a leading cause of death for young women, and over 75% of SLE patients experience skin manifestations – cutaneous LE (CLE). Mechanisms of CLE pathogenesis are still unknown, so treatments rely on broad immunosuppression. Mucosal-associated invariant T cells (MAITs) are innate-like T cells that respond to microbial-derived antigens and have tissue repair capacity but are decreased in SLE. Here, we present new findings supporting a protective role for MAITs in SLE/CLE.

Methods: SLE and healthy PBMCs were analyzed by spectral cytometry (Dartmouth) and CytOF (Brigham, 145 SLE, 40 healthy). In 12-24 week old female MRL/lpr mice, spontaneous skin lesions (score >10) or systemic SLE (proteinuria) were treated with topical or systemic MAIT antigen (5OPRU, 1mM). 8-week-old female B6 and MAIT-deficient (*Mr1-/-*) mice were treated with imiquimod (TLR7 agonist) to induce SLE-like skin disease. MAIT profiling and expansion in non-lesional skin were conducted in 8-week-old female mice: MRL/lpr, B6, and *Mr1-/-*. Immune responses were assessed by flow cytometry; MAITs were identified by 5OPRU-loaded MR1 tetramer.

Results: MAIT cells were reduced in the circulation of SLE patients and had an activated/exhausted phenotype (CD25hiCD38hiCD69hi and CD107loCXCR3loCCR5lo), compared to healthy MAITs. In SLE-like skin of MRL/lpr mice, MAIT cells were reduced and more activated (> %$CD69^+PD1^+$), compared to controls (B6, MpJ). Topical administration of MAIT antigen (5OPRU) completely and durably resolved active CLE-like skin lesions. In contrast, skin lesions in mice treated with vehicle or 5OPRU + anti-MR1 Ig (blocks MAIT interaction with 5OPRU) never healed and continued to flare after treatment cessation. In the TLR7 agonist model of SLE, MAIT-deficient skin (*Mr1-/-*) had significantly increased expression of inflammatory (Ifng, Gzmb, Csf1) and interferon-stimulated genes, compared to the skin of imiquimod-treated B6 mice. MAIT expansion with 5OPRU (∼5-10-fold) in SLE-like non-lesional skin stimulated proliferation and expansion of regulatory T cell (Treg) and suppressed inflammatory and cytotoxic gene expression (Gzmb, Ifng, il6, Tnf). In SLE mice with marked proteinuria, systemic delivery of 5OPRU halted the rise in serum inflammatory cytokines (CXCL1, GCSF, IL2, IFNg) and stimulated systemic expansion of T_{reg}, including in the skin. The 5OPRU-mediated Treg expansion was MAIT-dependent, as no increase in Treg was seen in 5OPRU-treated *Mr1-/-* mice. MAIT expansion was captured in the skin after just 2 doses of 5OPRU and was accompanied by increases in monocyte-derived dendritic cells (moDCs) and Langerhans cells (LCs), in a MAIT-dependent fashion.

Conclusion: Topical and systemic expansion of MAITs reduces tissue and systemic inflammation, and overall disease burden in MRL/lpr mice. Their protective role in SLE is further supported by a second SLE model, where MAIT deficiency leads to heightened inflammatory and interferon responses. These effects may be mediated via MAIT-dependent expansion of Treg. MoDCs and LCs are identified as candidate antigen-presenting cells involved in MAIT activation and downstream Treg induction.

A First-in-class Biologic Selectively Targeting hla-b27-reactive T Cells in Ankylosing Spondylitis

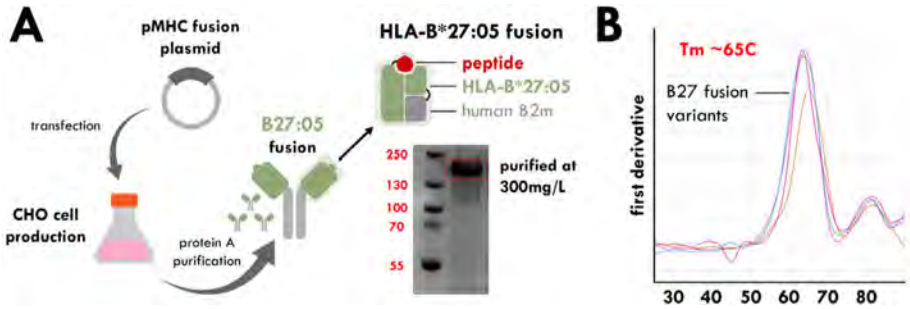
Patrick Holec, Megan Reitars, Nishant Singh and Isabelle Larsen, Fletcher Biosciences, Cambridge, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0885–0890)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Ankylosing spondylitis (AS), a chronic autoimmune disease strongly associated with HLA-B27:05, is currently managed with therapies that broadly suppress inflammation instead of targeting disease-driving immune cells. This limitation highlights the potential of emerging selective T cell depletion strategies such as those using anti-TRBV9 antibodies, which have recently demonstrated clinical promise. Here, we present a novel therapeutic approach utilizing engineered peptide–MHC (pMHC) fusion proteins designed to selectively deplete HLA-B27-restricted, autoreactive T cells in AS. These pMHC fusion molecules are optimized for stability and TCR affinity, offering a new avenue for antigen-specific immune modulation.

Methods: We engineered B27:05 fusion proteins presenting cross-reactive peptides identified from AS+ patient synovial TCRs. Using high-throughput protein screening, we identified mutations that enhance the stability of HLA-B27:05 and globally enhanced engagement of disease-associated T cells . Candidate pMHC fusion molecule were conjugated to select payloads to enable targeted cell killing. Selective T cell depletion was tested using T cell lines transduced with one of 50+ AS-associated or control TCRs. Additional evaluation was performed in vitro on patient PBMCs to evaluate drug efficacy and toxicity.

Results: Lead pMHC-Fc candidates demonstrated high expression (≥100 mg/L), thermal stability (Tm ≥ 60°C), and strong binding to ≥70% of patient-derived TCRs. MMAE-conjugated pMHC-Fc constructs selectively eliminated >80% of AS-specific T cell lines with low off-target toxicity. In primary human cells, pMHC-Fc-MMAE treatment resulted in dose-dependent depletion of CD8+ T cells based on antigen-reactivity, displaying no notable toxicity beyond on-target autoreactive T cells.



Production and biophysical characterization of B27:05 fusion proteins: (A) Schematic of the production pipeline: pMHC fusion constructs encoding HLA-B*27:05, beta-2-microglobulin, and a disease-relevant peptide are transfected into CHO cells, and purified via Protein A affinity chromatography, yielding expression levels of ~300 mg/L. (B) Thermal shift assay of purified B27:05 fusion proteins demonstrates high thermal stability, with melting temperatures (Tm) averaging 65°C across variants.

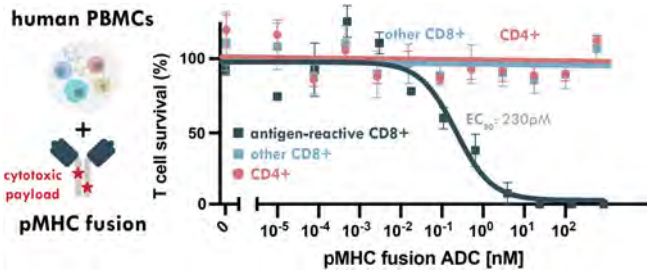
Specific depletion of AS-relevant T cells using B27:05 drug conjugates: A cytotoxic payload conjugated B27:05 was evaluated across a panel of 50+ TCR+ cell lines expressing either AS-relevant TCRs (green) or non-AS-related off-target TCRs restricted to A02 (blue), B27 (light green), C06 (red), or MHC class II alleles (gray). Following 72-hour treatment at 4 nM, selective depletion of HLA-B27-restricted TCR clones from AS+ patients was observed, with minimal off-target cytotoxicity across unrelated clones.



Selective cytotoxicity of pMHC fusion in primary human PBMCs: Treatment of antigen-specific PBMC cultures with pMHC-drug conjugate demonstrated potent depletion of antigen-reactive T-cells (EC50 = 230 pM) while sparing other T cell populations. This validates the ex vivo selectivity and potency of the pMHC fusion platform in physiologically relevant immune cell mixtures.

Conclusion: We demonstrate the first functional application of soluble, engineered HLA-B27:05 fusion molecules to selectively deplete autoreactive T cells in AS. This precision platform addresses a critical unmet need by targeting the root cause of inflammation without broad immunosuppression. These findings support the advancement of pMHC-based biologics as a novel, disease-modifying therapeutic class for AS and other HLA-associated autoimmune diseases.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0885–0890)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Immune checkpoint inhibitor (ICI) therapies for cancer can induce immune-related adverse events (irAEs) involving musculoskeletal (MSK) systems. ICI myotoxicity (ICI-M) can present as a triad of fulminant myocarditis, myositis and myasthenia gravis-like syndrome, calling for rapid recognition and precise therapeutic assessment. Abatacept shown promise as a treatment option for high-grade ICI-M [1]. Previously we identified a clonal CD38^{hi} cytotoxic CD8 T cell population specifically expanded in ICI-arthritis, indicating an irAE specific T cell response in ICI-MSK systems [2]. Regulatory CD8 T cells expressing KIR have been reported in autoimmunity and cancer patients[3]. Whether these T populations can help clinical recognition and therapeutic response assessment in high-grade ICI-M calls for further investigation.

Methods: We performed immunophenotyping, single-cell transcriptomic analysis and TCR analysis of T cells from blood and muscle tissue in a multi-center cohort of ICI-M patients (n=16). Blood of ICI-A (n=7), ICI-without irAE (ICI, n=9), and cancer-without ICI therapy (non-ICI, n=6) were used as control.

Results: scRNA-seq identified 11 distinct T cell clusters in ICI-M and ICI-A (Fig 1a-b). Transcriptomic features of the top four effector memory clusters, C1 GZMB+ GZMH+ GNLY+ cytotoxic CD8 T cells, C3/6 GZMK+KLRB+/HLADR+ cytotoxic CD8 T cells, and C4 KIR+ CD8 T cells, each showing unique cytotoxic characteristics (Fig 1c). C3/6 were identified as CD38hi-like

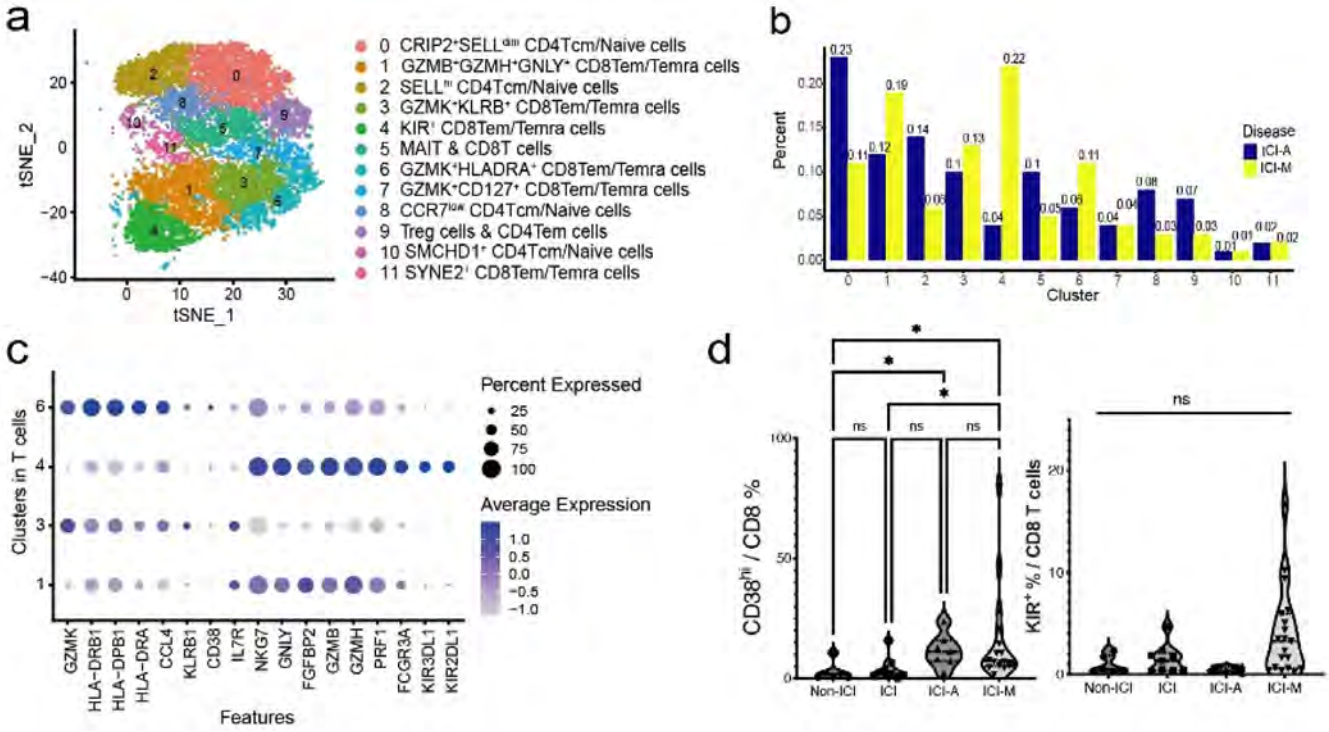

Figure 1. Transcriptomic features of ICI-M peripheral blood. scRNA-seq identified distinct T cell clusters (a) in ICI-M and ICI-A (b). Top four effector memory clusters showed distinct transcriptomic features (c). Frequency of CD38hi-like C3/6 and KIR+ C4 in ICI-M (d). Krustal-Wallis test. ns, not significant. *, p<0.05.

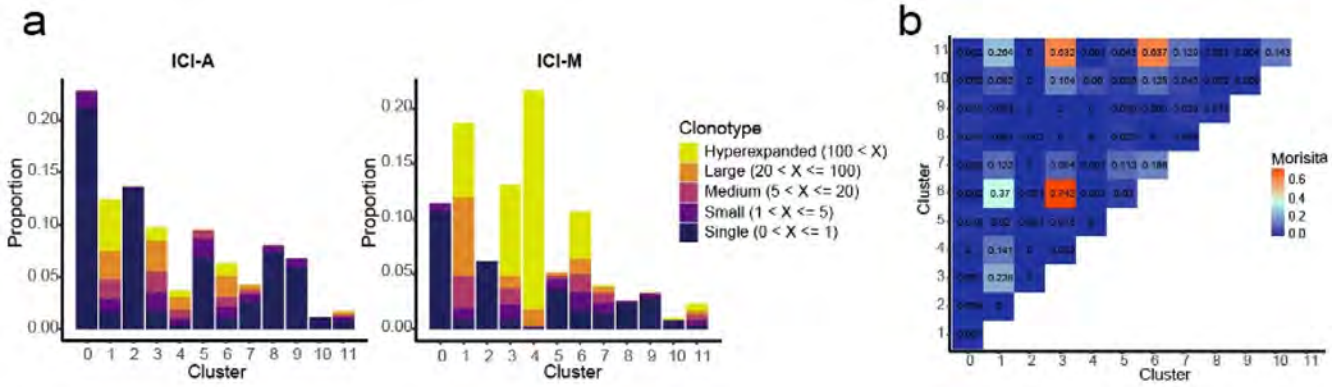

Figure 2. scRNA-seq TCR analysis showed clonality of ICI-M circulating T cells clusters (a) and their similarity represented with Morisita index (b).

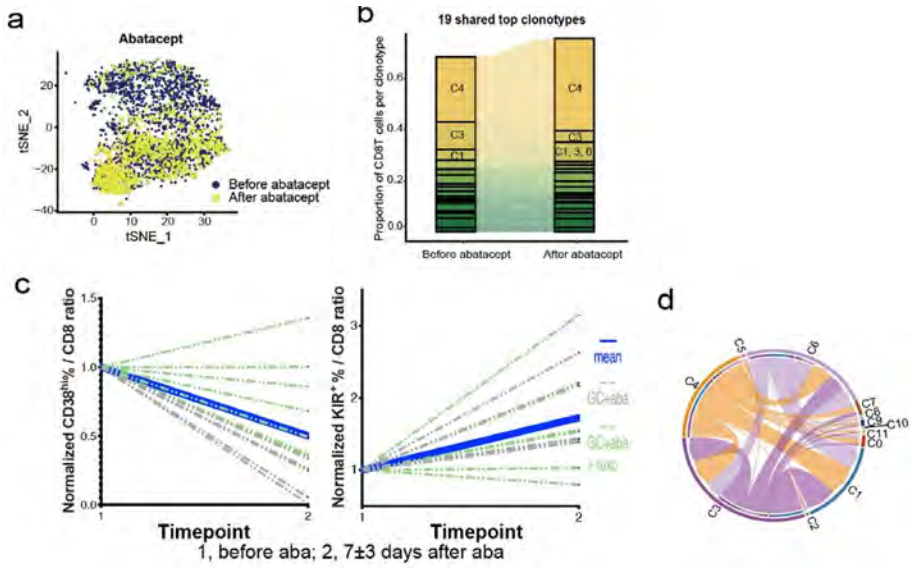

Figure 3. Therapeutic response to abatacept. tSNE plot showing abatacept altered the composition and clonality (a-b) of CD8 T cells in ICI-M. Flow cytometry analysis showed fold change of circulating CD38hi and KIR+ CD8 T cells in ICI-M before and after abatacept (c). Chord plot showing the inferred communication among T cell clusters. The edge width represents the communication probability. (d).

cells using a gene signature we previously identified [2]. Multi-color flow cytometry showed that circulating C3/6 and C4 are expanded in ICI-M (Fig 1d). C3/6 were also identified in muscle tissue of ICI-M patients.

TCR repertoire analyses revealed more prominent clonal expansion of cytotoxic CD8 Tem cells in ICI-M over ICI-A, particularly $CD38^{hi}$-like CD8 T cells (C3+C6) and KIR+ CD8 T cells (C4) (Fig 2a). C3/C6 shared clonality that's different from C4 (Fig 2b).

A tailored dosing of abatacept in addition to corticosteroids +/- ruxolitinib was applied based on the degree of CD80 blockade and successfully rescued clinically fulminant ICI-M in our multi-center cohort. The abatacept regimen altered the composition and clonality of CD8 T cells (Fig 3a-c). Using cellchat algorism, possible interactions were identified among KIR+ CD8 T cells (C4) and CD38like CD8 T (C3+C6) (Fig 3 c).

Conclusion: The dynamic of $CD38^{hi}$ CD8 T cells and KIR^{+} CD8 T cells effectively identified ICI-M patients and supported their therapeutic assessment during abatacept. Analyzing these populations may provide personalized treatment strategy for life-threatening irAEs.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0885–0890)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Antigen-specific therapies offer a promising approach to selectively modulating autoimmune responses without broad immunosuppression. Strong associations with specific Class I HLA alleles in ankylosing spondylitis (AS) with a linkage to HLA-B*27:05 (Odds ratio of 62) and birdshot uveitis (BU) with a linkage to HLA-A*29:02 (Odds ratio of 157) suggest a role for $CD8^+$ T cells, yet the causative autoantigens remain unknown. TScan's proprietary TargetScan platform offers an unbiased high-throughput method to identify the natural targets of disease-relevant T cell receptors and aid in the development of antigen specific tolerizing modalities.

Methods: We isolated $CD8^+$ T cells from synovial fluid of patients with AS and aqueous humor or vitreous humor from patients with BU. Single-cell TCR sequencing identified 42 unique paired α/β TCR sequences from the ankylosing spondylitis samples and 113 clonotypes from the BU samples. These TCRs, along with 14 previously published TCRs from AS patients, were gene synthesized and screened using the TargetScan platform against a comprehensive cell library representing the full human proteome presented naturally by cells engineered to express the disease associated HLA allele (HLA-B*27:05 for AS, HLA-A*29:02 for BU). Screening revealed multiple putative autoantigen targets which were subsequently evaluated for disease relevance.

Results: Using this approach, we identified over 10 putative Class I–restricted T cell targets for AS and two for BU. These targets were validated through orthogonal assays, including functional T cell activation, and exhibited expression patterns consistent with disease-relevant tissues. Minimal epitopes for each target were mapped to define the core sequences required for TCR recognition. Their identification provides new insight into the antigenic drivers of these conditions and highlights potential avenues for the development of antigen-specific therapeutics.

Conclusion: TScan's discovery platform enables the identification of novel Class I-restricted autoantigens in autoimmune diseases where no targets were previously known, filling a critical gap in the understanding of T cell-driven pathology. This technology provides a foundation for the development of antigen-specific therapeutics, including tolerogenic approaches aimed at restoring immune homeostasis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0885–0890)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Prior to the onset of clinically apparent inflammatory arthritis (IA)/synovitis (clinical RA), ACPA+ 'at-risk' individuals (ARI) show alterations in the abundance of effector T cell subsets in the peripheral circulation. However, it remains unclear which T cell subsets define the progression to clinical RA. A population of central memory CD4 T cells expanded over time as ACPA+ ARI progressed to clinical RA (termed 'converters'). In this study, we investigated the molecular phenotype of this expanding memory T cell population in converters.

Methods: We conducted a longitudinal analysis of peripheral blood mononuclear cell (PBMC) transcriptomes obtained by scRNA-seq. We performed linear mixed effects longitudinal modeling on samples from ACPA+ participants over a period of 2 years prior to the onset of clinical RA (n=13 converters; n=61 samples; mean 4.7 samples per converter; Table 1). These

Table 1: Summary of converter information

Variable	Baseline Visit (n = 13)	IA Onset (n = 13)	*P* value[1]
Age at sample collection, mean years (SD)	45 (14)	47 (14)	<0.01

samples were from a prospective longitudinal cohort study of ACPA+ individuals without baseline IA/synovitis. Cell-cell communication analyses to infer ligand-receptor interactions and downstream gene expression changes were performed using Liana and NicheNet.

Results: A memory CD4 T cell population that expanded almost 2-fold over time from baseline to conversion (FDR< 0.05) expressed PD1, ICOS, CXCR5 and KLRB1 transcripts, exhibited a transcriptionally activated state (P< 0.05) and were enriched for a published transcriptional signature of Tfh/Tph cells from RA synovial tissue (P< 0.01; Zhang 2019 Nature Immunol). Using an independent trimodal single cell validation dataset (Thomson 2023 Nature Immunol), we identified a CD4 memory population that expressed a similar PD1+ ICOS+ CXCR5+ KLRB1+ transcriptional signature. Notably, this population had the highest surface protein expression of PD-1 and ICOS, along with high expression of KLRB1 protein. We inferred key receptor-ligand communication between two lymphocyte populations that expanded as converters progressed to clinical RA: (1) the memory CD4 T cell population; and (2) CD27- TBX21+ atypical B cells. Potential receptor-ligand complexes included CD40LG-CD40, CD86-CD28, and SEMA4D-CD72, and was supported by downstream changes in gene expression following receptor-ligand interactions reported in both these populations.

Conclusion: These results suggest the increased population of central memory CD4 T cells in the peripheral blood of converters approaching transition to clinical RA is associated with changes in activated T cells with a B cell helper phenotype. This memory population could be similar to Tph cells found to be clonally expanded in RA synovium, but also shares features of Th17 cells, suggesting they could produce pro-inflammatory mediators that participate in disease pathogenesis. These findings are supported by inferred bidirectional signaling between these memory CD4 T cells and atypical B cells during progression to clinical RA. Our findings provide key insights into adaptive immune mechanisms that contribute to the progression from an at-risk state to clinical RA, and may suggest targets for early preventive intervention or biomarkers for RA prevention trials.

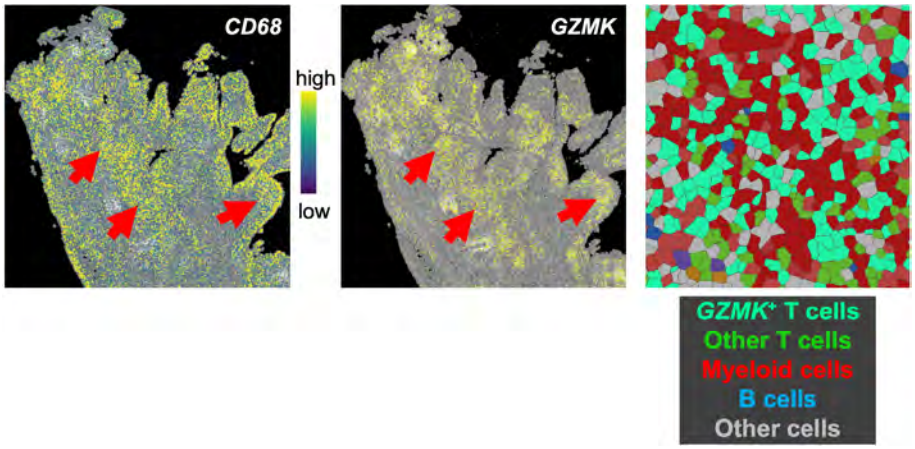

Figure 1. GZMK+ CD8A+ cells are located near myeloid cells in the sublining of RA synovial tissue. FFPE RA synovial tissue was submitted for spatial transcriptomic analysis on the Xenium platform. The panels on the left show density gradients of transcripts encoding CD68 (myeloid marker) and GZMK, respectively, superimposed on the tissue. Red arrows point to areas enriched in both CD68 and GZMK. The panel on the right shows a close-up view with cells shaded by cluster, showing intermingling of GZMK+ T cells (teal) and myeloid cells (red).

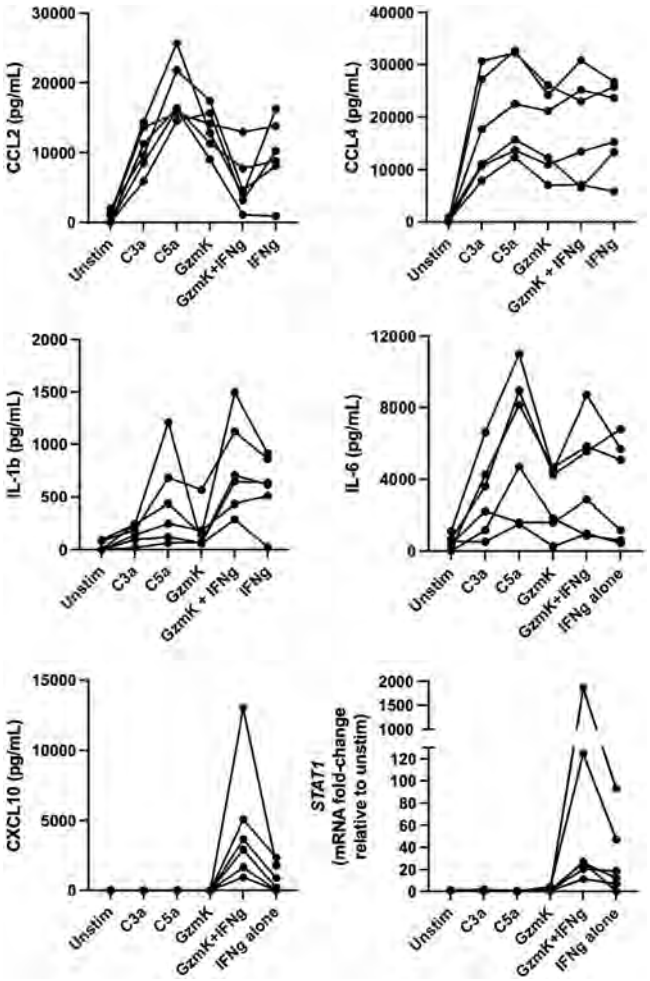

Figure 2. GZMK directly stimulates blood monocytes and also amplifies the effects of IFNγ. Human CD14+ monocytes were isolated from blood and stimulated with recombinant or serum-purified GZMK, IFNγ, C3a, or C5a, or a combination of GZMK and IFNγ for 24 hours. The supernatants were collected for analysis by ELISA, while the cells were lysed for analysis by quantitative RT-PCR. The lines connect samples from the same blood donor (N=6).

Background/Purpose: Granzyme K (GZMK)-expressing CD8 T cells have recently been detected in tissues from an increasing number of autoimmune conditions, but their role in disease pathogenesis is unclear. We have identified and characterized these cells in rheumatoid arthritis (RA), where they represent up to 30% of cells in inflamed synovium (joint lining) and express a gene program different from granzyme B (GZMB)$^+$ cytotoxic CD8 T cells. We recently showed that *Gzmk* knock-out mice exhibit a milder course antigen-induced arthritis, a mouse model of inflammatory arthritis, compared to wild-type mice, supporting a direct role for GZMK in the pathogenesis of inflammatory arthritis such as RA. GZMK$^+$ CD8 T cells have many potential effector functions. Resting GZMK$^+$ CD8 T cells continuously release GzmK, even in the absence of stimulation. They can also release cytokines such as IFNγ upon T-cell receptor (TCR)- or cytokine-mediated stimulation. Lastly, GzmK can initiate complement cascades, generating anaphylatoxins C3a and C5a. Our goal with this project is to localize GZMK$^+$ CD8 T cells in RA synovial tissue and characterize their molecular interactions with neighboring cells.

Methods: Spatial transcriptomic data were collected from three samples of human synovial tissue from patients with RA using a custom 377-probe panel on the Xenium platform (10x Genomics). For *in vitro* experiments, CD14$^+$ myeloid cells isolated from human peripheral blood mononuclear cells by magnetic-activated cell sorting and stimulated with recombinant or serum-purified GZMK, IFNγ, C3a, and/or C5a, for 24 hours and then analyzed by ELISA or RT-PCR.

Results: In spatial transcriptomic and immunofluorescence microscopy data, GZMK$^+$ CD8 T cells were preferentially located among myeloid cells in perivascular areas of the sublining in human RA synovial tissue (Figure 1). To investigate and compare molecular interactions between GZMK$^+$ CD8 T cells and myeloid cells, we stimulated CD14$^+$ blood monocytes *in vitro* with soluble factors produced by GZMK$^+$ CD8 T cells directly (GZMK, IFNγ) or via activation of complement cascades (C3a, C5a). We paid special attention to chemokines CCL2, CCL4, CXCL9, and CXCL10 since both monocytes and GZMK$^+$ CD8 T cells express the cognate receptors for these chemokines, CCR2, CCR5, and CXCR3. We found that recombinant GZMK induced monocytes to produce CCL2, CCL4, and IL-6 (Figure 2). GZMK did not induce CXCL9, CXCL10, or STAT1 on its own, but it amplified the ability of IFNγ to induce these classic interferon signature markers. The combination of GZMK and IFNγ also had modestly augmented effects on IL-1β and IL-6, while they dampened CCL2 production. C5a displayed more potent effects than C3a in terms of CCL2, CCL4, IL-1β, and IL-6 production.

Conclusion: GZMK$^+$ CD8 T cells localize near myeloid cells in the sublining of inflamed RA synovium. GZMK can directly induce monocytes to secrete CCL2, CCL4, and IL-6, and it can act together with IFNγ or through complement cascades to induce IL-1β and interferon signature genes. Together, these molecular interactions form a strong positive feedback loop, recruiting and activating additional GZMK$^+$ CD8 T cells and blood monocytes in inflamed RA synovium.

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA From Bench to Bedside (0891–0896)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: This trial aimed to compare the efficacy and safety of methotrexate (MTX) vs. tocilizumab (TCZ), in combination with glucocorticoid (GC), in patients with giant cell arteritis (GCA).

Methods: METOGiA is an open label randomized controlled multicenter trial, with a non-inferiority design. Results from the first 78-week period are reported here, in which patients received either TCZ 162 mg/week subcutaneously (SC) or MTX 0.3 mg/Kg/week SC (without exceeding 20 mg/week) during 52 weeks in combination with a GC taper regimen (42 weeks for new onset GCA, 36 weeks for relapsing GCA). Eligible patients were aged ≥50 years, diagnosed with new-onset or relapsing GCA and had active GCA within 6 weeks before randomization. The primary endpoint was collected at week 78 (W78) and was the percentage of patients alive, without relapse after initial remission or deviation from the GC taper regimen from inclusion to W78. Secondary endpoints included the percentage of patients alive, without relapse after initial remission or

Table 1: exploratory results for secondary endpoints

	TCZ n=110	MTX n=108	Difference with 95% confidence interval*	superiority p-value**
Alive without relapse after initial remission or deviation from the GC taper regimen from inclusion to W52	77 (70%)	58 (54%)	16% [4%, 29%]	0.01
Alive without relapse from inclusion to W52	91 (83%)	72 (67%)	16% [5%, 27%]	0.006

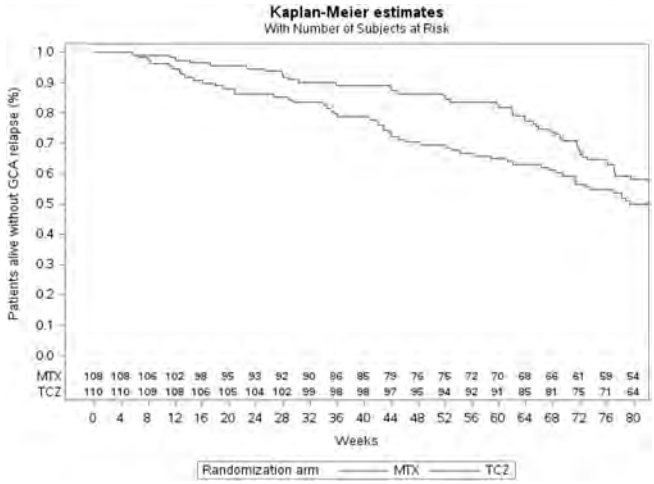

Figure 1: Relapse free survival (Kaplan-Meier estimates with number of subjects at risk)

deviation from the GC taper regimen from inclusion to W52; the percentages of patients in remission without prednisone or with prednisone ≤5mg/day at W52 and W78; the cumulative dose of prednisone at W52 and W78; and adverse events. Remission was defined as the absence of symptoms attributable to GCA and CRP≤10 mg/L. Relapse was defined as the recurrence of symptoms attributable to active GCA, whatever the value of CRP. Relapses were confirmed by an adjudication committee composed of 3 experts not participating to the study and blinded to the assigned study arm, CRP, ESR, fibrinogen and FBS values.

Results: A total of 230 patients were randomized in 39 French centers, among them 9 withdraw their consent and 3 were lost of follow up before reaching W78. Finally, 218 patients (TCZ, n=110; MTX, n=108) were analyzed in the intention-to-treat (ITT) population. GCA characteristics were balanced between groups, with 74% and 26% of patients having new-onset and relapsing GCA (TCZ: 77% and 23%; MTX: 71% and 29%), respectively. At W78, the primary endpoint was reached in 37% of MTX *vs*. 46% of TCZ patients, resulting in a 9% difference (95% CI: [-4%, 22%]), which did not meet the predefined non-inferiority margin of 20%. Thus, in the ITT population, MTX was not non-inferior to TCZ (P=0.054). However, TCZ was not superior to MTX at W78 (P=0.16). Results for secondary endpoints are detailed in **Table 1**. Relapse-free survival curves are depicted in **Figure 1**. By W78, 15 MTX-related SAEs occurred in 14 patients (8 infections, including 5 Pneumocystis infections, one of which was fatal) and 13 TCZ-related SAEs occurred in 11 patients (6 neutropenia, 3 infections). Seven deaths were reported at W78 (TCZ, n=1; MTX, n=6).

Conclusion: In the ITT population, MTX was not non-inferior to TCZ regarding the primary endpoint at W78, but was non-inferior for the remission rate with or without low-dose prednisone. At W52, results suggest that TCZ is more effective than MTX in maintaining remission and preventing relapse. These results must be confirmed by the per-protocol analysis (ongoing).

Abstract Number: 0892

Relapse and Immune Dysregulation in Giant Cell Arteritis Are Linked to Mosaic Loss of the Y Chromosome

Simon M. Petzinna, Sophie-Marie Kirch, Maike S. Adamson, De Xi, Claus-Jürgen Bauer, Lena Kreis, Pantelis Karakostas, Rayk Behrendt, Sebastian Zimmer, Raul N. Jamin and Valentin S. Schäfer, University Hospital Bonn, Bonn, Nordrhein-Westfalen, Germany

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA From Bench to Bedside (0891–0896)

Session Type: Abstract Session

Session Time: 10:00AM–11:30AM

Background/Purpose: Mosaic loss of the Y chromosome (mLOY) is the most common acquired somatic mutation. Epidemiological studies have linked mLOY to malignancies, as well as cardiovascular and chronic kidney disease. Mechanistically, mLOY leads to the loss of epigenetic regulators on the Y chromosome, resulting in proinflammatory and profibrotic signaling. This evidence suggest a broader role for mLOY in age-related immune dysregulation and inflammation. In this context, giant cell arteritis (GCA) is a compelling candidate for further investigation, as it exclusively affects individuals over 50. This study is the first to assess the prevalence, clinical impact and pathophysiological consequences of mLOY in GCA.

Methods: Male patients with a diagnosis of GCA were enrolled. Demographic, clinical and imaging data were collected. Blood samples were obtained at the time of inclusion. Extraction and quantification of DNA was performed. Extent of mLOY was assessed using a digital droplet PCR with a SNP-based assay targeting a 6 bp difference between the AMELX and AMELY genes. The extent of mLoY was calculated as 1 – [AMELY]/[AMELX]. Cytokine concentration in the blood serum of GCA patient were assessed using the LEGENDplex™ Human Inflammation Panel 1.

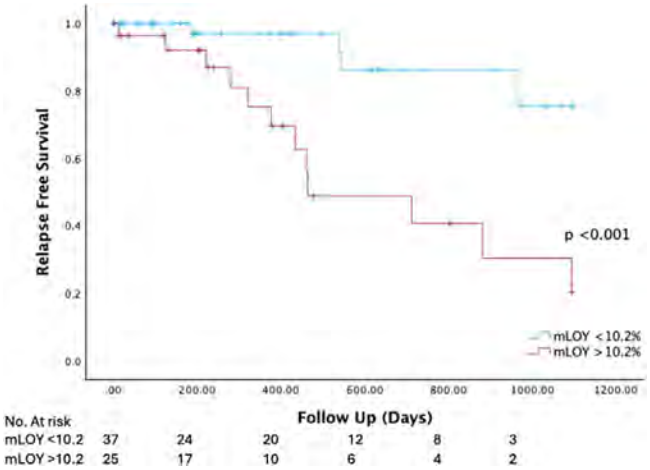

Figure 1: Survival Analysis for Predicting Relapse in Patients with Giant Cell Arteritis Figure 1 depicts the relationship between mLOY burden and relapse risk in GCA patients. Kaplan-Meier survival analysis demonstrates that patients with mLOY >10.2% had a significantly higher relapse risk ($p < 0.001$, univariate log-rank test) and a shorter median relapse-free survival (647 days [95% CI: 468–827]) compared to those with mLOY <10.2% (992 days [95% CI: 898–1,087]; $p < 0.001$). Abbreviations: GCA = giant cell arteritis, mLOY = mosaic loss of Y chromosome, No. = number.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

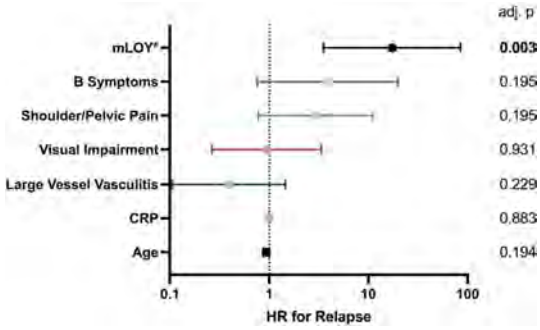

Figure 2: Cox Regression Analysis for Risk Factors Associated with Relapse in Giant Cell Arteritis This figure presents a Forest Plot summarizing the Cox regression analysis of relapse risk in patients with GCA, adjusting for factors potentially associated with relapse risk. The model included seven variables: age, mLOY burden > 10.2 %, CRP levels, visual impairment, constitutional symptoms (fever, night sweats, weight loss), large vessel vasculitis (LVV), and shoulder or pelvic pain. Abbreviations: Constit. Symptoms = constitutional sympttoms, HR = hazard ratio, mLOY = mosaic

Results: A total of 74 male patients with GCA (mean age 76.6 ± 10.7 years) were enrolled. At time of inclusion, 25.7% (19/74) exhibited active disease. During a mean follow-up of 599 ± 607 days, 24.3% (18/74) experienced at least one relapse, with a median time to relapse of 361 days (95% CI: 56.2–1470). The median mLOY burden was 17.8% (±23.7%). Receiver operating characteristic (ROC) analysis and Youden's index identified an optimal mLOY threshold of 10.2% for relapse prediction (AUC: 0.706, p = 0.006) with 39.2% (29/74) exceeding this threshold. Within three years, 43.1% of patients with mLOY >10.2% relapsed compared to 8.7% with mLOY < 10.2% (p < 0.001, Kaplan–Meier log-rank test). Median relapse-free survival was 647 days (95% CI: 468–827) for mLOY >10.2%, versus 992 days (95% CI: 898–1,087) for mLOY < 10.2%. In multivariable Cox regression adjusted for age and clinical covariates, mLOY >10.2% emerged as the only independent predictor of relapse (HR: 17.4; 95% CI: 3.5–86.0; p = 0.003). Multiplex cytokine analysis revealed a significant association between mLOY burden an IL-6 levels (p = 0.045, r = 0.24) in the overall cohort. Among patients in remission (n = 45), those with mLOY >10.2% had significantly higher IL-6 levels than those with lower mLOY (p = 0.010). In patients in remission receiving tocilizumab (n = 32), mLOY burden was associated with both IL-6 (p = 0.002, r = 0.54) and IL-17A (p = 0.026, r = 0.40).

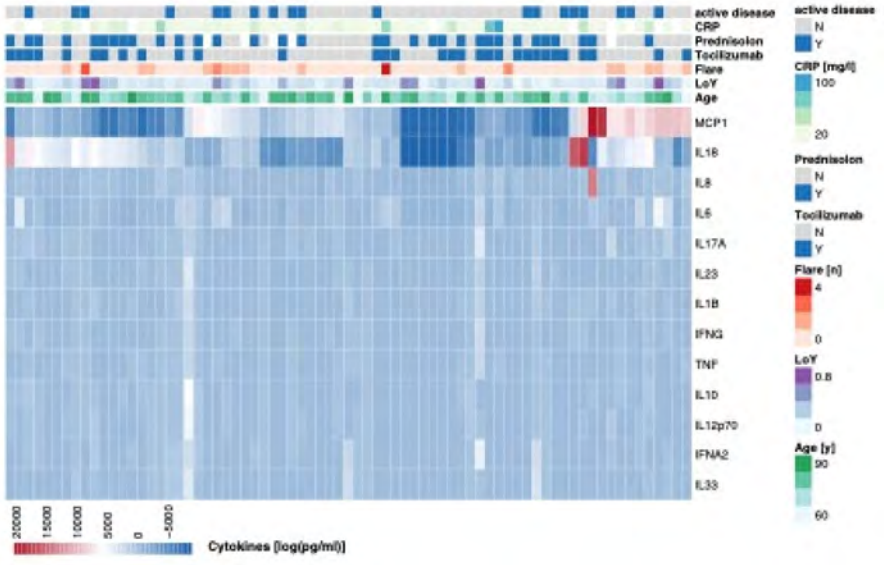

Figure 3: Inflammatory Cytokine Profile, Mosaic Loss of the Y Chromosome, and Clinical Parameters in Patients with Giant Cell Arteritis. Figure 3 depicts inflammatory cytokines measured by LegendPlex shown as heatmap. Clinical parameters are depicted above columns. In the overall cohort, mLOY as a continuous variable was positively associated with IL6 (p = 0.045). * = p<0.05 indicates statistical significance, Abbreviations: CRP= C-reactive protein, DA = disease activity, GCA = giant cell arteritis, IL = interleukin, Predn. = prednisolone, TCZ = tocilizumab, mg = milligram, mLoY = mosaic loss of the Y chromosome, N=no, Y=yes, y = years.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This is the first study to identify mLOY as a strong and independent predictor of relapse in male GCA patients, with a threshold of 10.2% mLOY burden associated with significantly reduced relapse-free survival. Elevated mLOY levels correlated with proinflammatory signaling, including increased IL-6 and IL-17A expression, particularly in patients receiving tocilizumab. Our findings suggest that mLOY may play an active role in the immunopathogenesis of GCA and serve as a prognostic biomarker to stratify patients at high risk of relapse.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA From Bench to Bedside (0891–0896)

Session Type: Abstract Session

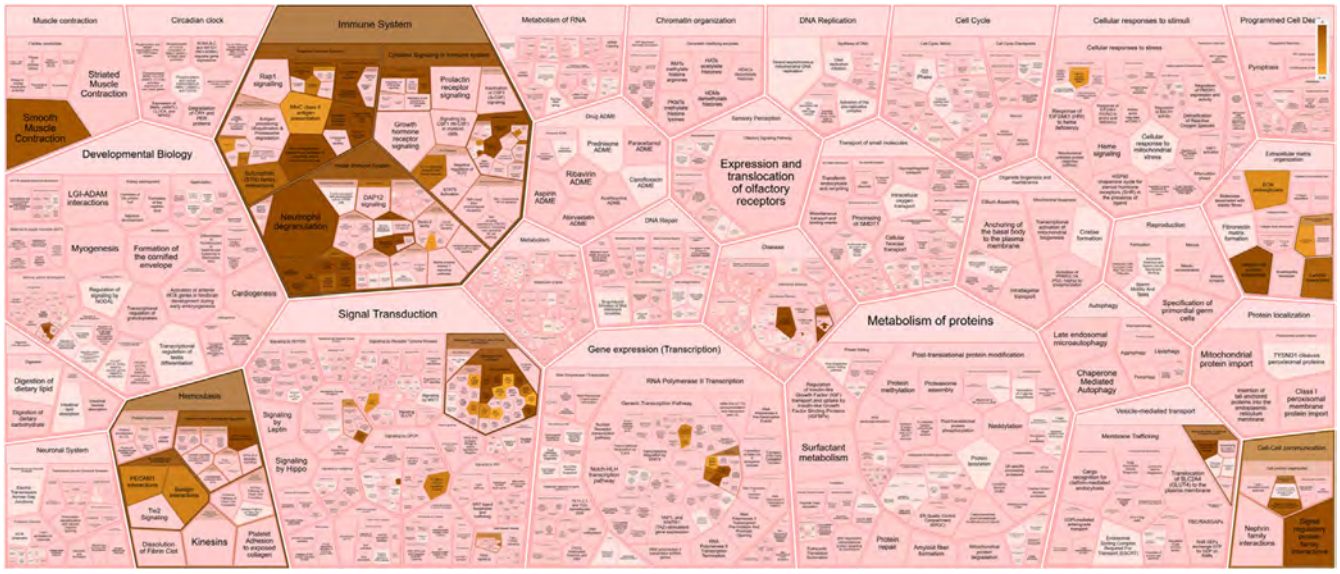
Session Time: 10:00AM–11:30AM

Background/Purpose: Giant cell arteritis (GCA) is the most common vasculitis in people over 50 years old and is a clinical diagnosis bolstered by non-specific inflammatory markers and variable pathologic findings on temporal artery biopsy (TAB). Patients with diseases that mimic GCA may undergo TAB during their workup, including those with atherosclerosis, infection, other autoimmune diseases, or simply older people with a new headache. Here we focus on the transcriptional differences in biopsy-positive GCA cases from clinically diverse controls at the level of the temporal artery.

Methods: We collected 46 TABs that were obtained during clinical care from 16 biopsy-positive GCA cases and 30 controls - polymyalgia rheumatica (3), rheumatoid arthritis (1), relapsing polychondritis (1), and granulomatosis with polyangiitis (2), infections (2), atherosclerosis (5), or an older person with new headache (16). Tissue was sequenced in bulk with RNAseq and analyzed for differential gene expression with edgeR with batch-effect correction with RUVseq and controlled for sex and age. Subsequent pathway enrichment was performed with Reactome and results were explored with data from the Human Aging Genomic Resource (HAGR) and the drug-gene interaction database (DGIdb).

Results: We found 2,279 genes to be significantly differentially expressed (DE) in biopsy-positive GCA cases compared to controls. Fifty-three pathways were enriched with an adjusted p-value < 0.05 (Fig. 1) and belonged largely to cytokine signaling (interleukin, interferon), neutrophil degranulation, cell-cell interaction (antigen presentation, integrin pathways, Fc receptor mediated signaling), and vascular activity (cell surface interactions at the vascular wall and hemostasis). Next, we found that 201 of our DE genes (8.8%) have been implicated in aging processes (HAGR). Among these is the secreted phosphoprotein 1 (*SPP1*) gene, also known as *osteopontin*, which had the largest expression fold change in cases vs controls (logFC: 6.23) in our data. *SPP1* is expressed in several immune cells, including macrophages, and is an important mediator of immune cell recruitment, migration and adhesion, macrophage activation and polarization, stimulation of inflammatory

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Fifty-three (53) pathways are significantly enriched with an false discovery rate (FDR) p-value <0.05 and belong largely to cytokine signaling (interleukin, interferon), neutrophil degranulation, cell-cell interaction (antigen presentation, integrin pathways, Fc receptor mediated signaling), and vascular activity (cell surface interactions at the vascular wall and hemostasis). Darker color corresponds with greater statistical significance (lower FDR p-value). Analysis and rendering performed at Reactome.org.

cytokines and tissue fibrosis. *SPP1* activates pathways of IL-6, IL-17, Jak/Stat, IFNγ, NFkB/ERK and granulomatous inflammation. In 2017, Prieto reported high *osteopontin* serum levels in GCA and suggested it as disease activity biomarker that is not suppressed by tocilizumab. Last, we found 705 of our genes linked to 5,824 established drugs in DGIdb, 1,564 of which are approved for use. Seventeen of these drugs were highly linked to our data (connected to 20+ genes). Fifteen drugs directly link to *SPP1*.

Conclusion: Our study recapitulates the roles of inflammation, aging and immune dysregulation in the pathophysiology of GCA that notably remain significant even with clinically diverse controls. We highlight several likely pathologic roles of *SPP1* in GCA, a gene which has not yet featured prominently in the field of GCA but may well be a key disease activity biomarker and therapeutic target. Finally, our data have provided a rich source of candidate drugs currently on the market that may effectively treat GCA.

Background/Purpose: Giant cell arteritis (GCA), a large-vessel granulomatous vasculitis, has been considered as a T cell-dependent condition. Interestingly, tertiary lymphoid structures, B cell and plasma cell infiltrates have been observed in the inflamed GCA arteries, together with an altered B cell homeostasis. This suggests that B cells can also play a role in GCA pathogenesis. Therefore, our objective was to examine the frequencies of circulating B cell subpopulations in the peripheral blood of patients with newly diagnosed GCA (nGCA).

Methods: Prospective non-interventional study on consecutive patients referred to our ultrasound (US) GCA fast track clinic, in whom newly diagnosed GCA (nGCA) was clinically confirmed (2022 ACR/EULAR criteria) over a period of 36 months. Peripheral blood was drawn immediately upon initial diagnosis and after obtaining written informed consent. For each patient, an age and gender-matched healthy control (HC) was also studied. PBMCs isolated by Ficoll- Hypaque were stained with antibodies to CD19, CD20, CD27, CD24 and CD38, and examined by flow cytometry. Patients were treated with standard therapy according to the updated 2018 EULAR recommendations.

Results: As compared with HC (n=88), nGCA patients (n=88) demonstrated significantly decreased numbers of circulating CD19+ B cells. These B cells demonstrated an altered subpopulation profile, with augmented proportions of CD19+-CD27-IgD+ naïve, CD19+CD27- IgD- double negative and CD19+CD27+CD20-CD38hi plasmablasts; at the same time, the proportions of CD19+CD27+IgD+ unswitched memory and CD19+CD27+IgD- switched memory B cells were significantly decreased whereas the proportion of circulating CD19+CD24hiCD38hi transitional B cells was not different to that observed in HC. All of these B cell population frequencies were comparable among the nGCA subgroups [cranial, large vessel or mixed (cranial + large vessel)], and in patients with or without associated polymyalgia rheumatica. Fourty-four nGCA patients donated blood for a second time, 6 months after treatment initiation. At that time, a rise in the circulating total B cell numbers, above that observed at baseline, was detected. In parallel, significant reductions in the proportions of circulating naïve B, transitional B cells and plasmablasts were apparent, together with an increase of CD27+ unswitched and switched memory B cells. Among the 46 patients who could be followed-up for 12 months, 19 experienced a relapse. Strikingly, the baseline numbers of circulating total CD19+ B cells had been significantly lower in patients who did not relapse as compared with those who relapsed; moreover, when examining separately the time-course evolution of these two groups, it was evident that only patients who did not experience a relapse demonstrated a rise of their CD19+ B cell numbers, whereas these numbers did not vary in those who relapsed.

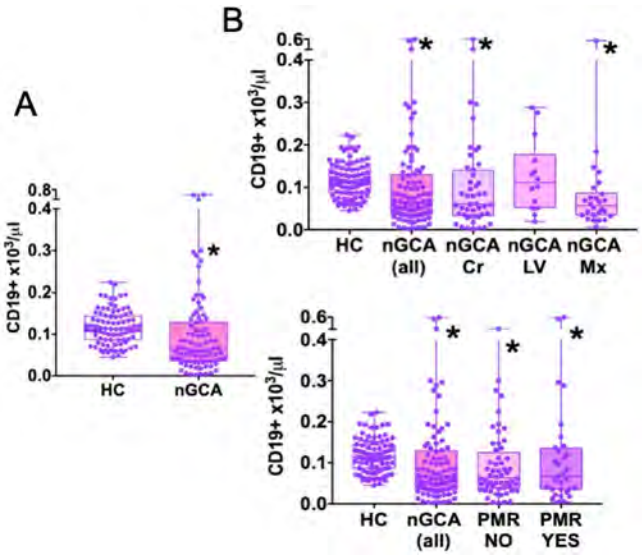

Figure 1. Absolute numbers of circulating CD19+ B cells in nGCA patients and HC.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Frequency of circulating B cell subpopulations in nGCA patients and HC

Conclusion: Patients with nGCA demonstrate a profoundly altered B cell profile at baseline that dynamically varies along the course of the disease. This points to the implication of B cells in GCA pathogenesis and may contribute to the design of personalized therapeutic strategies.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA From Bench to Bedside (0891–0896)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: This study assessed the occurrence of adverse events of serious infections, herpes zoster, and opportunistic infection during concomitant treatment with GCs and after GC tapering in patients with GCA receiving UPA or PBO in the SELECT-GCA trial.

Methods: Patients in this analysis from SELECT-GCA[1] were diagnosed with new-onset or relapsing GCA, had previous exposure to ≥40 mg prednisone (or equivalent) daily, and were on a baseline prednisone dose of ≥20 mg daily. Kaplan-Meier method was used to analyze adverse events through week 52, presented as time to first event (patients with no events were censored at the end of the study period). Event rates were calculated for data from patients with ≥1 event of the same type.

Results: Baseline characteristics of the treatment groups were similar.[1] Baseline GC doses for UPA were: 20 mg (30%, n=95); 30 mg (22%, n=70); 40 mg (29%, n=91); 50 mg (10%, n=32); 60 mg (9%, n=28). Baseline GC doses were similarly distributed for PBO: 20 mg (27%, n=30); 30 mg (26%, n=29); 40 mg (28%, n=31); 50 mg (14%, n=16); 60 mg (5%, n=6).

Rates of serious infections were lower with both doses of UPA than PBO through week 52 (UPA7.5, 7.9 [95% CI: 3.2, 16.3]; UPA15, 7.9 [4.3, 13.2]; PBO 12.7 [6.6, 22.2] events per 100 patient-years [E/100 PY]). Herpes zoster, a known risk for JAK inhibitors including UPA, had higher rates with UPA15 vs PBO (7.3 [95% CI: 3.9, 12.5] E/100 PY vs 4.2 [1.2, 10.9] E/100 PY) or UPA7.5 (4.5 [1.2, 11.6] E/100 PY). Rates of opportunistic infections were low in all groups, although numerically higher in the UPA15 group compared to PBO (2.2 [95% CI: 0.6, 5.8] E/100 PY vs 1.1 [0, 5.9] E/100 PY); no opportunistic infections were reported for UPA7.5.

In UPA-treated patients, rates of serious infections were comparable across during the GC-taper period (difference ≤ week 26 for UPA – PBO: 0.3 [95% CI: -5.8, 6.4] and -0.3 [-5.4, 4.8] E/100 PY for UPA7.5 and UPA15. Rates of serious infections were lower in the post-taper period with UPA7.5 or UPA15 relative to PBO (treatment difference from > week 26 to week 52: UPA7.5, -5.1 [95% CI: -12.1, 1.9] and UPA15, -4.6 [-11.1, 2.0] E/100 PY). Rates of herpes zoster were similar in UPA-treated patients during the GC taper (treatment difference for UPA – PBO: UPA7.5, -3.1 [95% CI: -7.8, 1.6] and UPA15, 1.4 [-4.0, 6.8] E/100 PY) and post-GC taper (treatment difference: 3.4 [95% CI: -0.4, 7.2] and 1.7 [-0.2, 3.6] E/100 PY). Of the 4 opportunistic infections in UPA15, 3 events occurred during the GC taper and 1 occurred post-taper.

Conclusion: The rate of serious infection through 52 weeks was lower in patients treated with UPA combined with a 26-week GC taper versus PBO with a 52-week GC taper, with rates lower with UPA relative to PBO after tapering GCs in the UPA groups. The decrease in serious infection rates during the GC-free phase suggests GC use may contribute to the risk of serious infections. GC tapering did not appear to affect the occurrence of HZ in the UPA groups. These results support the use of UPA15 with a standardized approach to GC tapering to reduce GC burden in older populations with an elevated infection risk.

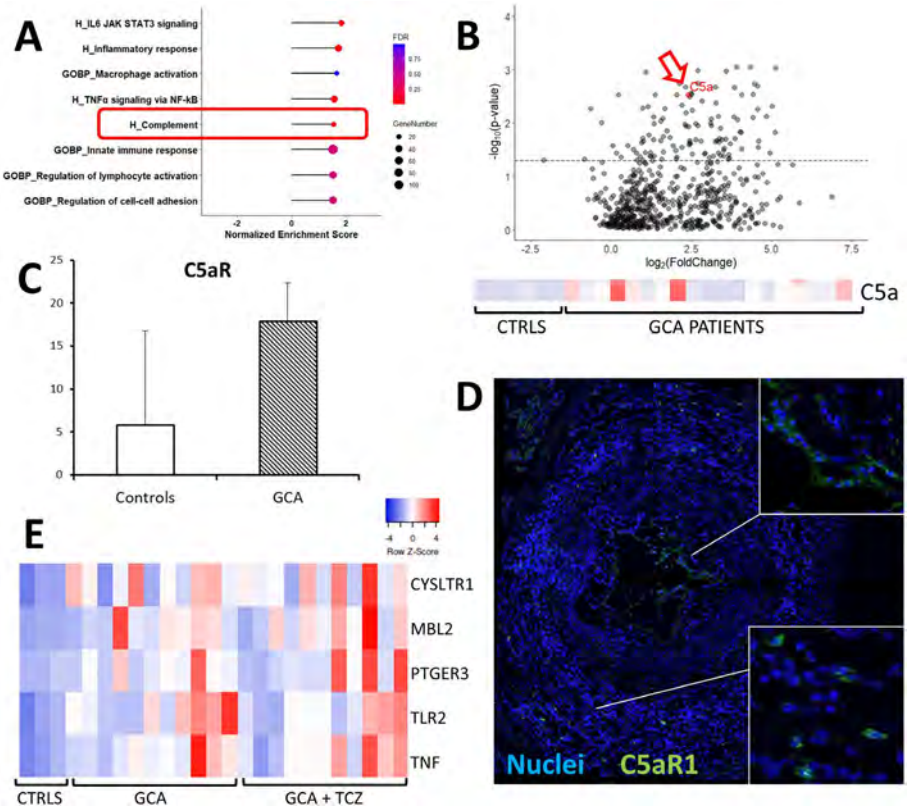
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA From Bench to Bedside (0891–0896)
Session Type: Abstract Session
Session Time: 10:00AM–11:30AM

Background/Purpose: Patients with giant-cell arteritis (GCA) are in an unmet need for reduction of GC exposure because of the high incidence of GC-related side effects in the elderly. Blocking C5a receptor 1 (C5aR1) with avacopan has allowed extreme minimization of GC exposure in ANCA-associated vasculitis. The complement system has not been investigated in GCA.

Aims: 1) to perform a transcriptomic analysis of cultured temporal artery biopsies from patients with GCA and controls 2) to perform a proteomic analysis of the supernatants of cultured arteries 3) to explore the expression in tissue of the C5aR1 4) to interrogate the transcriptomic data searching for transcripts regulated by C5aR1 signaling and the impact of blocking IL-6 receptor with tocilizumab (TCZ) on their expression.

Methods: Nanostring nCounter Human Inflammation Panel was applied to RNA extracted from ex-vivo cultured arteries (from 11 patients with GCA and 3 controls) with or without exposure to TCZ. Protein array (Ray-Biotech, 640 proteins) was applied to the corresponding supernatants. RT-PCR of C5aR1 was performed in frozen arteries from 10 patients with GCA and 10 controls and in cultured myofibroblasts alone or exposed to PBMCs. C5aR1 protein expression was explored by immunofluorescence. nCounter barcode counts were processed with nSolver 4.0 software. Normalized data were analyzed using R-Studio 4.0.3



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Transcriptomic analysis revealed up-regulation of complement pathways in arterial samples from patients with GCA (fig 1A). C5a was present in the supernatants of cultured GCA arteries and virtually absent in control arteries (fig1B). C5aR1 was overexpressed in temporal arteries from patients with GCA compared to controls (fig1C) and was expressed by inflammatory cells, endothelial cells and scattered vascular smooth muscle cells (fig1D).

Primary myofibroblasts derived from temporal arteries expressed C5aR1 when co-cultured with PBMCs. We interrogated the nanostring results in search for transcripts regulated by AP-1 (in the signalling cascade driven by C5aR1) but not regulated by transcription factors in the classical IL-6,IFNγ or GM-CSF cytokine signaling, based on ENCODE transcription factor targets dataset. 13 genes explored in the Human Inflammation panel had potential binding sites for AP-1 complex but not for STAT3, STAT1, STAT5 or SPI1). Of those, CYSLTR, MBL2, PTGER3, TLR2 and TNF transcripts were increased in samples from patients with GCA compared to controls and, in our experimental conditions, were not down-regulated by TCZ (fig1E)

Conclusion: Complement pathways are activated in GCA and C5a is present in the supernatant of cultured GCA arteries, indicating local processing of complement molecules. C5aR1 is expressed in GCA-involved arteries by inflammatory and stromal cells, suggesting a role in vascular remodeling. Transcripts regulated by C5aR1 (but not regulated by other cytokines present in GCA) were overexpressed in GCA and are not modulated by TCZ. Our findings suggest that blocking C5aR1 may contribute to abrogate inflammatory pathways in GCA. Exploring the transcriptomic and functional impact of C5aR1 inhibitor avacopan on cultured temporal arteries is in progress.

APECED Disease Reorganizes the B Cell Compartment Toward Alternatively Activated Subsets

william Galbavy, Hyunjin Kim, Brian Klotz, Marine Malbec, Carley Tasker, Eva Conde, Andrea Vecchione, Seblewongel Asrat, Benjamin Daniel, Weikeat Lim, **Andre Limnander** and Jamie Orengo, Regeneron, Tarrytown, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune PolyEndocrinopathy Candidiasis Ectodermal Dystrophy (APECED) is a rare syndrome of multi-organ autoimmunity driven by the presence of self-reactive T cells and autoantibodies caused by mutations in the gene Autoimmune regulator (Aire). Compared to the well-defined role of Aire in establishing and maintaining T cell central tolerance by helping medullary thymic epithelial cells eliminate self-reactive T cells, less is known about how Aire deficiency in APECED impacts B cells and causes a breakdown in peripheral B cell tolerance.

Methods: We performed single-cell sequencing analyses, flow cytometry, and autoantibody profiling of PBMCs and serum of 10 APECED patients and 10 controls.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We found robust changes in the B cell compartment of APECED patients relative to that of healthy donors, with a substantially lower percentage of naïve B cells and significant increases in antigen-experienced B cell phenotypes. Among these changes seen by scRNAseq compositional analysis were increases in Memory B cells (TACI+ CD27+), and Atypical B cells (CD21lo CD11c+ Tbet+). Serum autoantibody profiling with an array of ~23,000 proteins uncovered >200 APECED associated IgG autoantibody varieties, including to type I IFN, IL17, key enzymes including the cytochrome P450 family, neurotransmitter associated proteins, and others. The Atypical B cell subset in patients was found to be especially correlated to levels of IgG autoantibodies, and had a molecular signature enriched in antigen presentation and B cell activation genes.

Conclusion: These results demonstrate that the B cell compartment is altered in APECED patients relative to healthy controls, with a marked increase in multiple activated B cell subsets that may contribute to autoantibody production and disease manifestations.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Development of effective targeting strategies to eliminate sources of antibody production presents utility in the treatment of autoimmune diseases driven by pathogenic autoantibodies. Furthermore, targeting antibody producing cells has potential benefit in settings where a pre-existing antibody response might hinder delivery of a therapeutic agent. To test the impact of B-lineage targeting approaches on a specific antigen-specific antibody response, we utilized an adeno-associated viral (AAV) model of *in vivo* gene transfer. Adeno-associated viral (AAV) vectors have emerged as safe and effective vehicles for *in vivo* gene transfer, yet, the full potential of AAV gene therapies has so far been limited by the either pre-existing or the development of host neutralizing antibodies (nAbs) against AAV capsid. Strategies to overcome anti-drug antibody responses have the potential to vastly expand the utility and accessibility of therapies limited by preexisting nAbs, in addition to potential for use in autoimmune diseases driven by pathogenic antibodies.

Methods: We tested if anti-AAV antibodies could be eliminated *in vivo* by plasma cell depletion with Linvoseltamab, a fully-human T cell-bridging bispecific antibody targeting B cell maturation antigen and CD3 (BCMAxCD3), either alone or in combination with B cell depletion (to eliminate additional sources of anti-AAV Abs) and/or therapeutic FcRn blockade (to accelerate serum IgG clearance). To model a scenario of strong pre-existing AAV immunity, we first treated dual CD3-

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. and BCMA-humanized mice with AAV8 to induce high-titer anti-AAV Abs. Ten weeks later, we administered weekly doses of BCMAxCD3, anti-CD19/20 antibodies, and/or an FcRn blocking therapeutic and monitored anti-AAV IgG titers for five weeks.

Results: Mice treated with both BCMAxCD3 and FcRn blocker showed rapid anti-AAV IgG titer reductions to naïve or near-naive levels, and mice additionally treated with anti-CD19/20 antibodies universally exhibited undetectable titers after five weeks of treatment. Whereas treatment with BCMAxCD3, anti-CD19/20, or FcRn blocker alone elicited only minor titer reductions. Strikingly, upon administration of a second distinct AAV8 vector, 3/6 mice receiving BCMAxCD3 + FcRn blocker and 6/6 mice receiving all three agents achieved re-transduction at levels equivalent to seronegative control mice.

Conclusion: Collectively, these results suggest plasma cell depletion with BCMAxCD3 (+ FcRn blockade) can successfully target sources of antibody production and thereby eliminating a preexisting antigen-specific antibody response. Efficacy was further improved when combined with B cell depletion. Findings from this study provides insight into optimal strategies for durably eliminating an antigen-specific antibody response.

Altered B Cell Subsets Shared in Immune Checkpoint Inhibitor Associated Sicca Syndrome and Sjogren's Disease

Caroline Atlas[1], Balakrishnan Kamaraj[1], Omid Jamshidi[1], Adam Mor[1], Yevgeniya Gartshteyn[2], Teja Kapoor[3] and Robert Winchester[1], [1]Columbia University, New York, NY, [2]Columbia University Medical Center, Glen Rock, NJ, [3]Columbia University Irving Medical Center, New York, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sicca symptoms may develop in the setting of immune checkpoint inhibitor (ICI) therapy and are clinically indistinguishable from those encountered in Sjogren's disease (SjD). B cells are known to play a role in the pathogenesis of SjD and ICI adverse events. We characterized peripheral B cell subsets in patients with these conditions to uncover potential mechanisms of immune dysregulation.

Methods: Peripheral blood mononuclear cells (PBMCs) were obtained from 6 patients (1 healthy control, 1 patient with ICI-sicca syndrome, 4 patients with SjD) and analyzed by flow cytometry. We defined CD19 B-cell subsets on the basis of IgD, CD27, CD24 and CD38. Cells were gated as naïve (further subdivided into Transitional 1, 2, and 3), Unswitched/marginal-zone-like, Class-switched/Plasmablasts and Double Negative.

Results: In the differentiated mature B cell compartment (CD27+ IgD–), CD38 ^{hi} Plasmablasts and Class-Switched Memory B cells were decreased in all patients as compared to the control (14.4%±5.7 in SjD vs 8.4% in ICI sicca syndrome vs 40.4% in the control) (Figure 1)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

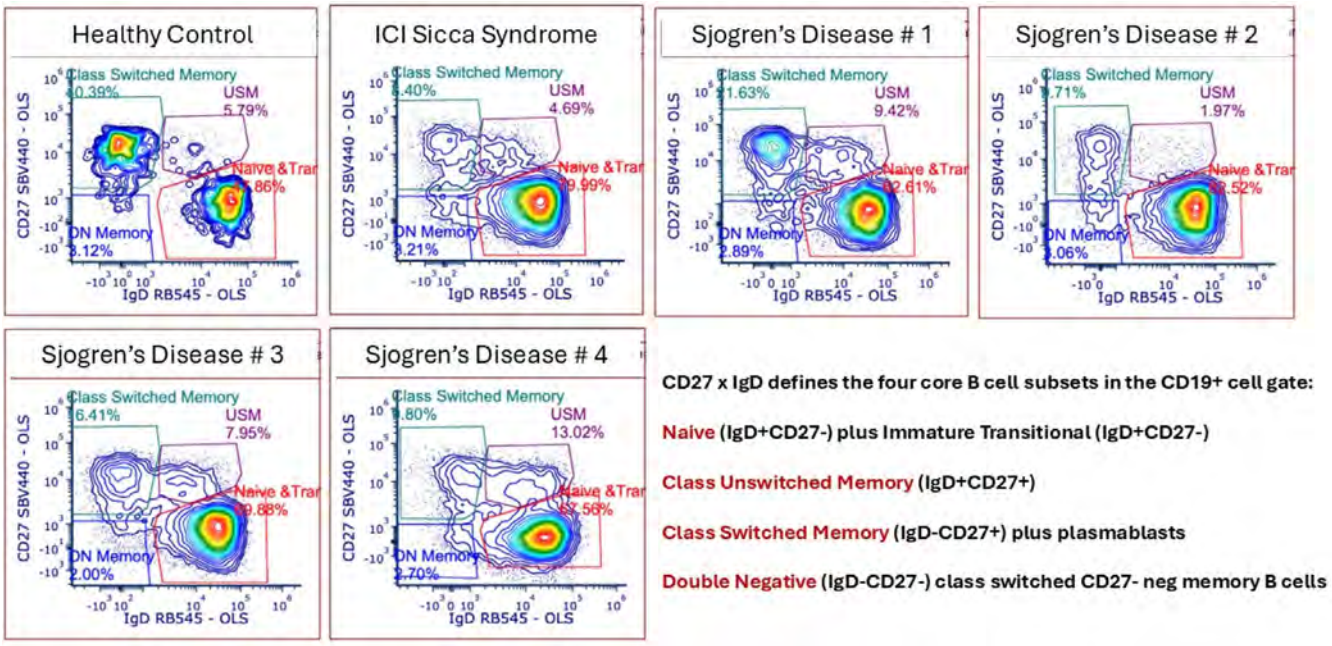

Figure 1

In the naive compartment (CD 27- IgD+), the more mature of the naive B cells (Transitional 3 subset, defined as CD 24-CD38-) were similarly decreased in disease as compared to the control (77.3%± 6.7 in SjD vs 86.0% in ICI sicca syndrome vs 95.7% in control). Conversely the less mature naive B cells (Transitional 1(CD24+CD38+) and Transitional 2 (CD24+CD38–)) were increased in disease relative to the control (Figure 2).

Additionally, the Activated Naïve B cell population was elevated in both diseases, suggesting increased peripheral activation.

In contrast, the percentage of Unswitched Memory (Marginal Zone) B cells and Double Negative Memory B cells were similar between the three groups.

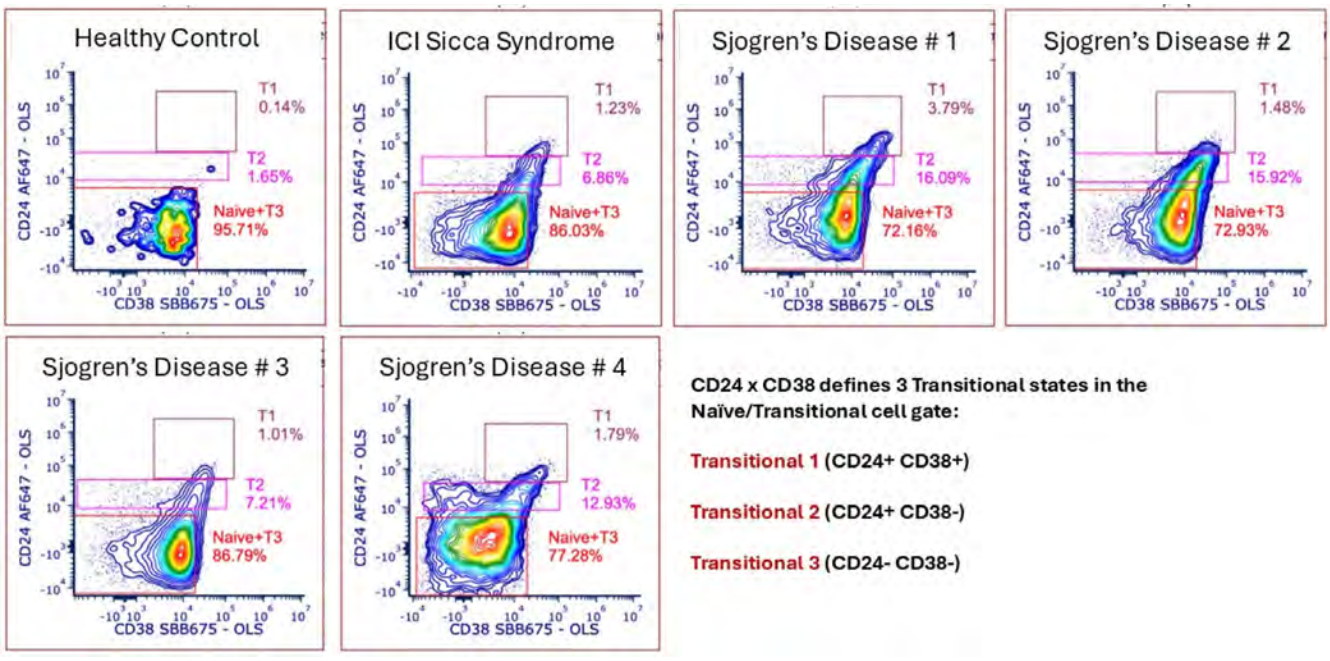

Figure 2

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In SjD and ICI-sicca syndrome there is an increase in the proportion of the less mature transitional 1 and transitional 2 B cells, with a simultaneous decrease in the proportion of transitional 3 B cells as well as the mature Class Switched memory and Plasmablast subsets. This may suggest a defect in B cell development in disease. The similar findings seen in SjD and ICI-sicca syndrome may suggest a shared pathogenesis between the two conditions.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: This study aims to characterize the metabolomic fingerprint of several systemic autoimmune diseases (SADs) and apply machine learning (ML) techniques to identify disease-specific biomarkers and improve patient diagnosis and stratification.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A total of 716 individuals from the PRECISESADS study, were analyzed, including 272 with rheumatoid arthritis (RA), 183 with systemic lupus erythematosus (SLE), 148 with primary antiphospholipid syndrome (PAPS), 70 with systemic sclerosis (SSc), and 43 healthy donors (HDs). Serum metabolomic profiles were assessed using nuclear magnetic resonance (Nightingale), alongside extensive clinical and analytical data. A combination of ML approaches, including unsupervised patient stratification, and a supervised Logistic Regression using 5-Fold Cross Validation was used to identify potential diagnostic signatures. Correlation analyses explored associations between metabolic alterations and clinical features.

Results: Several metabolites (metabs) were differentially expressed in each disease compared to HDs, with the most alterations in SSc (99 metabs) and APS (68 metabs), followed by SLE (30 metabs) and RA (17 metabs). Notably, some cardiovascular-related metabolites (e.g., histidine, albumin, L-LDL-C, L-LDL-CE) were simultaneously altered across all diseases, while each also exhibited unique metabolic change. ML generated disease-specific diagnostic signatures with AUCs above 0.8 in all cases.

Unsupervised clustering analysis of the entire cohort identified three patient clusters (C1, C2, C3), with each disease represented across all clusters in varying proportions. C1 showed significant differences compared to C3 in both clinical features and metabolomic profiles, while C2 represented an intermediate group. Patients in C1 had increased cardiovascular risk markers compared with C3, while C2 represented an intermediate group.

In APS, C1 was linked to higher thrombotic risk (aGAPSS), arterial events, and metabolic comorbidities, while C2 showed more venous thrombosis and pregnancy complications. In SLE, C1 had more cardiovascular risk factors, lupus nephritis, and anti-dsDNA positivity than C3. In RA, C1 showed higher rates of obesity, diabetes, and atherosclerosis, whereas C3 had greater disease activity and autoantibody positivity. In SSc, C1 was associated with dyslipidemia, lung fibrosis, and anti-U1-RNP, while C3 had more skin involvement and anti-centromere positivity.

Conclusion: Distinct metabolomic profiles were identified with shared and disease-specific alterations across systemic autoimmune diseases. ML revealed accurate diagnostic signatures and uncovered patient subgroups with unique clinical and metabolomic features, highlighting shared pathogenic mechanisms and disease-specific features and supporting the potential for personalized therapies targeting metabolic pathways.

Abstract Number: 0902

A Novel Approach to Study ANA+ B Cells in Lupus Integrating Flow Cytometry with Single-cell Culture

Deisy Muriel Velez arteaga[1], Yemil Atisha Fregoso[2], Hasret Gunduz[3] and Betty Diamond[4], [1]The Elmezzi School of Molecular Medicine, New Rochelle, NY, [2]The Feinstein Institute, Long Island, NY, [3]The Feinstein Institute, Long Island, [4]The Feinstein Institutes for Medical Research, Manhasset, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Studying antinuclear antibody (ANA) producing B cells at the single-cell level offers critical insights into their fine specificity and functional characteristics. However, conventional techniques including bulk B cell cultures, ELI-Spot assays, and single-cell sequencing present several limitations. To overcome some of these limitations, we developed an integrated platform that combines flow cytometric detection of ANA$^+$ B cells with an optimized single-B cell culture system (Nojima).

Methods: We employed a flow cytometry assay using biotinylated nuclear extracts to detect ANA reactive B cells, followed by single cell sorting and culture in the presence of feeder cells expressing CD40L and adding BAFF, IL-2, IL-21 (Figure 1).

Results: This approach enabled the isolation and in vitro expansion of ANA-producing B cells coming from patients with SLE and healthy donors from naïve, marginal zone and memory B cell subsets. Following 26 days of culture, a high proportion of wells produced significant immunoglobulin levels: 82% of naïve, 67% of marginal zone, and 57% of IgG$^+$ memory B cell cultures exceeded 1 μg/mL. ANA reactivity in culture supernatants was confirmed by HEp-2 cell staining (shown in figure

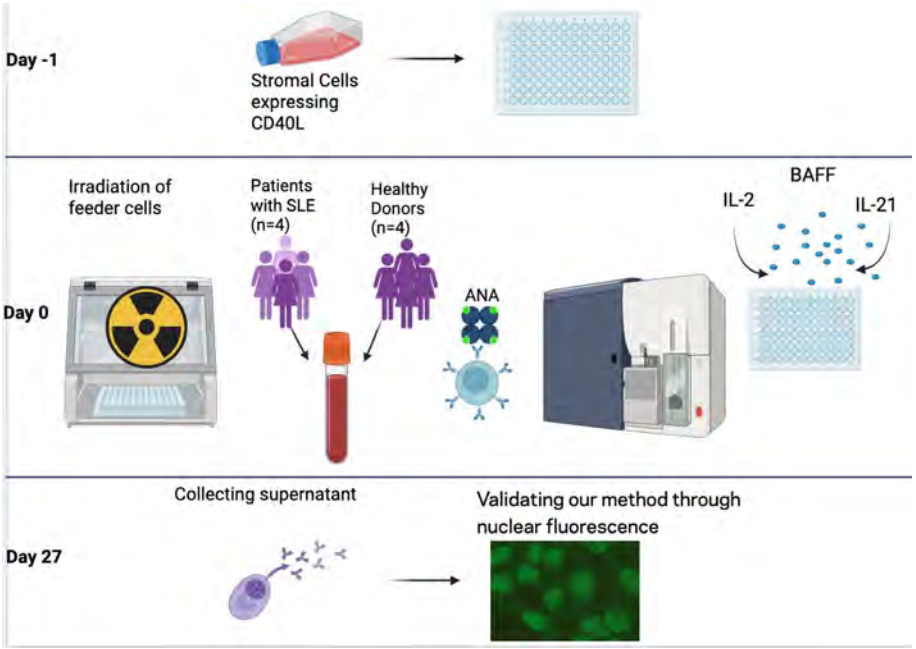

Figure 1: Experimental approach. Seeding the feeder cells until they reach 70% confluence. Irradiating the tissue culture plates with the feeder cells and then sort the cells directly into the tissue plate. Add cytokines and change media replacing cytokines every 3 days. End the culture by day 26, estimate the immunoglobulin production on the supernatant by ELISA. Finally validate the method by testing the supernatants in Hep2 cells.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Percentage of wells producing immunoglobulin by day 26 in 96-well single-cell cultures of B cell subsets from ANA-negative and ANA-positive donors using two seeding methods. Values represent the proportion of wells (out of total plated) that produced detectable IgM (for naïve and marginal zone B cells) or IgG (for memory B cells) above 1 and 10ug/mL threshold. Comparisons are shown for manually seeded versus index plate-sorted cells, grouped by ANA status.

B Cell Type	ANA Status	Percentage of wells producing >1μg/mL	Percentage of wells producing>10μg/mL
Naïve	ANA−	81%	75%
	ANA+	83%	71%
Marginal Zone B cells	ANA−	68%	53%
	ANA+	65%	56%
Memory (IgG)	ANA−	56%	53%
	ANA+	57%	41%

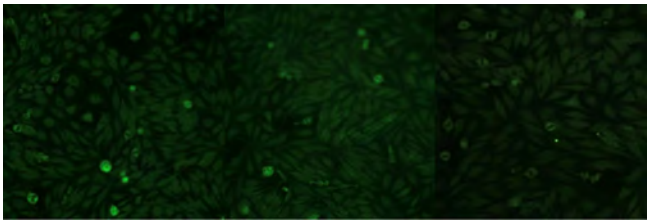

Figure 2. Hep 2 Staining in ANA sorted cells from a patient with SLE showing different nuclear patterns.

2), yielding a sensitivity of 95% and specificity of 68%, validating the functional identity of the expanded B cells. Studying previously sorted ANA+ cells significantly increases the efficiency of the assay. In order to study the immunoglobulin form 100 ANA^{+} cells would ordinarily require screening 2,857 B cells (assuming ANA prevalence of 5%), whereas our approach reduces this to just 150 cells.

Conclusion: This method provides a robust platform for isolating and expanding ANA-producing B cells, enabling the production of autoantibodies for further study. The approach has potential applications in elucidating SLE pathogenesis.

Abstract Number: 0903

Ianalumab's dual mode of action: targeting B cells through enhanced B cell depletion and blockade of B cell-activating factor receptor signaling

Catherine Wioland[1], Corinne Vedrine[2], Caroline Walter[1], Fanny Marque[2], Thomas Dannequin[2], Melanie Cecci[1], David Buffet[1], Cindy Schmid[1], Elena Degl'Innocenti[1], Gautier Robert[1], Grazyna Wieczorek[1], David Schubert[1], Catriona Paape[1] and **Isabelle Isnardi**[3], [1]Novartis Pharma AG, Basel, Switzerland, [2]Novartis Pharma AG, Basel, Basel-Stadt, Switzerland, [3]Novartis, Gueberschwihr, France

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: B cells are key players in the pathogenesis of Sjögren's disease (SjD) and other systemic autoimmune diseases, supporting B cell depletion as an attractive therapeutic strategy in these patients. However, survival signals mediated by high levels of B cell-activating factor (BAFF) may interfere with B cell depletion, as well as drive disease flares. Ianalumab, an investigational afucosylated monoclonal Ab targeting BAFF-receptor (BAFF-R), has been shown to deplete B cells through enhanced antibody-dependent cellular cytotoxicity (ADCC) with concurrent blockade of BAFF:BAFF-R mediated signals [1]. Here, we extensively characterize the properties of ianalumab on B cells *in vitro*, as well as its ability to deplete circulating and tissue B cells in C57/B6 mice and in the spontaneous non-obese diabetic (NOD) mouse model of SjD.

Methods: *In vitro* B cell killing was assessed using isolated NK cells and B cells from healthy volunteers (HVs) and patients with SjD or SLE. *In vitro* blockade of BAFF stimulation was evaluated through Western blots of Nuclear Factor Kappa B Subunit 2 (NF-*k*B2) intact and cleaved forms, B cell proliferation measured by thymidine incorporation, and quantification of IgG secretion. The efficacy of B cell depletion following administration of ianalumab in C57/B6 and NOD mice was investigated using flow cytometry and/or histology in blood and relevant organs.

Results: In an ADCC assay co-culturing purified NK cells with B cells from HVs, ianalumab showed a 44-fold increased potency compared to rituximab (**Fig. 1A**). This increased potency was also observed when NK cells from patients with SjD and SLE were tested (**Fig. 1B**). Additionally, ianalumab effectively prevented BAFF from binding to BAFF-R expressing cells. This blockade of BAFF-R on human B cells correlated with effective inhibition of BAFF-induced cleavage of NF-κB2, proliferation and IgG production. Notably, ianalumab was able to inhibit B cell proliferation with the same potency, when induced by a BAFF trimer or 60-mer (**Fig. 2**). *In vivo*, ianalumab induced a significant reduction of B cell subpopulations in blood and lymphoid organs of B6 mice. Ianalumab was also able to prevent B cell infiltration in the salivary glands of NOD

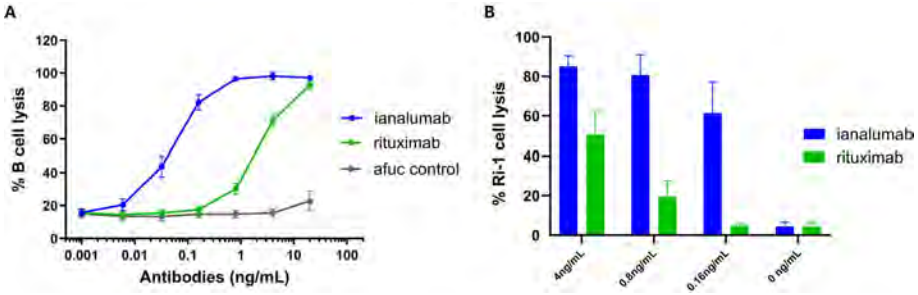

Figure 1. Ianalumab shows superior potency to rituximab in ADCC. A. B cells and NKs from HVs (N=7 donors) where cocultured in the presence of ianalumab, rituximab or an irrelevant afucosylated antibody, and B cell lysis was evaluated after 60 min. B. NK cells from patients with SjD (N=3 donors) were cocultured with RI-1 cells in the presence of ianalumab or rituximab and Ri-1 cell lysis was evaluated after 60 min.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

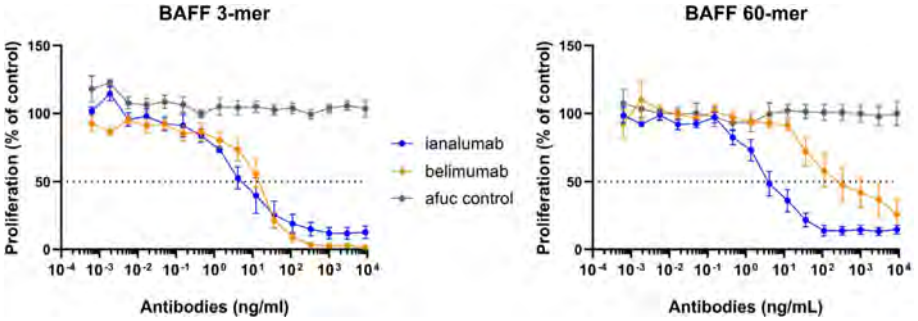

Figure 2. Ianalumab inhibits proliferation of human B cells from HVs (N=7 donors) stimulated by BAFF in combination with anti-IgM. Purified B cells were stimulated with BAFF 3-mer or BAFF 60-mer, in the presence of anti-IgM. Cell proliferation was measured by 3H-thymidine incorporation.

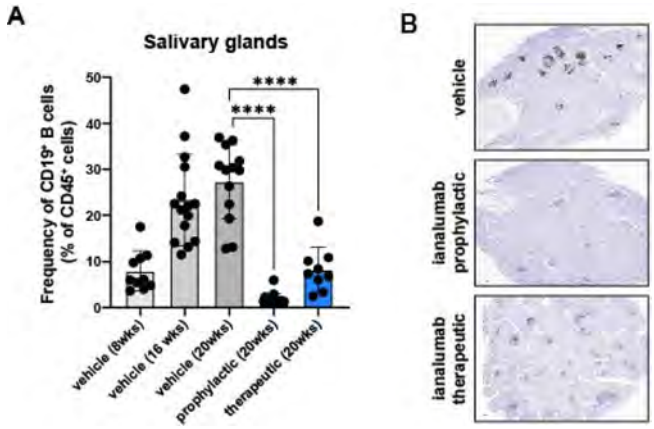

Figure 3. Ianalumab reduces infiltration of B cells in spleen and salivary glands of NOD SjD mice. A. Proportion of CD19+ cells analysed at 20 weeks in salivary glands using flow cytometry. B. CD45R+ B cells analysed on paraffin sections of submandibular salivary glands.

mice when given prophylactically and to decrease B cells infiltrating the salivary glands therapeutically, showing its ability to reduce B cells in the target organs of mice suffering from systemic autoimmunity (**Fig. 3**).

Conclusion: Ianalumab, through its dual mechanism of action, addresses limitations of first-generation B cell targeting therapies for auto-immune diseases by providing more potent B cell depletion and additional BAFF-R blockade on remaining B cells. Accordingly, patients with SLE (NCT03656562) or SjD (NCT02962895) treated with ianalumab for up to 52 weeks showed sustained reduction in disease activity in phase 2 trials [2,3]. Ongoing phase 3 studies in SjD, SLE and LN will provide further evidence on the efficacy and safety of ianalumab in larger patient populations.

SLAMF7 Drives Plasma Cell Differentiation in Rheumatoid Arthritis Synovium.

Jabea Ekabe[1], Ken Yasaka[2], Ruoqiao Wang[3], Nida Pellett[4], Javier Rangel-Moreno[2], Juilee Thakar[3], Jennifer Anolik[4] and Accelerating Medicines Partnership: RA/SLE Network (AMP RA/SLE), [1]University of Rochester, Brighton, NY, [2]University of Rochester, Rochester, NY, [3]University of Rochester, Rochester NY, [4]University of Rochester Medical center, Rochester, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: B cells contribute to rheumatoid arthritis (RA) pathogenesis through antibody-dependent and -independent mechanisms. Thus, identifying regulators of B cell fate in RA is essential for developing targeted therapies. SLAMF7, a transmembrane protein in the SLAM family, is known for promoting monocyte pro-inflammatory responses. Although plasma cells and some B cells express SLAMF7, its influence on B cell function and differentiation in RA remains unclear. We hypothesized that SLAMF7 regulates B cell differentiation into plasma cells (PCs) and contributes to RA progression via modulation of autoantibody-dependent and independent functions.

Methods: We analyzed single-cell transcriptomic and surface protein expression (CITE-seq) data from paired blood and synovia of RA patients (n = 61) from the Accelerating Medicines Partnership RA/SLE cohort. SLAMF7 surface protein expression was validated by flow cytometry in peripheral blood mononuclear cells (PBMCs, n = 12) and synovial fluid mononuclear cells (SFMCs, n = 7). Immunohistochemistry was performed on RA synovial tissue to localize SLAMF7 expression in $CD20^+$B cells and $CD138^+$PCs. Purified total B cells were differentiated into age-associated B cells (ABCs) using ABC polarizing conditions, then further differentiated into PCs in the presence or absence of recombinant human SLAMF7 protein (n = 3). The effect of SLAMF7 on B cell proliferation was assessed using CFSE dye dilution assays (n = 3). Data analysis was conducted using Seurat v5, Flowjo, and GraphPad Prism.

Results: SLAMF7 gene expression was significantly increased in synovial compared to blood B cells ($p < 0.05$) and greater than 80% of PCs expressed SLAMF7. Age-associated B cells (ABC) and activated B cell clusters upregulated SLAMF7 in RA synovium. $SLAMF7^+$ B cells exhibit higher plasma cell gene score compared to $SLAMF7^-$ B cells, indicating a positive correlation between SLAMF7 expression and plasma cell differentiation. Flow cytometry confirmed higher SLAMF7 surface expression in synovial B cells versus blood B cells (17.25% vs. 4.67%, $p < 0.05$). $SLAMF7^+$B cells in synovial fluid were significantly enriched in double negative (DN, 46.9% vs. 1.91%) and memory B cell populations (30.4% vs. 8.27%, $p < 0.05$). Among DN subsets, DN2 ($IgD^-CD27^-CD11c^+$

$CXCR5^-$, 54.25%) and DN3 ($IgD^-CD27^-CD11c^-CXCR5^-$, 41.7%) B cells were the predominant $SLAMF7^+$ DN populations. SLAMF7 expression in DN2 cells was significantly higher in synovium compared to blood (54.25% vs. 16.7%, $p < 0.05$). Immunohistochemistry confirmed $SLAMF7^+$expression by synovial $CD20^+$B cells and $CD138^+$PCs. Functionally, *in vitro* stimulation with recombinant SLAMF7 significantly suppressed B cell proliferation ($p < 0.05$), while enhancing plasma cell differentiation, as determined by increased expression of CD38 and CD27.

Conclusion: Our results demonstrate significant SLAMF7 upregulation in RA synovial B cells and implicate SLAMF7 as a functional regulator of B cell functions. SLAMF7 promotes plasma cell differentiation but also inhibits B cell proliferation, suggesting dual roles in modulating B cells within inflamed joints.

Preclinical Characterization of IBI3034, an TACI and BCMA Chimeric Fc Fusion Protein, that Potently Modulates B Lymphocytes and Serum Immunoglobulin for the Treatment of B cell Related Autoimmune Disease

Yao Xiong, Shuaixiang Zhou, Zhimin Zhang, Bin Li, Zhihao Ming, Yuyu Wu, Liu Li, Chang Li, Fenggen Fu, Zhihai Wu, Shun Wang, Guogang Yuan, Yuling Song, **Jinyang Li**, Huizhong Xiong and Bingliang Chen, Innovent Biologics (Suzhou) Co., Ltd., Suzhou, Jiangsu, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Dysregulated B-cell activation plays a pivotal role in the pathogenesis of various autoimmune diseases. B-cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL) are essential cytokines that support B-cell survival and differentiation. Elevated levels of these cytokines are associated with autoimmune conditions such as Systemic Lupus Erythematosus (SLE), IgA nephropathy (IgAN), and Rheumatoid Arthritis (RA). Therapeutic agents targeting these cytokines, including the anti-BAFF antibody Belimumab, anti-APRIL antibody Sibeprenlimab, and the BAFF/APRIL dual inhibitor Telitacicept, have demonstrated significant clinic efficacy, particularly in SLE and IgAN. These findings highlight the therapeutic potential of targeting BAFF and APRIL. However, the limitations associated with single-target therapies or unbalanced inhibition of these cytokines underscore the need for innovative approaches in drug development. Here we described IBI3034, a novel chimeric fusion protein, currently at the Investigational New Drug (IND) stage, designed to address these challenges in B-cell-related autoimmune diseases.

Methods: Variants chimeric constructs combining TACI and BCMA fused with Fc were designed and generated for screening. IBI3034 was selected based on its protein developability, dual binding affinity to BAFF and APRIL and *in vitro* inhibitory effects on B cells. The *in vitro* activity comparison of IBI3034 and related benchmarks were evaluated head-to-head via reporter cell lines and BAFF and APRIL induced proliferation of human B cells derived from human peripheral blood mononuclear cells (PBMCs). Then *in vivo* efficacy of IBI3034 and related benchmarks were evaluated by analyzing B-cell depletion in the spleen and serum immunoglobulin levels in BAFF-induced mouse models, KLH mouse models, and cynomolgus monkeys. Additionally, the therapeutic potential of IBI3034 was assessed in mouse models of SLE and RA.

Results: IBI3034 demonstrated potent and balanced binding ability to BAFF and APRIL at nanomolar level, effectively inhibiting the proliferation of human B cells induced by a BAFF/APRIL mixture with an IC50 of 7.7 nm. In vivo studies revealed significant depletion of various B-cell subpopulations, including marginal zone B cells, germinal center B cells, and plasma cells, accompanied by reduced serum immunoglobulin levels in BAFF-induced and KLH mouse models. Notably, a single dose of IBI3034 markedly suppressed peripheral antibody-secreting cells and immunoglobulin production up to day 35 in cynomolgus monkeys. Furthermore, IBI3034 significantly reduced proteinuria levels with extended survival in a lupus mouse model and ameliorated arthritis inflammation in an RA mouse model.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: IBI3034, a novel TACI/BCMA chimeric Fc fusion protein, exhibits potent and prolonged effects on B-cell and plasma cell depletion and immunoglobulin suppression through balanced dual inhibition of BAFF and APRIL. This innovative therapeutic approach holds promise for providing deeper clinical benefits and more convenient dosing intervals for patients with B-cell-mediated autoimmune diseases.

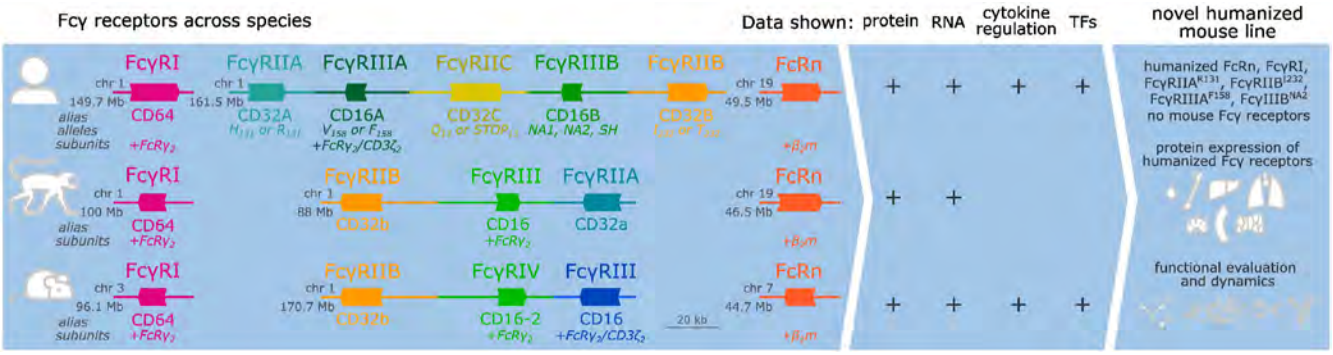
Session Time: 10:30AM–12:30PM

Background/Purpose: Fc receptors mediate the effector functions of antibodies by linking adaptive and innate immunity. Immunoglobulin G (IgG), the most abundant antibody in circulation and widely used in clinical therapeutics, interacts with a range of Fc gamma (Fcγ) receptors expressed in a cell type–specific manner. However, a systematic understanding of Fcγ receptor and neonatal Fc receptor (FcRn) expression across species and immune subsets is incomplete, limiting translational insights from preclinical models. This study aimed to create a comprehensive atlas of Fcγ receptor and FcRn



Fcγ receptors across species, their genomic mapping, and the characterization of a novel mouse model with humanized Fcγ receptors.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Protein expression profiles of Fcγ receptors in humans, macaques, mice and humanized mice.

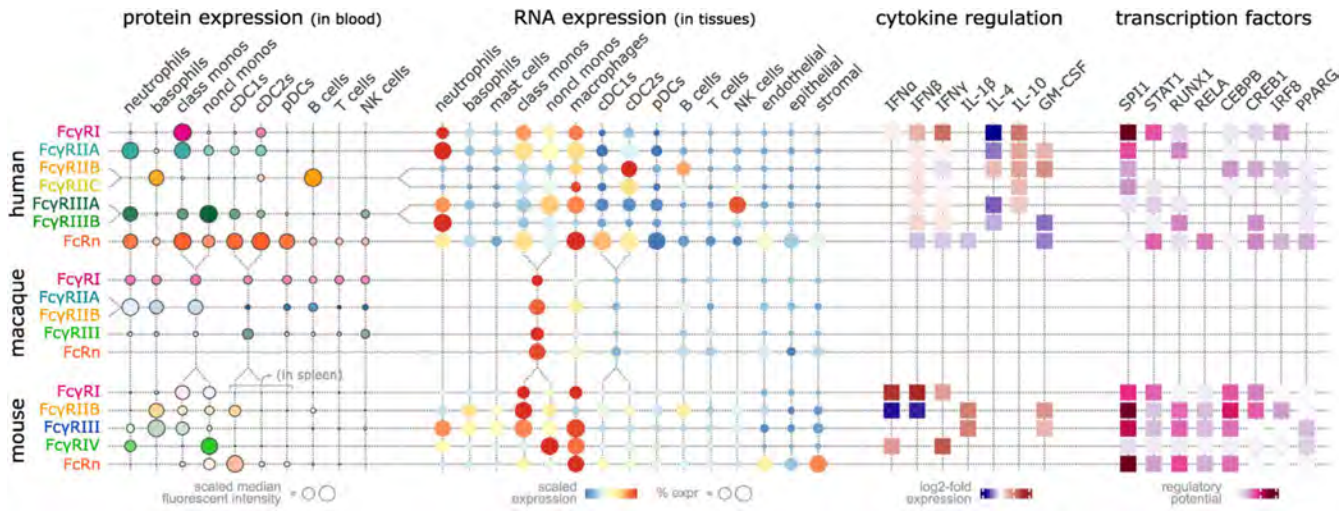
expression across species and identify regulatory factors governing their expression. In parallel, we sought to address species-specific limitations by developing a humanized mouse model for improved antibody evaluation.

Methods: We profiled Fcγ receptor and FcRn expression in humans, cynomolgus macaques, and mice using multimodal approaches including flow cytometry, single-cell RNA sequencing, and integration of chromatin accessibility and transcriptional regulatory data. Gene regulatory networks were inferred using NicheNet, SCENIC+, ChIP-seq, and perturbation experiments to predict transcription factor (TF) influences. To overcome limitations of current preclinical models, we engineered knock-in mice in which five key human Fcγ receptors as well as FcRn are expressed under control of their endogenous human promoters.



Fcγ receptors protein and RNA expression, with upstream cytokines and gene regulatory factors across species.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Our cross-species comparison revealed marked differences in Fcγ receptor diversity, abundance, and cell type–specific expression, with especially poor conservation in myeloid and granulocyte subsets. Regulatory network analysis uncovered distinct TF programs controlling Fcγ receptor expression across species. The novel humanized FcγR/FcRn mouse model demonstrated physiologic expression of human Fcγ receptors in the appropriate immune and non-immune subsets. Functional validation showed that these receptors mediate canonical Fc-dependent processes, including antibody-dependent cellular cytotoxicity, antigen presentation, anaphylaxis, and antibody pharmacokinetics. Cytokine stimulation further revealed plasticity in receptor expression, mirroring human immune dynamics.

Conclusion: This study provides a reference atlas of Fcγ receptor and FcRn biology across species and introduces a novel, functionally validated humanized mouse model. Together, these resources will aid mechanistic studies and improve the preclinical assessment of antibody-based therapeutics.

E-602 (Efgitasialase alfa) Enhances Memory B Cell Depletion and Reduces Profibrotic Macrophages *via* Desialylation in Autoimmune Disease

Hrishikesh Mehta[1], Vijayashree Mysore[1], Chih-Hsing Chou[1], Lizhi Cao[1], Rui Liu[2], Tianrui Fan[2], Jijun Yuan[2], James Broderick[1] and **Li Peng**[1], [1]Palleon Pharmaceuticals, Waltham, MA, [2]Shanghai Henlius Biotech, Shanghai, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Abnormal cell surface glycosylation has been observed in various autoimmune diseases, including systemic lupus erythematosus (SLE) and membranous nephropathy. Among these glycan modifications, sialoglycans function as immune-inhibitory molecules that pathogenic cells, such as cancer cells and pathogenic immune cells, exploit to evade immune surveillance. Elevated levels of surface sialoglycans have been detected on memory B cells and other pathogenic immune subsets in autoimmune conditions, contributing to their resistance to immune-mediated clearance and conventional therapies. Clinical studies have linked poor depletion of $CD27^+$ memory B cells to suboptimal treatment outcomes. This study investigates E-602, an engineered human sialidase, as a novel therapeutic approach to enzymatically remove sialoglycans from the surface of pathogenic immune cells.

Methods: We assessed the effect of E-602-mediated desialylation in ADCP and CDC assays using Raji cells or human primary B cells from healthy donor PBMCs in the presence of anti-CD20 or anti-CD19 antibodies. We then evaluated its impact on depleting CD27+ memory B cells using PBMCs from SLE patients. In vivo efficacy was tested in a lymphoma mouse model, an MRL/lpr SLE mouse model, and non-human primates. We also investigated whether E-602 reduces profibrotic M2-like macrophages in chronically inflamed tissues using tumors as a surrogate in mouse tumor models.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: E-602 enhanced ADCP and CDC across multiple anti-CD20 and anti-CD19 B cell-targeting antibodies. It improved anti-CD20-mediated depletion of CD27+ memory B cells by ~50% from SLE patients, which express high levels of sialoglycans and are typically resistant to depletion using anti-CD20 antibodies alone. In lymphoma and MRL/lpr SLE mouse models, E-602 enhanced anti-CD20-mediated B cell depletion. In non-human primates, E-602 improved B-cell depletion in lymph nodes, which are often resistant to B-cell depletion compared to peripheral blood. Additionally, E-602 reduced profibrotic M2-like macrophages by ~ 90% compared to the vehicle control in the tumor microenvironment, which serves as a surrogate for chronic inflammatory tissue.

Conclusion: E-602 offers a novel therapeutic strategy through enzymatic desialylation of pathogenic immune cells to enhance their depletion and restore immune balance. Its dual MoA targets two key pathogenic subpopulations: memory B cells, which drive autoantibody production and contribute to disease relapses, and M2-like macrophages, which promote fibrosis and organ damage. This combination could potentially improve tissue level B cell depletion and reduce pro-fibrotic macrophage induced tissue damage. Based on a favorable safety and tolerability profile demonstrated in the completed Phase 1 GLIMMER-01 trial in oncology patients, E-602 represents a scientifically novel, safe, and broadly applicable add-on to existing B-cell-targeting antibody therapies in a wide range of patients with autoimmune diseases.

Abstract Number: 0909

Loss of MicroRNA29 expression in B cells and skin microbiota synergize to promote atopic dermatitis in mice.

Marcus Hines[1], Timothy Borbet[2] and Sergei Koralov[2], [1]New York University Grossman School of Medicine, New York, NY, [2]NYU Langone Medical Center, New York

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The microRNA(miR)29 family is encoded by two separate loci, the miR29ab1 and miR29b2c alleles. We have previously shown that the microRNA(miR)29 family regulates the survival and function of peripheral B cells by analyzing mice with miR29-deficient B cells (B29KO). Furthermore, these B29KO mice develop itching and skin inflammation akin to atopic dermatitis, with a 50% mortality rate. Our investigations using B29KO mice revealed a novel target transcript, Il4ra. This gene encodes the cytokine IL-4 which is an important signaling molecule for immune cell activation and differentiation. In B cells, IL-4 regulates class switch recombination to IgE and affinity maturation in germinal center reactions. We hypothesized that the miR29 family regulates the IL4 signaling cascade in B cells, conferring a susceptibility for developing atopic dermatitis.

Methods: miR-29ab1$^{fl/fl}$ mice (obtained from Dr. Mark Ansel's lab) and miR-29b2c$^{-/-}$ mice (obtained from Dr. Jining Lu's Lab) were bred with mb1-cre animals from Jax Labs and maintained on a C57BL/6J background. Littermates without full deletion of miR-29 family of miRNAs were used as controls. We employed flow cytometry, histology, ex vivo stimulation cultures, single-cell RNA sequencing, and statistical analysis software (GraphPad) to analyze data.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We found B29KO B cells have higher expression of Il4ra by both qPCR and single-cell sequencing. Differential gene analysis and pathway enrichment show B29KO mice exhibit heightened IL4 signaling, reduced activation, and negative regulation of cytokine production relative to littermate controls. Ex vivo studies using B cells from B29KO mice revealed an increase in IgE class switching compared with wild-type B cells - a finding recapitulated in B29KO mice that have higher serum IgE titers. When treated with a neutralizing anti-IL4Ra antibody, the phenotype of B29KO mice are rescued from mortality. Interestingly, we found that skin swabs from phenotypic B29KO mice transferred the phenotype to healthy B29KO mice but not littermate controls. Donor and recipient mice were found to be colonized with Staphylococcus aureus and xylosus.

Conclusion: Our data suggest that regulation of Il4ra by miR-29 impacts B cells responsiveness to IL-4 signaling and, as a result, the susceptibility to atopic dermatitis in mice via genetic susceptibility and microbial triggers.

Development of Four Distinct Human IgG4-Producing Mouse Models Recapitulating IgG4-Related Disease

MIN GANG KIM[1], JINA YEO[2], HEA RIM KANG[3], JAE HYUN MOON[3], Seon Uk Kim[4], SeoYoon Ban[5], MI HYEON KIM[6], Eun Young Lee[7] and Seoul National University College of Medicine, [1]Seoul National University College of Medicine, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Gachon University Gil Medical Center, Incheon, Republic of Korea, [3]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea, [4]Seoul National University, Jongno-gu, Seoul, Republic of Korea, [5]Department of Cancer biology, Graduate School of College of Medicine, Seoul National University, Korea, Seoul, Republic of Korea, [6]Hallym university dongtan sacred heart hospital, Seocho-gu, Seoul, Republic of Korea, [7]Seoul National University College of Medicine, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4RD) is an immune-mediated fibroinflammatory condition characterized by multi-organ involvement, elevated serum IgG4, and IgG4-positive plasma cell infiltrates that form tumor-like lesions and fibrosis. However, conventional mice lack the IgG4 subclass, precluding in vivo modeling of IgG4RD. We aimed to develop humanized mouse models that produce human IgG4 and replicate key features of IgG4RD.

Methods: I established four distinct human IgG4-producing xenograft models using NSG (NOD-scid IL2rγ^{null}) and NSG-hIL6 (human IL-6 transgenic NSG) immunodeficient mice as hosts. The models included the following:

1. NSG mice injected with human peripheral blood mononuclear cells (PBMCs).

2. NSG-hIL6 mice, after sublethal irradiation, engrafted with human CD34^{+} hematopoietic stem cells via intrahepatic injection.

3. NSG-hIL6 mice intravenously injected with Epstein–Barr virus (EBV)-immortalized B cells derived from IgG4RD patients.

4. NSG mice injected with a luciferase-tagged, human IgG4-secreting K562 cell line.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In all models, human IgG4 in mouse serum was measured by ELISA. Spleen, kidney, and salivary gland tissues were analyzed by histology and immunohistochemistry for $IgG4^+$ cell infiltration, inflammation, and tumefactive lesions.

Results: All four models produced human IgG4 in circulation at significantly elevated levels relative to controls (a hallmark of IgG4RD), confirming engraftment. Histopathology of the spleen, kidney, and salivary glands showed dense $IgG4^+$ lymphoplasmacytic infiltration with associated inflammation, tissue hypertrophy, and pseudotumor-like lesions, closely mirroring human IgG4RD pathology with fibroinflammatory tissue remodeling. Notable differences among the models were observed. The EBV-immortalized B cell model exhibited the highest serum IgG4 concentrations and the most extensive $IgG4^+$ cell infiltration. The luciferase-expressing K562 model enabled bioluminescent tracking of IgG4-secreting cells, visualizing their migration and organ colonization. Finally, the $CD34^+$ HSC model allowed observation of IgG4 class switching, a fundamental process in IgG4RD.

Conclusion: I developed four complementary humanized mouse models that recapitulate key features of IgG4RD. These *in vivo* models are valuable tools for investigating IgG4RD pathogenesis and testing new therapies. Each model has unique advantages: the PBMC model provides a straightforward platform for inducing IgG4 production; the $CD34^+$ HSC model allows analysis of IgG4 class switching; the EBV-B cell model yields high serum IgG4 levels with severe multi-organ involvement; and the IgG4-secreting K562 model enables longitudinal bioluminescent tracking of IgG4-producing cells. Together, these models form a comprehensive platform for in-depth mechanistic studies and the development of new therapies for IgG4RD.

A Novel Fcrn × Albumin Bispecific Antibody Demonstrates Extended Half-life And deep Igg Reduction in Preclinical Mouse Models

Hang Su[1], Lulu Li[1], Zenglin Pei[1], Barry Duplantis[2], Yuhao Wang[2], Yi Li[1] and **Quan Yu**[1], [1]Ailux, Shanghai, China (People's Republic), [2]Ailux, Boston, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune diseases such as rheumatoid arthritis, systemic lupus erythematosus, and Sjögren's syndrome are characterized by elevated levels of pathogenic autoantibodies that drive inflammation. The neonatal Fc receptor (FcRn) prolongs the half-life of IgG by mediating its recycling, and FcRn blockade has emerged as a promising strategy to reduce pathogenic autoantibodies. However, the inhibition of IgG recycling also leads to a shortened half-life of FcRn blockers, necessitating frequent dosing. Here, we report a novel bispecific antibody, based on an effector-silent human IgG1 backbone, that targets both human FcRn (hFcRn) and human serum albumin (HSA). The optimized bispecific design enables potent FcRn inhibition while leveraging albumin binding to prolong half-life without compromising pharmacologic activity.

Methods: Parental anti-FcRn IgG and anti-HSA VHH were generated through epitope-focusing antibody discovery and NGS-powered phage display screening, followed by bispecific format optimization and affinity tuning. Binding properties and FcRn-blocking activity were evaluated in vitro using biochemical and cell-based assays. In vivo functional and pharmacokinetic studies were performed in hFcRn/HSA/$Rag1^{-/-}$ transgenic mice.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The bispecific antibody demonstrated sub-nanomolar binding affinity to hFcRn, cross-reactivity with cynomolgus FcRn, and potent inhibition of IgG-FcRn interaction. Structural modeling and in vitro experiments confirmed that HSA binding to hFcRn was maintained in the presence of anti-FcRn or HSA antibody. A single intravenous dose of the bispecific antibody in transgenic mice led to rapid and profound clearance of exogenous administrated circulating human IgG. The bispecific antibody exhibited a prolonged serum half-life compared to the parental anti-FcRn antibody and other FcRn blockers, and did not meaningfully affect circulating HSA levels.

Conclusion: The rationally designed FcRn × HSA bispecific antibody effectively blocks FcRn-mediated IgG recycling while achieving extended systemic exposure and a favorable preclinical safety profile. These findings support its potential as a long-acting therapeutic candidate for the treatment of autoantibody-driven diseases with reduced dosing frequency.

CD11c$^+$CD21$^-$ Autoimmune-Associated B Cells Derived from Double-Negative IgD$^-$CD27$^-$ Subsets Exhibit Enhanced IFNLR1 Expression in Systemic Lupus Erythematosus

Roukaya Yaakoub, Diana Alzamareh, Alexander Bae William and Jennifer Barnas, university of rochester, rochester, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune-associated B cells (ABCs) are increasingly recognized for their role in the pathogenesis of systemic lupus erythematosus (SLE), yet their developmental origins and specific functions remain unclear. Interferon-lambda (IFN-λ), a type III interferon implicated in SLE, may have distinct effects from the well-established pathogenic role of interferon-alpha (IFN-α), still its contribution remains incompletely understood. Prior studies suggest that ABCs—characterized by a CD11c$^+$CD21$^-$ phenotype—are most prevalent within the double-negative (DN) B-cell subset, which also shows heightened responsiveness to IFN-λ. We hypothesize that CD11c$^+$CD21$^-$ ABCs, predominantly arising from the DN IgD$^-$CD27$^-$ B-cell subset, exhibit enhanced responsiveness to IFN-λ, contributing to their pathogenic role SLE through upregulated IFNLR1 expression.

Methods: To investigate the development and function of ABCs, peripheral blood mononuclear cells (PBMCs) were isolated from patients with SLE (n = 18). Flow cytometry was employed to quantify CD11c$^+$CD21$^-$ ABCs across four B-cell subsets: naïve, switched memory (SM), unswitched memory (USM), and DN. IFNLR1 expression was later assessed within these subsets (n = 3).

To explore the intrinsic differentiation potential of ABCs, *in vitro* stimulation assays were performed using sorted-purified naïve, SM, USM, and DN B cells from healthy donors (HDs) (n = 3). Cells were cultured under ABC-inducing conditions, including B-cell receptor stimulation, R848 (TLR7/8 agonist), IFN-γ, IL-21, and BAFF. Following culture, the induction of CD11c$^+$CD21$^-$ ABCs and IFNLR1 expression were analyzed by flow cytometry.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Flow cytometric analysis of PBMCs from SLE patients (n = 18) revealed that CD11c$^+$CD21$^-$ ABCs were most enriched within DN B-cell subset. Their frequency was significantly higher relative to total CD19$^+$ B cells compared to other subsets. The mean frequencies of ABCs were 6.46% in DN, 2.59% in USM, 1.37% in naïve, and 0.29% in SM B cells (**$p < 0.02$**).

In vitro differentiation assays using sorted B-cell subsets from HDs (n = 3) demonstrated that DN and SM B cells exhibited the highest propensity to differentiate into ABCs under stimulatory conditions. The mean frequencies of induced ABCs were 46.2% for DN, 32.4% for SM, 13.4 for naïve and 4.3 for USM B cells.

Assessment of IFNLR1 expression showed significantly elevated levels on CD11c$^+$CD21$^-$ ABCs within the DN subset in SLE patients (**$p < 0.02$**). *In vitro*, ABCs derived from DN B cells exhibited a 6.3-fold increase in IFNLR1 expression under ABC-inducing conditions, compared to 2.5-fold, 1.6-fold, and 1.6-fold increases in ABCs derived from SM, naïve, and USM B cells, respectively.

Conclusion: These findings identify the DN B-cell subset as a key origin of CD11c$^+$CD21$^-$ autoimmune-associated B cells in SLE and highlight their enhanced capacity for IFNLR1 expression. The preferential differentiation of DN B cells into ABCs, coupled with their heightened responsiveness to IFN-λ, driven by increased IFNLR1 expression, suggests a distinct IFN-λ–mediated pathway in B-cell–driven autoimmunity. This IFN-λ–IFNLR1 axis may represent a novel therapeutic target for modulating B-cell–driven autoimmunity in SLE.

Session Title: (0897–0915) B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IRF5 is a transcription factor and regulator of immune responses activated downstream of pattern recognition receptors, in particular endosomal toll-like receptors (TLR), TLR7, TLR8 and TLR9. IRF5 regulates pro-inflammatory cytokines (TNFα, IL-6, IL-12, IL-23), autoantibody production and Type I IFN, and is selectively expressed and activated in specific cell types such as dendritic cells, monocytes, macrophages, and B cells. Human genetic and functional studies have linked IRF5 in the pathogenesis of multiple autoimmune diseases, including SLE, RA, and Sjögren's, and *Irf5*-deficient mice are protected from lupus onset and severity. In SLE, endosomal TLRs recognize nuclear self-antigens, triggering IRF5 activation and driving the breakdown of immune tolerance via a cascade involving B cell activation, autoantibody and pro-inflammatory cytokine production. Despite its strong mechanistic and genetic validation, IRF5 has historically

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

remained undrugged likely due to its activation complexity and multiple functional isoforms. IRF5 is well suited for targeted protein degradation. KT-579, an oral IRF5 degrader, has demonstrated potent and selective activity in preclinical studies, offering a novel approach to modulating this key driver of immunity.

Methods: Peripheral blood mononuclear cells (PBMCs) derived from healthy or SLE donors were cultured with KT-579 in the presence or absence of TLR7, TLR8 or TLR9, to evaluate KT-579 selectivity, potency and functional activity. Oral IRF5 degrader was tested in mouse models of acute TLR7 or TLR9 activation, and MRL.lpr and NZBW1 lupus models.

Results: KT-579 was selective for IRF5 in the detectable proteome, including other IRF family proteins. KT-579 demonstrated sub nanomolar potencies across relevant cell types tested, and inhibited pro-inflammatory cytokines, Type I IFN production and response, and IgG levels downstream of TLR7, TLR8 or TLR9 induction in healthy or SLE PBMC assays. *In vivo*, KT-579 led to dose-dependent inhibition of both TLR7 or TLR9 induced TNFα, IL-6 and IL-12, unlike a TLR7/8 inhibitor. In the MRL.lpr lupus model, KT-579 doses achieving >85% degradation led to significant reduction of proteinuria and 100% survival. In the long term NZBW1 spontaneous lupus model, daily oral doses achieving >80% IRF5 degradation resulted in sustained reduction of proteinuria, circulating ANA and total kidney lesions. In both lupus models, IRF5 degradation was well tolerated, and IRF5 degrader activity was superior to approved or clinically active drugs. KT-579 achieved deep depletion (≥90%) across multiple species with low oral doses, and did not show adverse effects at concentrations up to 200-fold the projected human efficacious levels in preclinical safety studies.

Conclusion: We report here the first potent, selective, oral IRF5 degrader development candidate, KT-579, which depletes IRF5 in human primary cells, SLE patient derived cells, and lupus disease models, demonstrating superior activity to existing standards of care agents. These findings position KT-579 as a novel, first-in-class, oral therapeutic agent with the potential to transform the treatment landscape of lupus and multiple autoimmune diseases driven by IRF5 dysregulation.

Background/Purpose: The cellular and molecular mechanisms underlying the progression from anti-citrullinated protein antibody (ACPA) positivity to clinical rheumatoid arthritis (RA) remain poorly understood. Defining these early immunologic events is essential for identifying predictive biomarkers and developing preventive strategies.

Methods: We conducted longitudinal single-cell profiling of peripheral blood mononuclear cells (PBMCs) collected at two timepoints: a preclinical baseline and a follow-up approximately one year later. Participants were classified into three groups: (1) $ACPA^+$ converters who were ACPA-positive at baseline and developed clinical RA at follow-up; (2) $ACPA^+$ non-converters who did not develop clinical RA; and (3) healthy controls who were ACPA-negative and RA-free at both timepoints. B cells were isolated and analyzed using an integrated multi-modal single-cell approach, including 5′ scRNA-seq, VDJ-seq, and CITE-seq.

Results: Single-cell analysis revealed a marked preclinical expansion of $IGHM^+$ $IGHD^+$ $CXCR5^+$ $CD69^+$ activated naïve (aNAV) B cells in $ACPA^+$ converters. These aNAV cells exhibited a distinct pro-inflammatory transcriptional profile, characterized by upregulation of genes involved in immune activation, antigen presentation, impaired tolerance, and cellular stress, compared to non-converters and healthy controls. VDJ repertoire analysis revealed that within converters, IgM-expressing aNAV cells dominated the BCR landscape and exhibited elevated clonal diversity along with distinct V–J gene rearrangements across both heavy and light chains. Recombinant monoclonal antibodies derived from these IgM^+ aNAV cells demonstrated broad autoreactivity to multiple RA-associated autoantigens, including both native and citrullinated epitopes. In contrast, aNAV cells from non-converters more closely resembled those of healthy controls in their transcriptional profiles, BCR repertoires, and autoreactivity patterns.

Conclusion: These findings identify a preclinical expansion of $IGHM^+$ $IGHD^+$ $CXCR5^+$ $CD69^+$ naïve B cells in $ACPA^+$individuals who progress to RA. These cells are transcriptionally stressed, pro-inflammatory, and resistant to immune tolerance. Their BCR repertoire is enriched for diverse, autoreactive IgM antibodies with distinct V–J rearrangements. This autoreactive IgM pool may contribute to early immunologic activation and the eventual onset of rheumatoid arthritis.

Background/Purpose: Pathological elevation of type I interferon (IFN-I) , B-cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL) has been robustly documented across multiple autoimmune diseases. But blocking these pathways individually only demonstrates limited efficacy with a considerable proportion of patients exhibiting inadequate therapeutic responses, which may be attributed to pathogenic heterogenicity of disease and population. IFN-I is required for B cell

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

activation and differentiation as well as other multiple immune cells, while BAFF and APRIL synergistically sustain plasma cell survival and clonal expansion. We developed a fusion protein (vTACI-aIFNAR) by covalently linking a BAFF/APRIL-neutralizing TACI variant to an IFN-I-blocking anti-IFNAR antibody. This multi-pathway blocker is designed to achieve greater therapeutic effect, thereby improving outcomes across heterogeneous patient populations.

Methods: Single-cell RNA sequencing data of PBMCs from 175 systemic lupus erythematosus (SLE) patients and 99 healthy controls were obtained from the cellxgene database and analyzed. Binding affinity was evaluated by surface plasmon resonance. The B cell proliferation, STAT-1 phosphorylation and plasma cell generation were measured in function related cellular assays. *In vivo* efficacy was evaluated using two distinct murine models: an allogeneic salivary gland protein-induced Sjögren's syndrome (SS) model and the NZBWF1/J spontaneous SLE model. Safety profiling was performed through a 4-week repeated-dose Good Laboratory Practice (GLP) toxicology study in cynomolgus monkeys.

Results: Pseudobulk RNA-seq analyses revealed elevated BAFF, APRIL, and IFN-I expression in SLE patients compared to healthy controls, with 82.3% exhibiting concurrent overexpression of IFN gene signature (IFGS) and BAFF, 40.6% of IFGS and APRIL, 37.7% of BAFF and APRIL, and 37.5% of all three factors, which indicates pathogenic heterogeneities of SLE patients. The vTACI-aIFNAR displayed robust BAFF/APRIL binding and potent suppression of B cell proliferation driven by these factors, while its IFN-I binding and STAT-1 phosphorylation inhibition were similar to that of anti-IFNAR antibody. Notably, vTACI-aIFNAR surpassed TACI-Fc and anti-IFNAR in blocking IFN-α/BAFF/APRIL-induced plasma cell generation *in vitro*. In murine SS models, the murine surrogate of vTACI-aIFNAR restored salivary flow rates in a dose-dependent manner, outperforming both TACI-Fc and anti-IFNAR antibody at equimolar doses. SLE models demonstrated marked alleviation in proteinuria, anti-dsDNA IgG/IgM level, and renal histopathology following treatment. GLP-compliant primate toxicity studies confirmed favorable tolerability with a 43× safety margin relative to projected clinical exposure.

Conclusion: Collectively, our findings demonstrate that the multi-pathway blocker, vTACI-aIFNAR, shows greater therapeutic effect with favorable tolerability profiles, implying enhanced therapeutic efficacy across diverse autoimmune patient subsets. These preclinical advantages substantiate its clinical translation potential for autoimmune disorders.

UVB-Irradiated Keratinocyte Extracellular Vesicles Trigger Innate Immune Activation via Type I Interferons and STING Pathway

Ahmed Eldaboush[1], Darae Kang[2] and Victoria Werth[3], [1]Department of Dermatology, Perelman Shool of Medicine, University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Potomac, MD, [3]University of Pennsylvania, Wynnewood, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Extracellular vesicles (EVs) are cell-derived nanoparticles that mediate cell-cell communication. EVs are implicated in photosensitive autoimmune diseases like dermatomyositis (DM) and systemic lupus (SLE), where UVB radiation can trigger systemic flares. Given UVB's limited dermal penetration, we hypothesize that keratinocyte-derived EVs

(KEVs) mediate UVB inflammation via relaying proinflammatory signals from keratinocytes (KCs) to dermal immune cells. Our prior work showed KEVs elicit inflammation in healthy control (HC) PBMCs, but specific immune cell targets remain undefined. This study identifies immune cell subsets responsive to KEVs.

Methods: HaCaT KCs were pretreated ±1 ng/mL IFN-β for 24h (to mimic DM skin), then irradiated with 0 or 75 mJ/cm^2 UVB and cultured overnight in EV-free media. KEVs were isolated by ultracentrifugation, resuspended in PBS, and incubated overnight with HC PBMCs. Cells were analyzed by flow cytometry.

Results: EVs from UVB-irradiated KCs (UVB-KEVs) significantly induced IFNβ compared to sham-KEVs in conventional dendritic cells (cDCs) [p=0.002], monocyte-derived dendritic cells (MoDCs) [p=0.039], macrophages [p=0.019], CD4$^+$ T cells [p=0.036], CD8$^+$ T cells [p=0.015], and CD19$^+$ B cells [p=0.036]. A similar trend was observed in natural killer cells (NKs) [p=0.09] and plasmacytoid dendritic cells (pDCs) [p=0.149], though not significant. Notably, only EVs from IFNβ-pretreated irradiated KCs (IFNβ-KEVs) significantly stimulated IFNβ in pDCs [p=0.015] and NKs [p=0.007].

UVB-KEVs also induced IFNγ in MoDCs [p=0.034], macrophages [p=0.005], CD8$^+$ T cells [p=0.047], and B cells [p=0.039], with non-significant increases in NKs [p=0.2], pDCs [p=0.06], and CD4$^+$ T cells [p=0.06]. However, only IFNβ-KEVs significantly induced IFNγ in pDCs [p=0.001].

UVB-KEVs increased p-NFκB in NKs [p=0.033], CD4$^+$ T cells [p=0.021], CD8$^+$ T cells [p=0.029], and B cells [p=0.031], with a trend in pDCs [p=0.052]. UVB-KEVs significantly upregulated p-STING in NKs [p=0.0008], pDCs [p=0.006], MoDCs [p=0.0009], macrophages [p=0.0008], CD4$^+$ T cells [p=0.017], CD8$^+$ T cells [p=0.019], and B cells [p=0.01], with a similar but non-significant trend in cDCs [p=0.12]. However, IFNβ-KEVs significantly increased p-STING in cDCs [p=0.03] and more than UVB-KEVs [p=0.043].

p-STING activation was highest in macrophages and MoDCs. IFNγ was highest in pDCs (only with IFNβ-KEVs); IFNβ was most induced in cDCs and pDCs (again only by IFNβ-KEVs). IFNβ-KEVs uniquely induced both IFNβ and IFNγ in pDCs. Of note, cDCs were previously found to be enriched in DM skin of antimalarial non-responders and express high IFNβ and p-STING, and blood pDCs and cDCs in DM patients secreted more IFNβ than HCs, and pDCs are enriched in DM skin, producing high IFNβ and IFNγ.

Conclusion: UVB-KEVs trigger type I IFN production and activate STING, both upregulated in DM and SLE. Responses were more prominent in innate immune cells. IFNβ-KEVs distinctively activated cDC p-STING and drove pDC IFNβ and IFNγ, both critical in DM/SLE pathogenesis. This suggests a mechanism by which UVB triggers systemic inflammation via KEVs. Ongoing studies aim to block KEV release, dissect their cargo, and mitigate their proinflammatory effects.

Abstract Number: 0917

Synovial Tissue Neutrophils are Associated with Disease Activity and Early Remission in Rheumatoid Arthritis

Annabelle Small[1], Vincent Wong[2], Christopher Altmann[1], Helen Weedon[3], Malcolm Smith[4], Susanna Proudman[5] and Mihir Wechalekar[6], [1]Flinders University, Bedford Park, South Australia, Australia, [2]College of Medicine and Public Health, Bedford Park, South Australia, Australia, [3]Flinders University of South Australia, Bedford Park, South Australia, Australia, [4]Flinders University, Adelaide, South Australia, Australia, [5]Royal Adelaide Hospital and University of Adelaide, Medindie, South Australia, Australia, [6]Flinders Medical Centre and Flinders University, Bedford Park, South Australia, Australia

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0916–0933) Innate Immunity Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Neutrophils drive local pathology of rheumatoid arthritis (RA) in the synovial tissue (ST) through local production inflammatory mediators, cytokines, and extracellular traps. However, despite these roles, the relevance of their infiltration into the ST with regards to disease activity and response to treatment remain poorly understood. Thus, this project sought to assess the relationship between neutrophil infiltration into the early RA ST and clinical outcomes.

Methods: Arthroscopic ST samples preserved in FFPE from n=32 patients with treatment-naïve RA (< 12 months of onset, fulfilling 2010 ACR/EULAR criteria) were routinely stained with hematoxylin and eosin, and neutrophils judged by morphology by two independent observers. Six field of views (20x) from each section were manually assessed for neutrophil infiltration. Raw counts were reported for (1) marginating neutrophils in blood vessels, (2) tissue-infiltrating neutrophils, (3) combined total counts, and (4) total counts converted into a semiquantitative (SQA) score: 0=< 3 observed; 1=3-10 observed; 2=11-22 observed; 3=23-54 observed; 4=55-85 observed; 5= >85 observed. Manual scoring was validated by immunohistochemistry for CD15, and by comparison with matched bulk RNA sequencing data from the ST of the same patients which had previously been deconvoluted using CIBERSORT.

Results: Data was visualized by heatmap (Figure 1). Neutrophil infiltration measured by CIBERSORT was moderately positively correlated with DAS28CRP (r=0.1952, p=0.0145). Manual scores had a stronger positive correlation with DAS28CRP of higher significance (total: r=0.5409, p=0.0020; tissue infiltrating: r=0.4771, p=0.0077; marginating: r=0.6139, p=0.0003;

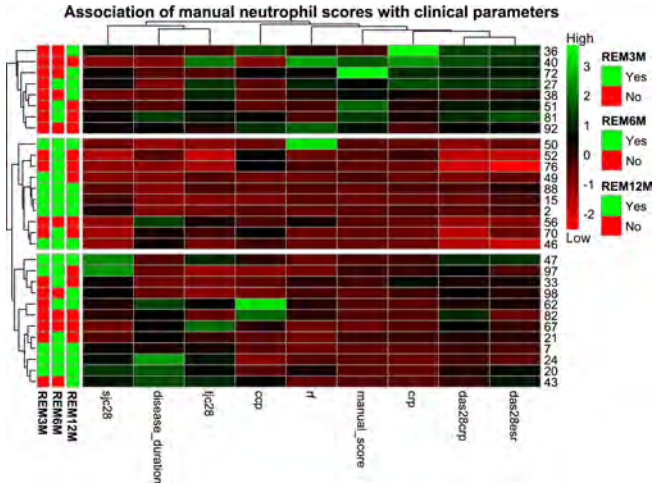

Figure 1. Heatmap of baseline characteristics and total manually determined neutrophil scores of our cohort (n=32), annotated with remission status at 3, 6, and 12 months (judged as DAS28CRP<2.4).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

SQA: r=0.6444, p=0.0001). All manual scores positively correlated with CRP (total: r=0.4775, p=0.0057; tissue infiltrating: r=0.3939, p=0.0257; marginating: r=0.6135, p=0.0002; SQA: r=0.5881, p=0.0004). Margination and SQA scores were positively correlated with RF titre (p=0.0123 and 0.0302, respectively). No association between neutrophil scores were observed with disease duration, tender or swollen joint counts or CCP status or titre. Finally, patients who reached early remission (DAS28CRP< 2.4 at 3 months) had lower manual neutrophil infiltration scores at baseline than those who did not (total: p=0.0189; tissue infiltrating: p=0.0155; SQA: p=0.0102).

Conclusion: RA ST neutrophil content prior to treatment initiation was associated with baseline disease activity, CRP levels and RF titres; patients who achieved early remission had lower neutrophil counts at baseline. Together, these outcomes suggest that ST neutrophil content may prove useful as an objective, predictive measure of disease activity, and has the potential to identify patients less likely to achieve early remission.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is severe and poorly understood inflammatory condition. Tumor necrosis factor receptor 1 (TNFR1) is activated by TNF and is found on most cell types. TNFR1 signaling triggers complex formation via its death domain (DD), activating proinflammatory processes through NFκB and various cell death pathways. Using a combination of genetic, *in vitro* and *ex vivo* studies, we have discovered a novel class of *TNFRSF1A* variation in children with sJIA.

Methods: We performed trio exome sequencing in a child with sJIA and targeted sequencing of *TNFRSF1A* in 525 sJIA cases. TNFR1 DD interactions were examined by modeling, Förster resonance energy transfer (FRET) and immunoprecipitation. TNFR1 variants were assayed *in vitro* for NFkB and cell death, and receptor localization was analyzed by superresolution microscopy (SRM). Patient peripheral blood mononuclear cells (PBMC) were compared to age matched control

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. PBMC using single cell RNA sequencing (scRNAseq) and SRM. Resting/LPS stimulated monocyte phenotypes, cell death and cytokine secretion were compared to age matched controls *ex vivo*.

Results: Trio exome sequencing identified a novel, *de novo* nonsense variant of *TNFRSF1A* that excludes the transmembrane domain and DD (K203X), while targeted sequencing found 2 subjects with ultra rare variants in the DD (P367S, E398K). All variants showed defective NFκB signaling and attenuated cell death *in vitro*, attributable to their impaired ability to nucleate the TNFR1 signaling complex, while SRM found reduced surface expression and enhanced Golgi localization of all 3 variants. scRNAseq of K203X PBMC revealed a paucity of classical and nonclassical monocytes. Instead, most monocytes formed a unique patient specific cluster that exhibited suppressed TNF signaling with paradoxical overactivation of NFκB signaling, resulting in a distinct inflammatory signature. Functional enrichment analysis revealed markedly reduced vesicular trafficking and autophagy related pathways, accompanied by activation of stress responses and innate immune pathways. Key regulators of Golgi and endosomal function were consistently downregulated across multiple pathways, indicating widespread disruption of Golgi homeostasis in K203X monocytes. Indeed, K203X PBMC displayed larger areas positive for a Golgi marker, indicative of fragmentation and damage. K203X monocytes also displayed a strongly M1 skewed transcriptional program, adopting a proinflammatory M1 like phenotype and producing abundant inflammatory cytokines even under steady state conditions. Finally, K203X monocytes showed downregulation of cell death related genes and demonstrated striking resistance to apoptosis upon stimulation with LPS or Fas ligand *ex vivo*, consistent with a hyperinflammatory, antiapoptotic state.

Conclusion: By investigating a novel loss of function variant of TNFR1, we identified a unique mechanism of immune dysregulation. This is characterized by dysfunctional trafficking and chronic accumulation of K203X TNFR1 in the Golgi, which leads to endosomal and autophagic failure, disruption of Golgi homeostasis, and ultimately cascading cellular stress that leads to hyperactive immune function.

Session Time: 10:30AM–12:30PM

Background/Purpose: Extracellular vesicles (EVs) are secreted by virtually all cells and are known to carry bioactive cargo including proteins, RNA, DNA and metabolites. Analysis of the cargo of EVs derived from the synovium may provide insight into disease-specific molecular pathways of arthritis. So far, most studies characterizing EVs in disease were based on bulk analysis, neglecting the complexity of EV populations present in biofluids of patients. To investigate and characterize distinct

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. EV subpopulations in synovial fluid of patients with rheumatoid arthritis (RA) and osteoarthritis (OA) we have established an novel immunocapture separation method based on magnetic nano-sized beads targeting cell type specific markers. CD90/THY1 was selected as a synovial fibroblast marker due to the reported contribution of CD90+ to synovitis.

Methods: EVs were isolated from synovial fluid of patients with RA and OA via size exclusion chromatography (SEC) and subsequently characterized by Nano Tracking Analyzer (NTA), NanoFlow cytometry (NanoFCM) and Western Blot (WB). For separation of a CD90+ EV population prototype anti-CD90 MicroBeads (Miltenyi Biotec) were used. WB and mass-spectrometry (MS)-based proteomics were applied to analyse the EV subpopulations. The proteomic profile of separated EV subpopulations was compared with published reference single cell RNA-Seq Data from inflamed synovial tissue. Disease specific proteomic profiles of EVs from RA and OA were compared.

Results: Using our immunocapture approach we were able to separate CD90+ EVs from synovial fluid of arthritis patients. WB confirmed a CD90 enrichment, while proteomic analysis revealed a stromal cell signature in the CD90+ EV-population, in comparison to markers for infiltrated immune cells like T cells, B cells, monocytes and neutrophils enriched in the CD90- EVs. The comparison of EV populations derived from RA and OA synovial fluid showed CD90+ EVs in both diseases. Analysis of RA-derived EVs showed a prominent neutrophil and macrophage signature, while OA enriched proteins were of fibroblast, macrophage, endothelial and epithelial cell profile. Proteomic analysis revealed several proteins enriched in RA known for their involvement in inflammation (TREM1, CXCR1, CXCR2, RETN, PADI4, LOXL3, CTSZ, MPO) or in cartilage degradation (MMP8). In contrast, in OA proteins involved in cartilage degradation and bone destruction were significantly enriched (ADAM10, FMOD, GPRC5a, INPP4N, LRP1, TNXB, SPARCL1) as well as protein candidates associated with OA pathogenesis and severity (CAPG, CTSA, LTBP1, LUM, LRP1).

Conclusion: Using a novel immunocapture approach we were able to separate cell type specific subsets of EVs from synovial fluid of arthritis patients. Proteomic analysis confirmed a stromal cell pattern in CD90+ EVs and revealed enrichment of disease specific proteins in EVs derived from RA and OA synovial fluid respectively. The ability to investigate distinct cell-type specific EV subsets in synovial fluid provides insight into pathogenetic mechanisms in the synovium and may lead to the identification of biomarkers in a liquid biopsy approach.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: NEMO-deleted 5 autoinflammatory syndrome (NEMO-NDAS) is an inflammatory disease caused by mosaic splice-site variants that lead to exon 5 skipping in *IKBKG*, encoding NEMO. Patients (pts) present with systemic inflammation, gdT-cells expansion, high serum IFNg, portal hypertension (PH) and porto-sinusoidal vascular disorders (PSVD). Here, we characterize the effect of exon 5-skipped NEMO on NFκB σιγναλινγ ιν Υ937 χελλσ, ανδ ασσεσσ ιντεστιναλ βαρριερ ανδ γυτ μιχροβιομε δψσρεγυλατιον ιν τηε πατηογενεσισ οφ ΠΗ ανδ ΠΣς∆.

Methods: U937 cells with exon 5-skipped NEMO were created by CRISPR (MUT) and compared to wildtype U937 cells (WT). NFkB signaling, cell viability, p65 nuclear translocation, NEMO/IKKb colocalization, and mRNA transcription profiling were assessed in TNF-stimulated MUT and WT U937 cells. We assessed immune activation and target killing in pts' PBMCs cocultured with WT and/or MUT U937s and quantified live U937 cells by flow cytometry. To characterize the gut-liver-axis, we analyzed intestinal fatty-acid-binding protein (I-FABP) concentrations in serum, and the stool microbiome (including virome), in NEMO-NDAS pts, inflammatory controls, and healthy household controls (HCs).

Results: Following TNF stimulation, nuclear translocation of p65 was significantly attenuated in MUT U937 cells consistent with impaired NFkB signaling. Additionally, increased susceptibility to TNF-induced cell death of MUT U937 cells was associated with a lack of upregulation of the anti-apoptotic genes *BIRC3*/cIAP2 and *CFLAR*/c-FLIP.

To test the killing potential of expanded gd T cells in pts' PBMCs, we cocultured pts' PBMCs with WT or MUT U937 cells. While viability of WT U937 cells is not affected by the pts' PBMC, mutant U937 cells are killed. When mixed WT and MUT U937s were cocultured with PBMCs, both WT and MUT U937s had decreased survival compared to PBMC-free conditions. Exploration of contributing cell types and pathomechanisms is ongoing.

Liver-gut-axis evaluation suggested that NEMO-NDAS pts have increased IFABP serum levels compared to CANDLE pts and HCs, suggestive of increased intestinal permeability and impaired gut barrier function. Microbiome studies showed increased abundance of Faecalibacterium phages and a decrease in metabolic protective markers, which is consistent with previously reported data in liver disease.

Conclusion: Exon 5-skipping in NEMO impairs NFkB signaling, sensitizes U937 cells to TNF-induced cell death, and leads to U937 cell death in cocultures with PBMCs from NEMO-NDAS pts. We hypothesize that exon 5-skipped NEMO impairs gut epithelial cell function and leads to dysbiosis and increased microbial translocation that contribute to PH and PSVD in NEMO-NDAS. Whether impaired gut barrier and dysbiosis contribute to activation and expansion of gd T cells in NEMO-NDAS is under investigation.

Background/Purpose: Citrulline (CIT) and malondialdehyde-acetaldehyde (MAA) co-adduct native proteins in RA tissues to create a dual pro-inflammatory and pro-fibrotic milieu. Our previous work demonstrated that supernatants from macrophages stimulated with CIT-MAA co-modified fibrinogen induce inflammatory, fibrotic, and invasive phenotypes in synovial and lung fibroblasts. However, the intracellular signaling pathways preceding cytokine release remain poorly defined. The aim of this study was to elucidate the inflammatory signaling pathways in macrophages following stimulation with CIT-MAA co-modified fibrinogen.

Methods: The human monocytic cell line (U-937) was differentiated into macrophages (M0 cells) using phorbol 12-myristate-13-acetate (PMA) and then stimulated with fibrinogen (FIB) that was unmodified, MAA-modified (FIB-MAA), CIT-modified (FIB-CIT), or CIT-MAA co-modified (FIB-CIT-MAA). After 1-hr of antigen stimulation, cells were lysed and protein was analyzed using Western blot analysis targeting the phosphorylated forms and total levels of p38 MAPK, NF-κB (p65), ERK1/2, STAT1, STAT3, STAT6, Akt1, Akt2, JNK, and β-actin. After 48-hrs of stimulation, supernatants were collected and analyzed by ELISA for concentrations of TNFα, IL-1β, IL-6, and MCP-1. After initial testing by Western blot, for each treatment group, there was a replicate group pre-treated with a p38 inhibitor (BIRB-796) or an NF-κB inhibitor (BAY 11-7085) for 1-hr before antigen stimulation. Statistical analysis was performed using one-way ANOVA with Tukey's multiple comparisons test.

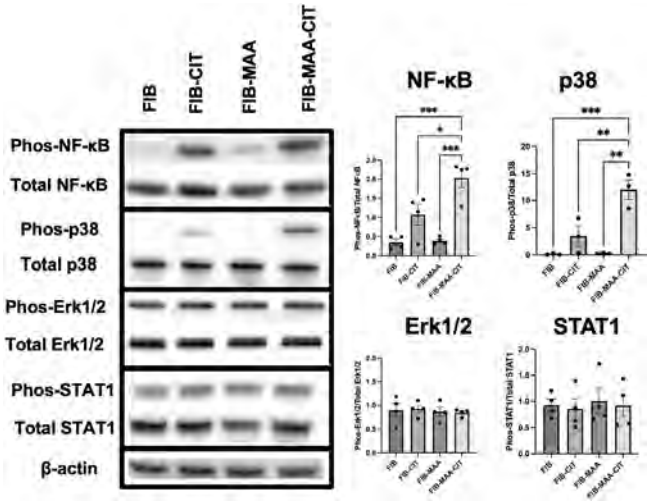

Figure 1. Intracellular Signaling Pathways Activated after Macrophage Stimulation Demonstrated by Western Blot. Macrophages were stimulated for 1-hr with fibrinogen (FIB) that was unmodified or modified with citrulline (CIT) and/or malondialdehyde-acetaldehyde (MAA) prior to measurement of intracellular signaling. Band intensity was quantified using KwikQuant Image Analyzer software. Graphs are plotted as a phosphorylated protein normalized to total protein. Note: phosphorylated Akt1, Akt2, JNK, STAT3, and STAT6 not detected (not shown); One-way ANOVA was performed and the statistical differences between groups are shown in *: * p<0.05; ** p<0.01; *** p<0.001.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. ELISA Demonstrating Decreased Cytokine Production in Macrophages After Inhibition of p38 or NF-κB. 48-hr cytokine concentrations in supernatants were measured for; A) TNFα, B) IL-6, C) IL-1β, and D) MCP-1. One-way ANOVA was performed and the statistical differences between groups are shown in *: * p<0.05; ** p<0.01; *** p<0.001; **** p<0.0001.

Results: Western blot demonstrated that M0 cells treated with FIB-CIT had significantly increased p38 and NF-κB phosphorylation compared to unmodified FIB, with FIB-CIT-MAA further enhancing phosphorylation of these specific signaling molecules (Fig 1). No significant changes were observed in ERK1/2 and STAT1 following stimulation with any of the antigens. Additionally, phosphorylated Akt1, Akt2, JNK, STAT3, and STAT6 were not detected. Inhibition of signaling pathways after pre-treatment with p38 MAPK and NF-κB inhibitors was validated by Western blot. ELISA revealed that FIB-CIT-MAA stimulation significantly increased secretion of TNF-α, IL-1β, IL-6, and MCP-1 compared to both unmodified FIB, FIB-MAA, and FIB-CIT. Addition of inhibitors to p38 and/or NF-κB decreased release of all 4 cytokines, but only NF-κB inhibition fully abrogated their release (Fig 2).

Conclusion: CIT-MAA co-modified fibrinogen stimulates macrophage activation via the p38 and NF-κB pathways, promoting secretion of pro-inflammatory mediators including TNF-α, IL-1β, IL-6, and MCP-1. Inhibition of these pathways attenuates inflammatory cytokine production, supporting a mechanistic link between CIT-MAA adducts and disease progression in RA. Future research will validate this finding using human monocytes and identify whether agents targeting these post-translational modifications as well as downstream signaling pathways have the potential to attenuate RA progression.

Background/Purpose: Complement component C3 plays a central role in the alternative pathway (AP) and is implicated in the pathogenesis of C3 glomerulopathy (C3G), a rare renal disease. To model human-specific complement dysregulation, we developed two humanized C3 mouse models: B6-hC3 (expressing human C3 transgene) and B6-hC3 mC3 KO (expressing human C3 transgene with knockout of mouse C3). These models were designed to induce unregulated C3 activation via the alternative pathway (AP) and recapitulate C3G-like phenotypes. Through phenotypic assessment and RNA sequencing, we sought to elucidate molecular mechanisms underlying disease development and investigate sex-associated gene expression signatures.

Methods: A human C3 transgene was introduced into B6 mouse embryos to generate B6-hC3 mice. Additionally, the endogenous mouse C3 gene in B6-hC3 mice was knocked out to generate B6-hC3 mC3 KO mice. Both B6-hC3 and B6-hC3 mC3 KO mice were evaluated longitudinally for renal dysfunction via urinalysis. RNA sequencing (RNA-seq) was performed on both B6-hC3 and B6-hC3 mC3 KO mice to identify differentially expressed genes and pathways between strains and sexes.

Results: Both B6-hC3 and B6-hC3 mC3 KO strains developed hallmark features of C3G. However, B6-hC3 mC3 KO mice exhibited more severe renal dysfunction and damage compared to B6-hC3. Notably, female B6-hC3 mC3 KO mice developed higher levels of proteinuria and exhibit diverse renal lesions compared to males, suggesting sex-specific susceptibility. RNA-seq analysis revealed strain-specific transcriptomic profiles between B6-hC3 and B6-hC3 mC3 KO strains, as well as sex-associated gene expression signatures between male and female B6-hC3 mC3 KO mice.

Conclusion: In this study, two novel humanized mouse models that recapitulate key features of human C3G were established. Phenotypic and transcriptomic analyses reveal critical differences between strains and sex, making these models valuable platforms for future mechanistic studies of C3G and for the preclinical evaluation of targeted complement-modulating therapies.

Influenza Virus Infection Alters the MHC Class II Self-Immunopeptidome to Present Lupus-Associated Autoantigens

Julia Rood[1], Stephanie Suh Kyung Yoon[2], Mary Heard[1], Michael Hogan[2], Nicola Ternette[3], Edward Behrens[4] and Laurence Eisenlohr[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Dundee, Dundee, Scotland, United Kingdom, [4]CHOP, West Chester, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Viral infections and major histocompatibility complex class II (MHC II) are both implicated in the genesis of systemic lupus erythematosus (SLE), but a mechanistic understanding of how these factors promote autoimmunity is lacking. One phenomenon observed for MHC class I-restricted self-peptides – but which remains largely unexplored for MHC II – is the ability of viruses to alter processing and presentation of endogenous self-antigens. We investigated the impact of infection with influenza, a virus associated with autoantibody formation in healthy individuals and disease flares in SLE patients, on the repertoire of self-peptides presented by MHC II.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A murine antigen presenting cell (APC) line expressing C57Bl/6-derived I-Ab, BALB/c-derived I-Ed, and class II transactivator-driven antigen processing and presentation components was either infected with the mouse-adapted H1N1 influenza strain PR8 or mock-infected *in vitro*. MHC II:peptide complexes were immunoprecipitated, and peptides were fractionated by reversed-phase high-performance liquid chromatography, analyzed by nano-ultra-performance liquid chromatography-tandem mass spectrometry, and identified from a database containing the influenza and mouse proteomes.

Results: An average of 9,895 peptides were identified among influenza-infected APCs per experimental replicate. Self-peptides comprised >95% of the MHC II immunopeptidome in influenza-infected cells, concordant with published observations from other intracellular pathogens. Among these self-peptides, 24-40% were unique to infected, rather than uninfected, cells. Functional annotation clustering revealed significant enrichment of ribosomal proteins and ribonucleoproteins (RNPs) among peptides unique to infected cells. Multiple unique epitopes were identified from ribosomal P0, a known target of anti-ribosomal P antibodies in SLE patients. We also identified peptides derived from histones, other nuclear DNA-binding proteins, and complement proteins including C3, an autoantibody target in at least one-third of SLE patients. Peptides derived from complement C3 were separately identified in published MHC II immunopeptidome data from H1N1 influenza-infected human cells.

Conclusion: Active influenza infection *in vitro* substantially alters the MHC II self-immunopeptidome and is associated with presentation of SLE autoantigens. These data suggest that influenza manipulates non-classical endogenous antigen processing pathways within APCs to expose new self-epitopes capable of activating autoreactive CD4+ T cells in SLE. Future studies will investigate intracellular processing of these peptides and their presentation in murine models of SLE to elucidate the mechanistic role of viral infection in promoting autoimmunity.

Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Post-translational modifications (PTMs) of self-proteins are implicated in the pathogenesis of rheumatoid arthritis (RA). The PTMs, malondialdehyde-acetaldehyde (MAA), citrulline (CIT), and the co-modification of MAA and CIT have been demonstrated to be overrepresented in RA tissues in addition to exerting robust proinflammatory and profibrotic effects on macrophages and fibroblasts. Previous studies have shown that MAA and MAA-CIT protein antigens bind to scavenger receptors on macrophages. These data showed increased binding to TLR4, SRBII and SREC. However, little

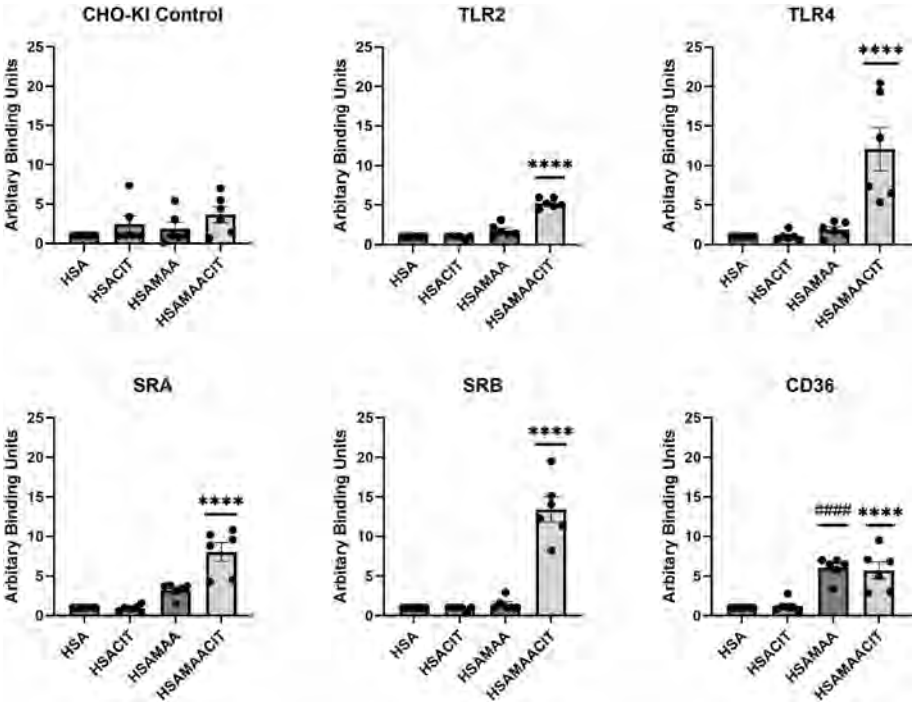

Figure 1. Arbitrary binding unit quantification following Western Blotting of post-translationally modified HSA to scavenger receptors of the different transfected CHO cells. Control CHO-K1 cells and CHO cells expressing TLR2, TLR4, SRA, SRB, and CD36 were incubated with 25 μg of HSA, HSA-CIT, HSA-MAA, or HSA-MAA-CIT for 90 minutes at 40C. Cells were washed and binding was determined by a cellular ELISA using an HRP conjugated anti-human albumin antibody that was detected using TMB substrate measuring the absorbance at 450 nm on an ELISA reader. To quantify binding, arbitrary binding units were developed by normalizing the data to native HSA. Anova was used to compare binding across treatment groups. Comparisons to native HSA shown above the bars (**** p<0.0001, ####p<0.0001). HSA-MAA-CIT demonstrated statistically significant binding to TLR2, TLR4, SRA, and SRB transfected CHO cells as compared to native HSA, HSA-CIT, and HSA-MAA. In CHO cells expressing CD36, both HSA-MAA-CIT and HSA-MAA demonstrated a statistically significant increase in binding to the scavenger receptor compared to HSA and HSA-CIT N=6 for each group.

is known as to whether MAA-CIT modified antigens bind additional receptors let alone which specific receptor(s) bind them. Therefore, it was the purpose of this study to determine which specific receptors bind MAA-CIT modified proteins, and whether this binding alters the morphology of the cells.

Methods: Chinese Hamster Ovary (CHO) cells transfected with a single scavenger receptor (SR): TLR2, TLR4, SRA, SRB and CD36 were incubated with 25 μg of Human serum albumin (HSA) modified with; CIT (HSA-CIT), MAA (HSA-MAA) or MAA-CIT (HSA-MAA-CIT) antigens for 90 minutes on ice. An in-cell ELISA was performed to determine binding capacity. Briefly, cells were washed and incubated with a horseradish peroxidase (HRP) conjugated anti-human albumin antibody

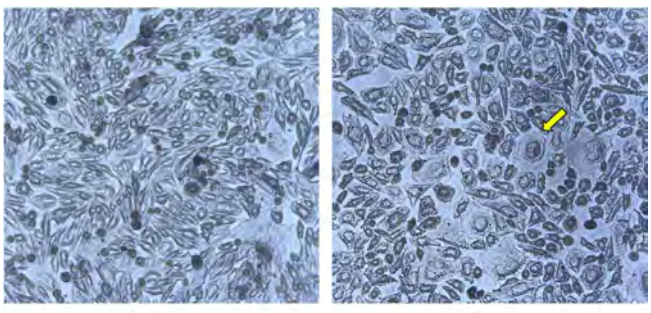

Figure 2. Representative images of CHO-K1 and CHO-TLR4 cells stimulated with HSA-MAA-CIT. Following 90 minutes of incubation with 25 μg of HSA-MAA-CIT, CHO cells transfected with TLR4 scavenger receptors demonstrate marked morphological changes compared to CHO-K1 controls. CHO-K1 control cells (left) display a spindle-shaped morphology, whereas CHO-TLR4 cells (right) show a larger polygonal morphology.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

followed by detection using TMB substrate. Reactivity was determined at 450nm and data normalized to native HSA to look for arbitrary binding units. Additionally, following exposure and incubation on ice, the cells were photographed and evaluated for morphological changes using a Nikon overhead microscope at a magnification of 20X.

Results: Binding data revealed significant increases ($p < 0.0001$) in MAA-CIT binding to TLR2, TLR4, SRA, and SRB compared to native HSA, HSA-CIT and HSA-MAA antigens (**Figure 1**). Interestingly, MAA and MAA-CIT bound equally to CD36 compared to HSA and HSA-CIT antigens suggesting MAA is the major modification resulting in binding to CD36. In other studies, the cells were imaged following incubation with MAA-CIT antigens and showed drastic morphological changes in cellular phenotype (**Figure 2)**. Changes included increased cellular size and shape compared to control CHO cells (no SR receptor) following MAA-CIT binding to TLR4 CHO cells, with similar changes being observed with the CHO cells expressing various SRs.

Conclusion: Findings from this study demonstrate that MAA-CIT modified protein binds multiple different scavenger receptors. Results confirm previous data showing that MAA-CIT co-modified antigen binds more to TLR4, and SRB receptors than TLR2 or SRA. Interestingly, MAA and MAA-CIT bind CD36 receptors at a similar compacity. While MAA-CIT binds all the receptors at similar levels, suggesting co-modification with MAA-CIT may be a better ligand than MAA or CIT alone. Further studies are warranted to investigate these receptors on human macrophages from patients with RA and how the morphological changes observed translate to effects on cellular function.

Pathogenic role of SPP1+ macrophages in Rheumatoid Arthritis

Megan M. Hanlon[1], Catherine Manning[1], Kevin Wei[1], Ursula Fearon[2] and Ellen M. Gravallese[3], [1]Brigham and Women's Hospital at Harvard Medical School, Boston, MA, [2]Trinity College Dublin, Dublin, Dublin, Ireland, [3]Brigham and Women's Hospital, Harvard Medical School, Chestnut Hill, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Synovial tissue macrophages (STMs) represent a mixed population of cells contributing to the pathogenesis of rheumatoid arthritis (RA). We identified an enrichment of Secreted phosphoprotein-1 (SPP1) STMs in RA compared to healthy control (HC) synovial tissue. We show SPP1+ STMs are also enriched in individuals at risk for RA (IAR), suggesting they represent an early disease-specific myeloid subset (1). The aim of this study was to uncover the specific contributions of SPP1+ STMs to RA pathogenesis, which may provide opportunities to reinstate joint homeostasis.

Methods: Peripheral blood was obtained from HC and RA patients. CD14+ monocytes were isolated and differentiated either in the presence of M-CSF (50ng/ml) or Ca2+ (2.5 mM) for 7 days to derive Macs or SPP1-expressing-Macs (S-Macs), respectively. Inflammatory cytokine production by these cells, and their defining metabolic parameters were measured by RT-PCR, ELISA and by the Seahorse-XFE technology. Paraffin embedded synovial tissue biopsies were obtained from HC, from RA patients undergoing key-hole arthroscopy, and from seropositive IAR who have no clinical signs of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

inflammation. Spatial transcriptomics was performed using a custom Xenium 5K+ panel. Only RA patients who fulfilled the revised ACR criteria were included in this study.

Results: RA SPP1+ STMs correlate significantly with clinical inflammation and display the highest expression of glycolytic genes compared to all other STMs. RA S-Macs have increased expression of SPP1 at both the gene and protein level compared to Macs. S-Macs display increased expression of IL-6, TNF, IL-1b and IL-8 and the glycolytic genes HIF1a and HK2 compared to Macs. Importantly, this is more pronounced in cells derived from RA vs HC indicating priming in the RA periphery. RA S-Macs display decreased baseline oxidative phosphorylation and maximal respiratory capacity compared to Macs derived from HC/RA blood, while concomitantly skewing the ECAR/OCR ratio in favor of glycolysis, indicating that RA S-Macs rely heavily on glycolysis. Finally, we conducted Xenium in situ spatial profiling technology to measure RNA expression levels of 5100 genes in unique paraffin-embedded synovial tissue from HC, IAR and RA. We annotated cell clusters (including macrophages, fibroblasts, T, B cells) and identified their localization to serve as a map of the synovial cellular organization across the evolution of disease.

Conclusion: We demonstrate that SPP1+ STMs correlate with clinical inflammation in RA and are metabolically reprogrammed towards glycolysis, leading to sustained induction of pro-inflammatory responses. Xenium spatial analysis allows us to determine the cellular interactions and disease stage-specific factors that shape SPP1+ STMs in RA synovium. These cells may thus represent a potential pathway for therapeutic targeting.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IRAK4 plays a pivotal role in the innate immune response by acting downstream of Toll-like receptors (TLRs) and the interleukin-1 receptor (IL-1R), with both kinase activity and scaffolding functions. This dual role makes it a critical target for modulating inflammatory signaling. However, traditional IRAK4 kinase inhibitors have shown limited

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

efficacy due to their inability to disrupt the scaffolding function. IRAK4-targeting PROTACs offer a more comprehensive strategy by inducing selective degradation of IRAK4 protein. Here, we report the discovery and characterization of SIM0711, a potent and selective oral IRAK4 PROTAC for the treatment of autoimmune diseases.

Methods: We developed and extensively characterized SIM0711 through a series of *in vitro* and *in vivo* studies. SIM0711 was benchmarked against KT-474 (an IRAK4 PROTAC) and PF-06650833 (a selective kinase inhibitor). IRAK4 degradation and kinetics were assessed in human immune and stromal cells. Downstream cytokine inhibition (IL-6 and/or IL-8) was measured by ELISA followed by TLR4, TLR8, TLR9, and IL-1R stimulation. *In vivo* efficacy and pharmacodynamic effects on cytokine production were evaluated in multiple mouse models of inflammation. Additionally, oral dosing studies in rodents, dogs, and non-human primates (NHPs) were conducted to characterize IRAK4 degradation, PK/PD relationships, bioavailability, and safety.

Results: In comparison to the benchmark PROTAC KT-474, SIM0711 achieved near-complete IRAK4 degradation in diverse human immune cells and stromal cell lines, with faster degradation kinetics observed in primary human monocytes. Meanwhile, SIM0711 induced more complete inhibition of IL-6 and IL-8 secretion upon TLR4, TLR7, TLR9, and IL-1R activation, outperforming both PF-06650833 and KT-474 *in vitro*. *In vivo*, SIM0711 significantly reduced inflammation and demonstrated superior efficacy over KT-474 in multiple mouse models. This enhanced efficacy correlated well with deeper IRAK4 degradation in PBMCs and near-complete suppression of pro-inflammatory cytokine release at the site of inflammation. Additionally, SIM0711 showed improved oral bioavailability, robust IRAK4 degradation (> 90%), favorable PK/PD properties and good safety profiles across rodents, dogs and NHPs. Notably, SIM0711 exhibited a more balanced tissue distribution than KT-474, with preferential accumulation only observed at the inflamed site, potentially contributing to an improved therapeutic window.

Conclusion: These findings support SIM0711 as a potential best-in-class IRAK4 PROTAC for the treatment of a range of autoimmune diseases. Its robust IRAK4 degradation, superior anti-inflammatory efficacy, and favorable pharmacological profile highlight its strong therapeutic potential. IND submission is expected by Q3 2025.

Background/Purpose: Lupus is a chronic autoimmune disease with a global loss of self-tolerance. Lupus patients are photosensitive where exposure to even ambient sunlight results in skin inflammation. Lymph carries signals such as antigens and antigen-presenting cells from the skin to the lymph node. We recently demonstrated that exposure to ultraviolet radiation (UVR) causes reduced lymph flow from skin to lymph node in lupus mouse models and that improving flow reduced B and T cell responses by increasing fibroblastic reticular cell (FRC) CCL2 expression and FRC proliferation (Howlader, Ambler et al. *Journal of Clinical Investigation*, vol. 135, no. 10, 2025, e168412). How improved flow can affect the lymph node stromal compartment is not understood. Migratory dendritic cells (DCs) travel in the lymph from skin to lymph node, where they can change FRC phenotype. Reduced interferon signaling results in increased FRC CCL2 expression and increased expansion of FRCs. Here, we hypothesize that improving lymph flow allows for more migratory DCs to mediate FRC proliferation through reduced interferon signaling.

Methods: We used an inducible lupus mouse model where topical imiquimod (a TLR7 agonist) induces a lupus-like phenotype with elevated type I IFN signaling. Mice were exposed to UVR 4 days/week to study photosensitivity. We improve flow through manual lymphatic drainage (MLD), which is a light skin stretching technique that helps promote the movement of lymphatic fluid out of a swollen area. To assess the role of DCs, we generated bone marrow chimeras using zDC-DTR donors into B6 recipients, enabling selective depletion of DCs via diphtheria toxin (DT). We analyzed LN immune and stromal populations by flow cytometry and quantified interferon stimulated gene (ISG) expression by qPCR.

Results: Improving lymph flow increased the number of migratory dendritic cells in the lymph node and not Langerhans cells or resident dendritic cells. Depletion of migratory dendritic cells prior to MLD reversed the FRC proliferation, indicating that migratory DCs are required for FRC proliferation. MLD led to reduced expression of lymph node ISGs and adding interferon reverses MLD induced FRC expansion. We currently are investigating if migratory dendritic cells are required for the reduced interferon signaling.

Conclusion: Our results support a potential DC-stromal axis that plays a role in lupus photosensitivity. Imporving lymphatic flow promotes migratory DC entry into LNs, which appears to suppress IFN signaling and promote FRC proliferation. These findings highlight a lymphatic-dendritic cell-stromal axis as a potential therapeutic target to alleviate photosensitivity-associated autoimmunity.

Background/Purpose: Neutrophil Extracellular Traps (NETs) contribute to the pathophysiology of multiple immune-mediated inflammatory diseases including Rheumatoid Arthritis (RA), and may be promising therapeutic targets. The first-in-class therapeutic anti-citrullinated histone antibody CIT-013 binds citrullinated histones H2A and H4 in NETs and has demonstrated efficacy in models of NET-mediated inflammation by inhibiting de novo NET formation and by enhancing clearance of existing NETs by Fc receptor-mediated phagocytosis (Chirivi et al 2021; van der Linden et al 2024).

In this study, we describe the use of a NET targeting antibody as an in vivo radiotracer to detect and visualize NETs in inflamed tissues.

Methods: Mice with collagen induced arthritic (CIA) mice with no, mild, moderate and established disease (n=10/group) were intravenously injected with indium-111 labeled mouse anti-citrullinated histone antibody (mACHA). Twenty-four hours after injection, whole body Single Photon Emission Computed Tomographic (SPECT) imaging was performed on selected animals. For all animals, tissue distribution of the radiotracer was quantified ex vivo by measuring gamma radiation.

Results: In CIA mice, indium-111 labeled mACHA distributes to inflamed joints and can be detected in animals with mild inflammation with increasing accumulation of the radiotracer in the fore and hind paws correlating with higher arthritis severity. Furthermore, the radiotracer enables a highly sensitive detection of inflammation in joints not apparently inflamed upon visual inspection, such as the knee.

Conclusion: mACHA can be used as a radiotracer to visualize NETs in sites of inflammation. This proof of principle imaging study enables a human whole body PET CT imaging clinical study in RA and hidradenitis suppurativa patients during 2025. This clinical study will lead to further insights in CIT-013's distribution, target engagement and mechanism of action in patients with immune mediated inflammatory diseases.

SP2H, a Targeted Degrader of STimulator of INterferon Genes (STING), selectively inhibits STING-driven inflammation in vitro and in vivo and improves survival in Trex1$^{-/-}$ mice

Martin Jakobsen[1], Pernille Noer[2], Kristina Byskov[3], Emil Nilsson[4], Laura Ryø[5], Claus Olesen[2] and **Richard BETHELL**[6], [1]Aarhus University, Aarhus, Denmark, [2]Sulis Therapeutics, Aarhus, Denmark, [3]Notify Therapeutics, Aarhus, Denmark, [4]Sulis Therapeutics, Aarhus C, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Sulis Therapeutics, Stockholm, Sweden

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: STING plays a critical role at the intersection of innate and adaptive immunity and has been linked to the pathogenesis of SSc and SLE. While initially characterized as the adaptor protein leading to type 1 IFN induction downstream of the cytosolic DNA sensor cyclic guanosine-monophosphate adenosine-monophosphate synthase (cGAS),

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

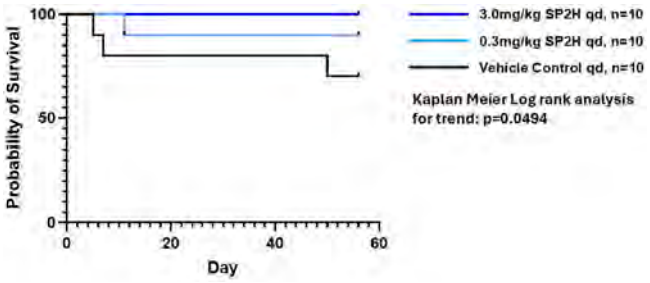

Figure 1: Kaplan Meier analysis of the survival of Trex1-/- mice treated with vehicle control, 0.3mg/kg SP2H or 3mg/kg SP2H sc qd. Each group comprised 5 male and 5 female animals. Animals were randomized by body weight, anti-dsDNA antibody titer and serum lactate dehydrogenase titer at age 5 weeks. Treatment was initiated at age 6 weeks and continued daily for 8 weeks.

STING can be activated independently of cGAS by several other mechanisms. Beyond its role in IFN induction, STING directly activates other pathways, e.g. NF-kB-driven inflammatory cytokine expression and the PERK-eIF2a arm of the unfolded protein response. We developed SP2H - a targeted STING degrader, preventing all STING driven activation mechanisms - as a new treatment strategy for SSc, SLE and other diseases characterized by excessive STING activation.

Methods: SP2H's effects on STING protein levels, and on inflammatory cytokine expression induced by STING agonists, were assessed *in vitro* using established cell lines and primary human fibroblasts. Inhibition of STING activation by single sub-cutaneous (sc) doses of SP2H *in vivo* was assessed in C57Bl6 mice following a single 1mg/kg dose of the STING agonist diABZI. Survival, serum cytokine levels and inflammatory gene expression were assessed in Trex1$^{-/-}$ mice following treatment with 0.3mg/kg and 3.0 mg/kg or vehicle control once daily (qd) sc SP2H for 56 days (n=10/group).

Results: SP2H selectively degraded STING *in vitro* with DC_{50} values of 40-100nM, and inhibited IFN-b expression induced by STING agonists with EC_{50} values of 20-100nM. When given 16h prior to diAZBI, single sc doses of SP2H (either 0.3mg/kg, 1mg/kg or 3mg/kg) resulted in a >1.2log$_{10}$ reduction in diABZI-induced serum interferon-b levels at all three doses, and dose-dependent reductions in serum CXCL10 (0.6-1.6log$_{10}$), CCL2 (1.3-2.3log$_{10}$), all $p< 0.0001$, and IL-6 (1.6-2.7log$_{10}$), all $p< 0.01$ (ANOVA). Treatment of Trex1$^{-/-}$ mice with SP2H for 8 weeks was well tolerated and improved overall survival (Kaplan-Meier analysis, log rank analysis for trend p=0.0494), with 100% survival at the higher SP2H dose as shown in Figure 1. The 3mg/kg dose of SP2H resulted in >4.5-fold lower serum levels of both CXCL10 and TNF-a (both $p< 0.0001$, ANOVA) compared to vehicle controls at the end of treatment, and significantly reduced expression of inflammatory genes (*CXCL10, TNF-a, IFN-b, CCL2, IFIT1, ISG15, IFI44, MX1*) in the heart.

Conclusion: Targeted degradation by SP2H leads to selective STING depletion and inhibition of STING-driven inflammation *in vitro* and *in vivo*. Treatment of Trex1$^{-/-}$ mice with SP2H was well-tolerated, improved survival and reduced inflammation, supporting further clinical development of SP2H as a potential treatment for diseases driven by the pathological overactivation of STING.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0916–0933) Innate Immunity Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: IRF5, an undrugged transcription factor, is an autoimmune susceptibility gene that has been linked to RA and other autoimmune diseases including SLE, Sjögren's, and SSc. IRF5 is a regulator of immune responses activated downstream of pattern recognition receptors, like toll-like receptors (TLR). IRF5 regulates pro-inflammatory cytokines (TNFα, IL-6, IL-12, IL-23), autoantibody production and Type I IFN. IRF5 is selectively expressed and activated in specific cell types such as dendritic cells, monocytes, M1 macrophages, and B cells. RA is a chronic disease where the target tissue is synovial joints. The joints are characterized by heavy leukocyte infiltration. Inflamed synovium contains a larger number of activated macrophages and T cells in addition to B cells and dendritic cells. Studies in IRF5 deficient mice show attenuated arthritis severity in models of RA. Despite its strong mechanistic and genetic validation, IRF5 has historically remained undrugged likely due to its activation complexity and multiple functional isoforms. IRF5 is well suited for targeted protein degradation, where a single binding event drives activity. KT-579, an oral IRF5 degrader, has demonstrated potent and selective activity in preclinical in vitro myeloid assays and in vivo RA models, offering a new approach to modulating this key driver of immunity.

Methods: THP-1 monocytic cell line or peripheral blood mononuclear cells, monocytes, M1 macrophages, and dendritic cells were cultured with KT-579 in the presence or absence of TLR4, TLR7, or TLR8 stimulation and measured for pro-inflammatory cytokines including TNFα, IL-6, IL-12, IL-23, IFNy and IL-1β. KT-579 was tested in the antigen-induced arthritis (AIA) mouse model of RA and compared to the JAK inhibitor, tofacitinib.

Results: KT-579 was highly selective for IRF5 in the detectable proteome, including other IRF family proteins. In vitro, KT-579 demonstrated nanomolar inhibition of IL-1β, TNFα, IL-12, IL-23 and IFNγ, in a cell-type and stimulant-dependent manner, downstream of TLR activation. In the AIA model of RA, daily oral dosing with KT-579, achieved ~90% degradation of IRF5 and led to significant reduction in joint swelling comparable to tofacitinib. IRF5 degradation led to reduction of circulating pro-inflammatory cytokines including IL-12, IL-6 and CXCL1 and infiltrating Th1 T cells, that was differentiated from tofacitinib. In addition, KT-579 achieved deep IRF5 depletion (≥90%) across multiple species with low oral doses, and did not show adverse effects at concentrations up to 200-fold the projected human efficacious levels in preclinical safety studies.

Conclusion: We report here the first selective, potent, oral IRF5 degrader that can sufficiently deplete IRF5 and impact myeloid cell effector function by potently inhibiting pro-inflammatory cytokines found to be critical in amplifying inflammatory responses, including cytokines that promote Th1 and Th17 T cell responses, and can reduce joint swelling in a mouse model of RA. These findings support KT-579 as a novel therapeutic agent with the potential to be a first-in-class oral therapy for the treatment of RA and other autoimmune diseases.

Reduced mitophagy in salivary glands of Sjögren's disease patients is associated with mitochondrial structural damage

Salvador Campos[1], **Sergio Aguilera**[2], Juan Gutiérrez[1], Isabel Castro[3], Patricia Carvajal[3], Lorena Carvajal[1], Sergio González[4], Claudio Molina[5], María-Julieta González[6] and María-José Barrera[5], [1]Universidad San Sebastián, Santiago, Region Metropolitana, Chile, [2]Clinica Indisa, Santiago, Region Metropolitana, Chile, [3]Departamento de Tecnología Médica, Facultad de Medicina, Universidad de Chile, Santiago, Region Metropolitana, Chile, [4]Escuela de Odontología, Universidad Mayor, Santiago, Region Metropolitana, Chile, [5]Facultad de Odontología, Universidad San Sebastián, Santiago, Region Metropolitana, Chile, [6]ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Region Metropolitana, Chile

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0916–0933) Innate Immunity Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Primary Sjögren's disease (pSjD) is a systemic autoimmune disease characterized mainly by immune-mediated damage to exocrine glands. Previously, we found decreased expression of ATG5 and Beclin along with increased p62 protein levels in labial salivary glands (LSG) of SjD patients, suggesting decreased macroautophagy[1], which may contribute to the pathogenesis. On the other hand, recent evidence suggests that SjD is strongly associated with mitochondrial dysfunction, which may be related to inflammation as well as chronic fatigue, present in 70% of SjD patients. The increased presence of swollen mitochondria with membrane disorganization has been observed in salivary epithelial cells from SjD patients[2], suggesting reduced clearance by mitophagy. The aim of this study was to determine the levels of mitophagy markers in LSG from pSjD patients.

Methods: SGs from pSjD patients (n=9) and controls (n=5) were analyzed. Mitochondrial ultrastructure was observed by transmission electron microscopy (TEM). Protein levels of mitophagy markers of the PINK-Parkin-dependent pathway (pPINK, PINK, pParkin, Parkin), -independent pathway (BNIP3L) and LC3 were determined by Western blot. The localization of LC3 and mitochondrial markers was determined by immunofluorescence. In human salivary cells stimulated with pro-inflammatory cytokines, mitochondrial ultrastructure was evaluated by TEM.

Results: LSGs from pSjD patients showed increased protein levels of PINK and pPINK and decreased protein levels of p-Parkin, Parkin and BNIP3L. In addition, LC3-II was decreased. Increased PINK protein levels suggest mitochondrial damage because this protein accumulates when mitochondria lose their membrane potential; however, Parkin, pParkin, and BNIP3L are decreased, suggesting that the canonical and alternative pathways of mitophagy are reduced in LSG of SjD patients. The COXIV staining pattern by immunofluorescence showed a more fragmented mitochondrial network in SjD

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients, consistent with smaller mitochondria observed by TEM. Pro-inflammatory cytokines such as IL-1β induced an increase in the presence of mitochondria altered with myelin-like figures inside.

Conclusion: In LSG samples, we identified the major markers related to mitophagy and found that PINK Parkin-dependent and -independent pathways are decreased in LSG of pSjD patients. Reduced mitophagy could explain the presence of more fragmented and damaged mitochondria. *In vitro* results show that some pro-inflammatory cytokines such as IL-1β could induce important structural changes in mitochondria, supporting the idea of a link between inflammation and mitochondrial damage. The results of this work contribute to the understanding of the altered mechanisms in pSjD and raise the idea of evaluating future innovative therapies aimed at improving mitophagy, mitochondrial morphology and function

Compartment-specific NK-cell phenotypes reveal distinct maturation and activation states in inflammatory arthritis

Franca Sophie Deicher[1], Tarik Exner[2], Maren Claus[3], Schayan Yousefian[4], Lea Rodon[5], sophie leonhardt[6], Jörg Distler[7], Carsten Watzl[3], Hanns-Martin Lorenz[8], Simon Haas[4], Daniel Hübschmann[9] and **Wolfgang Merkt**[10], [1]Uniklinik Düsseldorf, Düsseldorf, Germany, [2]University Hospital Heidelberg, Heidelberg, Germany, [3]IfADo, Leibniz Institute Dortmund, Dortmund, Germany, [4]Charite, Berlin, Berlin, Germany, [5]University Hospital Heidelberg, Heidelberg, Hungary, [6]Heidelberg University, Heidelberg, Germany, [7]University Hospital Duesseldorf and HHU, Duesseldorf, Germany, [8]Universitätsklinikum Heidelberg, Heidelberg, Germany, [9]Heidelberg University, Berlin, Germany, [10]University Hospital Dösseldorf, Dösseldorf, Germany

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Synovial natural killer (NK) cells contribute to inflammation in arthritis by secreting cytokines and modulating synovial fibroblast activation. The aim of this study is to describe systemic versus local inflammatory changes of NK-cell subsets as well as their physical cell-cell interactions in arthritis patients.

Methods: Spectral flow cytometry was used to compare paired peripheral blood (PB) and synovial fluid (SF) immune cells from patients with active inflammatory arthritis and healthy controls. Physical cell-cell interactions within tissues were studied by applying a recently developed cellular interaction mapping framework *Interact-omics (Vonficht et al., 2025, accepted in Nature Methods)*.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Our paired approach revealed significant local enrichment of immature and activated NK-cells in SF, characterized by elevated markers of early differentiation, immune checkpoint regulation, and tissue residency, highlighting tightly controlled immune activation at inflamed sites. Single-cell analysis confirmed heterogeneity within SF-NK-cells, suggesting multiple co-existing activation states and developmental stages. PB-NK-cells from patients differed profoundly from healthy controls, showing less immature NK-cell subsets and an enrichment of mature, pro-inflammatory subsets indicative of

NK cells display phenotypic changes in peripheral blood and synovial fluid in patients with inflammatory arthritis. A Graphical experimental design. B Cell frequencies. Frequencies of the indicated cell types were plotted as a percentage of PBMC. C Sample correlation analysis on a pseudobulk level. NK cells were correlated as described in the methods section. Hierarchical clustering revealed three subgroups which correspond to cells of different tissue and patient group (healthy and inflammatory arthritis). D Sample-wise principal component analysis. Samples were grouped by PCA and colored by tissue and patient group (left) and the metaclusters (right) as calculated in C. E Differential expression analysis. Fold-changes (x-axis, asinh_fc) were calculated as described in the Methods section. Notably, NK cells analyzed from peripheral blood show significant phenotypic differences comparing healthy controls and patients with inflammatory arthritis, including expression changes of CD161, KLRG1, PD-1 and CD56. Comparison of NK cells extracted from peripheral blood and synovial fluid show a differential phenotype with the elevation of activation markers such as NKG2A and CD69 and the corresponding downregulation of CD16 and CD57. PB: peripheral blood, SF: synovial fluid. P-values were calculated as described in the methods section where p-values above 0.05 were considered not significant (n.s.).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. systemic immune activation. Cellular interaction mapping revealed mainly NK/neutrophil interactions of patients' NK-cells, while interactions with B-cells, T-cells or monocytes were negligible.

T-cells also displayed profound local and systemic alterations. Cellular interaction mapping revealed that next to NK-cell/neutrophil interactions, interactions between B-cells with monocytes and T-cells with neutrophils characterize joint inflammation.

Conclusion: This paired high-dimensional analysis revealed systemic and local alterations in NK-cell subsets shaped by co-existing developmental stages and immune regulatory mechanisms. Cellular interaction mapping indicated that neutrophils are a main interaction partner of NK-cells in inflamed joints.

Spatial Transcriptomics Reveal Altered Immune Dynamics Regulating Placental Development In a Humanized-TLR8 Mouse Model of Spontaneous Anti-Phospholipid Antibody Induced Pregnancy Loss

Yunwei Xia[1], Paul Hoover[2], Arnon Arazi[3] and Anne Davidson[1], [1]Feinstein Institutes for Medical Research, Manhasset, NY, [2]Brigham and Women's Hospital, Boston, MA, [3]Feinstein Institutes for Medical Research, Acton, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0916–0933) Innate Immunity Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: TLR8 has been implicated in adverse outcomes of human pregnancy. We previously reported a mouse model of spontaneous aPL-induced pregnancy loss in *Sle1* mice expressing a human TLR8 transgene (Sle1.hTLR8tg). These mice experience dystocia, fetal resorptions, and placental developmental abnormalities, with both the *Sle1* and *hTLR8* loci required for the phenotype. Growth defects occur as early as embryonic day (e)8.5; bulk RNA-seq and flow cytometry revealed immune dysregulation, including decreased expression of IL15, decreased uterine (u)NK cells and increased myeloid cells as well as junctional zone thinning and placental ischemia. It is unclear how hTLR8 initiates the signaling cascade that leads to these changes in immune dynamics within Sle1.hTLR8tg placentas, or how other placental cell populations interact with uterine NK cells to regulate their recruitment and function.

Methods: To better define the spatial relationships during Sle1.hTLR8tg pregnancy, placental tissue was harvested from Sle1 and Sle1.hTLR8tg mice at e9.5 (decidualization and spiral artery remodeling occurring) and e13.5 (fully formed placenta). Spatial transcriptomics (n=2-3 per group, per timepoint) was performed using the 10x Xenium platform and a predesigned Mouse Tissue Atlas panel (379 gene targets) together with a custom panel (89 immune genes, including *hTLR8*).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

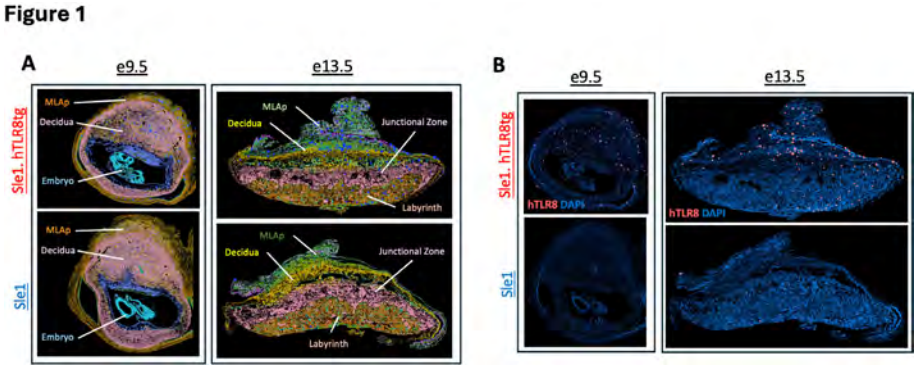

Figure 1. Spatial transcriptomics of e9.5 and e13.5 placentas in Sle1 and Sle1.hTLR8tg mice. A. K-Means Clustering at e9.5 (k=7) and at e13.5 (k=8) corresponds with distinct placental layers and cells types present during each stage of placental development. B. hTLR8 expression (red) with DAPI staining (blue) in Sle.1hTLR8 and Sle1 placentas at e9.5 (left) and e13.5 (right).

Results: K-Means clustering identified major placental regions, including decidua, junctional zone, labyrinth, and mesometrial lymphoid aggregate of pregnancy (MLAp) (**Fig.1A**). *hTLR8* was expressed only in Sle1.hTLR8tg placentas, primarily in decidua and MLAp, and in low amounts in the junctional zone and labyrinth (**Fig.1B**). *hTLR8* expression co-localized preferentially with *Itgam* (CD11b) (**Fig.2A**) but also with a small number of stromal cells. At e9.5, Sle1.hTLR8tg placentas displayed clusters of immune cells (*Cd8a, Ifng, Ncr1, Klrd1, Klrb1c, Itgam*) at the junction of the MLAp and decidua (**Fig.2B**) not observed in *Sle1* placentas and persisting through d13.5, suggesting an inflammatory/cytotoxic phenotype. An increase in placental CD8 cells was confirmed by flow cytometry. NK cell receptors (*Klrb1c, Ncr1, Klrd1*) and granzymes showed variable downregulation patterns, depending on the sub-type and placental region (**Fig.3A-B**) *Ifng* and *Cd8a* were expressed both in the MLAp and decidua (**Fig.3C**).

Conclusion: Several unique uNK cell subsets populate mouse and human placentas. The different distribution and variable downregulation of NK cell receptors and granzymes in our spatial data suggests a greater degree of uNK cell heterogeneity than previously appreciated. Future studies include understanding if these NK receptor expression patterns reflect different functions (e.g. differential granzyme production) and looking for potential correlations with human uNK subsets.

Additionally, increased expression of *Cd8a* and *Ifng* in the MLAp and their close proximity to clusters of myeloid and uNK cells suggests a pro-inflammatory environment by which myeloid cells are activated via hTLR8 and activate CD8 cells to kill target cells such as stromal and uNK cells that are required for production of key cytokines and placental growth factors.

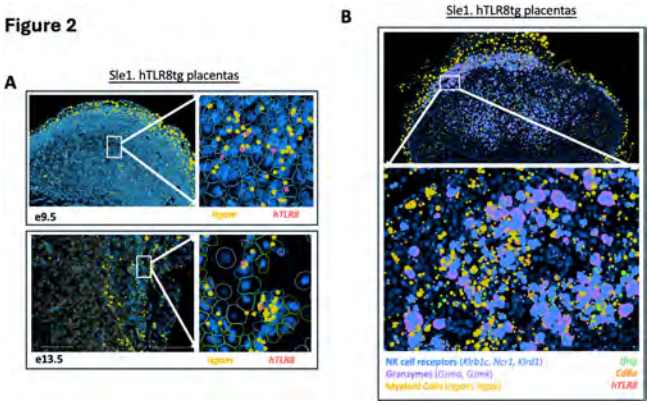

Figure 2. Co-localization of hTLR8 and immune-related genes suggests inflammatory milieu in Sle1.huTLR8tg placentas. A. Sle1.huTLR8tg placentas at e9.5 (top) and e13.5 (bottom) with inlay showing co-expression of hTLR8 (pink) with Itgam (gold-CD11b). B. Local clusters of NK cells (represented by granzyme and NK cell receptor genes), myeloid cells (represented by Itgam and Itgax), along with Ifng, Cd8a, and hTLR8 in e9.5 Sle1.huTLR8tg placenta.

Figure 3

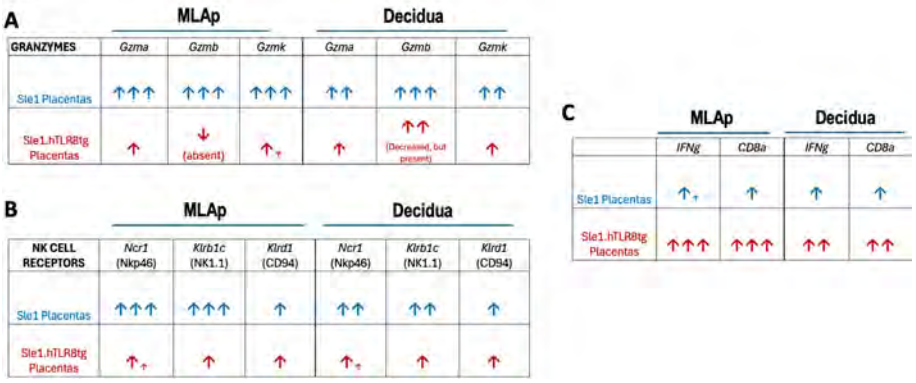

Figure 3. Immune cell-related gene expression patterns in Sle1 and Sle.1hTLR8tg placentas at e9.5. A. Granzyme genes were all downregulated in Sle1.hTLR8tg placentas compared with Sle1 placentas, but Gzmb downregulation was markedly different between the MLAp (where it was virtually absent) and the decidua (with only a modest decrease in expression). B. NK cell receptor genes were similarly downregulated in Sle1.hTLR8tg placentas, but Klrb1c showed the largest decrease whereas Klrd1 remained unchanged. Expression of Ncr1 and Klrb1c differed between the MLAp and decidua regions, suggesting a distinct composition of uNK subsets in each region. C. Ifng and Cd8a expression were both increased in Sle1.hTLR8tg placentas, particularly in the MLAp, with the large majority of Ifng co-localizing with Cd8a+/Itgam-/Itgax- cells (as opposed to cells expressing NK cell receptor genes), showing that CD8+ T cells are the main producers of IFNg at e9.5 in Sle1.hTLR8tg placentas.

The Use Of Preclinical Models To Understand Drivers Of Lupus Pathogenesis

Arielle Glatman Zaretsky[1], Carley Tasker[1], Pablo Abreu[1], Ciara Torres[2], Li-Hong Ben[1], Scott MacDonnell[1], Andre Limnander[1] and Jamie Orengo[1], [1]Regeneron, Tarrytown, NY, [2]Regeneron, Tarrytown

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic, multisystem autoimmune disease with a prevalence of 1.4-15.13/100,000 adults globally. SLE is highly heterogenous and can involve dysregulation of the adaptive and innate arms of the immune system, leading to aberrant lymphocyte activation, autoantibodies, immune complex formation, and/or organ damage. Notably, clinical benefit has been demonstrated in subsets of lupus patients. Thus, it is critical to appropriately model disease and differentiate disease drivers in relevant preclinical models, allowing better stratification of patient subsets for the development of effective therapeutics and opening the door for new target discovery.

Methods: Two mouse models of lupus-like disease were evaluated: NZB/W lupus prone mice and C9orf72-deficient mice, which display a lupus-like phenotype previously described to include elevated autoantibodies and circulating cytokines, glomerulonephropathy, splenomegaly and lymphadenopathy. Profiling of immune populations and serological readouts was performed over time using age matched female WT, NZB/W, and C9orf72 KO animals. Overexpression of IFNα via hydrodynamic DNA delivery (HDD) was used to evaluate the role of IFNα in these strains, while TACI-Ig-mediated B cell depletion was performed to determine the contribution of B cells to pathogenesis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The respective contributions of IFNa and BAFF, representing pathways with approved targeted therapeutics in SLE, were evaluated and analyzed between these strains. Systemic low dose IFNα synchronizes and significantly accelerates disease progression across NZB/W animals, while disease progression in C9orf72$^{-/-}$ mice is unaltered by overexpression of IFNα. These data suggest that lupus-like disease in NZB/W mice can be exacerbated by IFNα and thus may model patients for whom Type I IFN is a key driver of disease. Although disease in C9orf72$^{-/-}$ is unchanged by IFNα, overexpressing TACI-Ig to bind and sequester BAFF and APRIL in the C9orf72-deficient lupus model reversed lupus-associated phenotypes. TACI-Ig-mediated depletion of BAFF/APRIL in C9orf72$^{-/-}$ resulted in a decrease in B cells and a rapid reduction in anti-dsDNA antibodies. These data indicate that the C9orf72$^{-/-}$ model captures the dysregulated B cell tolerance pathways that can drive disease in some subsets of lupus patients.

Conclusion: Here we describe two models of SLE-like disease that respond differently to manipulation of key pathways targeted by existing approved therapeutics. Taken together, these data suggest that NZB/W and C9orf72$^{-/-}$ mice recapitulate distinct disease mechanisms relevant to human patients and can be used in preclinical efforts to validate therapeutic strategies for a heterogeneous SLE patient population.

Oral Antibiotic Treatment Reduces Anxiety in a Murine Model of Neuropsychiatric Manifestations of Systemic Lupus Erythematosus

Cecilia Stumpf[1], Brianna Thompson[2], Vanessa Manada De Lobos[2] and Carla Marie Cuda[3], [1]Northwestern University, Elmhurst, IL, [2]Northwestern University, Chicago, [3]Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Unclear mechanisms underlying diffuse NPSLE (anxiety, cognitive dysfunction) lead to the devastating impact of this disease on patients' health-related quality-of-life. Dysbiosis of gut microbiota is observed in patients with, and mouse models of, SLE. Fecal microbiota transfer from SLE-prone B6.*Sle1Sle2Sle3* (B6.TC) mice, as well as patients with SLE, induced production of anti-dsDNA antibodies as well as an inflammatory response in germ-free C57BL/6 (B6) mice, suggesting dysbiosis may be involved in SLE pathogenesis. We and others show that oral antibiotic treatment (OAT) have beneficial effects on systemic manifestations in SLE-prone mice. However, the impact of OAT on behavioral deficits in SLE is largely unexplored. OAT can induce anxiety and cognitive deficits in control mice, yet OAT has shown dramatically protective effects in Alzheimer's disease and multiple sclerosis models, potentially through modulating the gut-microbiota-brain-axis and altering microglial activation. As we find microglial activation in NPSLE-prone mice, we will elucidate the impact of OAT on behavioral deficits in NPSLE.

Methods: Separate cohorts of 4-week-old female B6 and B6.TC (Jackson #007228) mice were given autoclaved water plus ampicillin, neomycin sulfate, metronidazole (1 g/L), and vancomycin (0.5 g/L), supplemented with 2% sucralose or 1% sucrose 2x/wk for 5 wks with no observable weight loss. Mice underwent behavioral tasks. Perfused brains from the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

sucralose cohort were extracted after intravenous CD45 labeling to exclude remaining circulating immune cells, dural meninges were removed, and cells were analyzed by flow cytometry. Brains from the sucrose cohort were similarly processed, individual preps were hashed, and live $CD45^+$ cells were FACSorted (n=3/strain) for cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq; 10X Genomics 5' v2; analysis pending).

Results: OAT significantly reduced anxiety in B6.TC mice in the Zero maze task with no positive effect on known defects in coordination and motor learning in the Rotarod task. As expected, OAT induced mild anxiety in B6 mice in the Zeromaze task. Results were independent of the choice of sweetener. OAT did not impact systemic disease markers, including splenomegaly and lymphadenopathy. Analysis of sucralose-treated mice shows characteristic increases in total microglia, the disease-associated microglia (DAM) subset, macrophages, and extra-vascular CD4+ T cells in B6.TC mice compared to B6 mice. We did not observe the characteristic increase in extra-vascular CD8+ T cells, suggesting sucralose may impact this population in B6.TC mice. Strikingly, analysis of OAT mice shows further expansion of total microglia, DAM, and macrophages, as well as an increase in extra-vascular CD8+ T cells in B6.TC mice compared to B6 mice.

Conclusion: We find that OAT reduces anxiety in NPSLE-prone mice and further expands total microglia, DAM, and macrophage populations already elevated in disease. Future studies will identify changes in the activation status of these and other immune cell subsets in the brain by CITE-seq to interrogate potential mechanisms linking dysbiosis of gut microbiota to anxiety and other manifestations of NPSLE.

Ultrasound-Mediated Blood–Brain Barrier Permeabilization Enables Targeted Drug Delivery in a Murine Model of Neuropsychiatric SLE

Doaa Tehawey[1], Roni Gattegno[2], Baruh Polis[1], Mike Bismuth[2], Melodie Zaknoun[1], Tali Ilovitsh[2] and **Chaim Putterman**[3], [1]Azrieli Faculty of Medicine, Safed, Israel, [2]Tel Aviv University, Tel-Aviv, Israel, [3]Albert Einstein College of Medicine, Safed, Israel

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Neuropsychiatric SLE (NPSLE) is a severe complication of SLE, characterized by CNS involvement leading to cognitive, behavioral, and neurological deficits. While monoclonal antibodies may offer therapeutic potential for the treatment of SLE, their efficacy in NPSLE is limited by the blood brain barrier (BBB), which restricts drug delivery into the CNS. We evaluated a novel method of focused ultrasound (FUS) with nanobubbles (NB) as a noninvasive strategy to transiently open the BBB and enhance CNS antibody delivery in a NPSLE model.

Methods: We utilized 12-week-old female MRL/lpr mice, an established model of NPSLE. Two separate experiments were conducted to evaluate BBB opening. Firstly, two 10 week-old female B6 mice underwent retro-orbital injection of NB (180 nm diameter, phospholipid shell, octafluoropropane gas core) followed by unilateral transcranial FUS treatment targeting the right hemisphere (NB-FUS), according to a previously established non-neurotoxic protocol from the Ilovitsh laboratory (Gattegno R et al, *J Cont Release, 369*, 506-516, 2024). FUS parameters included a center frequency of 850 kHz, peak negative pressure of 210 kPa, 4 ms pulses at a repetition frequency of 1 Hz, applied for a total duration of 1 minute.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

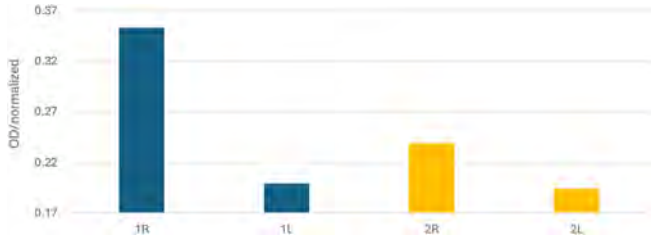

Figure 1. Brain EB concentration. Optical density reading comparison between the FUS-treated right hemispheres (R) and the untreated left hemispheres (L) within individual mice.

Immediately after FUS application, Evans blue (EB) dye was injected retro-orbitally. Mice were sacrificed, and the brain hemispheres were separated, individually homogenized, and quantitatively analyzed using ELISA to measure the EB concentration and assess differential BBB permeability between the treated and untreated sides.

In the second experiment, 6 MRL/lpr lupus-prone and 6 MRL+ control female mice at 10 weeks of age underwent the same NB-FUS protocol. In this study, BBB permeability was assessed by quantitating the fluorescence of two tracers: EB and FITC-labeled dextran (150 kDa), both injected immediately after FUS application. Brains were harvested and processed for fluorescence microscopy to evaluate the intensity of tracer uptake and its distribution in the brain parenchyma.

Results: Quantitative analysis revealed notably higher EB concentrations in the NB-FUS-treated hemispheres in both mice. The following normalized EB concentrations were observed: right hemisphere (1R: 0.353, 2R: 0.239) and left hemisphere (1L: 0.199, 2L: 0.194) (Figure 1), indicating successful spatially targeted disruption of the BBB. In the second experiment, EB penetration was macroscopically visible within the FUS targeted hemisphere in 8/12 mice. Fluorescence microscopy confirmed localized EB and FITC tracer presence in the treated hemisphere with minimal signal in the contralateral side, indicating successful BBB permeabilization. Representative mice are shown in Figure 2. No obvious differences in dye delivery were seen between the two strains. Repeating this experiment with a labeled murine antibody specific for a candidate NPSLE target is in process.

Conclusion: FUS with NB effectively and safely increases BBB permeability in a classic murine NPSLE model. These results support the potential application of this innovative method for targeted CNS delivery of peripherally administered therapeutic agents in autoimmune neuroinflammatory diseases, including NPSLE.

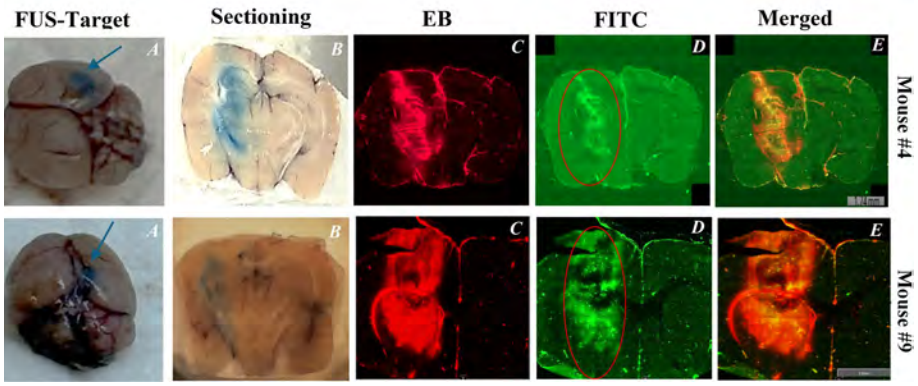

Figure 2: Focal ultrasound application following nanobubble administration locally permeabilizes the BBB and enables delivery of an antibody-sized molecule into the CNS. A. Representative image of MRL/lpr mouse brains immediately after ultrasound treatment, showing localized blue staining indicative of EB penetration into the brain parenchyma. B. A brain section during cryostat slicing, demonstrating widespread EB presence throughout the targeted ultrasound-treated region. C. Magnified (4×) image of the brain highlighting EB distribution in red fluorescence within the treated area. D. Magnified (4×) image showing FITC fluorescence in green (circled in red), indicating distribution of this additional tracer within the treated brain region. E. Merged image of C and D combining EB (red) and FITC (green) signals, demonstrating both tracers' penetration and co-localization within the ultrasound-targeted area.

MRL-lpr Mice Display Altered Nociception: A new model for lupus peripheral neuropathy

Melodie Zaknoun[1], Doaa Tehawey[1], Baruh Polis[1] and **Chaim Putterman**[2], [1]Azrieli Faculty of Medicine, Safed, Israel, [2]Albert Einstein College of Medicine, Safed, Israel

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

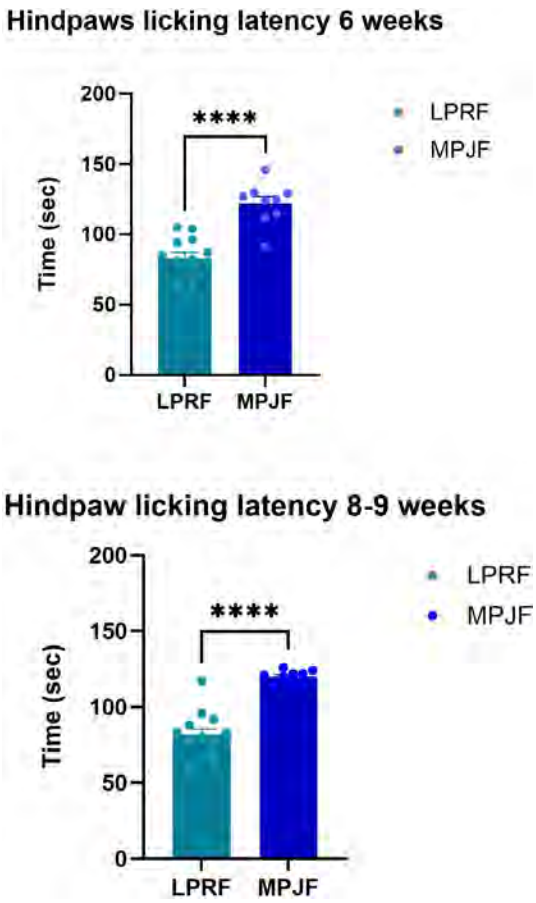

Figure 1: Top: Hindpaw licking latency at 6 weeks of age. Bottom: Hindpaw licking latency at 8-9 weeks of age. LPRF, female MRL/lpr mice; MPJF, female MRL/+ mice.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

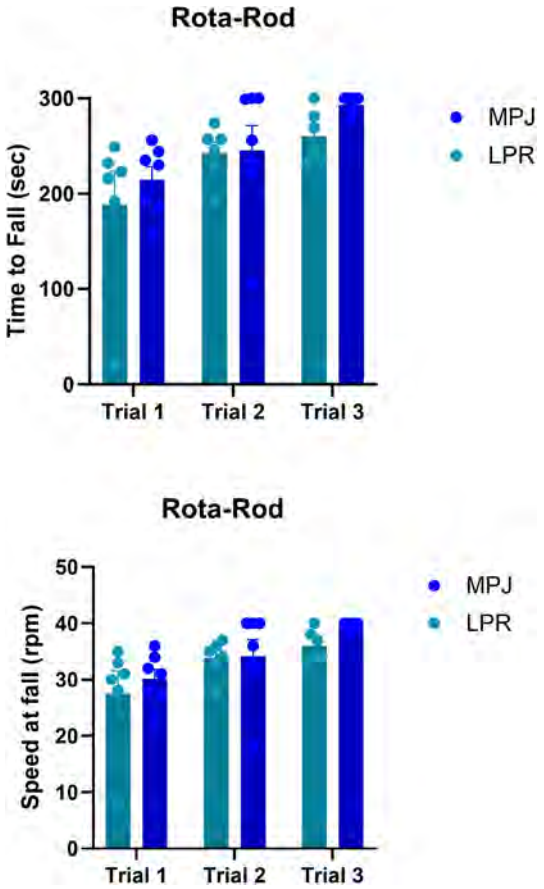

Figure 2: Top: Time in seconds until the mouse fell off the apparatus. Bottom: Speed recorded at the time of the fall. MPJ and LPR, female MRL/+ and MRL/lpr mice at 15 weeks of age, respectively.

Background/Purpose: Of the 19 ACR case definitions for NPSLE, seven involve the peripheral nervous system. MRL/lpr mice spontaneously develop anti-dsDNA antibodies, nephritis, and skin disease, as well as depressive-like behavior and cognitive abnormalities (Polis B, Autoimmunity, 57,2024). However, while peripheral neuropathy is common in human lupus (Florica B, Sem Arth Rheum, 203,2011), whether MRL/lpr mice display peripheral nervous system disease has not been carefully studied.

Methods: To better evaluate sensory function and develop an assay to easily monitor the effects of therapeutic interventions, we enhanced traditional rodent nociception testing by incrementally raising the temperature from 40 to 52°C within 180 seconds. The test focuses on paw licking, which signifies the behavioral reaction to the thermal stimulus. This careful modulation allowed us to accurately record the latency, or response time, for the animals to lick their fore- and hind paws. Female MRL/lpr, and age and sex matched congenic control MRL mice, were tested at 6, 8, and 12 weeks of age.

Rota-Rod testing was performed using Stanford's laboratory protocol. Time to fall and speed at fall were both measured for analysis. Female MRL/lpr and age and sex matched congenic control MRL mice were tested at 15 weeks of age.

A standard open field test was done where the animals were left to explore the field for 5 minutes in minimum abrasive conditions. The total time spent in the center zone and the total distance traveled by each mouse were measured. Female MRL/lpr and age and sex matched congenic control MRL mice were tested at 15 weeks of age.

Results: Nociception: We found that already at 6 weeks of age, while there is no difference in anti-dsDNA antibody levels or other characteristic clinical or serologic signs of disease activity, MRL/lpr mice exhibited a notable increase in thermal hyperalgesia, as seen by a decreased mean latency until hind paw-licking responses (withdrawal): 82.69+/-15.03 seconds (n=13)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

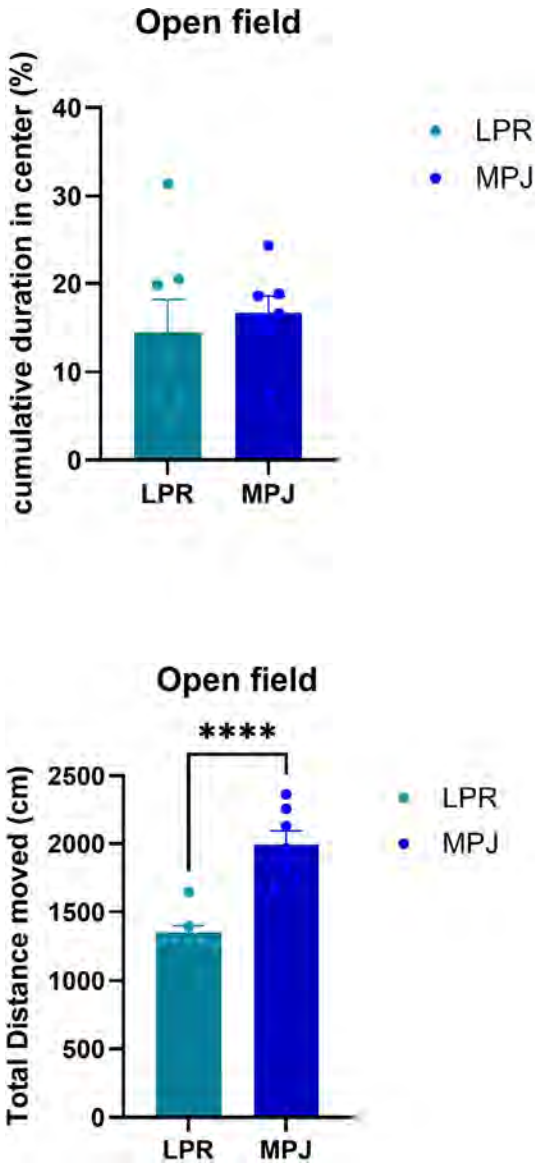

Figure 3: Bottom: Cumulative time spent in center zone shown in %. Top: Total distance traveled in cm. LPR and MPJ, female MRL/lpr and MRL/+ mice at 15 weeks of age, respectively.

compared to the control MRL strain 122+/-15.15 (n=9) (Figure 1) ($p< 0.0001$, Unpaired t-test). Similar thermal hyperalgesia responses were observed in MRL/lpr mice also at 8-9 weeks ($p< 0.0001$, Figure 1), and 12 weeks of age (data not shown). Similar testing using a cold plate approach is in process.

Rota-rod: No significant differences were observed in the time to fall/speed at fall between the MRL/lpr mice (n=6) and the MRL strain (n=7)(Figure 2), a finding not supporting a difference in proprioception between these strains.

Open Field: MRL/lpr showed a significant decrease in total distance traveled in the open field (1348+/-140.1, n=7) compared to the MRL strain (1995+/-263.3, n=7 ($p< 0.0001$, Unpaired t test), a result not supporting locomotor hyperactivity in the MRL/lpr strain. There was no significant difference observed in the cumulative time spent in the center zone (Figure 3).

Conclusion: MRL/lpr mice display significantly heightened temperature sensitivity already at 6 weeks of age, before many other disease manifestations are evident.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Short Term Antibiotic Treatment Improves the Neurobehavioral Phenotype of MRL/lpr Mice

Melodie Zaknoun[1], Doaa Tehawey[1], Baruh Polis[1] and **Chaim Putterman**[2], [1]Azrieli Faculty of Medicine, Safed, Israel, [2]Albert Einstein College of Medicine, Safed, Israel

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Neuropsychiatric lupus (NPSLE) is a common and prognostically significant manifestation of SLE, affecting 20-40% of lupus patients. The ACR identified 19 clinical syndromes associated with NPSLE, which range from severe manifestations such as psychosis and transverse myelitis to milder involvement in the form of headaches, mood disorders, and cognitive deficits.

The gut microbiota has been implicated in the pathogenesis of autoimmune diseases, including SLE. Microbes significantly influence mammalian metabolism, the immune system, and behavior. The gut-brain axis is a communication network connecting the CNS with the gut's enteric nervous system, facilitating information exchange between the brain and digestive functions. Recent studies emphasize the gut microbiota's crucial role in this relationship.

Our goal was to examine whether modulation of the gut-brain axis using a short course of antibiotic treatment would affect the development, progression, and severity of neuropsychiatric disease in the MRL/lpr strain.

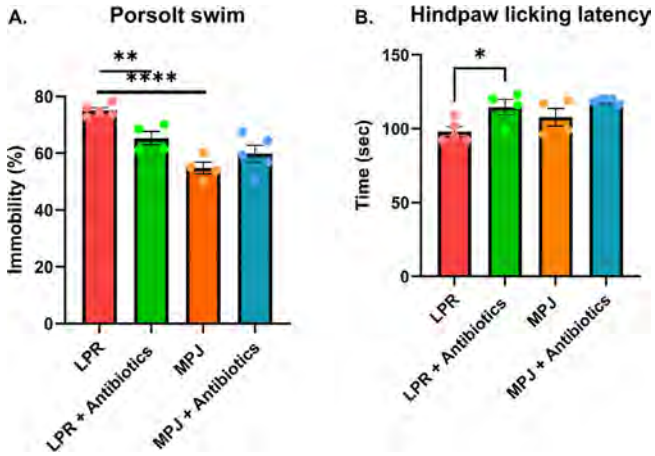

Figure 1: A. In the Porsolt swim test, the mouse is placed in a water filled cylinder for 10 minutes. Mobility time was measured, and immobility is calculated based on the ratio of time that the mice were immobile (i.e. displaying despair, or depressive-like behavior) over the total time. B. To test thermal hypersensitivity, mice are placed on a plate heated to a temperature of 40°C and increasing to 52°C within three minutes. The latency, or response time, for the mice to lick their hind paws was measured for analysis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

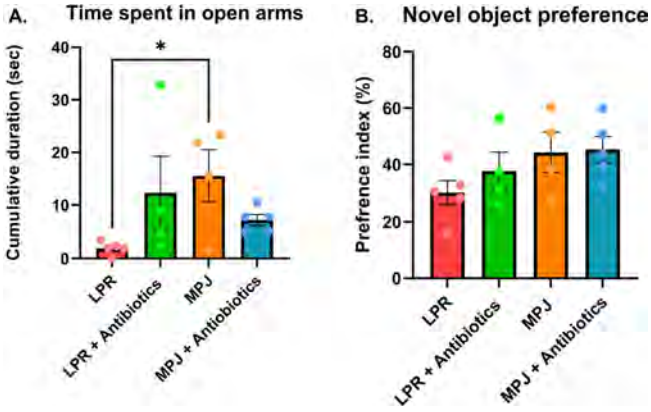

Figure 2: A. To assess for anxiety, the elevated plus maze test was employed. The maze was placed in a dark infra-red lit room and the mouse placed on the maze for 5 minutes. Time spent in open arms compared to the total time was recorded and analyzed using Ethovision software. B. In assessing memory with the novel object location test, each mouse was first placed in an arena with two similar objects for 5 minutes. After an interval of 60-90 minutes, the mouse is put in the same arena in which one of the objects was moved to a new location. The preference index (normal >50%) was calculated by dividing the time spent in the area of the newly moved object by the total time spent in both object zones.

Methods: Antibiotic Treatment: 6-week-old MRL/MpJ and MRL/lpr mice were given vancomycin 0.5 g/L in drinking water for 2 weeks, with the water being refreshed every 3 days. Control mice of these strains received regular water with no additives.

Behavioral Testing: After 2 weeks of treatment, the mice were given 4 weeks for gut microbiome recovery. Behavioral testing began at 12 weeks of age, and included standard tests for depressive-like behavior (Porsolt swim test), thermal hypersensitivity (hot plate), anxiety (elevated plus maze (EPM)), and cognition/memory (novel object location (NOL)), with rest periods of 1-3 days between the tests.

Results: Porsolt swim test: MRL/lpr showed significantly worse depressive-like (despair) behavior as shown by increased immobility in the Porsolt swim test (75.1+/-2.2 seconds) as compared to the MRL/MpJ group (65.3+/-4.7; P< 0.0001). Moreover, antibiotic-treated MRL/lpr showed significant attenuation of this phenotype (less immobility), as compared to non-treated MRL/lpr mice (Figure 1A).

Hot plate: Antibiotic treated MRL/lpr mice showed significantly increased latency until hind paw licking (114.5+/-10.7 vs 98+/-7.4 in the untreated group, p=0.029), indicating decreased thermal hypersensitivity and improved nociception. No significant change was observed in thermal hypersensitivity with antibiotic treatment in the MRL/MpJ strain (Figure 1B).

EPM: Untreated MRL/MpJ mice displayed less anxiety as compared to MRL/lpr mice, as reflected by significantly more time spent in the open arms (15.5+/- 9.9 vs 1.9+/-1.2, p=0.018). Notably, antibiotic treated MRL/lpr mice trended to less anxiety compared to the untreated MRL/lpr group (Figure 2A).

Novel Object Location: Although untreated MRL/lpr mice did appear to have the worst performance on this cognitive test of spatial memory, no significant differences were observed between the groups (Figure 2B).

Conclusion: A short term course of intestinal decontamination with oral vancomycin attenuates several key features of neuropsychiatric disease in MRL/lpr lupus mice. Studies to determine the effects on other disease features and elucidate the mechanisms of protection are in progress.

Exploring the Mechanism of Action and Related Biomarkers of BTK Inhibitor/Degrader in Systemic Lupus Erythematosus

Chengfeng Xue[1], Jingjing Wang[1], Mengwen Huang[1], Ting Liu[1], Panpan Wang[1], Donghai Chen[2], Xue Wang[1], Yawei Xu[1], Yajun Gong[1], Jun Yang[1], Xiaoshan Yu[1], Ke Wang[1], Yuqing Zhu[1], Kaixuan Zhu[1], Tianqi Tang[1], Wantong Qi[1], Yaqiong Pei[1], Qiyao Zhang[1], Fugang Li[2], Qingyang Gu[1] and Xiangnan Qiang[1], [1]WuXi AppTec, Shanghai, China (People's Republic), [2]WuXi ApptTec, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with diverse clinical and immunological manifestations. Bruton's tyrosine kinase (BTK) is a crucial intracellular kinase in regulating B cell development and function, and also showed pivotal impacts in numerous pathways. Small molecule inhibitors of BTK have been widely used in treating B-cell malignancies and autoimmune diseases (e.g., rheumatoid arthritis, atopic dermatitis, SLE). BTK degraders can eliminate the kinase scaffolding function and remove resistance mutations, displaying a therapeutic potential in SLE. However, the mechanism of action of BTK inhibitors/degraders in SLE is not well understood. The aim of this study is to explore the mechanism of action and identify biomarkers for BTK inhibitor/degrader by comparing cellular and protein-level changes in the mouse SLE model before and after treatment, and to predict its clinical efficacy and mechanism.

Methods: scRNA-seq and protein data from healthy donors and SLE patients, obtained from public databases, were used to narrow down the scope of biomarker research. Adoptive transfer of $CD4^{+}$T cells from BM12 spleen and lymph node to C57BL/6 mice was performed to induce the lupus-like model. Normal, vehicle, Ibrutinib (BTK inhibitor), and NX-5948 (BTK degrader) were administered daily, and the mice were sacrificed around week 2. The plasma levels of anti-double-stranded DNA (anti-dsDNA) IgM and IgG were detected by ELISA. Cell subtypes, activation, proliferation and BTK expression in splenic cells were characterized by flow cytometry. The cytokines in the plasma were analyzed by Olink technology.

Results: The BM12-induced SLE mouse model generally shares a common set of features that correlate with clinical manifestations of human SLE. Compared to normal mice, the levels of anti-dsDNA IgG and IgM increased in the model group, with an expansion of Tfh, GCB, and plasma cells. Olink analysis results indicate elevated levels of cytokines and chemokines, including TNF, IFN-γ, IL-6, CCL4, and CSF1. Both Ibrutinib and NX-5948 attenuated the BM12-induced lupus-like symptoms, including the reduction of anti-dsDNA IgM and IgG. Compared to Ibrutinib treatment, the BTK protein level in B cell, dendritic cell, monocyte and macrophage were effectively decreased in NX-5948 treatment group. Both Ibrutinib and NX-5948 treatment decreased the number of GCB, plasma cell and the expression of CD69 and CD86 in B cells. The reduction of IL-4 and IL-6 in plasma, along with the downregulation of CD25 expression on B and T cells, suggests that the use of BTK inhibitors and degraders inhibit the interaction and activation of B and T cells.

Conclusion: This study conducted a detailed comparative analysis at the cellular and protein levels among normal mice, SLE model mice, and those treated with a BTK inhibitor or degrader. Our study compared clinical data with disease model data to determine their correlation and used this model to explore the mechanisms of action of BTK inhibitors and degraders. We hope that this research approach can be applied to the study of more diseases.

Resident Macrophages Localize Near Fibroblasts and Drive Reprogramming in Lupus Nephritis Through Direct and Soluble Signaling

Chirag Raparia[1], Paul Hoover[2], Arnon Arazi[3], Nir Hacohen[4] and Anne Davidson[1], [1]Feinstein Institutes for Medical Research, Manhasset, NY, [2]Brigham and Women's Hospital, Boston, MA, [3]Feinstein Institutes for Medical Research, Acton, MA, [4]Broad Institute of MIT Harvard, Cambridge, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is a severe manifestation of SLE that can progress to renal fibrosis, and eventual renal failure. In LN, tubulointerstitial inflammation and macrophage infiltration are associated with a poor prognosis. Alongside macrophages, the renal fibrotic niche contains fibroblasts, and endothelial cells; however, the mechanisms of their crosstalk remain poorly understood. Using spatial transcriptomics in LN mouse models and single-cell analysis of in vitro cocultures, we reveal macrophage-driven fibroblast activation as a potential driving feature of renal fibrosis in LN.

Methods: Spatial transcriptomics in NZB/W F1 mice was performed using the 10x Genomics Xenium 389 gene platform, with markers for cell interior and boundaries and an additional gene panel customized to identify high-resolution myeloid populations. Primary NZB/W mouse embryonic fibroblasts (MEFs) were cocultured with FACS-sorted renal resident macrophages (RMs) from nephritic and pre-nephritic NZB/W mice. Cocultures were analyzed by flow cytometry and scRNA-seq. Data were processed using Seurat and Harmony, and cell-cell communication was inferred using CellChat. MEF scratch wound assays with conditioned media (CM) from cocultures were performed, followed by bulk RNA-seq and GSEA for pathway analysis.

Results: Resident macrophages are located in the interstitium and acquire a damage associated Spp1+ gene expression profile during nephritis. In nephritic mice, resident macrophages, and not infiltrating macrophages, preferentially colocalized with FAP^+ fibroblasts in renal infiltrates and peritubular spaces (Fig. 1A-B), correlating with areas of renal damage and fibrosis. In NZB/W MEF-RM cocultures, flow cytometry and scRNA-seq revealed *Spp1*+ and *Spp1*- macrophage populations and a heterogenous expansion of fibroblast populations, including *Fap*$^+$ and *Periostin*$^+$ MEFs, enriched for pro-fibrotic and inflammatory gene signatures (Fig. 2A). CellChat analysis identified signaling from $Spp1^+$ macrophages to Fap^+ MEFs via IL-1, TNF, and OSM, and GRN (Fig. 2B), facilitating a tissue remodeling phenotype. CM from nephritic cocultures induced a pro-inflammatory transcriptional program in MEFs, characterized by elevated *Cxcl1, Cxcl5, Cxcl14, and Hif1a*, confirmed by GSEA (Fig. 2C). Nephritic CM-treated MEFs experienced impaired wound closure in a scratch assay after 18 hours (Fig. 2D). In a separate study, we demonstrated that mouse and human LN resident kidney macrophages display similar transcriptional profiles and occupy comparable locations within the kidney. This similarity suggests that our findings in mouse models may also be applicable to human LN.

Conclusion: $Spp1^+$ resident macrophages in nephritic kidneys localize with and drive fibroblast activation and reprogramming through direct interaction and soluble signaling. Direct macrophage signaling via IL-1, TNF, OSM, and GRN promotes both pro-fibrotic and inflammatory fibroblasts, while indirect signaling induces a pro-inflammatory signature and impairs

In Vivo PanCAR Therapy Utilizing Circular RNA for Treatment of Autoimmune Diseases

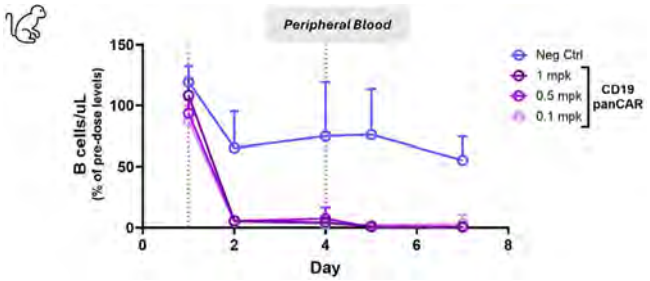
Juliet Crabtree, Thomas Lee, David Soto, Prapti Vyas, Akinola Emmanuel, Matthew Theisen, Karolina Kosakowska, Maja Sedic, Rajat Das, Muthusamy Jayaraman, Megan Hoban, Joe Bolen and **Isin Dalkilic-Liddle**, Orna Therapeutics, watertown, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Recently, traditional *ex vivo*-generated chimeric antigen receptor T (CAR-T) cell therapies have shown success in the clinic for autoimmunity indications. However, manufacturing, safety, and accessibility remain potential challenges in the *ex vivo* CAR-T approach. The prospect of an *in vivo* CAR-T cell therapy, without the need for patient cell isolation, cell culturing, and the safety risks associated with preconditioning regimens, remains a therapeutic goal. Orna Therapeutics' panCAR™ combines a synthetic, circular, coding RNA platform (oRNA®) and proprietary immunotropic lipid nanoparticle (LNP) to drive CAR expression on the surface of immune effector cells after *in vivo* administration, with a potential to provide a transient, re-dosable, and scalable immune cell therapy without the need for preconditioning lymphodepletion.

Methods: anti-CD19 panCAR™ is a non-viral platform combining anti-CD19 CAR expressing oRNA with a proprietary immunotropic LNP. Anti-CD19 panCAR was evaluated for expression in T cells and depletion of target B cells *in vitro* and *in vivo* in humanized CD34+ models upon intravenous injection. In a humanized model of lupus, anti-CD19 panCAR was dosed four times weekly, B cell levels and anti-double stranded DNA (anti-dsDNA) titers were evaluated. In cynomolgus macaques, anti-CD19 panCAR was dosed intravenously twice three days apart (Q3Dx2) at three doses levels (0.1, 0.5, and 1mpk). B cell levels were then evaluated in periphery and in lymphoid tissues by flow cytometry.

Results: With anti-CD19 panCAR oRNA-LNP, high surface expression of anti-CD19 CAR was observed in a dose-dependent manner and was maintained over 96 hours on human and NHP immune cells *in vitro*. Furthermore, CAR-mediated cytotoxicity was observed for T cells from both species, killing CD19-expressing cell lines. In the humanized mouse model, anti-CD19 CAR oRNA-LNP when administered intravenously showed significant B cell reductions in peripheral blood, spleen, and bone marrow at 24 hours (55-95%) and sustained depletion 7 days after a single dose. The functional activity of anti-CD19 panCAR can be adjusted by the dose level and dose number administered, demonstrating the tunability of the platform. *in vivo* panCAR, injected in a humanized mouse model of lupus, showed complete reduction of



CD19 panCAR completely depletes B cells in peripheral blood in NHPs: Cynomolgus macaques were dosed day 1 and day 4. CD20+ B cell levels were measured in peripheral blood by flow cytometry. Levels are normalized to average B cell levels from two pre-dose timepoints for each animal. mean+/- st dev

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. CD19 panCAR robustly depletes B Cells in lymphoid tissues in NHPs. Animals were taken down 3 days post last dose and CD20+ B cell levels were measured in lymphoid tissues by flow cytometry.

B cells accompanied by anti-dsDNA titer reduction. While mice receiving rituximab exhibited reduced B cell numbers, the depletion did not correlate with reduced anti-dsDNA titers. Finally, in NHPs, our cross-reactive anti-CD19 compound showed complete (>98%) and sustained depletion of B cells in peripheral blood two weeks after the last dose and showed robust depletion in the spleen (>99%), lymph nodes (>97%), and bone marrow (>96%) three days after the last dose.

Conclusion: Our platform provides a non-viral, transient, tunable, and scalable approach without the need for preconditioning lymphodepletion that shows robust activity *in vitro* and *in vivo*. In NHPs intravenous dosing resulted in deep B cell depletion in peripheral blood and lymphoid tissues. Collectively, our pre-clinical data demonstrates the potential of Orna's *in vivo* panCAR therapy to treat B cell mediated autoimmunity.

Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Though immune targeted therapies have improved outcomes in lupus nephritis, a significant number of patients experience renal damage and even progression to end stage renal disease. Recently, sodium and glucose cotransporter 2 inhibitors (SGLT2i) have proven efficacious in preventing adverse renal outcomes in patients with a variety of chronic diseases. In addition to inducing shifts in cellular metabolism, SGLT2i have anti-inflammatory and antifibrotic properties. Here, we hypothesize that systemic SGLT2i-driven metabolic changes could modulate humoral autoimmunity and inflammation in lupus.

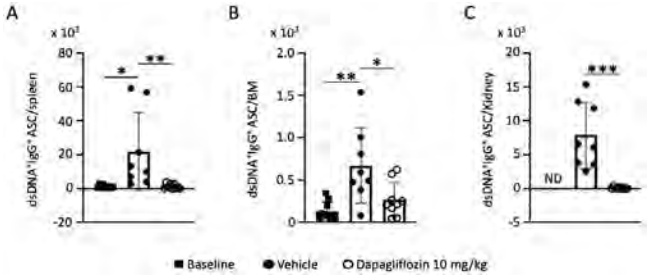

Figure 1. Dapagliflozin therapy at early stages of lupus impairs the production of splenic autoreactive antibody secreting cells (ASC) and affects their accumulation in the kidney and bone marrow (BM) of NZB/NZW female mice. 23 weeks old NZB/NZW female mice were treated with SGLT2i vs vehicle for 12 weeks. Spleen, kidney, and BM cell suspensions were used to enumerate dsDNA-specific IgG+ ASC by ELISpot. Live cells were counted by the trypan blue exclusion method to calculate the total number of autoreactive ASC per organ. A) Splenic, B) BM and C) renal dsDNA-specific IgG+ ASC were significantly reduced in NZB/NZW female mice treated with dapagliflozin. n = 8 – 10 NZB/NZW female mice/group. ND: No detected. Statistical significance was calculated with two-tailed, unpaired Student's t test in data with normal distribution or with Mann Whitney in groups with no normal distribution. *, $p < 0.05$; **, $p < 0.005$; ***, $p < 0.0005$.

Methods: 10-week-old MRL/lpr female mice were treated daily with dapagliflozin at 10 mg/kg or vehicle by gavage for 11 weeks. NZB/NZWF1 female mice were treated daily with dapagliflozin (10mg/kg) by gavage at early (23 weeks) and late disease (28 weeks) for 10-12 weeks and monitored weekly for proteinuria (n = 10 mice/experimental group). Sera was collected to measure autoantibodies, creatinine, and glucose by ELISA and colorimetric assays. Immune cells were enumerated in the spleen, bone marrow (BM), and kidneys by flow cytometry, immunofluorescence, and ELISPOT. Inflammation, fibrosis, and immune cell infiltration were assessed in kidneys by histology and quantitative PCR. Metabolite abundances were analyzed with untargeted metabolomics on kidney tissue.

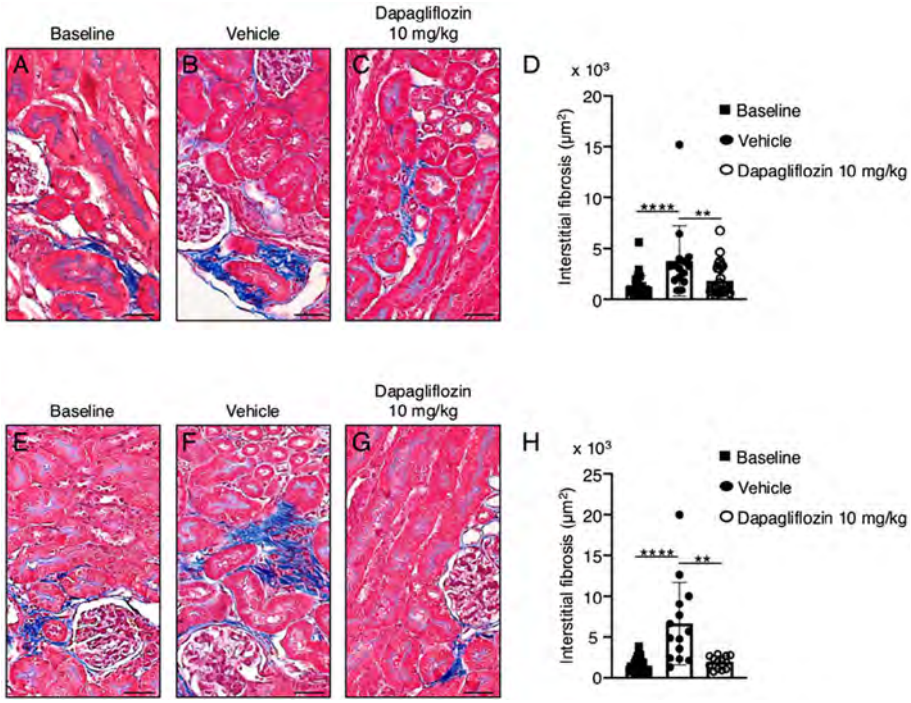

Figure 2. Dapagliflozin therapy modulates interstitial kidney fibrosis at early and advanced lupus stages in NZB/NZW female mice. 23 weeks old (early lupus) or 28 weeks old NZB/NZW female mice (advanced lupus) were treated as previously described. Kidneys were fixed in neutral buffered formalin and embedded in paraffin. Kidney sections were stained with Masson's Trichrome. Areas of interstitial fibrosis were measured with an automated tool of Zeiss microscope. A-C) Representative 200X magnification pictures of interstitial fibrosis in kidneys of NZB/NZW female mice treated with dapagliflozin at early stages of lupus. E-G) Representative 200X magnification pictures of interstitial fibrosis in kidneys of NZB/NZW female mice treated with dapagliflozin at advanced stages of lupus. Morphometric analysis of interstitial fibrosis after therapy at D) early lupus vs H) advanced lupus. Blue stain = collagen deposition. Scale bar = 20 μm. Statistical significance was calculated with two-tailed, unpaired Student's t test in data with normal distribution or with Mann Whitney in groups with no normal distribution. **, $p < 0.005$; ****, $p \leq 0.0001$.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: SGLT2i therapy unexpectedly reduced autoreactive plasma cells (aPCs) in the spleen, BM, and kidney when initiated at early stages of disease in both mouse models (Figure 1 NZB/NZW). Splenic germinal centers (GCs) and generation of plasmablasts (PBs) in both spleen and BM were significantly inhibited in NZB/NZW mice treated early with dapagliflozin ($p < 0.005$ for splenic PBs, $p \leq 0.0001$ for BM PBs, compared to vehicle treated). In contrast, though SGLT2i treatment of late disease was less efficacious to target splenic GCs, aPCs were still reduced ($p < 0.05$) in the kidney of NZB/NZW mice. T regulatory cells (Tregs) were systematically increased in the axillary lymph nodes, extrafollicular areas of the spleen, and renal interstitium of SGLT2i treated MRL/lpr mice ($p < 0.005$ compared to vehicle treated). We also observed a significant enrichment in regulatory T follicular helper cells in splenic GCs of SGLT2i-treated NZB/NZW mice ($p \leq 0.0001$). Periarterial inflammation ($p < 0.005$, $p < 0.05$) and interstitial fibrosis ($p < 0.005$) were significantly ameliorated in the kidneys of MRL/lpr and NZB/NZW mice at early and late disease (Figure 2).

Conclusion: The immune modulatory and antifibrotic effects of SGLT2i in lupus prone mice support their potential as a novel treatment approach. Considering the essential role of glucose in the formation of GCs and plasma cells, our data suggests that a shift in glucose metabolism induced by SGLT2i may be the driving force behind the decrease in germinal centers, autoreactive plasma cells, and plasmablasts in MRL/lpr and NZB/NZW mice. Additional studies are underway to further define whether SGLT2i target oxidative stress in the kidney and to elucidate the systemic effects of SGLT2i on Tregs, GCs, and autoreactive PCs.

Abstract Number: 0943

Type I and Type II IFNs have both independent and overlapping effects on SLE disease severity

Haylee Cosgrove[1], Xiaoyan Gong[1], Aidan Matunis[1] and **Jeremy Tilstra**[2], [1]University of Pittsburgh, Pittsburgh, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The pathogenesis of systemic lupus erythematosus (SLE) is thought to be strongly influenced by the interferon (IFN) signaling pathway, particularly type I IFNs (IFNα/β). However, recent work suggests a significant role for type II IFN (IFNγ) and type III (IFNλ) in SLE. While anifrolumab was recently approved for the treatment of SLE, response rates were ∼16% above placebo for lupus patients in general, and for LN, complete remission rates were ∼10% over placebo, reaching under 28%. Thus, while efficacious, this suggests an opportunity to understand why these patients were not more responsive to therapy. One potential reason is that nearly 2/3 of type I IFN genes are also regulated by IFNγ, suggesting that there may be compensatory or redundant mechanisms by which IFNs regulate lupus pathogenesis.

Methods: We created two knock-out alleles, one targeting the type I IFN receptor (Ifnar1) and one targeting the type II IFN receptor (Ifngr1) on the MRL/lpr lupus-prone background. We then intercrossed these alleles to develop a cohort comprising four separate genotypes: WT, *Ifngr1*$^{-/-}$, *Ifnar*$^{-/-}$, and *Ifngr*$^{-/-}$*Ifnar1*$^{-/-}$ (DKO) mice. These cohorts were analyzed for disease pathology, including proteinuria, renal histology, autoantibodies, and immune cell activation. To corroborate our murine

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

findings, we also assessed 3 published datasets derived from human lupus nephritis patients to evaluate gene signatures for type I vs. type II IFN activation profiles.

Results: Here, we demonstrate that deficiency of *Ifnar1* has limited effects on disease endpoints in the MRL/lpr model, whereas deficiency *of Ifngr1* exhibits a dominant protective effect. However, when *Ifnar1* was deleted in concert with *Ifngr1*, we observed an additive effect. Both *Ifngr1*$^{-/-}$ and DKO MRL/lpr mice had increased survival compared to WT or *Ifnar*$^{-/-}$ mice, and this was accompanied by ameliorated lupus nephritis. Given the survival advantage of the DKO and Ifngr*1*$^{-/-}$ deficient MRL/lpr mice, we aged these mice to 27 weeks (far beyond the standard survival age of WT MRL/lpr mice). At this delayed time point, DKO mice showed improvement in glomerular disease, reduced lymphoproliferation with markedly reduced lymphadenopathy, and improved survival. When examining immune activation, we found a substantial B cell phenotype, with DKO mice exhibiting reduced age-associated B cell numbers, reduced autoantibodies, and suppressed germinal centers compared to *Ifngr1* deficiency alone. In human cohorts, we examined the unique type I and II IFN signatures and found that both were associated with the presence of lupus nephritis but, in fact, the type II IFN signature in kidney parenchymal cells is more significantly associated with the presence of lupus nephritis.

Conclusion: This data suggests that type I IFNs do, in fact, regulate disease activation in MRL/lpr mice. However, due to redundant and overlapping transcriptional regulation and the strong type II IFN signature seen in many mouse models and likely patients, blocking type I IFNs alone may not be sufficient to ameliorate disease. Furthermore, both type I and type II IFNs are responsible for regulating B cell phenotypes, which are instrumental in driving both human and murine lupus.

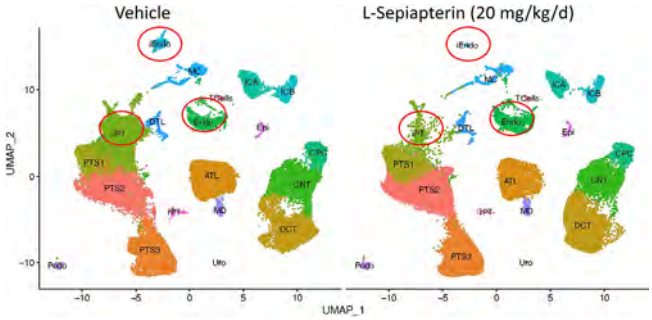
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a disease of endothelial (EC) dysfunction. We hypothesize that much of this dysfunction stems from uncoupling of endothelial nitric oxide synthase, which leads to inflammatory and fibrotic states in endothelial cells. In the uncoupled state, eNOS produces superoxide rather than nitric oxide. Sepiapterin (PTC923) increases functional coupling of eNOS homodimers through its in vivo product, BH_4. We have reported that in a murine model of lupus nephritis (NZM2410), PTC923 improves survival and renal pathology. This study was designed to explore potential mechanisms through which this clinical effect is occurring, with a specific focus on pathways of inflammation, oxidative stress, and fibrosis.

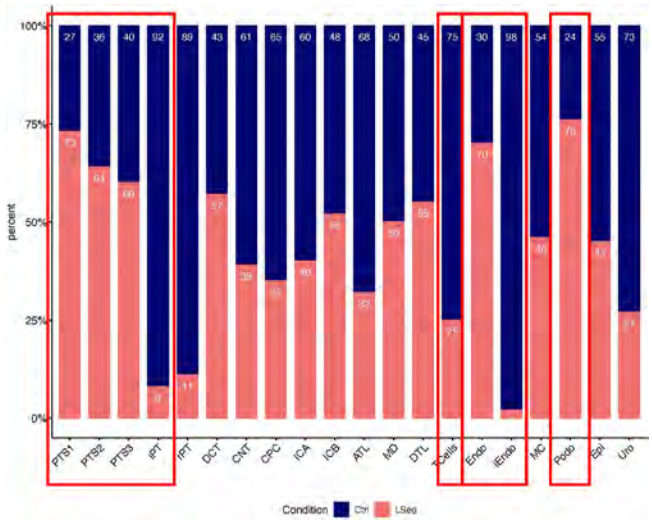
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



UMAP of cell clusters identified by single nuclear RNA sequencing of from renal cortical cells from NZM2410 mice (n=5) treated with PTC923 (L-Sepiapterin, right side) or vehicle (left side) during active nephritis (28 weeks). Circled cell clusters indicate those that are different between groups. iEndo= injured endothelial cells, Endo=endothelial cells, iPT=injured proximal tubule cells, PTS1,2,3=proximal tubule segments 1,2, or 3), rPT=re-covering proximal tubule cells, Podo=podocytes, MC=mesangial cells, MD=macula densa, etc.

Methods: Female NZM2410 mice were aged to 22 weeks, when NZM2410 mice in our colony develop proteinuria. Mice were randomized to receive either vehicle (n=5) or 20 mg/kg/day (n=5) of PTC923 (L-sepiapterin) for 6 weeks. Mice were euthanized, and renal cortex was harvested for single nuclear RNA sequencing (snRNA-seq). Cell-specific gene markers were used to cluster cells, and differential expression of genes (DEG) was determined for each cell type. DEG with p adjusted < 0.05 and log2fold changed > 1.5 were analyzed. Pathway analysis was performed, and CellChat was used to analyze DEGs and hypothesize potential ligand-receptor interactions between cells.

Results: Endothelial cells (ECs) and proximal tubule (PT) segment 1, 2, and 3 cells were differentially increased PTC923 treatment. Inversely, injured PT cells (iPT), injured ECs (iECs), and T cells were reduced in PTC923 treated mice (Figures 1 and 2). ECs from PTC923-treated mice had increases in genes associated with nitric oxide production. Among iECs, Pdgfc and Pdgfd and among ECs, Pdgfc (associated with signaling for fibrosis) were significantly reduced in PTC923-treated mice. An analysis of redox-regulated genes revealed reductions in pathways that enrich for platelet derived growth factor binding transmembrane receptor protein phosphatase activity in PTC923-treated mice. Using CellChat, ligand-receptor interactions between injured ECs and mesangial cells are hypothesized via Pdgfd-Pdgfrb and Pdgfc-Pdgfra. In parallel, Col1a1 and Col3a1 as well as other genes associated with fibrosis were reduced with PTC923 in mesangial cells (Figure 3).



Graph indicating the percentage of cells in each cluster that are present in PTC923 (L-Sep, n=5) treated mice (salmon color) versus vehicle-treated mice (n=5, blue color). See figure 1. Additional cell types: DCT= distal convoluted tubule, CNT=connecting tubule, CPC=cortical principle cell, ICA=intercalated cell type A, ICB=intercalated cell type B, ATL=ascending thick limb or Henle, DTL=descending thick limb of Henle, Epi=parietyal epithelial cells, Uro=urothelial cells.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Heatmap of differential gene expression from renal cortical cells of NZM2410 mice treated with L-Sepiapterin (PTC923) or vehicle from 22 to 28 weeks of age. Red indicates genes relatively increased in vehicle-treated mice, and blue indicates genes increased in PTC923-treated mice. Pdgf=platelet-derived growth factor, Col=collagen, Tnc=tenascin c, Fn1=fibronectin-1. iEndo= injured endothelial cells, Endo=endothelial cells, iPT=injured proximal tubule cells, PTS1,2,3=proximal tubule segments 1,2, or 3), rPT=recovering proximal tubule cells, Podo=podocytes, MC=mesangial cells, MD=macula densa, etc.

Conclusion: PTC923 therapy in the NZM2410 model of lupus nephritis reduces injured cells and genes associated with inflammation and fibrosis and increases EC expression of genes in pathways associated with ion channels and nitric oxide production. These data suggest that targeting eNOS uncoupling in ECs acts via reducing redox-regulated pathways and increasing nitric oxide production.

Background/Purpose: Nerve injury-induced protein-1 (Ninj1) is an adhesion molecule that plays various roles in immune and stromal cells, including the modulation of inflammation and a critical role during cell death. Dysregulation of inflammatory pathways and cell death has been linked to the development of autoimmune diseases, such as systemic lupus erythematosus (SLE). Therefore, we hypothesized that Ninj1 may be involved in the pathogenesis of SLE.

Methods: Ninj1-deficient (*Ninj1*$^{+/-}$) and wild-type (WT) C57/B6 mice were induced to develop lupus-like autoimmunity using two induced models triggered by topical application of the Toll-like receptor 7/8 (TLR7/8) agonist imiquimod (IMQ) or by intraperitoneal injection of pristane. We assessed the mice for clinical phenotype, immune dysregulation, and organ damage.

Results: In comparison to WT mice, *Ninj1*$^{+/-}$ mice exposed to IMQ exhibited greater splenomegaly at the expense of extramedullary hematopoiesis, more severe anemia, decreased spleen lymphocyte counts, and increased spontaneous neutrophil extracellular trap (NET) formation. Although we observed no differences in autoantibody levels or proteinuria, *Ninj1*$^{+/-}$ mice developed more lupus-associated renal disease, as evidenced by increased immune complex deposition and exacerbated kidney inflammation and damage. In the pristane model, Ninj1 deficiency worsened diffuse alveolar hemorrhage and lung inflammation. Furthermore, *Ninj1*$^{+/-}$ M2 bone marrow-derived macrophages (BMDM) exposed to IMQ *in vitro* showed defective activation of the p38/Erk 1/2 mitogen-activated protein kinase (MAPK) and Akt signaling pathways, which are important in M2 macrophage polarization.

Conclusion: Preliminary, these findings suggest that Ninj1 deficiency aggravates murine lupus, at least in part, by impairing the anti-inflammatory roles of M2 macrophages. Further experimentation is needed to identify the immune system defects associated with Ninj1 deficiency, particularly in the affected tissues, and to understand their implications for autoimmune diseases.

A Novel Preclinical Tool for Evaluating CD20 Antibody Efficacy Based on BAFF/CD20 Dual-target Humanized Mice

Juan Liang[1] and Ting Wang[2], [1]Gempharmatech, Nanjing, Jiangsu, China, [2]GemPharmatech, Nanjing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: CD20, a well characterized B-cell surface marker involved in B-cell activation and differentiation, plays a critical role in the pathogenesis of B-cell mediated diseases such as B-cell lymphomas, rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Due to its selective expression on B-cells, CD20 is an attractive

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. target for antibody therapies targeting B-cell related diseases. Previously, we established a SLE model in transgenic mouse strains through the overexpression of human BAFF on a C57BL/6 mouse background (B6-hBAFF,T036794). To facilitate the preclinical evaluation of CD20-targeted therapeutics, we further developed a dual humanized model by crossing this mouse strain with CD20 humanized mice (BALB/c-hCD20,T057498) to obtain BAFF/CD20 dual-target humanized mice(T065937).

Methods: Serum samples from wild-type mice, hBAFF mice and hBAFF/hCD20 mice aged 8 to 27 weeks old were analyzed for anti-dsDNA autoantibodies, total IgG and IgM level via ELISA. Spleens and peripheral blood were also collected to assess B-cell populations by flow cytometry. To evaluate pharmacological response, 8-week-old hBAFF/hCD20 mice received intraperitoneal injections of ritixumab twice weekly for 20 weeks. During the administration period, serum and blood samples were collected for longitudinal assessment of immunoglobulin levels and B-cell counts.

Results: The hBAFF/hCD20 mice demonstrated a spontaneous SLE-like phenotype comparable to B6-hBAFF mice. These included elevated levels of serum IgG and IgM levels beginning at 8 weeks of age, which increased progressively as animals aged. High levels of anti-dsDNA autoantibodies, along with an increased ratio of B-cell frequency in the spleen and blood were observed, confirming an autoimmune phenotype. Following 60 days of rituximab treatment , the levels of IgM and anti-dsDNA antibodies in the serum were reduced, while the level of IgG was unchanged. By day 79, the numbers and proportions of total CD19+ B cells and plasma B cells in the peripheral blood significantly decreased, suggesting effective B-cell depletion and attenuation of the SLE phenotype.

Conclusion: We have established a novel dual humanized hBAFF/CD20 transgenic mouse model that exhibits spontaneous SLE features and enables the evaluation of CD20-targeted therapies. This model represents a powerful in vivo platform for investigating B-cell depleting agents in autoimmune disease settings.

Outcomes of DNRAb-mediated neuronal damage.

Methods: We used a model of lupus-like cognitive impairment that is initiated when antibodies that cross-react with DNA and excitatory neuronal receptors penetrate the hippocampus, causing immediate, self-limited, excitotoxic death of hippocampal neurons, which is then followed by a significant loss of dendritic complexity in surviving neurons and impairment in spatial memory.

Results: This injury creates a maladaptive equilibrium that is sustained in mice for at least 1 year. We identified a feedforward loop of microglial activation and microglia-dependent synapse elimination dependent on neuronal secretion of high mobility group box 1 protein (HMGB1) which binds the receptor for advanced glycation end products (RAGE) and leads to microglial secretion of C1q, upregulation of interleukin-10 with consequent downregulation of leukocyte-associated immunoglobulin-like receptor 1 (LAIR-1), an inhibitory receptor for C1q. While we previously showed that treatment with a centrally acting angiotensin-converting enzyme inhibitor restored a healthy equilibrium, microglial quiescence and intact spatial memory, we now show that a centrally acting angiotensin receptor blocker also is effective, confirming the angiotensin pathway as a mediator of neuronal damage.

Conclusion: We have identified a mechanism by which neuroinflammation can be sustained in a feedforward process despite no intrinsic, genetically determined abnormality of neurons or microglia and no continuing external triggers for inflammation. The inhibition of angiotensin II/angiotensin receptor 1 signaling is able to half the self-sustaining inflammatory cycle by lifting the suppression of LAIR-1, which enables microglia and neurons to return to a state of quiescence and a healthy homeostasis. This has the translational implication that there needs to be a direct manipulation of the cells in the CNS to modulate or abort the inflammatory process.

Presentation of Apoptotic Cell-Derived Autoantigens in Systemic Autoimmune Disease

Lance Peterson[1], Hannah KL De Cleene[2], Cheryl Lichti[2], David Bending[3] and Kodi Ravichandran[2], [1]Rheumatology and Immunology, Pediatrics, Washington University School of Medicine, St. Louis, MO, [2]Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO, [3]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, England, United Kingdom

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus is a chronic, multisystem autoimmune disease characterized by the dysregulated clearance of dying cells, which results in the release of damage-associated molecular patterns and intracellular targets of disease-associated autoantibodies. Dendritic cells are important mediators of 'efferocytosis' (the phagocytosis of apoptotic cells) and present apoptotic cell-derived autoantigens to $CD4^+$ T cells via endocytic processing and MHC class II binding. Despite autoreactive T cells being essential to the pathogenesis and progression of diverse autoimmune diseases, there is only a nascent understanding of their autoantigen specificities. Prior studies have utilized almost exclusively model antigen systems (e.g. ovalbumin), without focus on cell death- and other inflammation-associated endogenous autoantigens.

Methods: We have developed and validated a mass spectrometry-based approach to characterize apoptotic cell-derived peptide autoantigens presented by dendritic cells (the 'efferocytic immunopeptidome'). Furthermore, we have developed a novel approach for testing T cell antigen recognition, using TCR-dependent expression of a fluorescent timer protein, that operates independently of cytokine production, proliferation or effector function. This approach will be used to define populations of autoreactive T cells during homeostasis and in multiple mouse models of lupus.

Results: Our mass spectrometry studies have identified unique subcellular pools of antigens presented in the efferocytic immunopeptidome, including those of nuclear and ribosomal origin. Through our studies on T cell autoreactivity, we identify a small population of T cells from naïve and diseased mice that are reactive against the efferocytic immunopeptidome.

Conclusion: Efferocytosis promotes the presentation of unique pools of cellular peptide antigens that represent a potential source of autoantigen and the driving of autoreactive T cell modulation of diverse immune pathology. We hypothesize that T cell autoreactivity against apoptotic cell-derived antigens will be associated with pathogenic loss of tolerance or protective regulatory responses during disease.

Session Date: Monday, October 27, 2025

Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune disease is far more common in women than men. We have determined that the skin of healthy women is primed for autoimmunity due to increased baseline epidermal expression of the transcription coregulator VGLL3. Accordingly, VGLL3 overexpression in transgenic (TG) mouse epidermis causes cutaneous and systemic murine lupus. Intriguingly, VGLL3 is also reported to act variably as an oncogene and tumor suppressor, revealing pleiotropic roles. While fibrosis is a hallmark of multiple autoimmune skin diseases, few animal models successfully recapitulate fibrosis, limiting mechanistic investigation.

Methods: Trichrome staining, immunostaining, qPCR, bulk RNA-seq, and single-cell RNA-seq (scRNA-seq) were used to analyze skin from mouse models of epidermal VGLL3 overexpression and human skin from patients with cutaneous lupus and healthy controls. Seurat, IPA, CellChat, and CellPhoneDB were used for analysis of scRNA-seq data. Human keratinocytes overexpressing VGLL3 and primary human skin fibroblasts were used for conditioned media experiments.

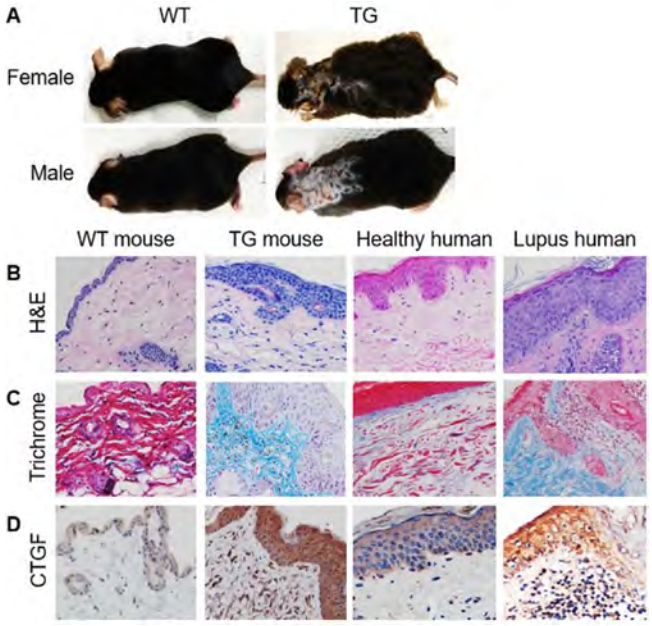

Figure 1. Epidermal VGLL3 overexpression leads to autoimmune skin fibrosis. A. Gross images of female and male transgenic (TG) and wild-type (WT) mice with epidermal overexpression of Vgll3. B. H&E staining of murine lesional TG and WT skin and human lupus patient and healthy control skin. C. Trichrome staining of murine and human skin as in (B). D. 23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We demonstrate that epidermal VGLL3 also drives autoimmune skin fibrosis. Integrating single-cell transcriptomic data from TG mice and human lupus patients, we establish a role for VGLL3-overexpressing keratinocytes in initiating autoimmune skin fibrosis through altering fibroblast transcriptional states. In pre-lesional skin, VGLL3-overexpressing keratinocytes upregulate specific cytokines including TNF and CCL20 and promote an interferon-rich environment, inducing pre-lesional fibroblasts to activate a profibrotic, proinflammatory transcriptional program implicated in fibrotic disease. Conditioned media experiments confirm a direct effect of keratinocytes on fibroblasts, increasing transcription of CCL2, a chemokine implicated in multiple fibrotic diseases. Analysis of fibroblasts reveals expansion in pre-lesional and lesional skin of a population of profibrotic fibroblasts that are shown by ligand-receptor analysis to be one of the most differentially activated cellular communicators in diseased skin. Fibroblast subclustering identifies a transgenic mouse-specific cluster of *Tnc*-positive fibroblasts, which have been shown to be crucial in the progression and maintenance of fibrotic skin diseases by promoting fibroblast activation and sustaining fibrotic responses. Analysis of human cutaneous lupus scRNA-seq data corroborates many of our murine lupus findings in human disease.

Conclusion: These results suggest that VGLL3 and keratinocytes play a dual role in early autoimmune skin fibrosis through both fibroblast reprogramming and immune cell recruitment and support the use of the *K5-Vgll3* model for investigation of autoimmune skin fibrosis.

Ep300-Catalyzed Rad50 Lactylation Compromises Genomic Stability and Drives CD4+T cells Cell Senescence in SLE

Mingyang Zhang[1], huanzi dai[2], cun lan[3] and mingyang sun[3], [1]Daping Hospital, Army Medical University, chongqing, Chongqing, China (People's Republic), [2]Daping Hospital & Research Institute of Surgery, Army Medical University, Chongqing, PR China., Chongqing, China (People's Republic), [3]Daping Hospital, Army Medical University, chongqing, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Senescent $CD4^+$ T cells are increasingly implicated in systemic lupus erythematosus (SLE) pathogenesis. While metabolic reprogramming in lupus T cells enhances glycolysis and lactate accumulation, the role of lactate-induced posttranslational modifications (PTMs) in promoting T-cell senescence remains unexplored.

Methods: Peripheral blood $CD4^+$ T cells were isolated from SLE patients and healthy donors to assess lactylation levels and senescence markers (e.g., p21). A pristane-induced lupus model was established in BALB/c mice, and splenic $CD4^+$ T cells were analyzed for lactylation profiles using lactylome proteomics. Co-immunoprecipitation (Co-IP) coupled with mass spectrometry identified lactyltransferases interacting with Rad50, a DNA repair protein. To validate functional roles,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Lactylation levels and senescence marker p21 expression in peripheral blood $CD4^+$ T cells from healthy donors and systemic lupus erythematosus (SLE) patients.

$CD4^{cre}Ep300^{fl/fl}$ mice (with CD4+ T cell-specific EP300 deletion) were generated and subjected to pristane-induced lupus. Rad50 lactylation was quantified using site-specific antibodies, while senescence markers, serum anti-dsDNA/IgG levels, and renal histopathology were evaluated.

Results: SLE patients exhibited elevated lactylation levels in $CD4^+$ T cells compared to healthy controls, paralleled by increased p21 expression (Figure 1). Lactylome profiling identified Rad50 as the most prominently lactylated protein linked to DNA damage repair. Co-IP proteomics revealed Ep300 as the primary enzyme catalyzing Rad50 lactylation (Figure 2). In pristane-induced lupus mice, $CD4^+$ T cells displayed heightened Rad50 lactylation, amplified p21-driven senescence, elevated autoantibodies, and severe renal damage. These phenotypes were rescued in $CD4^{cre}Ep300^{fl/fl}$ mice (Figure 3).

Conclusion: EP300-mediated lactylation of Rad50 disrupts its DNA repair function, fostering genomic instability and pathogenic senescence in $CD4^+$ T cells during lupus progression. Targeting this pathway may offer a novel therapeutic avenue for SLE.

Epidermal IFNκ Increases Circulating and Cutaneous Monocytes in a C57/Bl6 Overexpression Mouse Model

Patrick O'Brien, Benjamin Klein, Deborah Colesa and J. Michelle Kahlenberg, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus is a heterogeneous inflammatory autoimmune disease affecting a variety of organs, including skin manifestations such as photosensitivity and cutaneous lesions. The skin of human lupus patients is primed for disease through a variety of cellular mechanisms, including an increase in Type I interferons (IFNs) such as interferon kappa (IFNk) that activate immune cells and prime for photosensitivity. Here, we study the effects of epidermal transgenic (Tg) *Ifnk* overexpression to determine the role of skin-derived type I IFNs in driving lupus phenotypes. This experimental work utilized mice of C57/Bl6 background.

Methods: TgIFNk mice were generated utilizing the K14 promoter to direct *Ifnk* expression to the basal epidermis as previously reported. Mice were monitored for spontaneous lesions in a 12-month survival cohort. Where indicated, 3-month-old mice were exposed to 300mJ/cm^2 UVB 12 hours before euthanasia. Phenotypes of TgIFNk and wild type C57/Bl6 mice were studied via complete blood count (CBC), ELISA, flow cytometry, immunohistochemistry (IHC), immunofluorescence (IF), and quantitative real-time polymerase chain reaction (qrt-PCR) performed on blood, spleen, skin, kidney, and urine harvested at time of euthanasia. All data analysis was performed using GraphPad Prism 10, including two-way ANOVA, one-way ANOVA, or unpaired t-Test where appropriate.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Organ weights (1A-C), Complete blood count (1D), and flow cytometry (1E) of mice generating spontaneous lesions (IfnkTG BL6 skin lesions), and age-matched sex-matched non-lesional TG or wild type (WT) controls illustrating lymphadenopathy, splenomegaly, anemia, increased circulating neutrophils, and increased circulating myeloid cells.

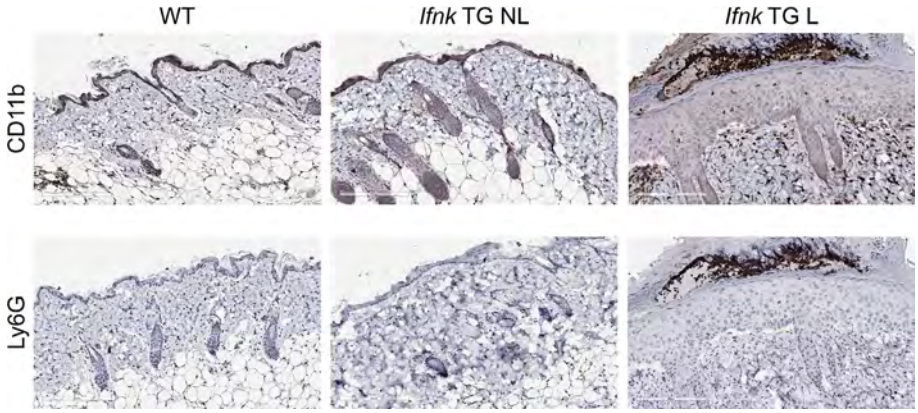
Results: In the C57/Bl6 background, only 4 percent of TgIFNk mice developed spontaneous skin lesions, and no mice developed proteinuria. Lesional mice demonstrated elevated circulating leukocytes compared to age-matched sex-matched non-lesional TgIFNk and WT controls. This increase was driven primarily by an expansion of neutrophils. In the skin,



Immunohistochemistry (IHC) of CD11b and Ly6G for spontaneous lesions (IfnkTG BL6 skin lesions), and age-matched sex-matched non-lesional TG or wild type (WT) controls.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. UVB experiment graphical abstract and flow cytometry results showing a reduction in monocytes in the spleen compared to an increase in monocytes in the skin.

however, immunohistochemistry revealed that skin lesions were enriched primarily in monocytes and monocyte-derived dendritic cells. Non-lesional skin showed no change in CD11b+ cells between genotypes, suggesting that increased circulating neutrophils drive enhanced recruitment of myeloid cells upon cutaneous lesion formation. WT and TgIFNk mice undergoing UVB irradiation exhibited increased monocytes in the skin, but no difference was noted between strains.

Conclusion: TgIFNk mice on the C57/Bl6 background exhibit increases in circulating inflammatory innate immune cells and aggressive myeloid-driven skin disease in a minor subset of mice. Future work seeks to further characterize the function of these innate immune cells in both spontaneous lesions and UVB-mediated disease activation.

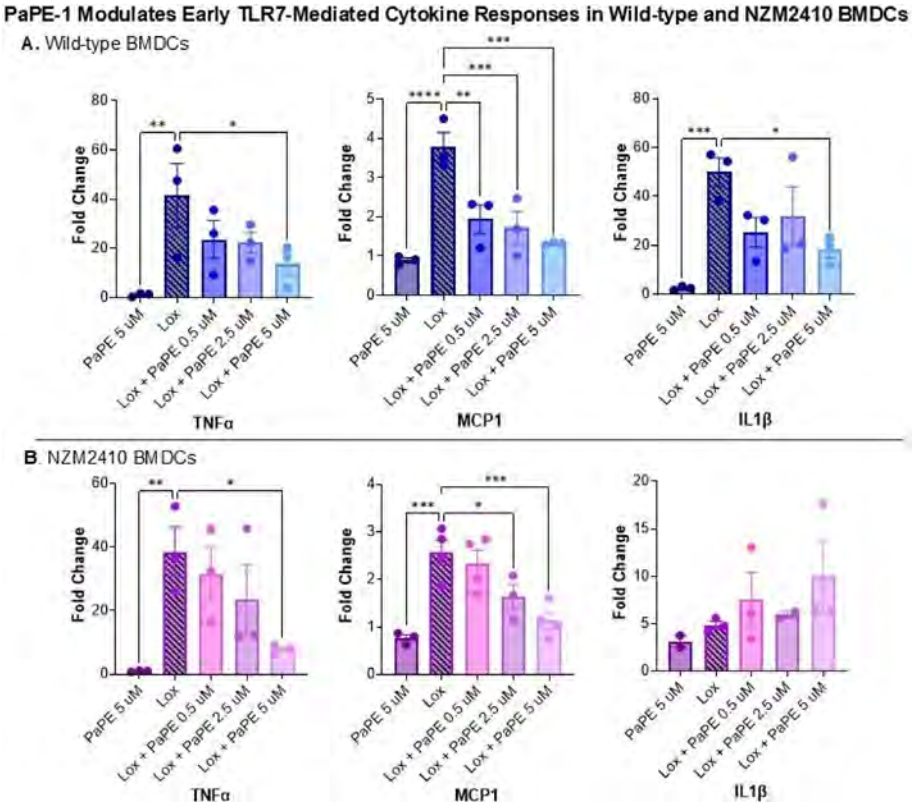

Figure 1. mRNA expression of inflammatory cytokines was measured by qPCR in BMDCs 45 minutes after TLR7 stimulation and PaPE-1 treatment. Fold change was calculated relative to housekeeping gene RPL30. Error bars represent standard error of the mean (SEM). Statistical analysis was performed using one-way ANOVA. Data represent biological replicates.*<0.05, **<0.01, ***<0.001, ****<0.0001

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease that disproportionately affects women, underscoring the critical role of sex chromosomes and sex hormones—particularly estrogen—in disease pathogenesis. Estrogen signaling via estrogen receptor alpha (ERα) has been implicated in both the onset and progression of SLE; however, the therapeutic potential of selective estrogen receptor modulators (SERMs) remains underexplored.

PaPE-1, also known as "pathway preferential estrogen," is a low-affinity, non-nuclear ERα agonist that selectively activates extranuclear estrogen signaling pathways. PaPE-1 has demonstrated beneficial effects in non-reproductive tissues, including reduction of proinflammatory cytokines and enhancement of endothelial repair, while avoiding classical estrogenic actions such as cell proliferation in breast and reproductive tissues. These properties suggest that PaPE-1 could attenuate inflammation and tissue damage in lupus without increasing estrogen-related risks, making it a promising candidate for therapeutic intervention in SLE.

Methods: We utilized ex vivo bone marrow–derived dendritic cells (BMDCs) from female wild-type C57BL/6J and NZM2410 lupus-prone mice. To model lupus-relevant innate immune activation, BMDCs were stimulated with the Toll-like receptor 7 (TLR7) agonist loxoribine (Lox). Cells were cultured in charcoal-stripped, phenol red-free medium and treated with PaPE-1 or vehicle control. Inflammatory responses were assessed by mRNA expression of key cytokines at 45 minutes and 24 hours post-stimulation using quantitative PCR. All experiments included biological replicates.

Results: PaPE-1 modulated TLR7-induced proinflammatory cytokine expression in a dose-dependent manner in BMDCs from both wild-type and lupus-prone NZM2410 mice. Treatment with PaPE-1 significantly reduced MCP-1 and TNFα mRNA expression at 45 minutes post-stimulation. In wild-type BMDCs, IL-1β expression also showed a clear dose-dependent reduction. This effect was not observed in NZM2410 BMDCs, likely due to a markedly attenuated IL-1β response to TLR7 stimulation at this early timepoint (~5-fold in NZM2410 vs. ~45-fold in wild-type). These 45-minute findings are

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

shown in Figure 1. The blunted early cytokine response in NZM2410 BMDCs may reflect altered kinetics or reduced TLR7 sensitivity due to chronic immune activation. However, by 24 hours, PaPE-1 induced a dose-dependent reduction in IL-1β and IL-6 expression in NZM2410 BMDCs, suggesting altered timing of immune-regulatory effects in lupus DCs.

Conclusion: These preclinical findings support PaPE-1 as a promising therapeutic candidate for SLE. Its selective activation of non-nuclear ERα signaling and ability to attenuate TLR7-induced inflammatory responses highlight its potential to modulate pathogenic immune activation in lupus. The observed time-dependent effects underscore the importance of kinetic profiling in future studies. Further investigation is warranted to clarify PaPE-1's mechanisms of action and assess its translational relevance, including studies in human immune cells and at extended timepoints.

Session Date: Monday, October 27, 2025
Session Title: (0934–0954) Systemic Lupus Erythematosus – Animal Models Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multisystem autoimmune disease characterized by aberrant production of autoantibodies and chronic inflammation. Up to 80% of individuals with SLE experience cognitive, emotional, or behavioral symptoms, termed Neuropsychiatric Lupus (NPSLE). NPSLE cognitive impairment and mood disorders may be mediated by autoantibodies, with specific symptoms related to the varied targets of these autoantibodies and the region of blood brain barrier (BBB) injury.

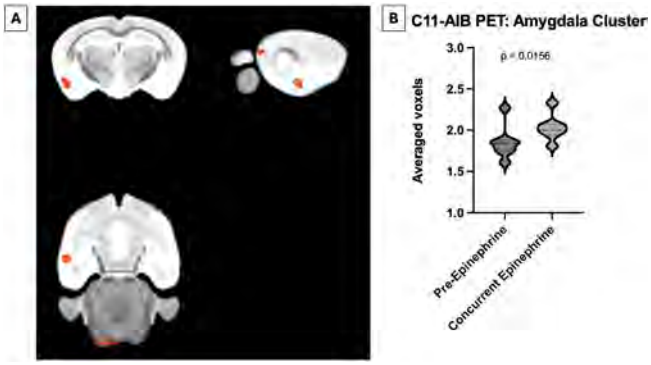

Figure 1: Epinephrine induces a specific blood brain barrier breach in the area of the amygdala in both DNRAb+ and control animals. A) Visualization of thresholded C11-AIB PET scan comparing both DNRAb+ and DNRAb- animals pre-epinephrine and post-epinephrine administration. B) Quantification of C11-AIB PET scan average of voxels in the amygdala, normalized by global mean in each mouse comparing both DNRAb+ and DNRAb- animals pre-epinephrine and post-epinephrine administration (p=0.0156, paired t test, n=8).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: DNRAb+ mice demonstrate significant neuronal loss in multiple regions of the amygdala compared to control mice. A) Representative images of immunofluorescence confocal imaging of LAD and BLA of DNRAb- and DNRAb+ mice. B) Cell counts per area using unbiased stereology of the lateral amygdala nuclei in DNRAb- and DNRAb+ mice. C) Cell counts per area using unbiased stereology of the basolateral amygdala nuclei in DNRAb- and DNRAb+ mice.

We use a murine model of NPSLE induced by anti-double-stranded DNA (dsDNA) antibodies (DNRAbs), which cross-react with the excitatory neuronal N-methyl D-aspartate receptor (NMDAR) and facilitate excitotoxic neuronal death. These antibodies are present in approximately 30% of patients with SLE and at a higher rate in those with NPSLE. Prior research in our lab has shown that epinephrine administration to DNRAb+ mice leads to acute neuronal excitotoxicity in the amygdala. Investigation of the chronic phenotype in the amygdala may lead to insights into the prevalence of persistent mood and anxiety disorders experienced by patients.

Methods: Female B6H2d mice used in this study are immunized with DWEYS peptide on a polylysine backbone to produce DNRAbs or with the polylysine backbone as a control. PET studies using 11C-AIB tracer are used for BBB permeability with epinephrine administration. Unbiased stereology and immunohistochemistry are used to identify cell type morphology, protein expression, and quantify neuronal loss. Behavioral testing includes object place memory, elevated plus maze, and fear conditioning. Mann-Whitney and T-tests are used for statistical analysis between groups.

Results: In this study, we characterize the chronic effects of DNRAb antibody penetration into the brain after systemic administration of epinephrine. We show that BBB permeability due to epinephrine is selective for the amygdala using 11C-AIB PET imaging, resulting in antibody deposition into the amygdala. We observe significant neuronal loss in the basolateral and lateral nuclei of the amygdala in DNRAb+ compared to DNRAb- mice, correlating with amygdala-related behavioral findings in anxiety testing. Finally we observe an abnormal morphology and lipid oxidation suggestive of axonal degeneration in surviving neurons.

Conclusion: Interestingly, the DNRAb-mediated neuronal pathology in the amygdala, which we currently hypothesize is due to ferroptosis, differs from that in the hippocampus, which is characterized by chronic microglial-dependent synaptic elimination and loss of dendritic arborization. Further investigation will focus on circuit disruption and detailed analysis of mechanisms of chronic neuronal damage. This work expands our understanding of the neuropathological mechanisms which can underly psychiatric symptoms in NPSLE.

Abstract Number: 0955

Surveying RNA methylation in scleroderma highlights roles for demethylases ALKBH5 and FTO in fibrosis

Alexander Cai[1], Alyssa Rosek[1], Neha Khanna[1], Anna Webber[1], Karly Kozicki[1], Dinesh Khanna[2] and Pei-Suen Tsou[2], [1]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA, Ann Arbor, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Recent studies indicate that genes involved in RNA methylation may play a significant role in cellular functions, and disruptions in RNA methylation have been linked to various pathological conditions, including autoimmune diseases. However, its specific role in systemic sclerosis (SSc) remains unclear. RNA methylation influences cellular biological functions by regulating gene expression, particularly through m6A RNA methylation. This reversible process relies on "writer" methyltransferases, "eraser" demethylases, and "reader" proteins that recognize m6A marks. Given the association of m6A marks with fibrosis, we examined the expression of genes involved in m6A RNA methylation by analyzing publicly available datasets and isolated dermal fibroblasts from both healthy controls and SSc patients, further focused on RNA demethylases in SSc fibroblasts.

Methods: Data from GEO was analyzed. RNA was extracted from skin fibroblasts isolated from healthy individuals and SSc patients. Gene expression was analyzed using quantitative PCR. Knockdown or inhibition of ALKBH5 or FTO was done by siRNAs or inhibitors ALKBH5-in-3 and FB23-2. Fibrotic endpoints were examined by various assays. Statistical analyses with a P value below 0.05 were considered statistically significant.

Results: Analysis of the GEO dataset generated in whole skin biopsies revealed a distinct pattern of gene expression. While methylation writers and readers, such as *WTAP*, *METTL14*, *YTHDC1*, and *YTHDF2* were significantly downregulated, the eraser demethylases *FTO* and *ALKBH5* were notably upregulated in SSc. This upregulation correlated positively with the modified Rodnan skin score (mRSS). Follow-up quantitative PCR analyses in dermal fibroblasts from healthy controls and patients with diffuse SSc substantiated these findings. Subsequent experiments demonstrated that the knockdown of ALKBH5 or FTO in SSc fibroblasts led to a significant reduction in the expression of pro-fibrotic genes, including collagen genes and TGFβ. Moreover, applying specific inhibitors to these demethylases resulted in marked anti-fibrotic effects, reducing collagen production and fibroblast activation.

Conclusion: Our research elucidates the critical roles of RNA demethylases ALKBH5 and FTO in SSc, particularly in the context of fibrosis. The upregulation of these enzymes and their significant correlation with mRSS suggest they are key drivers in the progression of fibrosis in SSc. Functional experiments demonstrate the potential of targeting ALKBH5 and FTO to reduce pro-fibrotic gene expression and fibroblast activation, offering promising therapeutic avenues for intervention. These findings contribute substantially to our understanding of the molecular underpinnings of SSc and suggest that modulating RNA methylation could be a viable strategy to mitigate fibrosis in this challenging disease. Further research is underway to fully explore the therapeutic potential and genes and pathways involved in RNA methylation and its impact on fibrotic diseases such as SSc.

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Several tissue resident populations undergo metabolic reprogramming during tissue fibrosis as a phenotypic adaptation to their changing metabolic demands. However, these shifts in metabolic profiles in fibrotic tissues have not been previously studied at single cell level with spatial resolution. Furthermore, the spatial cellular organization within metabolic niches in fibrotic tissues was not explored until now.

Here we aimed to identify and map distinct metabolically-defined fibroblast, macrophage and endothelial cell subsets in SSc skin, characterize their cellular metabolic microenvironments, and evaluate their association with progression of skin fibrosis in SSc.

Methods: Sections from skin biopsies of nine SSc patients and seven controls were prepared. Imaging mass cytometry (IMC), a spatial proteomics technique, was employed. An IMC panel of 38 metal-labelled antibodies, of which 22 antibodies targeting key enzymes and signalling molecules in several metabolic pathways was designed and validated in human skin. Data analysis was performed as described. The glycolysis or TCA/OXPHOS scores calculated with this approach robustly correlate with the activities of the respective pathways, as determined by functional assays.

Results: We analyzed the expression of key regulators of metabolic pathways such as glycolysis, tricarboxylic acid (TCA) cycle, oxidative phosphorylation (OXPHOS), fatty acid oxidation and synthesis, aminoacid internalization, pentose

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. phosphate pathway, hypoxia, reactive oxygen species production as well as of regulators of mitochondrial dynamics, collectively termed as metabolic regulome, in SSc and control skin.

Dermal cells of SSc patients with progressive skin fibrosis had a remarkably distinct metabolic regulome compared with patients with stable skin fibrosis and to controls, with upregulation of glycolysis and TCA/OXPHOS scores.

Unbiased fibroblast clustering identified eight distinct fibroblasts subsets defined by their metabolic regulome. Of these, a subpopulation of fibroblasts with high expression of glycolysis and TCA/OXPHOS enzymes (termed Met^{hi} Fib) was upregulated in SSc patients with progressive skin fibrosis, and expressed high levels of markers of activated fibroblasts, such as αSMA and FAP.

The metabolically-defined fibroblast subsets formed niches with endothelial cells and macrophages with similar levels of metabolic pathway activities, e.g. the Met^{hi} fibroblasts were located in spatial proximity to endothelial cells and macrophages that expressed high levels of glycolysis and TCA/OXPHOS enzymes.

Conclusion: We identified distinct metabolically-defined subsets fibroblasts in SSc and control skin, with an enrichment of metabolically highly active fibroblasts in progressive skin fibrosis. This fibroblast subset expressed myofibroblast markers and formed niches with endothelial cells and macrophages with a similar metabolic profile. Thus, metabolic phenotyping of fibroblasts and their niches by IMC-based spatial proteomics might identify SSc patients at risk for progression of skin fibrosis.

Background/Purpose: Regression of skin fibrosis is a feature of the natural history of dcSSc. The molecular mechanisms underlying this resolution remain unclear. This study aims to establish a molecular fingerprint characterizing regression of skin fibrosis in SSc patients.

Methods: All patients fulfilled the 2013 ACR/EULAR classification criteria for SSc. Regressors were defined by a 5-point decrease in the modified Rodnan's Skin Score (mRSS), and progressors by a 5-point increase at annual follow-up. Serum proteomics using the Olink High Throughput Explore panel (5,400 proteins) was performed on 44 SSc patients (25 regressors, 19 stable/progressors=non-regressors). Differentially abundant proteins (DAPs) were identified using the limma package. For single-cell RNA sequencing (scRNA-seq), peripheral blood mononuclear cells (PBMCs) were isolated from 15 SSc patients (5 each: regressor, progressor, stable) and 5 healthy controls. Single-cell libraries were prepared, and raw reads were aligned to the human genome using Cellranger 7.0. Transcriptomic data were analyzed with Seurat (v5.1.0), and differential gene expression analysis (DGEA) was performed using the MAST package, followed by Gene Set Enrichment Analysis (GSEA).

Results: Olink proteomics analysis identified 124 DAPs between skin regressors and skin non-regressors. Pathway enrichment analysis (PEA) on the DAPs revealed that MDK, THY1, JAM3, XG and VEGFB relate to cellular extravasation processes and SMOC2, RAMP2, CD160, VEGFB, HSPG2, PGF, EPHA2 to angiogenesis as top processes (Fig. 1). Seventy-three percent of these proteins are linked to monocyte extravasation.

PBMC scRNA-seq revealed 5 distinct clusters of monocytes (Fig 2A). Compositional analysis revealed a significant increase of clusters 0, 1 and 3 in the regressors compared to progressors (Fig 2B). To find whether a specific subset is involved in monocyte-vascular interactions, the expression of extravasation markers ITGAM, SELL, ICAM1, and S100A8/9 was used. These markers localized to clusters 0, 1 and 3 (Fig 2C). Additionally, chemotaxis marker CCR1 had an increased expression in clusters 0, 1, and 3, whereas CCR5 was unique to cluster 1 (Fig 2D).

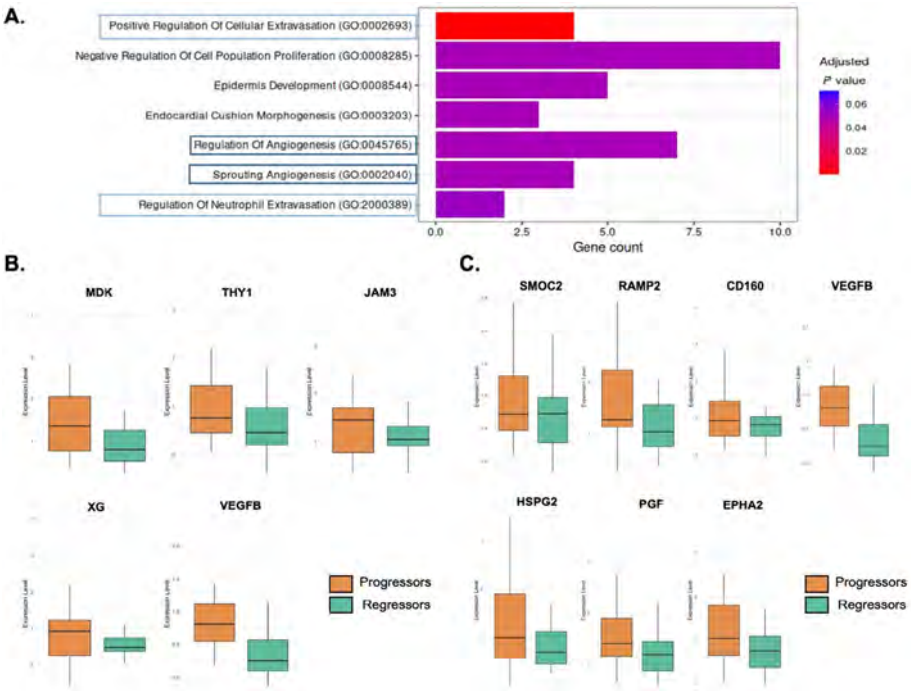

Figure 1. Serum proteomics reveals that differentially abundant proteins (DAPs) are linked to cellular extravasation and angiogenesis and downregulated in regressors. A) Enrichment analysis using GO Biological Processes of the 124 DAPS detected (Benjamini-Hochberg adjusted FDR < 0.3) shows that DAPs are linked to processes including 'Positive Regulation of Cellular Extravasation' and 'Regulation of Angiogenesis'. B) The DAPs linked to the cellular extravasation process all demonstrate a decreased expression in the regressors compared to the progressors. C) DAPs linked to the angiogenesis process show a decreased expression in the regressors compared to the progressors.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

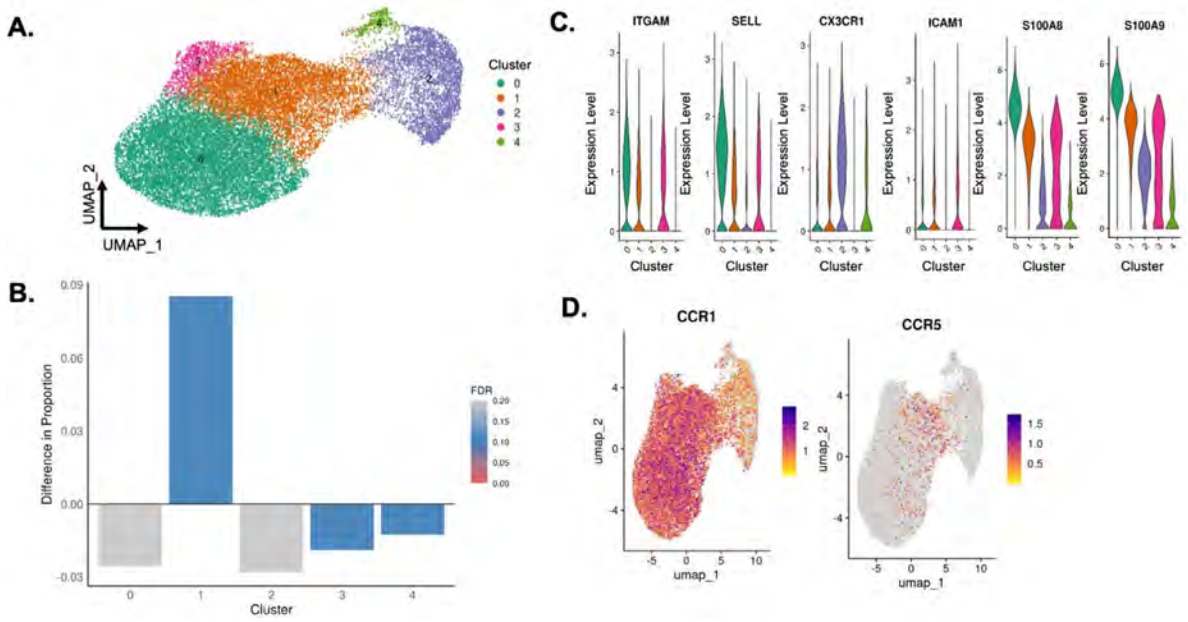

Figure 2. Monocytes in scRNA-seq display a signature related to monocyte extravasation that can be linked to cluster 1. A) UMAP of all monocytes in the PBMC scRNA-seq data revealed 5 distinct monocyte subpopulations. B) Compositional analysis shows that cluster 1 is significantly more abundant in the regressors compared to progressors (FDR = 0.11). C) Well-established markers related to cellular extravasation (ITGAM, SELL, CX3CR1, ICAM1, S100A8, S100A9) showed an increased transcript expression in cluster 1. D) CCR1, which mediates monocyte arrest showed increased expression in clusters 0, 1, and 3. CCR5, which is involved in monocyte spreading, shows a specific expression in only cluster 1.

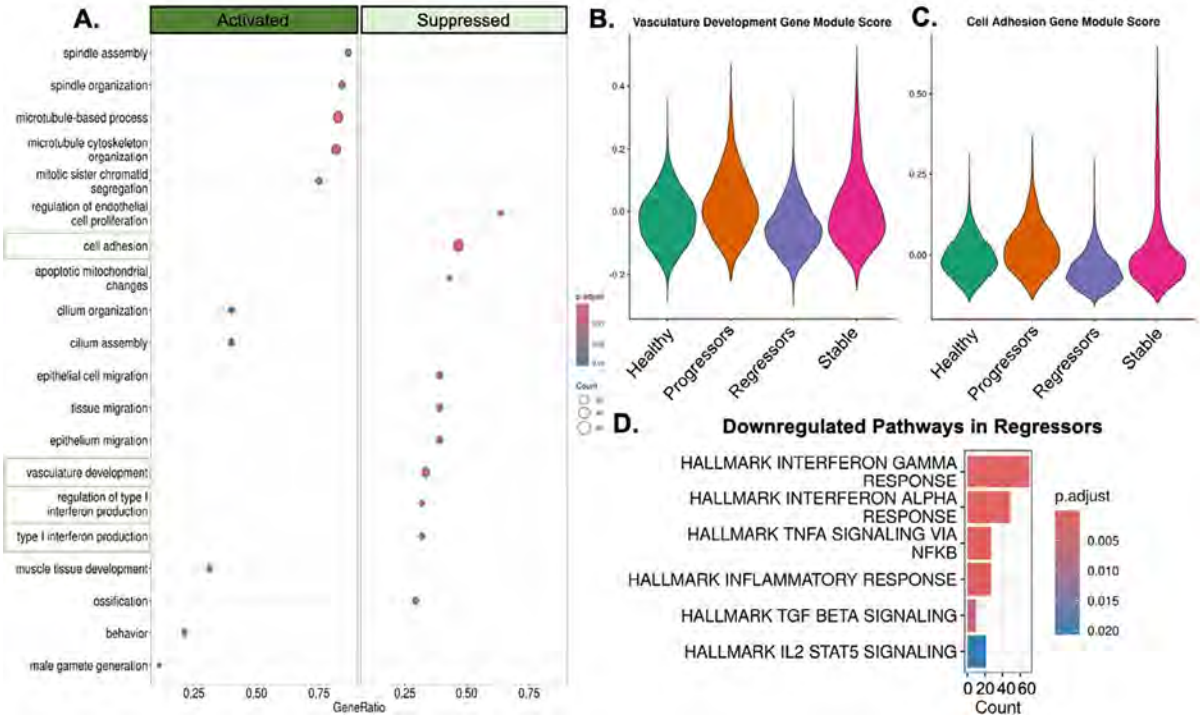

Figure 3. Characterization of Cluster 1 reveals a subpopulation of monocytes primed for extravasation. A) GSEA showed a suppression of gene sets 'regulation of endothelial cell proliferation' ad 'vasculature development' in the regressors. Similarly, gene sets 'regulation of type I interferon production' and 'type I interferon production' were also suppressed in the regressors. B) The gene module score for the vasculature development gene set was calculated using the aggregated expression of the genes in this gene set. The gene module score for 'Vasculature Development'-associated genes and 'Endothelial Cell Proliferation'-related genes D) were both found to be suppressed in the regressors compared to other patient groups. E) Pathway enrichment analysis confirmed that interferon alpha and beta (type I) response was among the top downregulated pathways in the regressors.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Further characterization of cluster 1 using GSEA revealed a suppression in the gene sets 'vasculature development' (including extravasation-related genes: ITGA5, MMP14, MMP2, MMP19, CCL2, SOCS3, HMOX1 and PPARG) and 'cell adhesion' (including extravasation-related genes: ITGA5, MMP14, MMP2, CCL2, SOCS3, SIGLEC1 and MERTK). The generated gene module scores reflect a consistent decrease in regressors compared to other patient groups (Fig 3A-C). Additionally, both PEA and GSEA on cluster 1 had a decreased expression of IFN-I genes in the regressors, which is linked to a decrease in vascular permeability (Fig 3D).

Conclusion: Our multi-omics approach identified a set of proteins linked to monocyte extravasation and a subcluster of monocytes characterized by extravasation markers. This subcluster also displayed a decreased IFN-I activity. Our data points to a reduction in monocyte extravasation to the tissue associated to the regression of skin fibrosis in SSc.

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is characterized by tissue fibrosis, which is defined as excessive and irreversible extracellular matrix (ECM) accumulation, leading to organ dysfunction. In SSc, ECM production is thought to be initiated by an inflammatory trigger. However, the precise kinetics of the inflammatory and fibrotic processes remain poorly

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Kinetic evolution of skin inflammation and fibrosis in the HOCl-induced systemic sclerosis mouse model (A) Evolution of dermal thickness (in µm, on Hematoxylin-Eosin stained histological sections) and collagen content (% per section, on Picrosirius-Red stained histological sections). Results presented as mean +/- SD, N = 8 per group. (B) Evolution of T cells and NK cells percentages among skin leukocytes, measured by flow cytometry. Results presented as mean +/- SD, n = 5-8 per group. (C) Expression of genes representative of inflammatory and fibrosis processes in the skin. Heat map expressed as log2 fold change of gene expression measured by qPCR in HOCl mice, normalized on PBS mice with ***β***actin gene as internal control. N = 12 per group. * : P<0,05 ; ** : P<0,01 ; *** : P<0,001.

described. Moreover, data regarding the independence of fibrosis from the initial inflammatory stimulus are lacking. This study aims to characterize the timing and interdependence of the inflammatory and fibrosis processes using an extended experimental mouse model of SSc.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Evolution of skin inflammation and fibrosis after stopping the inflammatory trigger in the HOCl-induced systemic sclerosis mouse model (A) Evolution of dermal thickness (in µm, on Hematoxylin-Eosin stained histological sections) and collagen content (% per section, on Picrosirius-Red stained histological sections). Results presented as mean +/- SD, N = 12 per group. (B) Expression of genes representative of inflammatory and fibrosis processes in the skin. Heat map expressed as log2 fold change of gene expression measured by qPCR in HOCl mice, normalized on PBS mice with ***β***actin gene as internal control. N = 12 per group. ** : P<0,01 ; **** : P<0,0001.

Methods: Experimental SSc was induced by daily hypochlorous acid (HOCl) injections into the backs of mice for 9 weeks. Mice (n = 8-12 per group) were sequentially sacrificed at day (D)7, D14, D21, D28, D35, D42 and D63. Moreover, a group of mice receiving HOCl injections until D42 was sacrificed at D63 (group D42+21), to study the evolution of fibrosis after stopping HOCl injections. Skin architectural changes and ECM accumulation were assessed by histological approaches. Leukocyte count and distribution were analyzed by flow cytometry. The dynamic progression of the skin inflammatory and fibrotic functional program was assessed by RT-qPCR using a panel of 22 representative genes.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Mice treated with HOCl showed early dermal thickening and collagen accumulation starting from D14 and D7, respectively, and progressing to a plateau by D28 (Figure 1A). HOCl injections impacted skin inflammatory cells in terms of number (higher number and percentage compared to control mice), localization (progressive infiltration from deep to superficial skin layers) and subset distribution (increase in NK et T cells percentages, no difference for myeloid cells or B cells, Figure 1B). Genes associated with inflammation were overexpressed in the skin from D7 to D42. Genes encoding ECM components were also upregulated starting from D7, with distinct peak expression times between type I collagen, type V collagen, and fibronectin (Figure 1C).

Three weeks after stopping HOCl injections, no decrease in dermal thickness or collagen accumulation was observed (Figure 2A). Inflammation regressed, with a significant decrease in the expression of inflammatory cytokine genes (*Ccl2, Cxcl1, Il6* and *Il1b*). A significant modification of the ECM component gene expression profile (decrease in *Col1a1* and *Col5a1* expression and increase in *Col7a1* expression) and a drop in the expression of myofibroblast differentiation genes were noted (Figure 2B).

Conclusion: Inflammatory and fibrotic parameters are closely intertwined in the HOCl model, with both processes appearing from the onset of HOCl injections. After cessation of the inflammatory trigger, progressive ECM remodeling is observed, though without a return to baseline. A better understanding of the temporal dynamics of these processes in this experimental model may elucidate inflammation and fibrosis resolution mechanisms in SSc and guide the optimal timing for evaluating anti-inflammatory and anti-fibrotic therapies, both in preclinical studies and clinical translation.

Longitudinal Multiomic Study of Skin, Peripheral Blood, and Serum: Serum Proteome Reflects the Disease Process at the End-organ Level and Predicts the Course of Modified Rodnan Skin Score

Bich Na Choi[1], Claudia Pedroza[2], Brian Skaug[3], Maureen Mayes[4] and Shervin Assassi[5], [1]UTHealth Houston Institute for Clinical Research & Learning Health Care, Houston, TX, [2]UTHealth Houston Institute for Clinical Research & Learning Health Care, Texas, TX, [3]UTHealth Houston Division of Rheumatology, Houston, TX, [4]UT Health Houston Division of Rheumatology, Houston, TX, [5]Division of Rheumatology, UTHealth Houston, Houston, Texas, USA, Houston, TX

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Clinically useful biomarkers for systemic sclerosis (SSc) are needed. While obtaining samples from affected organs like the skin and lungs is invasive and cannot be done routinely, serum is collected for routine clinical care. Prior studies showed serum protein profiles align more with skin molecular changes than with peripheral blood cells (PBCs), though they analyzed a limited number of proteins. The current study characterizes longitudinal large-scale serum proteomic profile alongside global gene expression in PBCs and skin biopsies from SSc patients and healthy controls.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

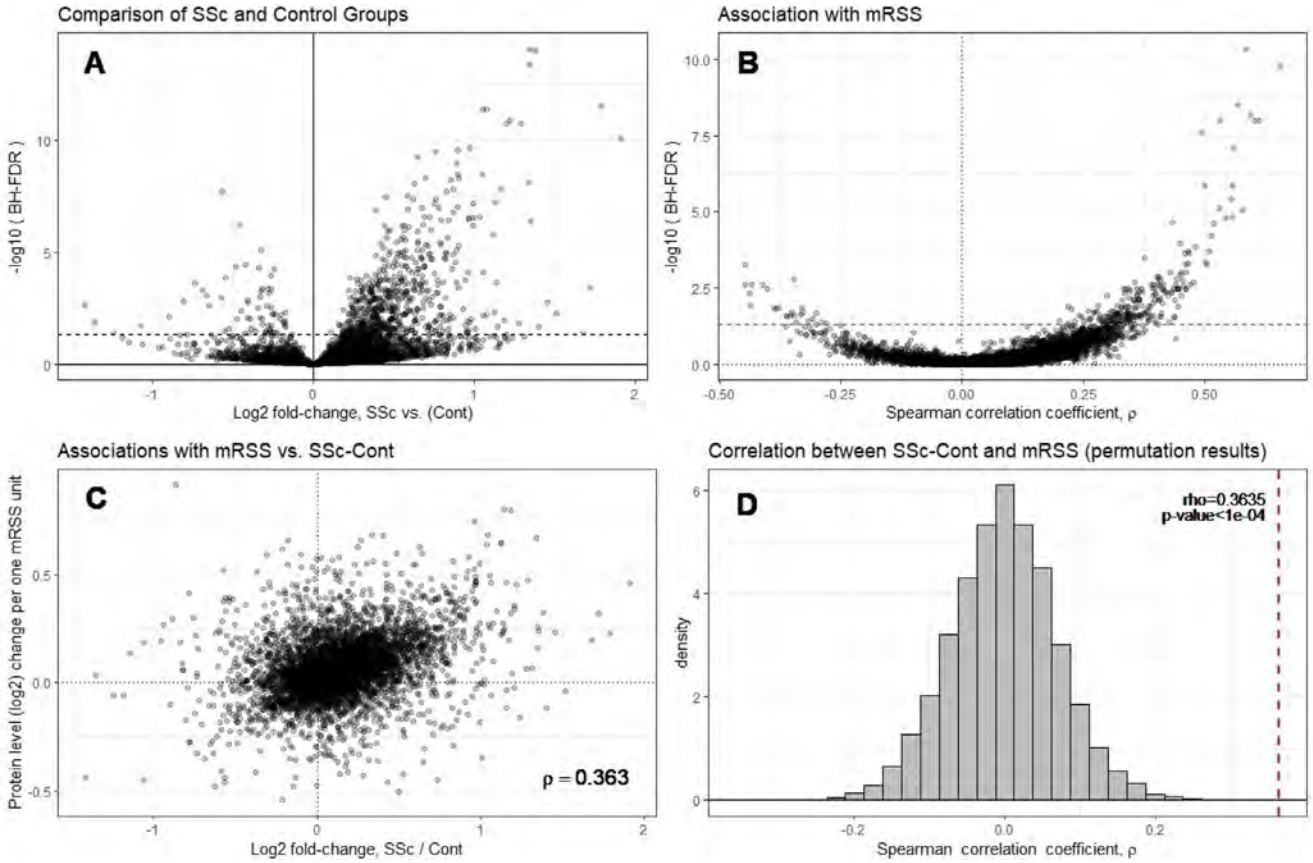

Figure 1. A) Volcano plot of differences between SSc-Controls; B) Volcano plot of the correlation between proteins and mRSS in SSc; C) Scatter plot of associations with mRSS and SSc-Controls differences; D) Permutation-based significance of correlation between differential serum protein expression (SSc vs. control) and its association with mRSS. The vertical red dashed line indicates the observed Spearman correlation coefficient based on the original sample annotation, while the histogram represents the null distribution of correlation values obtained from randomly permuted sample labels.

Methods: Three-level samples were collected from 109 SSc patients (disease duration < 6 year) and 42 matched controls. 98 SSc patients had a second sample and 47 had a third sample. 5416 serum proteins were measured using Olink Explore HT panel in serum samples. In addition, bulk global gene expression profiling was performed on concurrently collected skin and PBC RNA samples. An FDR adjusted p-value of 0.05 was considered statistically significant.

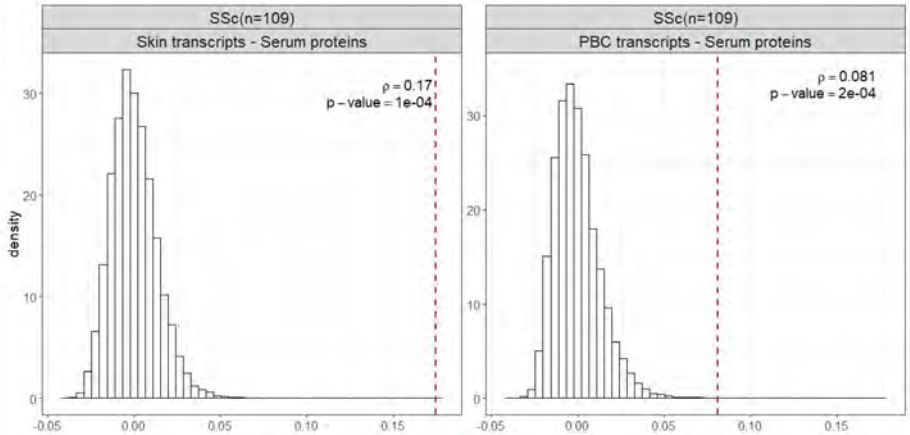

Figure 2. Concordance of between-sample similarities, measured by Spearman correlations, for pairwise comparisons of protein expression between skin and PBC. The Mantel test's observed concordance (vertical red dashed lines) was evaluated against null distributions created by random permutation of samples within each dataset.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

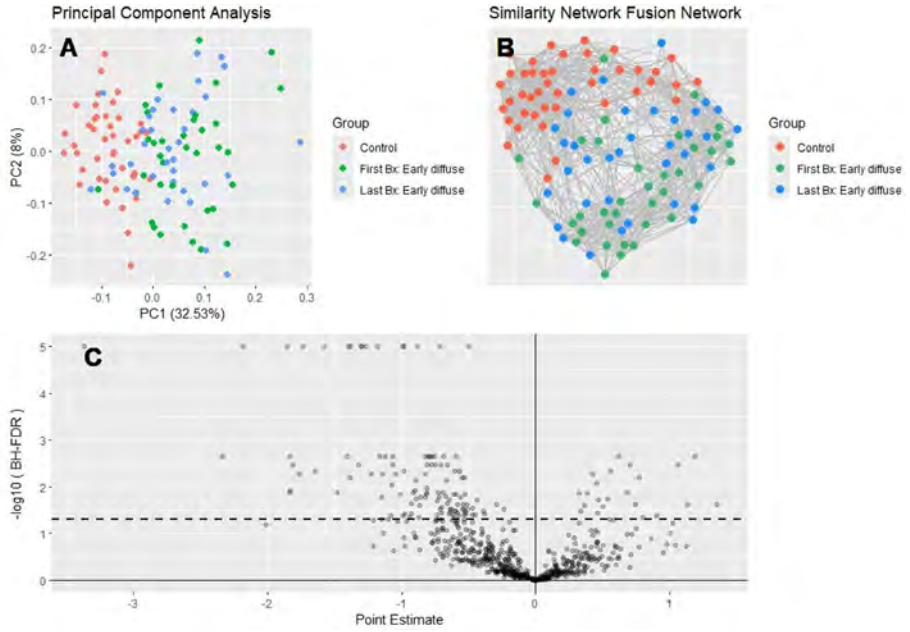

Figure 3. A) Principal component analysis (PCA) with differentially expressed serum proteins in healthy controls, first and last biopsies from early diffuse patients. B) Similarity Network Fusion (SNF) analysis of longitudinal serum protein and skin gene expression data from healthy controls and from the initial and final biopsies of early diffuse SSc patients. C) Volcano plot of serum proteins predictive of longitudinal mRSS change.

Results: The mean disease duration was 2.71 years and 61% of patients had diffuse SSc. In comparison of baseline SSc samples to controls, 697 proteins were significantly differentially expressed. Moreover, 249 proteins significantly correlated with modified Rodnan Skin Score (mRSS) (Figure 1A), of which 184 proteins were also differentially expressed in concordant direction in SSc vs control comparison (Figure 1B), indicating a significant correlation between direction of differential expression of serum proteins in SSc vs. control comparison and their association with mRSS (Figure 1C – permutation p-value < 0.0001 – Figure 1D).

The differential expression of serum proteins in SSc vs. control comparison correlated more strongly with the differential expression of corresponding transcripts in skin than in PBCs (ρ=0.17 vs ρ=0.081, Figure 2).

Similar to previously reported observations in skin, a comparison of the last to the initial serum samples in patients with early diffuse disease (n=36 – disease duration < 3 years) showed that the follow up serum samples clustered nearer to healthy controls than did initial serum samples (see the PCA analysis shown in Figure 3). Similar results were found when the skin transcriptomic and serum proteomic data were integrated using Similarity Network Fusion (SNF) analysis.

Among differentially expressed serum proteins, 141 baseline protein levels (20.1%) showed predictive significance for the rate of longitudinal change in mRSS after adjustment for disease duration and gender among patients with diffuse systemic sclerosis (Figure 3C), with 23 proteins being associated with faster increases in mRSS while 118 proteins were associated with slower increase or even a decrease in mRSS over time.

Conclusion: SSc proteomic signature reflects more closely the molecular dysregulations of skin than PBC and shows a trend towards normalization, paralleling the findings at the skin transcriptomic level. Moreover, serum proteins are associated with rate of change in mRSS over time and might aid in identifying patients with rapidly progressing skin fibrosis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: SSc is a rare, chronic, systemic autoimmune rheumatic disease characterized by progressive skin and internal organ fibrosis, severe vasculopathy and immune dysregulation with production of specific autoantibodies. SSc manifestations such as skin thickening, interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), and cardiac and gastrointestinal complications significantly impact patient quality of life. SSc pathophysiology is complex, but the association between autoantibodies and disease subtype, disease course, and occurrence of specific disease manifestations suggests a role in SSc pathophysiology. Moreover, several different autoantibodies have been reported that can directly

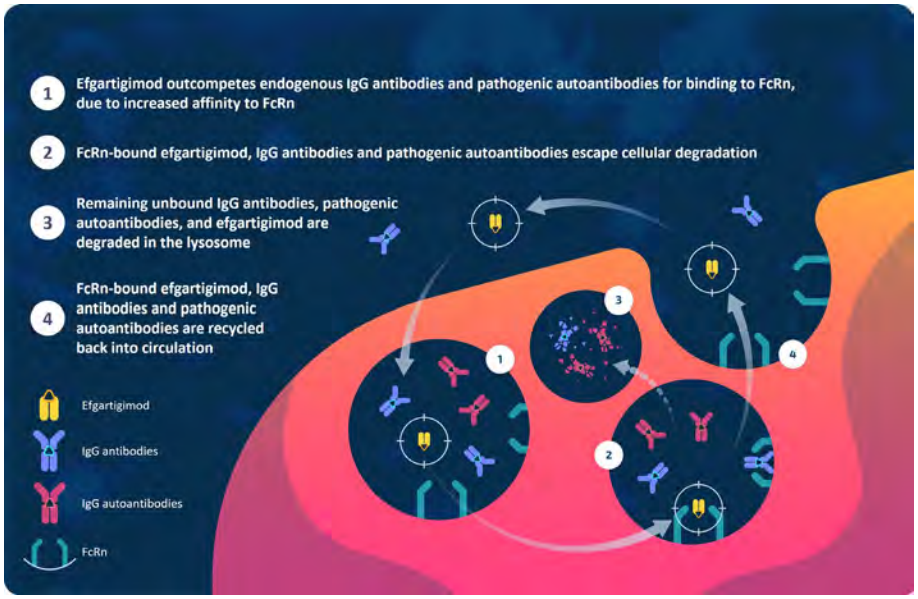

Figure 1. Mechanism of action of efgartigimod against IgG-mediated fibrosis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

promote inflammation and/or fibrosis. Currently approved therapies are at best slowing down disease progression, underscoring a high medical need for novel therapies.

Methods: Efgartigimod, a human IgG1-derived Fc fragment, is engineered to block the neonatal Fc gamma receptor (FcRn), enhancing IgG degradation and reducing circulating disease-causing IgG autoantibodies (Figure 1). Efgartigimod is approved for the treatment of generalized myasthenia gravis and chronic inflammatory demyelinating polyradiculoneuropathy (CIDP). We evaluated the effects of FcRn blockade in a topoisomerase I (topo I)-induced mouse model of SSc, which recapitulates the autoimmune, inflammatory, and fibrotic features of the disease.

Results: Treatment with the murine homologue of efgartigimod (an IgG-derived Fc fragment targeting mouse FcRn) was well tolerated. Both prophylactic (treatment started before the onset of immunization) and therapeutic (treatment 2 weeks after immunization with human topo I-antigen) administration of the murine homologue of efgartigimod significantly ameliorated dermal fibrosis and interstitial lung disease as evidenced by reduced dermal thickness, Ashcroft scores, myofibroblast number, and collagen content. Notably, the antifibrotic effects were comparable to those of nintedanib. Gene expression analysis in mouse skin revealed regulatory effects of the murine homologue of efgartigimod on inflammatory/autoimmune and fibrotic signaling pathways with inhibitory effects on CCL-chemokines, interleukins, S100A4, and on transforming growth factor β and JAK/STAT signaling. In addition, treatment with the FcRn blocker improved gastrointestinal transit that was delayed in mice immunized with topo I.

Conclusion: These findings highlight that, in a murine model of SSc, FcRn blockade may have potential to simultaneously target the autoimmune, inflammatory and fibrotic features of SSc and highlight the potential of autoantibody-reducing therapies as disease-modifying approaches in this disease. Indeed, a randomized, controlled phase II trial with efgartigimod in SSc is currently ongoing.

Background/Purpose: Retinoic acid-related orphan receptor-α (RORα) is a nuclear transcription factor implicated in immune regulation, circadian rhythm, and metabolism. However, its role in fibrotic diseases such as systemic sclerosis (SSc) remains undefined. Given that aberrant fibroblast activation and extracellular matrix deposition are hallmarks of fibrotic tissue remodeling, we investigated the mechanistic involvement of RORα in fibrogenesis and evaluated its therapeutic potential as a modulator of the Hippo signaling pathway.

Methods: In human samples (SSc and other fibrotic conditions) and in mouse fibrosis models, RORα expression was measured by quantitative PCR, Western blot, and immunofluorescence. RORα was silenced in cultured fibroblasts (siRNA) and in RORα-deficient mice to evaluate its function in fibrosis. The selective RORα inverse agonist SR3335 was used to pharmacologically inhibit RORα in three fibrosis models: bleomycin-induced skin and lung fibrosis, and CCl4-induced liver fibrosis. Transcriptomic profiling (RNA-Seq) identified RORα-dependent genes and signaling pathways.

Results: RORα expression was elevated in fibroblasts from various fibrotic diseases and organs, including hypertrophic scars, fibrotic skin, lungs and liver, compared to non-fibrotic controls. Increased RORα expression was also observed in murine SSc models. RORα knockdown in fibroblasts attenuated TGFβ-induced myofibroblast differentiation and collagen production. Similarly, pharmacologic inhibition of RORα with SR3335 reduced TGFβ-driven myofibroblast activation and extracellular matrix production (as indicated by decreased α-smooth muscle actin, type I collagen, and fibronectin) in human fibroblasts. In vivo, SR3335 treatment significantly ameliorated fibrosis in all three mouse models. RNA-Seq showed that RORα regulates a profibrotic gene network, including *COL1A1*, *ACTA2* (αSMA), *CTGF*, and *PAI-1*. Mechanistically, RORα modulates the Hippo signaling pathway, a key regulator of fibroblast activation. SR3335 abrogated TGFβ-induced Hippo reporter activity and prevented YAP/TAZ upregulation and nuclear translocation in fibroblasts.

Conclusion: RORα expression was upregulated in fibroblasts from fibrotic human tissues (skin, lung, and liver, including samples from SSc patients) and in fibrotic mouse models, compared to controls. RORα knockdown in fibroblasts attenuated TGFβ-induced myofibroblast differentiation and collagen production. Similarly, pharmacologic inhibition of RORα with SR3335 reduced TGFβ-driven myofibroblast activation and extracellular matrix production (as indicated by decreased α-smooth muscle actin, type I collagen, and fibronectin) in human fibroblasts. In vivo, SR3335 treatment significantly ameliorated fibrosis in all three mouse models. RNA-Seq showed that RORα regulates a profibrotic gene network, including COL1A1, ACTA2 (αSMA), CTGF, and PAI-1. Mechanistically, RORα modulates the Hippo signaling pathway, a key regulator of fibroblast activation. SR3335 abrogated TGFβ-induced Hippo reporter activity and prevented YAP/TAZ upregulation and nuclear translocation in fibroblasts.

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Sclerosis (SSc) is a rare autoimmune connective tissue disease and presents a significant medical challenge. It is characterized by fibrotic tissue remodeling, along with microvascular alterations and autoimmunity with the formation of specific autoantibodies. CD19- and BCMA-targeted B cell depletion therapies such as CAR-T cells or bispecific T cell engaging antibodies demonstrated profound efficacy for the treatment of SSc patients, including those who were previously unresponsive to multiple therapies. The mechanisms underlying B cell activation in target tissues of SSc patients are largely unknown. Our study focuses on characterizing immune cell infiltration and the cellular microenvironment in SSc skin, with a particular interest in the formation of tertiary lymphoid structures.

Methods: Skin punch biopsies from SSc patients were formalin-fixed, paraffin-embedded, and sectioned. Sections of 118 patients with SSc were screened by hematoxylin and eosin (H&E) histological staining for the presence of leukocyte aggregates or tertiary lymphoid structures. Ten representative samples containing tertiary lymphoid structures, six samples negative for lymphoid infiltrates and five samples derived from normal healthy skin were stained using metal isotope labeled antibodies targeting a panel of proteins of interest including markers of immune and stromal cell populations. The staining protocol was established using human tonsil sections. Imaging Mass Cytometry (IMC) was performed on the Hyperion platform (Standard BioTools) to collect data on the spatial distribution of protein targets and co-localization of cell populations within the skin tissue.

Results: Tertiary lymphoid structures were detected in 14 out of 118 skin samples (12%) (Figure 1). Large, diffuse lymphoid infiltrates were recognized in 19 Sections (16%) while 13 sections (11%) were negative for lymphoid infiltrates.

We were able to identify multiple stromal and immune cell clusters using our IMC panel with specific phenotypes of fibroblasts and endothelial cells in tertiary lymphoid structures. Immune cells were found to infiltrate defined stromal cell niches in the skin. Neighborhood analyses demonstrated context-specific interactions of leukocytes with stromal cells in these

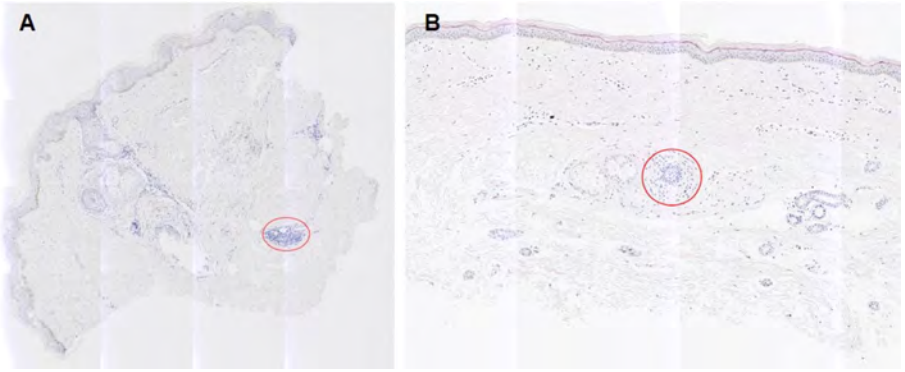

Figure 1: H&E stainings of tertiary lymphoid structures and large, diffuse lymphoid infiltrates in SSc skin sections. Exemplary images of tertiary lymphoid structures (A) and large, diffuse lymphoid infiltrates (B) in H&E stainings of SSc skin sections.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

tertiary lymphoid structures. We will further analyze the demonstrated specific cellular proximity and co-localization, with a focus on mechanisms potentially involved in immune activation and inflammation in SSc.

Conclusion: Tertiary lymphoid structures and large, diffuse lymphoid infiltrates were detected in nearly one third of the SSc samples that were screened (28%), while only 11% of samples were negative for infiltrates. Using a state-of-the-art technique such as IMC, we provide first data on the cellular composition, the topographical organization and the cellular interactions with tertiary lymphoid structures in SSc. These data may enable targeted inhibition of the formation of these structures and thereby interference with tissue resident immune responses in SSc.

Session Time: 10:30AM–12:30PM

Background/Purpose: In the complex pathogenesis of systemic sclerosis (SSc), macrophages are mainly involved in mechanism of progressive tissue fibrosis of skin and internal organs, particularly the lung[1,2]. Alternatively activated macrophages (M2) seem to drive the process through the synthesis of profibrotic molecules[3]. The presence on M2 macrophages of pro-fibrotic markers has been previously observed in ILD-SSc lung samples (i.e. presence of mixed M1/M2 cells showing TLR4)[3]. To characterize phenotype and functional M2 markers in circulating monocytes and cultured monocyte-derived macrophages (MDMs) obtained from SSc patients (pts) with progressive ILD (prog-ILD), versus non-progressive ILD (no-prog-ILD), and without ILD (no-ILD).

Methods: A total of 56 SSc pts, diagnosed according to the 2013 ACR/EULAR criteria, and 20 age-matched healthy controls (HC) were enrolled after providing informed consent. A subgroup of 37 SSc pts (10 with prog-ILD, 14 with no-prog-ILD, and 13 no-ILD; mean age 65±13 years) and 20 HC were assessed for circulating monocytes expressing M2 markers (CD204, CD163, CD206) and the M1 marker toll-like receptor-4 (TLR4) using flow cytometry. Monocyte-derived macrophages (MDMs) obtained from 29 SSc pts (13 with prog-ILD, 10 with no-prog-ILD and 6 no-ILD; mean age 64±14 years) and 5 HC were analyzed for gene expression (real-time PCR) and protein levels (Western blot) of these markers, along with Mer tyrosine kinase (MerTK) and transforming growth factor-β1 (TGF-β1) (ELISA). Statistical analyses were carried out using non-parametric tests.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Prog-ILD SSc pts showed a higher percentage of hybrid (M1/M2) circulating TLR4+CD204+CD206+CD163+-monocytes compared to no-prog-ILD and significantly higher compared to no-ILD SSc pts ($p< 0.05$). Cultured MDMs from prog-ILD SSc pts showed a gene expression and protein synthesis significantly higher for TGF- β1 ($p< 0.05$) and higher (not significant) for MerTK and CD206 compared to MDMs from no-prog-ILD SSc pts. The gene expression of TGF- β1 and TLR4, as well as the synthesis of TGF- β1, CD206, CD163, and MerTK were significantly increased in cultured MDMs from prog-ILD SSc compared to MDMs from no-ILD SSc pts (TGF- β1, TLR4 and M2 markers: $p< 0.05$; MerTK: $p< 0.01$).

Conclusion: The study shows that ILD-SSc pts are characterized by a significant increased percentage of circulating hybrid TLR4+M2 monocytes, and the related cultured MDMs express high levels of MerTK and TGF-β1 selectively in pts with prog-ILD. The detection of increased circulating TLR4+M2 monocytes and MerTK on MDMs from ILD-SSc pts is currently under investigation since might represent a potential solublebiomarker of progressive lung fibrosis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune conditions with skin involvement, including scleroderma (SSc), antiphospholipid syndrome (APS), systemic lupus erythematosus (SLE) and psoriasis (PSO), involve intricate interactions between immune cells and the vasculature, with endothelial cells (ECs) playing a critical role in disease pathogenesis. To elucidate the diverse functional roles of ECs in these conditions, we constructed a comprehensive single-cell atlas by integrating single-cell RNA sequencing (scRNA-seq) data from affected and healthy skin biopsies.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Cellular composition and endothelial subtypes across autoimmune skin diseases. (A) Schematic overview of the study design integrating single-cell RNA sequencing data from autoimmune skin diseases including APS, SLE, PSO, and SSc, along with healthy controls. (B) UMAP visualization of 23,410 endothelial and stromal cells from skin biopsies, annotated into arterial, venous, capillary, and lymphatic ECs, pericytes, and vascular smooth muscle cells (VSMCs). (C) Expression density of canonical markers confirming subtype identities, such as SEMA3G (arterial EC), RGCC (capillary EC), SELP (venous EC), LYVE1 (lymphatic EC), MYH11 (VSMC), and RGS5 (pericyte). (D, E) Relative abundance of vascular and stromal subtypes across disease groups. (F) Heatmap showing the averaged expression of key markers across identified cell types.

Methods: Skin biopsies from patients were analyzed using 10x Genomics scRNA-seq. Publicly available datasets from SSc (GSE249279), APS (GSE290946), SLE (GSE186476), PSO (GSE173706), and healthy controls (GSE249279 and GSE290946), generated using the same platform, were integrated **(Figure 1A)**. Skin biopsies from active skin of patients were analyzed using 10x Genomics scRNA-seq. Cell identities, gene expression profiles, and pathway activities were analyzed across endothelial and stromal populations.

Results: We profiled 23,410 endothelial and stromal cells, identifying arterial, venous, capillary, and lymphatic ECs, as well as pericytes and vascular smooth muscle cells (VSMCs) from all scRNA-seq datasets. Arterial and venous ECs were significantly reduced in SSc, while VSMCs were markedly increased. APS samples showed an expansion of arterial, capillary and venous ECs, whereas SLE and PSO exhibited cellular compositions similar to healthy controls (**Figure 1**). Pathway enrichment analysis of EC gene expression revealed both shared and disease-specific programs **(Figure 2)**. Across autoimmune conditions, common signatures relative to healthy controls included NF-κB signaling, leukocyte adhesion, and antigen presentation. APS-derived ECs were further enriched for antigen presentation, oxidized LDL response, leukocyte adhesion, and T cell activation pathways. SLE samples demonstrated prominent type I interferon responses, while SSc samples exhibited strong enrichment of intrinsic apoptotic pathways. No dominant pathway activation was observed in PSO.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Transcriptional and pathway-level profiling of endothelial and stromal cells across autoimmune skin diseases. (A) Multidimensional scaling (MDS) plots of endothelial and stromal cell subsets showing global transcriptomic distribution across APS, SLE, PSO, and SSc. (B) Volcano plots showing differentially expressed genes in vascular ECs, pericytes, VSMCs, and lymphatic ECs across disease groups. (C) Radar plots depicting pathway enrichment scores of arterial, venous, and capillary ECs across eight biological processes.

Deeper subclustering of vascular ECs defined seven endothelial subtypes, including SENA3G+ arterial ECs, RGCC+ capillary ECs, TLL1^{+} venous ECs, hypoxia-associated ECs, EndoMT, cycling ECs, and a previously undefined subset IL6^{+} venous ECs (**Figure 3**). IL6^{+} and EndoMT ECs were enriched in SSc and expressed pro-inflammatory, senescence-associated, and matrix remodeling genes. SLE and PSO had elevated IL6+ EC and cycling EC populations, potentially driving immune dysregulation and vascular proliferation linked to systemic organ damage. APS was marked by abundant EndoMT+ ECs, suggesting endothelial plasticity. Senescence and EndoMT scores were highest in SSc, followed by APS and SLE, and minimal in PSO.

Conclusion: This single-cell atlas defines dermal endothelial heterogeneity across autoimmune diseases. Notably, we identified a novel IL6^{+} EC subset enriched in SSc with pro-inflammatory and senescence signatures, and revealed distinct EC programs across diseases. These findings highlight EC subtype dynamics as potential contributors to immune dysregulation and fibrotic remodeling.

Background/Purpose: Systemic sclerosis (SSc) is characterized by progressive fibrosis driven by sustained fibroblast activation and senescence. Nicotinamide N-methyltransferase (NNMT), a SAM-dependent enzyme, is upregulated in SSc and contributes to both NAD^+ depletion and methylation imbalance. This study evaluates the therapeutic impact of a novel bisubstrate NNMT inhibitor, II559, in modulating fibroblast activation and reversing metabolic-epigenetic dysfunction in SSc.

Methods: We utilized TGF-β1 to induce fibroblast activation in healthy dermal fibroblasts and evaluated basal activity in primary SSc fibroblasts. Cells were treated with 30 μM II559 for 48–72 hours. Gene and protein expression of fibrosis markers (COL1A1, α-SMA, Fibronectin), senescence markers (p16, p21), and inflammatory cytokines (IL-6, IL-8) were assessed by qPCR, Western blot, and immunofluorescence. Epigenetic status was evaluated using H3K27me3 staining. 1MNA levels were measured to assess NNMT enzymatic activity. In vivo, a bleomycin-induced mouse model of dermal fibrosis was treated with II559 (10 mg/kg, intraperitoneally) for 28 days. Hydroxyproline, NAD^+, SAM, and SAH levels were quantified in skin tissues.

Results: TGF-β1 increased NNMT, fibrotic markers, inflammatory cytokines (Fig 1A,2A,2C), and reduced H3K27me3 (Fig 2C) in healthy fibroblasts; all were reversed by II559. In SSc fibroblasts, II559 downregulated p16/p21 (Fig 1B) and ECM proteins (Fig 1A), and restored repressive H3K27me3 marks. 1MNA levels were elevated with TGF-β1 and

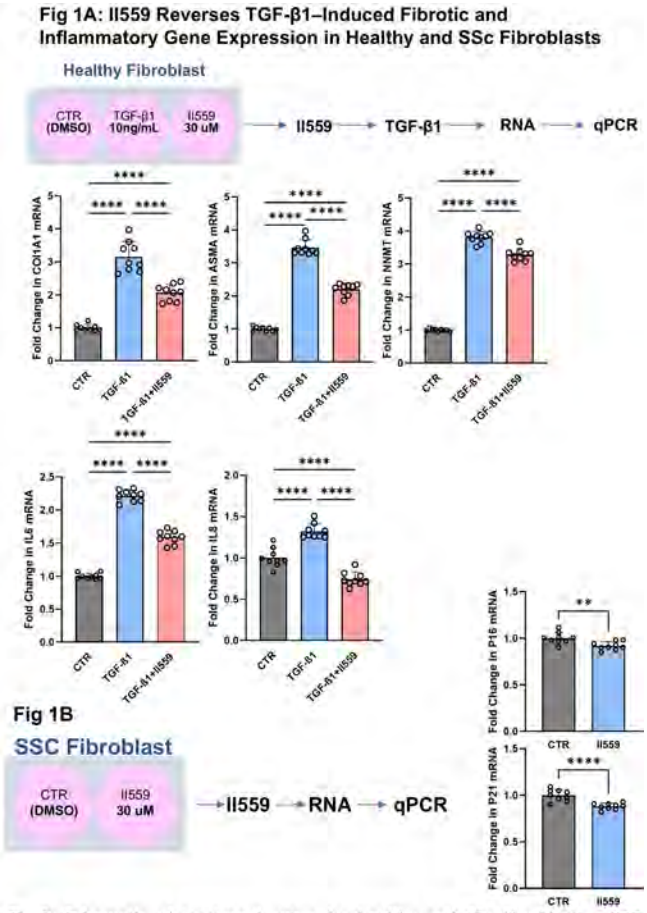

Fig 1: Schematic of treatment setup for healthy and SSc fibroblasts. qPCR showing that II559 (30 μM) attenuates TGF-β1–induced expression of COL1A1, α-SMA, IL-6, IL-8, and NNMT in healthy fibroblasts, and reduces p16 and p21 in SSc fibroblasts. Data shown as mean ± SEM.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig 2: (A) Western blot and **(C)** Immunofluorescence showing downregulation of COL1A1, α-SMA, NNMT P21 P-SMAD2/3 in TGF-β1–treated fibroblasts upon II559 treatment. Immunofluorescence shows that TGF-β1 reduces H3K27me3, a repressive histone mark; II559 restores its levels, indicating epigenetic re-silencing of fibrotic gene programs. **(B)** II559 suppresses NNMT enzymatic activity elevated by TGF-β1. . Data shown as mean ± SEM.

suppressed with II559 (Fig 2B, 3B), confirming target engagement. In vivo, II559 reduced skin fibrosis, hydroxyproline content, and restored NAD^+ and SAM without altering SAH levels (Fig 3A), suggesting recovery of redox and methylation potential.

Conclusion: NNMT acts as a metabolic-epigenetic driver of fibrosis in SSc. II559 reverses fibroblast activation by restoring NAD^+ and histone methylation balance, suppressing pro-fibrotic and inflammatory pathways. These findings support NNMT inhibition as a promising therapeutic strategy in SSc and justify further investigation through transcriptomic and chromatin accessibility profiling.

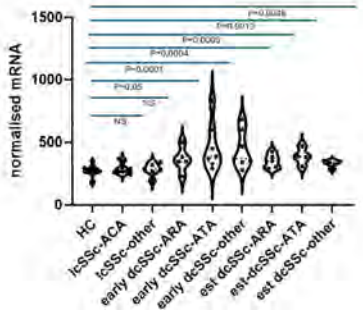
Figure 1 GPR68 mRNA expression in whole skin



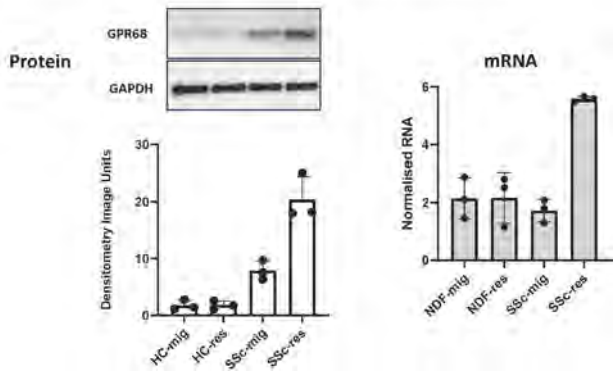
Background/Purpose: The cell surface protein GPR68 (ovarian cancer G protein-coupled receptor 1, OGR1) is a proton-sensing G-protein-coupled receptor (GPCR) that responds to extracellular acidity and regulates a variety of cellular functions. It has been associated with fibrosis and a recent phase 2 clinical trial of FT011 (asengeprast), an orally active small molecule inhibitor GPR68 suggested potential clinical benefit in diffuse cutaneous (dc) systemic sclerosis (SSc). We have explored differential expression of GPR68 in SSc skin and in pathogenic skin fibroblast subpopulations.

Methods: Normalised expression of GPR68 mRNA was explored in a well characterised cohort of SSc and control skin biopsies (n=68) comparing SSc stage, skin autoantibody and subset (ATA=anti-topoisomerase-1; ARA=anti-RNA polymerase 3; ACA=anti-centromere). Protein and RNA expression were examined in cultured SSc or control skin fibroblasts including migratory and non-migratory cells (n=3 each). Non-migratory "resident" fibroblasts have recently been characterised as a novel population strongly implicated in pathogenesis of SSc. Single cell analysis was used to further define GPR68 expression in fibroblasts and other cell types in SSc (n=12) and control (n=3) skin.

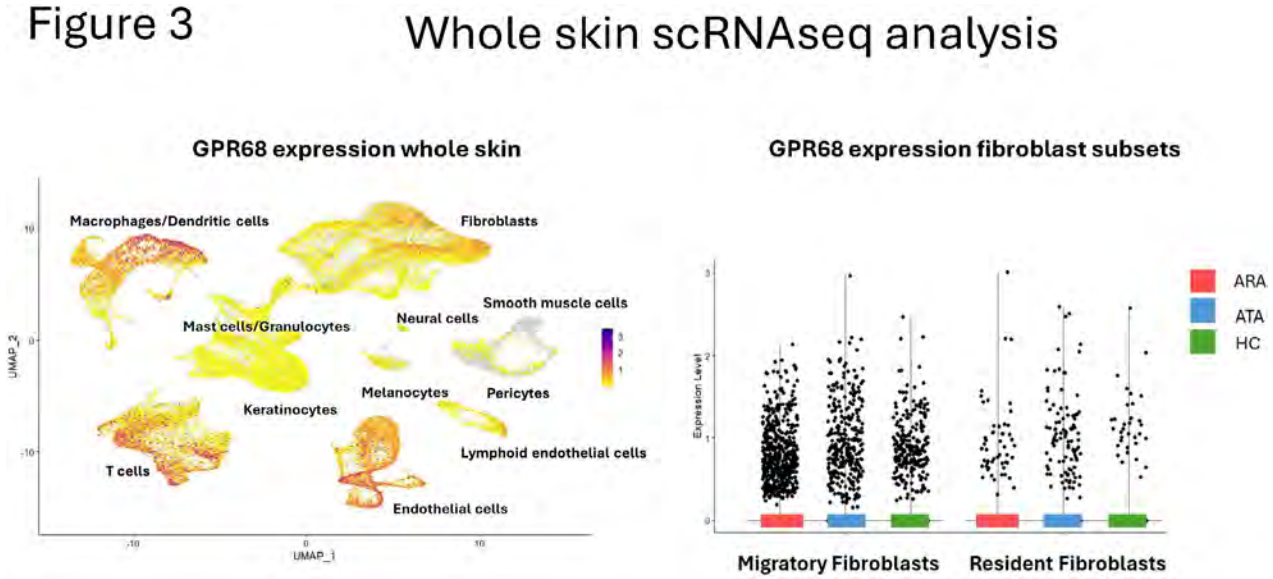
Results: There was increased expression of GPR68 RNA in skin of SSc that was most apparent in dcSSc (mean (SD) HC 268 (41) n=17; lcSSc 286 (45) n=15; dcSSc 396 (126) n=33). Further analysis suggested upregulation was greater in early (428 (153) n=19) than established (353 (53) n=14) dcSSc. ANA subgroups also showed differential elevation of GPR68 with highest levels in ATA+ dcSSc (436 (157) n=11), lower levels in ARA+ dcSSc (355 (75) n=10). Differential expression across subgroups is summarised in **Figure 1**.

GPR68 protein and mRNA were increased in cultured SSc dermal fibroblasts and highest in non-migratory cells in SSc compared with healthy control strains in bulk fibroblast culture (**Figure 2**). Single cell RNA analysis of skin confirmed expression of GPR68 in multiple relevant cell types including fibroblasts, endothelial cells, macrophages and T cells. Re-clustered fibroblast scRNAseq data suggested stage and ANA subset differences concordant with bulk RNAseq (**Figure 3**). Notably,

Figure 2 Fibroblast GPR68 Expression



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



GPR68 had greatest single cell expression in migratory fibroblasts for ARA+ and resident fibroblasts in ATA+ dcSSc skin suggesting differences across ANA subgroups.

Conclusion: We have demonstrated upregulation of GPR68 in SSc and increased expression in pathogenic fibroblast populations including the recently identified non-migratory "resident" fibroblast subpopulation that may be a key paracrine regulator of skin fibrosis. Our findings support the rationale for targeting GPR68 as a treatment for SSc fibrosis and help define the stage and subset of patients most likely to benefit from treatment.

Background/Purpose: The poor prognosis of SSc patients demands an urgent need to prevent disease onset. Recently, we reported a global pro-inflammatory gene signature of dermal fibroblasts in pre-stages of SSc (pre-SSc). Here, we provide a detailed analysis of which fibroblast subtype and which molecular events are characteristic of this pro-inflammatory gene signature in pre-SSc.

Methods: We recruited patients with pre-SSc (n=6), established SSc (eSSc, n=7), and healthy controls (HC, n=6) (**Table 1**). Pre-SSc was defined according to the VEDOSS criteria[1]. eSSc patients met the 2013 ACR/EULAR criteria with disease duration < 5 years since their first non-Raynaud manifestation. HCs were matched for age, sex, and ethnicity. Site-matched forearm skin biopsies were collected, processed following the Chromium Next GEM protocol, and analyzed with Seurat pipeline. We refined fibroblast subclusters with functionally meaningful annotations. Over-Representation Analysis (ORA) of marker genes confirmed subcluster identities. Group-wise compositional differences were assessed (Speckle). Pairwise differential gene expression analysis was conducted (MAST, FDR < 0.05). Pathway analyses, ORA and Gene Set Enrichment Analysis (GSEA), were performed (clusterProfiler). Module scores (MS) quantified pro-inflammatory and pro-fibrotic gene expression programs.

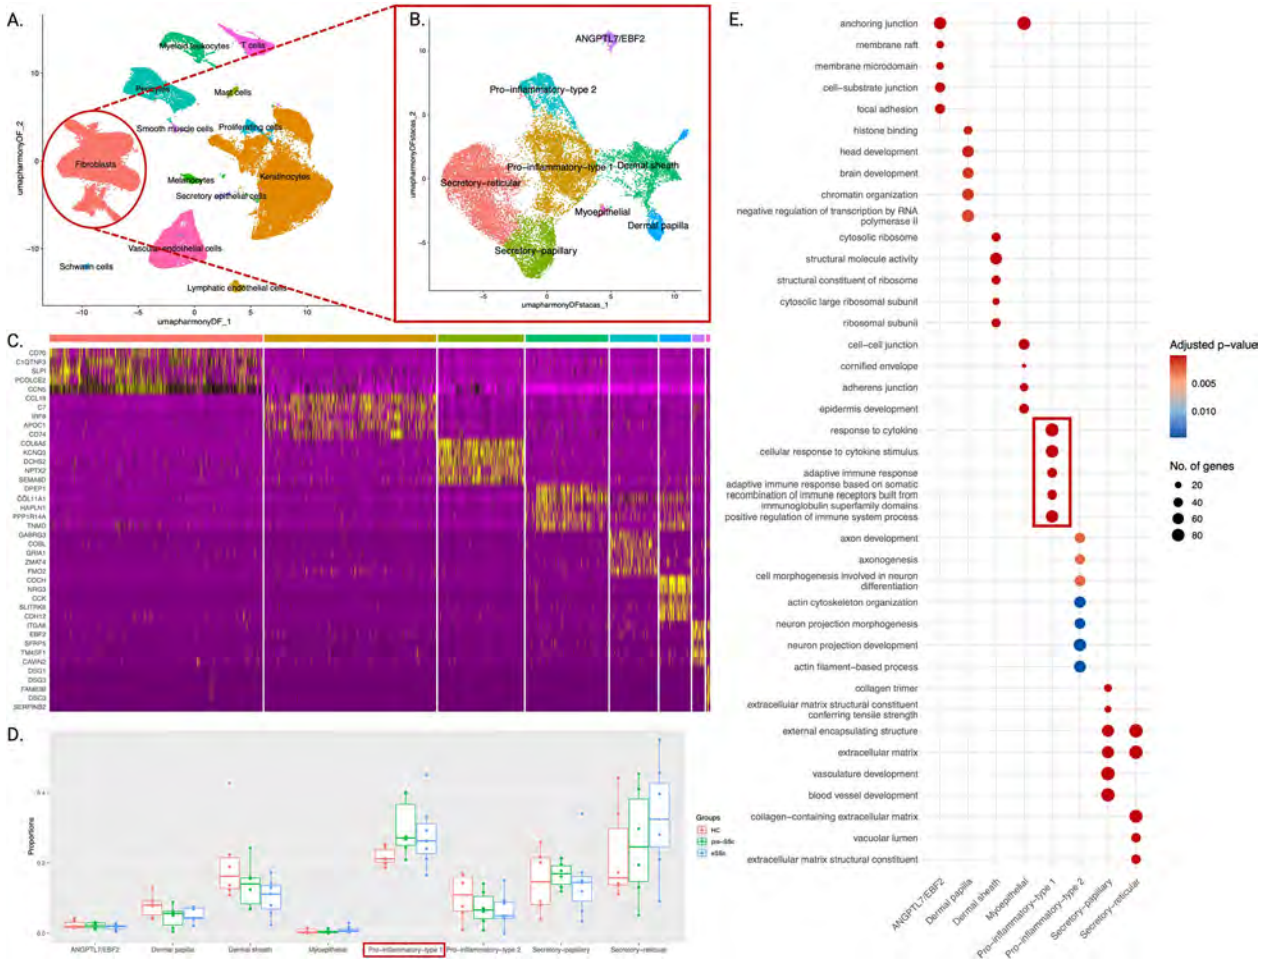

Figure 1. A) UMAP showing 13 identified dermal cell types. B) UMAP of 8 identified fibroblast subtypes. C) Heatmap of the top 5 marker genes per subtype. Color bars correspond to the fibroblast subtypes shown in (B). D) Box plot showing fibroblast subtype proportions per patient across healthy controls (HC), pre-SSc, and early SSc (eSSc) groups. A trend toward increased PF1 fibroblasts was observed in pre-SSc compared to HC (proportional ratio: 1.37; p = 0.06; FDR = 0.3) E) GO over-representation analysis reveals distinct functions for the 8 fibroblast subtypes. The top 5 significant pathways per subtype are shown, based on marker genes identified by FindAllMarkers (default settings; Benjamini–Hochberg adjusted FDR < 0.05; average log2FC > 0.5).

Results: We identified 8 subtypes of dermal fibroblasts including type 1 (PF1), and type 2 (PF2) pro-inflammatory fibroblasts (**Fig. 1A-C**). Cell compositional analysis showed an increase in PF1 fibroblasts in pre-SSc (**Fig. 1D**). ORA of top marker genes confirmed functional differences among fibroblast subtypes and indicated a specific role of PF1 in cytokine-related immune response (**Fig. 1E**). In pre-SSc vs. HC, PF1 yielded 283 significant differentially expressed genes, including *HLA-DRA*, *CD74*, *HLA-DPA1*, *HLA-DMA*, and *CCL21*, consistent with findings in the global fibroblast analysis (**Fig. 2A**). Notably, *HLA-DRA* and *HLA-DMA* were also highly upregulated in eSSc vs. HC (**Fig. 2B**). Pre-SSc PF1 showed significantly higher expression of inflammatory response-related genes compared to HC and eSSc (**Fig. 2C**). In PF1, pre-SSc showed higher expression of pro-inflammatory genes vs. HC, enriched in 17/20 top pathways linked to cytokine/chemokine signaling, leukocyte and T cell activation, and antigen presentation via MHC complexes in ORA (**Fig. 2D**), further supported by GSEA results (**Fig. 2E**). Notably, similar signatures were also observed in eSSc vs. HC in ORA (**Fig. 2F–G**). MS gradients in pre-SSc and eSSc suggest a shared inflammatory mechanism, strongest in pre-SSc and shifting toward a pro-fibrotic profile in eSSc (**Fig. 2H–I**).

Conclusion: Pre-SSc fibroblasts show marked upregulation of pro-inflammatory gene signatures, primarily driven by the type 1 subtype. These signatures peak in pre-SSc before fibrosis and persist into early fibrotic SSc, highlighting a critical window for preventive intervention. The enrichment of immune response-related pathways in pre-SSc offers key insights into early SSc pathogenesis and the potential targets for preventive therapies.

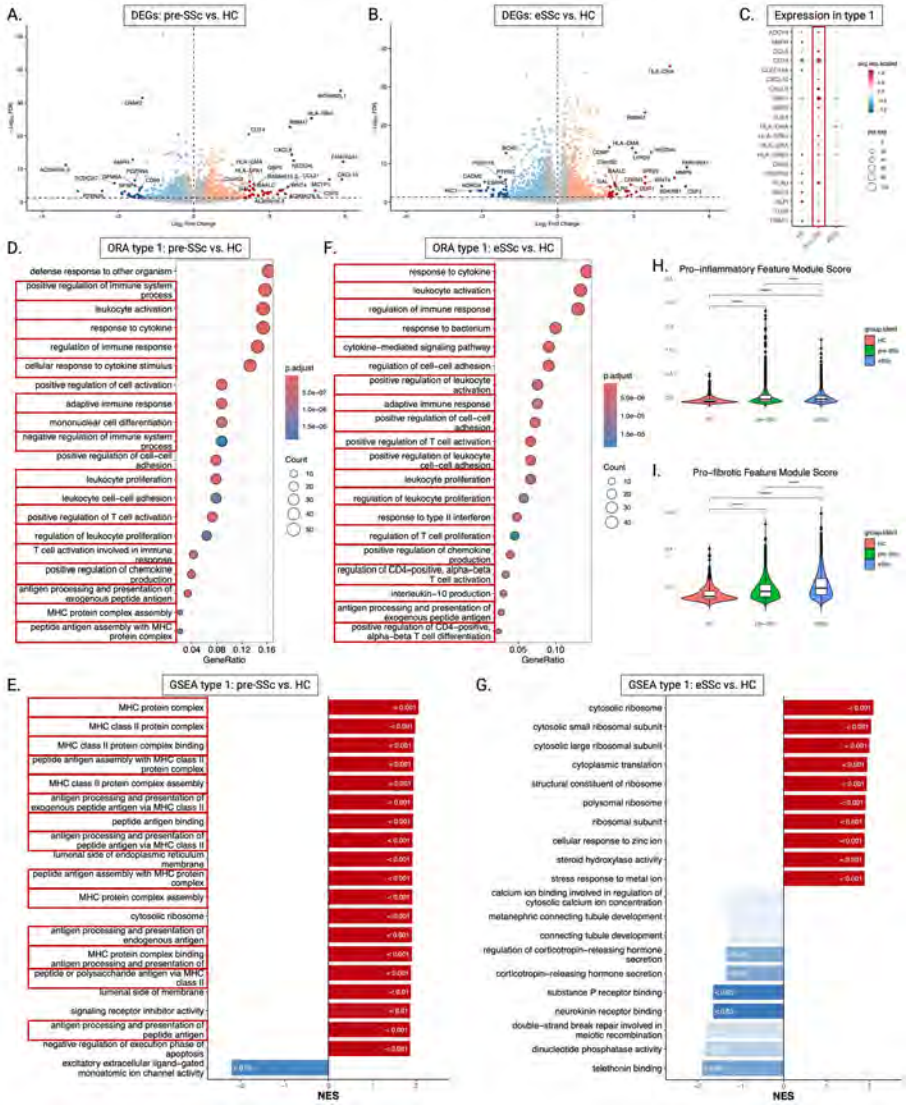

Figure 2. A) Volcano plot of differentially expressed genes (DEGs) in pre-SSc vs. healthy controls (HC), identified using the MAST model. Significant DEGs (|avg_log2FC| > 0.5; FDR < 0.05) are color-coded (blue: downregulated; orange: upregulated). Labeled genes meet stricter thresholds (|average $\log_2$FC| ≥ 2; FDR < 0.0005). B) Volcano plot of DEGs in eSSc vs. HC, as described in (A). C) Expression levels of inflammatory response-related genes in type 1 pro-inflammatory fibroblasts across HC, pre-SSc, and eSSc. Genes shown are from the intersection of significant DEGs in global fibroblasts and type 1 fibroblasts in the pre-SSc vs. HC comparison. D–E) GO-based over-representation analysis (ORA) and gene set enrichment analysis (GSEA) of differentially expressed genes (DEGs) in type 1 fibroblasts (pre-SSc vs. HC). ORA was performed using DEGs with |avg_$\log_2$FC| > 0.5 and FDR < 0.05. GSEA was based on DEGs ranked by score = avg_$\log_2$FC + (–$\log_{10}$FDR). FDR values above each NES bar indicate enrichment significance. F–G) ORA and GSEA of DEGs in type 1 fibroblasts (eSSc vs. HC), using the same thresholds and ranking method. H–I) Module scores across groups for pro-inflammatory (H) and pro-fibrotic (I) gene sets within type 1 fibroblasts. Pro-inflammatory genes include HLA-DRA, CD74, CXCL9, CXCL10, GBP1, HLA-DPA1, HLA-DRB1, PLAU, CCL21, TRAF1, GBP5, SLAMF8, CSF3, IFI30, OAS2, TLR2, IFIT2, IL4I1, CXCL11, HLA-DQA1; Pro-fibrotic genes include TNC, CTHRC1, COMP, COL4A4, CEMIP, LAMC2, WNT4, DDR1, COL4A3, IGFBP2, ADAM12, EDN1, IL23A, NOTCH4, CD37, PPARGC1A. **** indicates p < 0.0001.

Mesenchymal Stromal Cells in Systemic Sclerosis are Dysfunctional and Have a Profibrotic and Senescent Phenotype

Marianela Brizio[1], Benoit Brilland[1], Maximilien Lora[2], Mathieu Mancini[1], David Langlais[1], Marie Hudson[3] and Ines Colmegna[4], [1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, [3]McGill University, Montréal, QC, Canada, [4]The Research Institute of the McGill University Health Centre, Montréal, QC, Canada

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Mesenchymal stromal cells (MSCs) are non-hematopoietic multipotent cells with immunomodulatory, proangiogenic, and antifibrotic properties. MSC functions are mediated by paracrine soluble factors and small vesicles present in the MSC conditioned medium (CM). The three pathogenic axes in systemic sclerosis (SSc) are autoimmunity, vasculopathy, and fibrosis. We hypothesized that functional abnormalities of MSCs contributed to SSc pathogenesis.

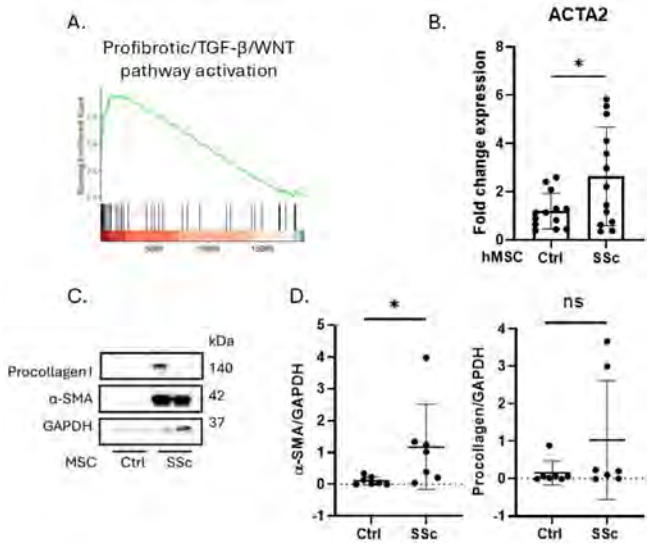

Figure 1. SSc MSCs display a myofibroblast-like phenotype A. Gene Set Enrichment Analysis (gene list: Zhu et al., 2024) B. Quantification of alpha-SMA gene expression (n=14, *p<0.05). C. Western blot representative images and quantification of alpha-SMA and procollagen protein levels(n=8, *p<0.05; ns: non-significant).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

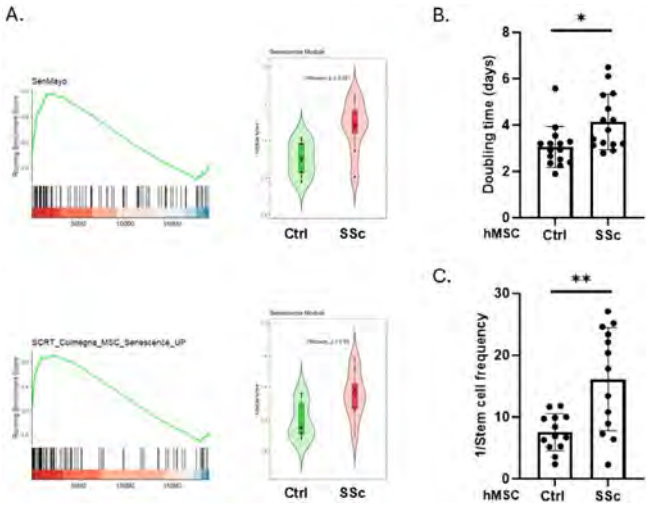

Figure 2. SSc MSCs have a senescent transcriptomic imprint underlying their reduced proliferation and clonogenic capacity A. Gene Set Enrichment Analysis plot for two gene lists (Gao et al., 2023, Psaroudis et al., 2022). B. MSCs population doubling (n=15) and C. Clonogenicity (n=15). *p<0.05 **p<0.01.

We aim to characterize the phenotype, transcriptomic signatures, and key functional properties of adipose-derived MSCs from SSc patients (SSc MSC).

Methods: MSCs were isolated from the adipose tissue associated with two 4 mm punch biopsies from the forearm of 15 SSc and 15 age- and sex-matched healthy controls (Ctrl). MSCs were characterized according to the International Society for Cell and Gene Therapy (ISCT) minimal criteria. RNA sequencing was performed on 8 SSc and 8 Ctrl MSCs. Proliferation (doubling time), stemness (fibroblast colony forming units: CFU-F), and immunopotency (flow cytometry) were assessed in vitro. MSC-CM cytokine profiling was done with the Luminex xMAP® platform.

Results: SSc and Ctrl MSC met ISCT criteria (i.e., adhered to plastic, differentiated into three lineages, and exhibited specific surface markers). Compared to Ctrl, SSc MSCs had 151 upregulated and 16 downregulated genes. Gene Set Enrichment Analysis (GSEA) documented the enrichment of proinflammatory and profibrotic pathways in MSCs recovered from SSc patients. However, SSc MSCs retain the capacity to inhibit the proliferation of activated T cells in vitro. SSc MSC depicted a myofibroblast-like phenotype, characterized by increased α–SMA gene and protein expression, and elevated levels of the profibrotic cytokine CCL2 in MSC-CM. SSc MSC had reduced proliferation and clonogenicity, and were enriched in senescence-associated gene sets.

Conclusion: SSc MSCs differ from Ctrl MSCs in their transcriptomic and functional properties. SSc MSCs have profibrotic and senescent phenotypes, which could contribute to amplify or perpetuate SSc pathogenic mechanisms. Future studies will evaluate the effect of MSC modulation on SSc severity.

FOXO1 Mediated Polysialic Acid Dysregulation in Severe Systemic Sclerosis (SSc): A Novel Biomarker and Therapeutic Target?

Lamia Khan[1], Lisa Willis[2], Jan Storek[3], Desiree Redmond[4], Robert Gniadecki[4] and **Mohammed Osman**[1], [1]University of Alberta, Edmonton, AB, Canada, [2]Department of Biological Sciences, University of Alberta, Edmonton, AB, Canada, [3]University of Calgary, Calgary, AB, Canada, [4]Department of Medicine, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a life-threatening autoimmune disease where fibroblasts (FB) contribute to disease severity by resisting apoptosis and driving excessive skin fibrosis. Among the limited treatment options, autologous stem cell transplantation (ASCT) is the only disease-modifying therapy, but its effects on restoring FB function remain unknown. We recently identified polysialic acid (polySia), a cancer-associated glycan, in skin sections from patients with SSc; polySia levels correlate with fibrosis and normalize post-ASCT. Additionally, severe-SSc skin has genomic instability associated with double-stranded-DNA-breaks (DSBs), which activate a transcription factor, FOXO1, to prolong FB survival. We hypothesized that the FOXO1 pathway might drive polySia expression, thereby contributing to increased cell survival and fibrosis.

Methods: We generated primary dermal fibroblast from skin biopsies of healthy controls (HC), less severe SSc (lSSc), severe fibrotic diffuse SSc (dSSc), and post-ASCT patients. DSB frequency, active (nuclear) FOXO1, and polySia levels were assessed using immunofluorescence/confocal microscopy and immunoblotting. Following FOXO1 pharmacological inhibition, we quantified polySia synthetic enzymes (ST8Sia2/4) and pro-fibrotic markers using qRT-PCR. Resistance-to-apoptosis was evaluated via TUNEL assay following inhibiting FOXO1 activity and polySia synthesis.

Results: In dSSc FB, DSBs, FOXO1 and polySia expression (ST8Sia2/4) were highest compared to lSSc and HC. Importantly, post-ASCT FB had decreased levels of these compared to dSSc. FOXO1 inhibition in dSSC resulted in increased resistance-to-apoptosis, decreased fibrotic-markers (e.g. fibronectin, CTGF) and ST8sia2/4 levels. Also, pharmacological inhibition of polySia synthesis increased resistance-to-apoptosis in dSSc FB. Suggesting that the FOXO1/polySia axis is critical for ASCT's beneficial effects in dSSc.

Conclusion: Our study identifies a novel DSB/FOXO1/polySia pathway as a key driver of severe SSc. This axis may serve as a biomarker for SSc disease progression and treatment response while providing insight into how ASCT restores fibroblast function. Targeting the FOXO1/polySia pathway could offer therapeutic potential for SSc and other fibrotic diseases.

Abstract Number: 0970

Genomic instability in systemic sclerosis is promoted by metabolic remodelling via a FOXO1-dependent axis

Lamia Khan[1], Junqin Wang[2], Aishwarya Iyer[2], Desiree Redmond[2], Dylan Hennessey[2], Sandra O'Keefe[2], Jan Storek[3], Charmaine van Eeden[2], Robert Gniadecki[2] and **Mohammed Osman**[1], [1]University of Alberta, Edmonton, AB, Canada, [2]Department of Medicine, University of Alberta, Edmonton, AB, Canada, [3]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a life-threatening autoimmune disease with limited treatment options, including autologous hematopoietic stem cell transplantation (AHSCT). We recently showed that dermal fibroblasts (DFs) in patients with diffuse cutaneous SSc (dcSSc) develop a cancer-like phenotype characterized by genomic instability and increased double-stranded DNA breaks (DSBs). However, little is known about the mechanisms promoting DF survival following the accumulation of genomic mutations and the effects of AHSCT on mutational frequency. We hypothesized that in response to reactive oxygen species (ROS), dcSSc DFs may promote a mitochondrial-dependent, resistance-to-apoptosis via the activation of the transcription factor forkhead box 1(FOXO1).

Methods: We characterized mutational frequencies and signatures in dcSSc (N =35) and AHSCT patients (N=9), using whole exome sequencing (WES) of dermal sections. We generated DFs from dcSSc, post-AHSCT (or age/sex matched health subjects). We quantified the frequency of DSBs by measuring γ-H2AX levels (immunoblot (IB)), and DSB nuclear foci (confocal microscopy). ROS and mitochondrial membrane potential were measured in DFs using flow cytometry. Changes in mitochondrial dynamics (fusion/fission, via IB), biogenesis (qRT-PCR), and morphology (confocal microscopy) were assessed. FOXO1 activation was determined by measuring nuclear (active) FOXO1, and expression of its downstream mRNA targets SOD2 and PDK4. Resistance-to-apoptosis was determined at baseline, following treatment with cyclophosphamide, a FOXO1-inhibitor, or with overexpression of constitutively active FOXO1 using TUNEL and cleaved caspase 3 levels (IB).

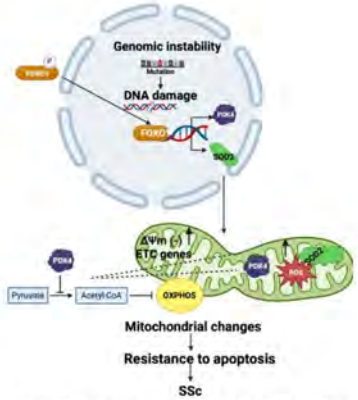

Figure 1. Overall Summary of our findings in diffuse cutaneous fibroblasts.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: dcSSc patients had a reduced mutational frequency in both the dermis and in DFs compared to patients treated with AHSCT. We detected a base-excision repair signature (which is promoted by increased ROS levels) in dcSSc DFs. This was associated with an increased frequency of DSBs and ROS in dcSSc DF compared to post-AHSCT and HC. dcSSc DF had increased indicators associated with mitochondrial remodelling, mitochondrial biogenesis, and mitochondrial fusion. Importantly, FOXO1 was exclusively activated in dcSSc, but not HC or post-AHSCT DF, and its activation was required for promoting apoptosis resistance. Finally, overexpression of constitutively active FOXO1 in HC DF resulted in similar metabolic changes as seen in dcSSc and increased DF survival.

Conclusion: Our study highlights a novel mechanism whereby genotoxic stress signals in dcSSc promote cell survival via metabolic stress remodeling (Fig.1). It also provides mechanistic insights for the effects of AHSCT on the mutational landscape in dcSSc. Future studies targeting this pathway may implicate this novel mitochondrial/FOXO1 pathway as a novel therapeutic strategy in patients with dcSSc.

Unraveling the role of the hippo pathway in systemic sclerosis: A focus on TEADs and VGLL3

Neha Khanna[1], Alyssa Rosek[1], Alexander Cai[1], Olesya Plazyo[2], Johann Gudjonsson[2], Dinesh Khanna[2] and Pei-Suen Tsou[2], [1]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA, Ann Arbor, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disorder characterized by excessive collagen production, leading to the thickening and hardening of skin and internal organs. Although its exact cause remains unknown and no cure exists, current treatments only alleviate symptoms without addressing the underlying disease mechanisms. Our research investigates the Hippo pathway, a key regulator of cell proliferation, apoptosis, and stemness. Dysregulation in this pathway within SSc results in increased YAP/TAZ transcriptional activity in fibroblasts via transcription factor binding, promoting fibrosis. Our previous work identified that the YAP inhibitor Verteporfin can reduce fibrosis. By targeting specific transcription factors and coactivators in the Hippo pathway, specifically TEADs and VGLL3, we aim to clarify its role in SSc fibrosis and develop more targeted therapies.

Methods: We examined TEAD1, TEAD2, TEAD3, TEAD4, and VGLL3 in SSc fibroblasts to assess their roles in fibrosis. Using Accell siRNA, we knocked down TEADs and VGLL3 individually in dermal fibroblasts from SSc patients. We evaluated changes in gene expression and cell functions including proliferation, migration, and contractility. Knockdown cells underwent single-cell RNA-sequencing. To induce pro-fibrotic phenotypes, healthy dermal fibroblasts were stimulated with TGF-β (10 ng/ml) for 1 or 72 hours. Statistical analysis was performed using GraphPad Prism v.10, with significance set at $p < 0.05$.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Knocking down TEADs and VGLL3 achieved over 50% gene downregulation in SSc dermal fibroblasts. Knockdown of TEAD1, TEAD3, or VGLL3 consistently reduced pro-fibrotic gene expression, whereas TEAD2 and TEAD4 did not. Protein-level confirmation by immunofluorescence showed significant decreases in alpha-smooth muscle actin, a key marker of fibroblast activation and myofibroblast differentiation, following TEAD1, TEAD3, or VGLL3 knockdown in SSc fibroblasts. VGLL3 downregulation consistently reduced cell proliferation and migration, while TEAD1 and TEAD3 downregulation impaired gel contraction. Single-cell RNA sequencing identified genes and pathways impacted by TEADs or VGLL3 knockdown. Interestingly, long-term TGF-β stimulation in healthy fibroblasts, which resulted in myofibroblast transformation in these cells, led to downregulation of TEAD1, 2, 3 and VGLL3. In contrast, transient activation of TGF-β, which resulted in increased p-SMAD2 in the nucleus, led to enhanced nuclear staining of TEAD1 or TEAD3, compared to non-treated fibroblasts.

Conclusion: TEAD1, TEAD3, and VGLL3 play crucial roles in mediating the pro-fibrotic effects of the Hippo pathway in SSc fibroblasts. These findings align with our prior research suggesting that disrupting YAP or VGLL3 binding to TEADs in the Hippo pathway could serve as a viable therapeutic strategy. Continued research will focus on the genes and pathways influenced by these transcription factors and coactivator, potentially benefiting treatment approaches for other fibrotic diseases.

Prominent endothelial senescence in systemic sclerosis skin

Poulami Dey[1], William D Brodie[2], Megan N Mattichak[3], Alexander Cai[3], Qi Wu[4], Johann Gudjonsson[5], Dinesh Khanna[5], John Varga[5] and **Pei-Suen Tsou**[5], [1]Michigan Medicine, Ann Arbor, MI, [2]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, Ann Arbor, [3]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA, Ann Arbor, [4]Michigan Medicine, Ann Arbor, [5]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is characterized by extensive damage of the microvessels in multiple organs. We and others showed that endothelial cells (ECs) isolated from SSc skin biopsies show dysregulated phenotypes including impaired angiogenesis, barrier dysfunction, and spontaneous/constitutive endothelial-to-mesenchymal transition (EndoMT). Notably, these are hallmarks of EC senescence. In this study, we therefore sought to determine the presence and role of EC senescence in SSc skin fibrosis.

Methods: Dermal microvascular ECs were isolated from skin biopsies of age-matched healthy individuals and SSc patients. Cellular senescence was assessed through qPCR, immunofluorescence, β-galactosidase expression and measuring the senescence-associated secretory phenotype (SASP). To investigate EC-specific senescence at the single-cell level, we analyzed skin biopsies from 18 healthy controls and 22 patients with early diffuse SSc. Senescence and extracellular matrix (ECM) scores were constructed using specific gene lists, and receptor-ligand interactions were evaluated. P values under 0.05 were deemed statistically significant.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

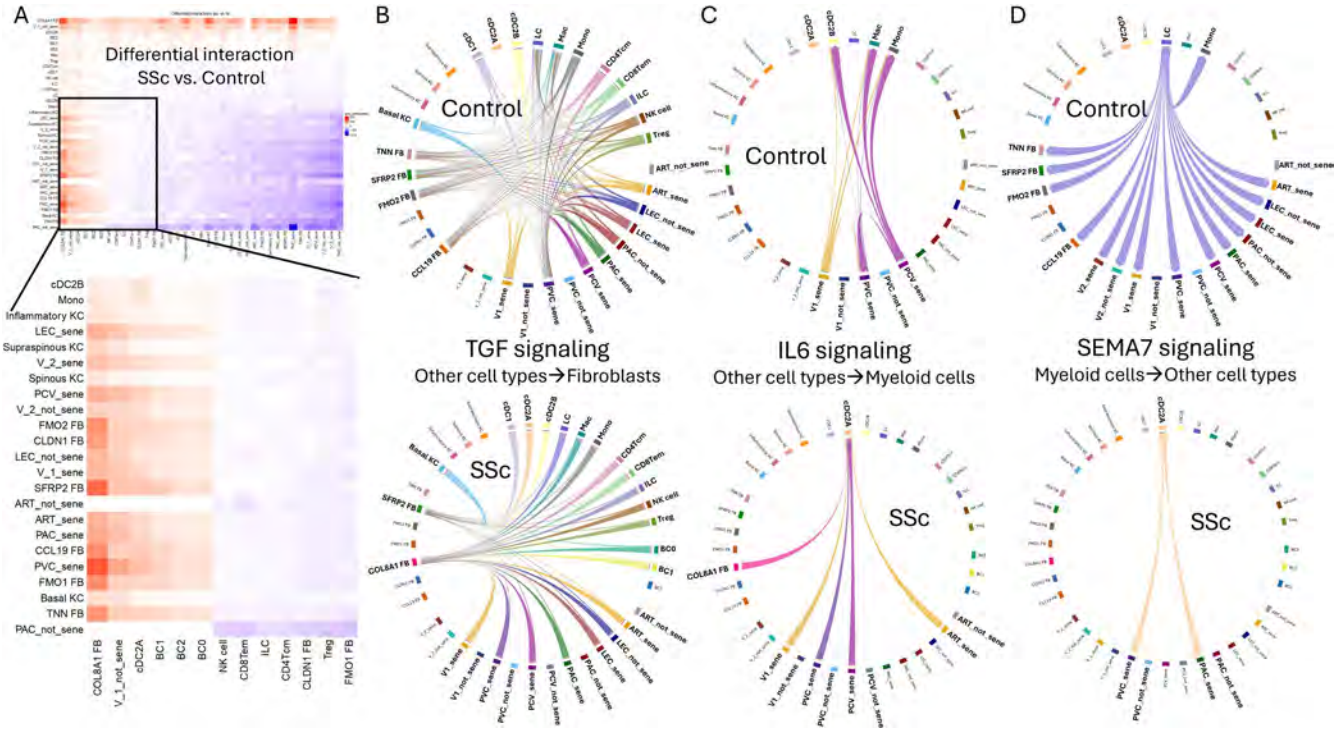

Figure 1. Bioinformatics analysis reveals that senescent SSc ECs engage in unique signaling interactions with myofibroblasts and DCs. Receptor-ligand interaction analysis, comparing SSc skin to controls, shows that senescent EC clusters have the strongest interactions with COL8A1+ myofibroblasts, cDC2A LAMP3+ DCs cells, and B cells, whereas non-senescent ECs exhibit minimal interactions (A). TGFβ signaling targeting COL8A1+ myofibroblasts in SSc skin originates predominantly from senescent ECs, among other cell types, unlike non-senescent ECs (B). In SSc skin, IL-6 signaling to LAMP3+ DCs is contributed by both COL8A1+ myofibroblasts and senescent ECs (C). Senescent PVC and PAC EC clusters interact with LAMP3+ DCs through SEMA7-integrin binding (D). ART: arterial, PAC: post-arterial capillary, PVC: pre-venular capillary, PCV: post-capillary venule, V: venule, LEC: lymphatic EC, FB: fibroblasts, KC: keratinocytes, LC: Langerhans cells, ILC: innate lymphoid cell.

Results: SSc ECs displayed increased senescence, with higher senescence markers (p16, p53, and β-galactosidase), DNA damage (γH2AX and phospho-ATM), SASP secretion (IL-6, IL-8, PAI-1, MMP1, HGF), and reduced eNOS activity, compared to age-matched healthy ECs. In SSc skin biopsies, senescence marker staining was prominently associated with small blood vessels. Single-cell RNA-seq revealed seven distinct EC clusters; one cluster, expanded in SSc biopsies, showed pronounced EndoMT traits. Most EC clusters exhibited significant senescence scores using the SenMayo gene list, independent of age. *CDKN1A*, a canonical senescence marker not included in SenMayo, was notably elevated in SSc ECs compared to controls. Cluster-specific senescence scores were highly correlated with ECM scores. Receptor-ligand analysis indicated that EC senescence in SSc was associated with signaling interactions with myofibroblasts and with dendritic cells. Dominant mediators for this cross-talk included the TGF-β, IL-6, and SEMA7 pathways (Figure 1).

Conclusion: By employing a multi-marker, stepwise approach, we identified senescent ECs in SSc skin microvasculature, confirming endothelial senescence as a key element of the disease. On-going studies are investigating the mechanistic role of senescent ECs in SSc-associated immune, vascular and fibrotic pathologies. This unusual EC phenotype may play a crucial pathogenic role in SSc and could serve as a potential target for senotherapy.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: S100 proteins are involved in the inflammatory responses of autoimmune diseases. We previously showed that S100 proteins regulate macrophage function via CD68. Based on this, we developed a novel human hybrid protein, human MIKO-1 (hMIKO-1), derived from the primary structure of human S100. This study aimed to investigate its effects on macrophage polarization and its therapeutic potential in a systemic sclerosis (SSc) mouse model with interstitial lung disease (ILD).

Methods: Murine macrophages were co-cultured with hMIKO-1 to evaluate its effect on macrophage polarization. In vivo, female C57BL/6 mice were injected subcutaneously with bleomycin (200 μg/mouse, every other day) to induce skin and lung lesions resembling SSc-associated ILD (SSc-ILD). Mice were divided into three groups: sham control, disease control (BLM + vehicle), and treatment (BLM + hMIKO-1). After four weeks, skin and lung tissues were collected and assessed histologically.

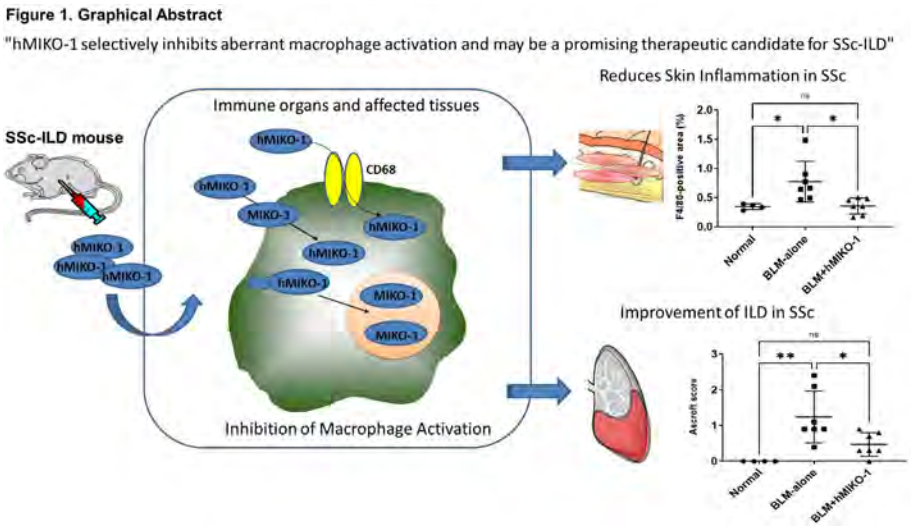

Figure 1. Graphical Abstract: Mechanism of Action and Therapeutic Effects of hMIKO-1 hMIKO-1 enters the macrophage cytoplasm via CD68-mediated uptake and endocytosis, forming complexes with β-actin and NF-κB. It subsequently binds to nuclear transport proteins and translocates into the nucleus. In THP-1 cells, hMIKO-1 significantly suppresses the mRNA expression of pro-inflammatory cytokines TNF-α and TGF-β. In systemic sclerosis (SSc) mouse models, hMIKO-1 reduces skin inflammation and improves interstitial lung disease (ILD). These findings suggest that hMIKO-1 selectively inhibits aberrant macrophage activation and may represent a promising therapeutic candidate for SSc-ILD.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

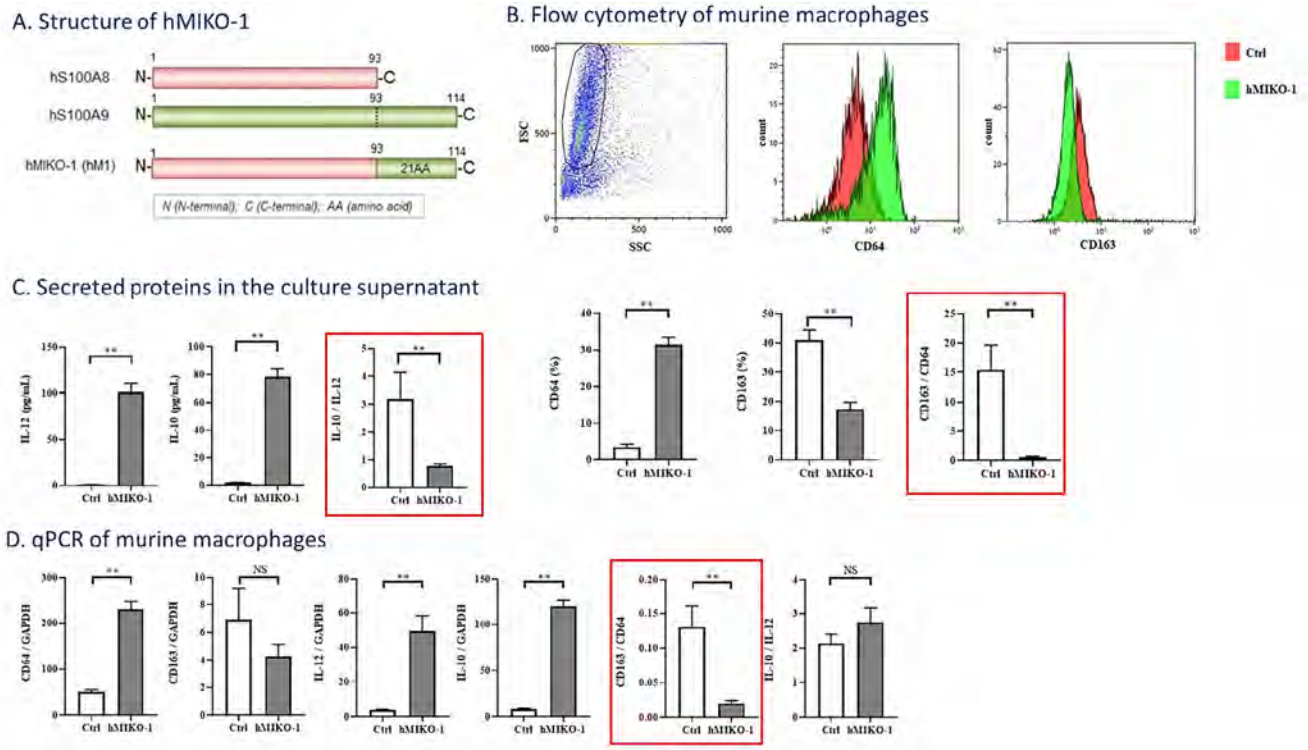

Figure 2. Inhibitory Effect of hMIKO-1 on M2 Polarization of Murine Macrophages (A) hMIKO-1 was designed based on the amino acid sequences of S100A8 and S100A9. (B–D) Co-culture with hMIKO-1 was conducted using murine peritoneal macrophages polarized toward the M2 phenotype. (B) Flow cytometry showed a significant reduction in the CD163/CD64 ratio compared to control, indicating suppression of M2 polarization. (C) The IL-10/IL-12 ratio in the culture supernatant also decreased significantly. (D) qPCR confirmed reduced CD163/CD64 expression, supporting the inhibitory effect of hMIKO-1. Ctrl: without hMIKO-1. Data are mean ± SD (n = 6). **p < 0.01; NS: not significant.

Results: hMIKO-1 significantly inhibited M2 polarization of murine macrophages in vitro. In vivo, lung fibrosis scores were significantly lower in the hMIKO-1-treated group compared to the disease control group, while no significant difference was found in skin fibrosis. F4/80-positive macrophages in both skin and lung tissues were significantly reduced in the hMIKO-1 group. Notably, hMIKO-1 accumulation differed between lungs and skin.

Conclusion: hMIKO-1 attenuated inflammation and fibrosis in the lungs of SSc-ILD model mice. Its limited effect in the skin may be due to differences in tissue accumulation. hMIKO-1 may serve as a potential targeted therapy for SSc-associated ILD.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Previous studies showed that monocyte-derived macrophages become pro-fibrotic in systemic sclerosis (SSc) and contribute to fibroblast activation. Macrophages are, however, a heterogeneous population. Macrophages of different ontogenies (monocyte-derived or tissue resident macrophages (TR-Macs)) can be functionally distinct in physiology and disease. However, the role of TR-Macs in the pathogenesis of SSc has not been studied thus far.

Here we aimed to evaluate the role of TR-Macs in SSc skin using induced pluripotent stem cells (iPSC)-derived macrophages and an *in vitro* human skin equivalent model.

Methods: TR-Macs were generated from SSc patients (SSc-TR-Macs) and healthy controls (healthy-TR-Macs). Functional differences were assessed using flow cytometry, phagocytosis assays, and RNA sequencing (RNA-seq). A three-dimensional human skin equivalent model was developed by co-culturing TR-Macs with fibroblasts and keratinocytes. Fluorescence staining was performed to analyze TR-Macs polarization, and single-cell RNA sequencing (scRNA-seq) was used to evaluate the subpopulations of fibroblasts and their communication with macrophages in an SSc skin equivalent in comparison to SSc skin.

Results: SSc-TR-Macs expressed higher levels of markers of M2 polarization and showed an increased phagocytic capacity compared to healthy-TR-Macs. Furthermore, SSc-TR-Macs exposed to SSc serum upregulated pro-inflammatory and pro-fibrotic pathways.

Incorporation of SSc TR-Macs in healthy human skin equivalents (containing healthy fibroblasts and keratinocytes) was sufficient to induce fibroblast-to-myofibroblast transition and excessive collagen I deposition without further stimuli. Furthermore, addition of SSc-TR-Macs in a skin equivalent formed by SSc fibroblasts greatly enhanced basal and TGFβ-induced fibroblast activation and collagen I deposition.

ScRNA-seq analysis demonstrated that SSc human skin equivalents (formed by SSc TR-Macs and SSc fibroblasts) recapitulate the composition, shifts in frequencies of fibroblast subpopulations, as well as fibroblasts-macrophages cell-cell communication networks observed in SSc skin.

Treatment with the antifibrotic drug nintedanib, as well as with the CD206-targeting peptide RP-832c (that targets M2 macrophages) effectively reduced collagen deposition in an SSc skin equivalent (containing SSc fibroblasts and SSc TR-Macs).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: Our study demonstrates a pro-fibrotic role of SSc TR-Macs in SSc skin. These Mac subsets are M2-like polarized and promote fibroblast to myofibroblast transition and fibrotic remodelling in an SSc skin equivalent. The SSc skin equivalent model containing TR-Macs recapitulates key fibroblast and Macs subpopulations and their cell-cell communication in SSc skin. Furthermore, not only drugs that target fibroblasts, but also drugs that specifically target macrophages demonstrate antifibrotic effects in the SSc skin equivalent containing TR-Macs. This model could be thus used for testing of antifibrotic drugs that interfere with the fibroblast-macrophage communication network in SSc.

Session Title: (0955–0977) Systemic Sclerosis & Related Disorders – Basic Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a progressive fibrotic disease characterized by fibroblast activation and immune dysregulation, with limited therapeutic options. Mitochondrial dysfunction is increasingly implicated in fibrosis, yet the role of mitochondrial translation remains underexplored. Linezolid, a clinically approved ribosome-targeting antibiotic, inhibits mitochondrial protein synthesis. We investigated whether targeting mitochondrial translation with linezolid could mitigate fibrosis in SSc.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: We employed complementary SSc models, including TGFβ-stimulated human dermal fibroblasts, three-dimensional SSc skin equivalents (SScSE), and precision-cut skin slices (PCSS) from SSc patients. In vivo, we used a multiorgan fibrosis mouse model mimicking key features of diffuse cutaneous SSc. Mechanistic studies included immunostaining, Western blot, Seahorse analysis, and nascent mitochondrial translation assays. Transcriptomic profiling was performed on fibroblasts, SSc tissue, and TGFβ-activated macrophages.

Results: Linezolid inhibited TGFβ-induced fibroblast activation across multiple models of SSc, including cultured human dermal fibroblasts, three-dimensional SSc skin equivalents (SScSE), SSc patient-derived precision-cut skin slices (PCSS), and an inflammation-driven murine fibrosis model. Treatment reduced αSMA expression, stress fiber formation, and collagen type I deposition, indicating effective suppression of fibroblast-to-myofibroblast transition.

Transcriptomic analyses revealed that linezolid reversed profibrotic gene expression programs and downregulated key signaling pathways such as TGFβ, WNT, and JAK-STAT. In SScSE, linezolid also modulated macrophage activation profiles, suppressing pathways involved in cytoskeletal remodeling and fibroblast stimulation.

Mechanistically, linezolid impaired mitochondrial translation in fibroblasts, evidenced by reduced incorporation of nascent mitochondrial proteins and decreased MTCO1 expression. This was accompanied by diminished oxidative phosphorylation capacity and lowered NAD^+/NADH ratios, contributing to functional metabolic disruption.

Conclusion: This study identifies mitochondrial translation as a critical regulator of fibroblast activation and immune cell function in SSc. By targeting this pathway, linezolid exerts potent antifibrotic effects across human and murine models. Given its clinical availability, these findings provide strong rationale for repurposing linezolid as a novel therapeutic strategy for fibrotic disorders.

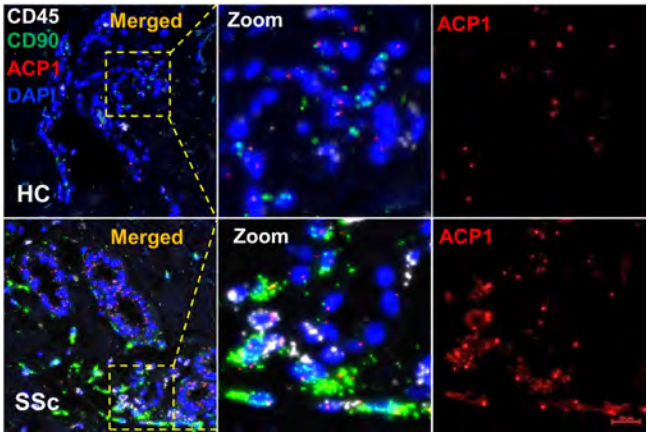

Figure 1. LMPTP expression is significantly upregulated in affected skin of SSc patients. LMPTP mRNA was quantified by RNAScope in situ hybridization using LMPTP (ACP1, red) , CD90 (fibroblast, green), CD45 (leucocytes, white) probes in both healthy (HC, n=4) and SSc patients (SSc, n=4) skin biopsies.

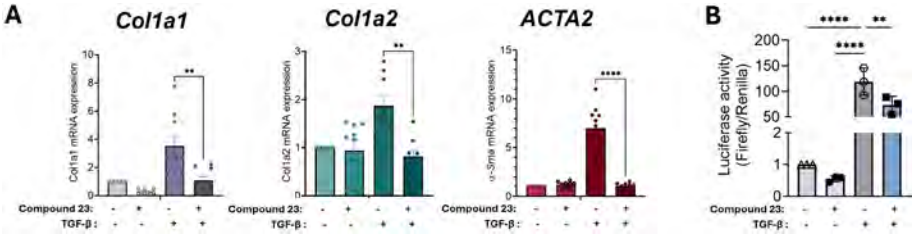

Figure 2. LMPTP inhibition reduces pro-fibrotic gene expression and dampens SMAD-dependent TGF-β signaling. A. qPCR analysis of COL1A1, COL1A2, and ACTA2 expression in human dermal fibroblasts treated with 10 μM Compound 23, stimulated with 10 ng TGF-beta1 for 24h. Error bars represent mean ± SEM normalized to control group. Statistical significance was determined using paired t test. **P < 0.01, ****P < 0.0001. B. SMAD-dependent luciferase reporter assay assessing SMAD3 transcriptional activity after 24-hour stimulation of 10 ng/mL TGF-β1 in 293T cells, with or without 10 μM Compound 23. Luciferase activity was normalized to Renilla. Error bars represent Mean ± SEM and representative at least three different experiments in triplicate. Statistical significance was assessed using One-way ANOVA test, **P < 0.01, ****P < 0.0001.

Background/Purpose: The identification of effective and safe anti-fibrotic agents is a critical unmet need in systemic sclerosis (SSc). Although fibrosis in SSc is driven by aberrant activation of pro-fibrotic signaling pathways downstream of protein kinase receptors, such as the receptor for transforming growth factor beta (TGFbeta), little is known in this condition about phosphatases, which oppose signaling by kinases. We sought to explore a potential role for the low molecular weight PTP (LMPTP) in fibrotic manifestations of SSc because the LMPTP promotes growth signaling pathways in cancer cells, is highly expressed in fibroblasts and complete knockout (KO) of the LMPTP does not induce any spontaneous phenotype.

Methods: Skin biopsies and lung explants from patients with early SSc were subjected to in situ hybridization for LMPTP. Primary dermal fibroblasts (DF) were subjected to treatment with two independent LMPTP inhibitors followed by assessment of TGFbeta signaling, immunoprecipitations, transcriptomics, proteomics and phospho-proteomics analysis. TGFbeta signaling reporter assays were performed in 293 cells. Mice were subjected to the bleomycin model of skin and lung fibrosis.

Results: We found that the LMPTP is upregulated in fibrotic skin of scleroderma patients (**Fig. 1**). An assessment of primary DF treated with small-molecule LMPTP inhibitors showed that LMPTP promotes TGFbeta signaling (**Fig. 2**). Mechanistically, LMPTP promotes early TGFbeta receptor (TGFBR) signaling through the dephosphorylation of a novel substrate. Global deletion of LMPTP in mice significantly attenuated the severity of skin and lung fibrosis in the bleomycin-induced model (**Fig. 3**). Similar results were obtained when mice were treated with an orally bioavailable LMPTP inhibitor.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

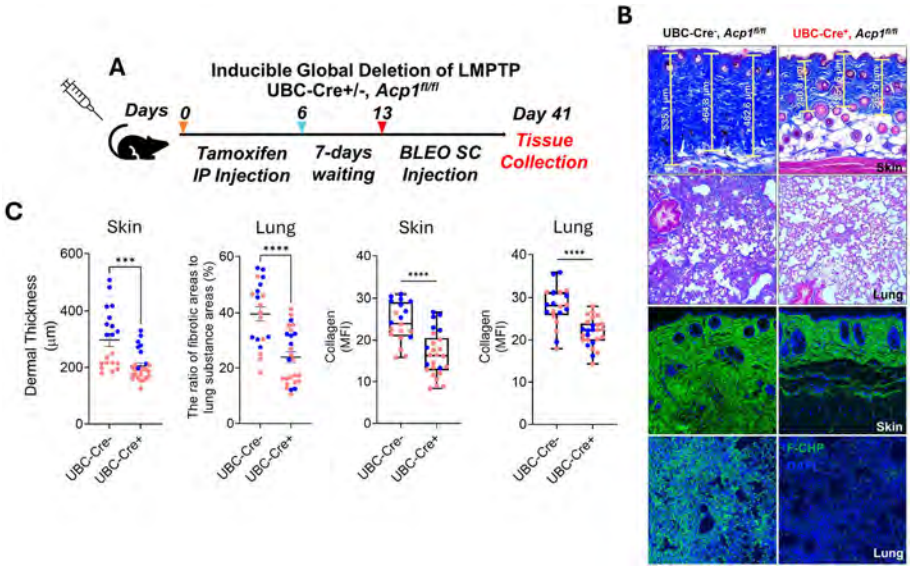

Figure 3. LMPTP promotes bleomycin-induced fibrosis in vivo. A. Schematic overview of tamoxifen-inducible ACP1 knockout mouse model and bleomycin-induced fibrosis protocol. B. Masson's trichrome and collagen-specific fluorescent staining (F-CHP) of skin and lung from wild-type and ACP1 KO mice after bleomycin treatment (Cre+, n=26; Cre–, n=20). Blue dots represent male samples and red dots represent female samples. C. Quantification of dermal thickness, collagen deposition, and fluorescence intensity in skin and lung. Data are shown as mean ± SEM. Statistical significance was determined using the Mann-Whitney test. *P < 0.05, **P < 0.01, ****P < 0.0001.

Conclusion: Taken together, these findings indicate a critical role for LMPTP in development of fibrosis through a novel mechanism of regulation of early TGFbeta signaling. As LMPTP KO mice are healthy and viable and LMPTP might be tractable for small molecule discovery, our study suggests that LMPTP inhibition is a potentially safe therapeutic strategy for preventing or treating fibrosis in scleroderma.

also known as NR0B1, has been shown to regulate fundamental cellular processes. However, its role in fibrotic diseases has not been investigated so far. Here, we aimed to characterize the role of DAX1 in the pathogenesis of SSc.

Methods: Expression of DAX1 was analyzed by Western blot, imaging mass cytometry (IMC) and immunofluorescence. The effects of DAX1 knockdown or DAX1 antagonist BPK-29 on collagen production and myofibroblast differentiation were analyzed in cultured human fibroblasts, in bleomycin- and cGvHD-induced dermal fibrosis in mice, human 3D full-thickness skin equivalents and precision-cut human skin slices (PCSS). DAX1 signaling in TGFβ-stimulated fibroblasts was analyzed by RNASeq, co-immunoprecipitation and chromatin-immunoprecipitation.

Results: The expression of DAX1 was upregulated in SSc patients in a non-canonical TGFβ signaling dependent manner. DAX1 induced the activation of WNT/β-catenin signaling to drive fibroblast-to-myofibroblast transition. Knockout of DAX1 in murine skin by topical injection of DAX1-siRNA inhibited fibroblast-to-myofibroblast differentiation and ameliorated dermal fibrosis in two complementary mouse models of fibrosis. The selective DAX1 antagonist BPK-29 attenuated the TGFβ-induced myofibroblast activation or fibrotic tissue remodeling in cultured human dermal fibroblasts, and in three dimensional full-thickness skin equivalents. Moreover, inhibition of DAX1 ameliorated the expression of disease-relevant genes including WNT signaling in precision-cut slices of SSc skin. Mechanistically, DAX1 dimerized with E2F4 to promote WNT/β-catenin signaling via induction of *WNT4* and *WNT10B* genes in cultured fibroblasts, in murine models of fibrosis and in precision-cut skin slices of SSc patients.

Conclusion: DAX1 is upregulated in SSc in a TGFβ-dependent manner to promote fibroblast activation via WNT/β-catenin signaling. Inactivation of DAX1 normalizes WNT/β-catenin signaling, inhibits fibroblast-to-myofibroblast transition and ameliorates experimental fibrosis. Targeting of DAX1 may thus offer potential for therapeutic intervention.

IL-17A+ HLA-DR-CCR6+ regulatory T cells: Dual role in T cell suppression and synovial inflammation in arthritis.

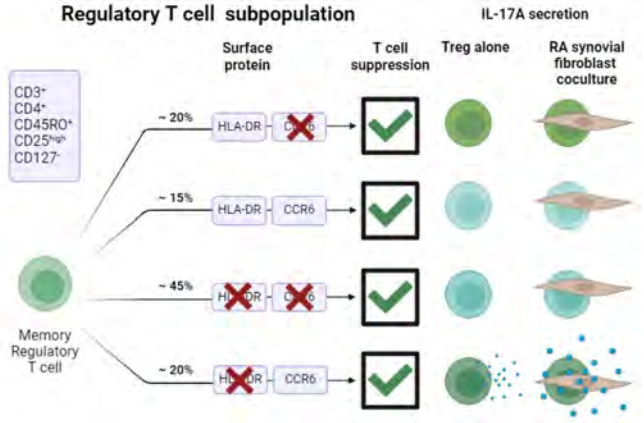
Bennie Heeswijk[1], Margot Bongenaar[1], Nadine Davelaar[1], Pascal de Jong[1], Hannah den Braanker[1], Radboud Dolhain[1] and Erik Lubberts[2], [1]Erasmus University Medical Center, Rotterdam, the Netherlands, Rotterdam, Netherlands, [2]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Regulatory T cells (Tregs) are essential for maintaining immune tolerance and limiting excessive immune responses. However, Tregs show high levels of heterogeneity and plasticity, indicated by the production of IL-17A. In rheumatoid arthritis (RA), IL-17A intensifies synovial inflammation by activating synovial fibroblasts. We aim to characterize Treg heterogeneity in RA patients and examine their functional characteristics and role in synovial inflammation.

Methods: CITE-seq was applied to T cells from four treatment-naïve RA patients and four healthy controls. Unsupervised clustering was performed to identify Treg subpopulations. These subpopulations were verified in PBMCs from 150 RA patients and 30 healthy controls using flow cytometry. A suppression assay was conducted to evaluate the suppressive

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Schematic overview of Treg subpopulation characteristics

capacity of the sorted Treg subpopulations. In addition, the cytokine-secreting potential of sorted Treg subpopulations was investigated using ELISA, as well as the effect of interaction with RA synovial fibroblasts on cytokine secretion.

Results: CITE-seq analysis from treatment-naïve early RA patients identified Treg subpopulations based on the presence of HLA-DR and CCR6. We verified the surface expression of HLA-DR and CCR6 on Tregs in PBMCs of patients with established RA, revealing a significant decrease in HLA-DR$^-$CCR6$^+$ Treg cells in RA patients compared to healthy individuals. Significantly fewer HLA-DR$^-$CCR6$^+$ Tregs were detected specifically in RA patients with moderate and severe disease activity.

We analysed suppressive function, cytokine secretion, and fibroblast interaction to investigate the functional differences between these subpopulations. We found that all Treg subpopulations suppress proliferation of CD4$^+$ responder cells. In addition, we revealed that activated HLA-DR$^-$CCR6$^+$ Treg exclusively secreted IL-17A. Co-cultures with RA synovial fibroblasts showed that HLA-DR$^-$CCR6$^+$ Tregs induced synovial fibroblast activation, indicated by the secretion of IL-6, IL-8, and MMP-3. Interestingly, IL-17A secretion was increased upon coculturing HLA-DR$^-$CCR6$^+$ Treg and synovial fibroblast , highlighting the potential plasticity of this HLA-DR$^-$CCR6$^+$ Treg subpopulation towards a proinflammatory phenotype.

Conclusion: Regulatory T cell subsets defined by HLA-DR and CCR6 markers were identified across different stages of RA and exhibited notable functional heterogeneity. Despite maintaining suppressive capacity, some subsets, particularly HLA-DR$^-$CCR6$^+$ Tregs, displayed pro-inflammatory features, including IL-17A secretion and activation of synovial fibroblasts. These findings underscore the complexity of Treg biology in RA and suggest that HLA-DR$^-$CCR6$^+$ Tregs may paradoxically contribute to disease progression under inflammatory conditions.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin-23 (IL-23) is a key cytokine in the pathogenesis of psoriatic diseases, as demonstrated by the clinical success of IL-23-targeted therapies. Monocytes are a primary source of IL-23, contributing to the inflammatory milieu.

IL-23 is known to drive the pathogenicity of T-helper (Th) cells with a $CCR6^+$ phenotype; however, its specific effects on distinct memory T cell subsets remain poorly defined. The $CCR6^+$ Th population is heterogeneous, comprising Th17 cells, which predominantly produce IL-17A, and Th17.1 cells, which mainly secrete interferon-gamma (IFN-γ). We aim to characterize the interactions between IL-23 and the different CCR6+ Ths, which is essential for advancing our understanding of psoriatic disease mechanisms and improving therapeutic strategies.

Methods: Human CCR6+, CCR6-, Th17, Th17.1 and classical Th1 cells were sorted from peripheral blood mononuclear cells (PBMCs). Transcription of IL-23R was determined with RT-PCR. CCR6+, CCR6-, Th17, Th17.1 and Th1 cells were stimulated with αCD3/αCD28, in the presence or absence of IL-23 for 72h before measuring cytokine secretion with ELISA. CD14+ monocytes were isolated using MACS and cocultured with Th cell populations before measuring IFN-γ secretion with ELISA.

Results: Ex vivo analysis revealed that $CCR6^+$ T-helper cells expressed significantly higher levels of IL-23R mRNA compared to $CCR6^-$ counterparts. Upon stimulation with IL-23, $CCR6^+$ Th cells secreted significantly more interferon-gamma (IFN-γ), but not interleukin-17A (IL-17A). To account for the heterogeneity within the $CCR6^+$ population, memory Th17, Th17.1, and classical $CCR6^-$ Th1 cells were further sorted and analyzed. Both Th17 and Th17.1 cells exhibited higher IL-23R expression than Th1 cells. Following IL-23 stimulation, Th17.1 cells produced significantly more IFN-γ, whereas Th17 and Th1 cells did not. IFN-γ was found to induce IL-23 production in $CD14^+$ monocytes. In co-culture experiments with monocytes, Th17.1 cells secreted significantly more IFN-γ than classical Th1 cells.

Conclusion: T-helper cell subsets exhibit distinct responses to IL-23, particularly in their ability to produce IFN-γ. Our data show that IL-23 selectively induces IFN-γ secretion in Th17.1 cells, but not in Th17 or classical Th1 cells. Additionally, IFN-γ promotes IL-23 production by monocytes, suggesting a proinflammatory feedback loop that may amplify Th17.1-mediated inflammation. When co-cultured with monocytes, Th17.1 cells produced more IFN-γ than Th1 cells,

Schematic overview of the IL-23/IFNg proinflammatory feedback loop.

further underscoring their heightened pro-inflammatory potential. These findings highlight a unique IL-23–IFN-γ axis in Th17.1 cells that may contribute significantly to local tissue inflammation in psoriatic diseases.

Expansion of Viral-Reactive CD8+ T cell Repertoire Stratified by Pathotype in New-onset ACPA+ Rheumatoid Arthritis

Carl Coyle[1], Wittaya Suwakulsiri[2], Lukas Andriessen[3], Megan Soon[4], Pascale Wehr[5], Sumera Qureshi[6], Christopher Altmann[7], Annabelle Small[8], Vincent Wong[9], Andrew Cope[6], Kevin Wei[10], Hendrik Nel[5], Mihir Wechalekar[11] and Ranjeny Thomas[2], [1]Kings College London, London, United Kingdom, [2]Frazer Institute, University of Queensland, Brisbane, Queensland, Australia, [3]Frazer Institute, University of Queensland, Woolloongabba, Queensland, Australia, [4]Frazer Institute, The University of Queensland, Brisbane, Australia, [5]University of Queensland, Woolloongabba, Queensland, Australia, [6]King's College London, London, United Kingdom, [7]Flinders University, Adelaide, Australia, [8]Flinders University, Bedford Park, South Australia, Australia, [9]College of Medicine and Public Health, Bedford Park, South Australia, Australia, [10]Brigham and Women's Hospital at Harvard Medical School, Boston, MA, [11]Flinders Medical Centre, Adelaide, Australia

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Development of Rheumatoid Arthritis (RA) is strongly associated with specific *HLA-DRB1* genotypes and the HLA-DR antigen binding groove, the shared epitope. *HLA-B*08* also increases risk of ACPA+ RA, and large numbers of CD8+, including granzyme K (GZMK)+ tissue-resident T cells (Trm), infiltrate RA synovial tissue (ST) in active, established RA. ST from DMARD-naïve patients can be classified into lymphomyeloid (LM), diffuse myeloid (DM) or pauci-immune (PI) "pathotypes". While most T cell receptor (TCR) repertoire analysis focused on highly inflamed LM ST, TCR repertoires of DM and PI ST are poorly characterized.

Methods: We compared CD45+ antigen-presenting cells (APCs) and TCR repertoire in arthroscopic ST and paired peripheral blood (PB) from 9 recent-onset DMARD-naïve ACPA+ DM- or PI-pathotype RA patients with symptom duration up to 1 year, using single-cell(sc) RNA/TCR-sequencing (all except one *HLA-DRB1*04:01* shared-epitope+). ST biopsies from 9 ACPA+ DM and 10 PI pathotyped RA patients were imaged using spatial transcriptomic profiling (5,101 genes, 10x Genomics).

Results: scRNAseq identified PB classical and non-classical monocytes, dendritic cells (DCs). In ST, myeloid DCs and macrophages were enriched in APC and lymphocyte-activation genes. In PI pathotype PB non-classical monocytes, ST myeloid DCs and macrophages were reduced compared to DM pathotype. CD4+ T cells had limited clonal expansion. The repertoire included public non-expanded viral-reactive clonotypes. Most memory CD8+ T cells expressed *GZMB, GRZK* or both. *GZMK+GZMB+/-* CD8+ T cell clones were moderately expanded and expressed Trm markers in ST, while *GZMB+GZMK-* CD8 clones were highly-expanded in PB. Grouping of lymphocyte interactions by paratope hotspots (GLIPH) identified cytomegalovirus (CMV) and Epstein-Barr virus (EBV)-reactive TCRs, which were GZMB+ in PB, and often shared in ST as GZMK + Trm. CMV-reactive clonal expansion occurred in DM and PI pathotypes, restricted by HLA-A*02:01 and HLA-A*03:01 evenly across pathotypes. In contrast, EBV-reactive clonal expansion (*GZMK*+, HLA-B*08-restricted) was highly-enriched

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

in the PI pathotype. Xenium spatial imaging in DM and PA ST identified small numbers of infiltrating *GZMB+GZMK+/-* CD8+ T cells and rare plasma cells. Besides larger macrophage infiltrates and expanded lining fibroblasts, PI T-cell infiltrates in DM were distinguished from PI pathotype by adjacent *Clec9A+* DCs or type 1 interferon-induced *CXCL11*.

Conclusion: The data suggest strong CD8+ PB clonal expansion towards latent viruses and bystander ST infiltration in early ACPA+ RA of both pathotypes, but with *HLA-B*08*-restriction skewed to EBV-reactive Trm in PI. MHC class I genes may shape the CD8+ Trm repertoire, viral antigen presentation and ST pathology in RA.

GNTI-350: A CAR-Treg Therapy Offering Durable Immune Reset with Improved Safety for B Cell–Driven Autoimmune Diseases

Christopher Moore[1], Travis Drow[2], Peter Cook[2], Annaiz Grimm[2], Victoria DeVault-Nelson[1], Jennifer Mellen[1], Payam Zarin[1], Alaina Burgess[1], Maegan Hoover[1], Tingxi Guo[1], Brock McKinney[2], Noelle Dahl[2], Aesha Vakil[2], Brian Christin[3], Gene Uenishi[1], Tiffany Chen[1], Alberto Del Rio-Espinola[4], David Rawlings[2] and Tom Wickham[1], [1]GentiBio, Cambridge, [2]SCRI, Seattle, [3]GentiBio, Seattle, [4]GentiBio, Basel, Switzerland

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: CD19 CAR T therapies have demonstrated promise in systemic lupus erythematosus (SLE) by transiently depleting B cells and resetting the immune system. However, long-term remission may require sustained regulation of autoreactive immune responses, including suppression of T follicular helper (Tfh) cells that drive pathogenic B cell maturation in germinal centers (GCs). Additionally, limitations such as cytokine release syndrome (CRS), neurotoxicity, and the cost of autologous manufacturing restrict applicability of current CAR T approaches in autoimmune settings.

Methods: To overcome these limitations, we developed GNTI-350, an allogeneic CD19 CAR-engineered regulatory T cell (CAR19 EngTreg) therapy designed to achieve robust immune reset by combining the B cell depletion capacity of CAR T cells with the suppressive function of Tregs. GNTI-350 cells are generated using a proprietary platform enabling (1) stable FOXP3 expression for lineage commitment, (2) a CD19-targeted CAR for selective B cell engagement, and (3) a chemically-inducible IL-2–like signaling complex (CISC) that supports Treg function in IL-2–deficient autoimmune settings through rapamycin addition. The platform enables efficient manufacturing with high purity and scalability.

Results: In vitro, CAR19 EngTregs exhibited hallmark Treg markers (FOXP3, CD25, CTLA-4, ICOS) and drove primary B cell depletion, while maintaining low inflammatory cytokine production (IFNγ, TNFα, IL-6) compared to CAR19 T effectors. Additionally, CAR19 EngTregs suppressed T cell proliferation, blocked B cell differentiation, and reduced immunoglobulin production. In vivo studies in the SLE123 model also demonstrated short-term depletion of peripheral B cells followed by a return to baseline levels within one month, mirroring transient clinical CAR19 T effectors. However, GNTI-350 achieved sustained immunologic reset: EngTregs persisted for over 7 months, suppressed Tfh cells, reduced GC B cells, lowered

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. disease-driving autoantibodies, and decreased kidney damage markers. Notably, these data demonstrate CAR19 EngTregs drive dual modulation of B and T cells, mimicking the function of follicular regulatory T cells (Tfr) that naturally restrain GC activity. In this context, GNTI-350 acted as a "super Tfr" by simultaneously suppressing Tfh cells and GC B cells—thereby disrupting the regeneration of pathogenic B cells and autoantibodies.

Conclusion: GNTI-350 is a first-in-class, allogeneic, antigen-targeted Treg therapy with the capacity to act as a potent "super Tfr," disrupting germinal center pathology by concurrently targeting B cells and Tfh cells. This dual mechanism offers a durable and safe immune reset, distinguishing GNTI-350 as a promising therapeutic candidate for B cell–driven autoimmune diseases such as SLE.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Herpes zoster (HZ) is a common infection, particularly in older adults and women, and can lead to complications like neuropathic pain. The risk is higher in immunosuppressed individuals. Shingrix™, a recombinant subunit vaccine, has proven effective in reducing HZ risk by stimulating robust CD4 and CD8 T-cell responses. However, data on its immunogenicity in patients with immune-mediated inflammatory diseases (IMIDs) remains limited.

This study aimed to evaluate B-cell and T-cell immune responses to the recombinant HZ vaccine in IMID patients treated with JAK inhibitors (JAK-i), anti-TNF therapies, or methotrexate (MTX), and to identify factors associated with reduced vaccine-induced immunity.

Methods: This study investigated both humoral and cellular immune responses following a two-dose regimen of the recombinant inactivated vaccine in 131 patients with IMIDs treated with JAK inhibitors, anti-TNF therapy, or MTX. The results were compared to those of 27 healthy controls matched for age and sex. Cellular immune responses were assessed through CD4+ (Th1) and CD8+ (cytotoxic) T-cell activation, while VZV-specific IgG antibody levels were used to evaluate humoral responses.

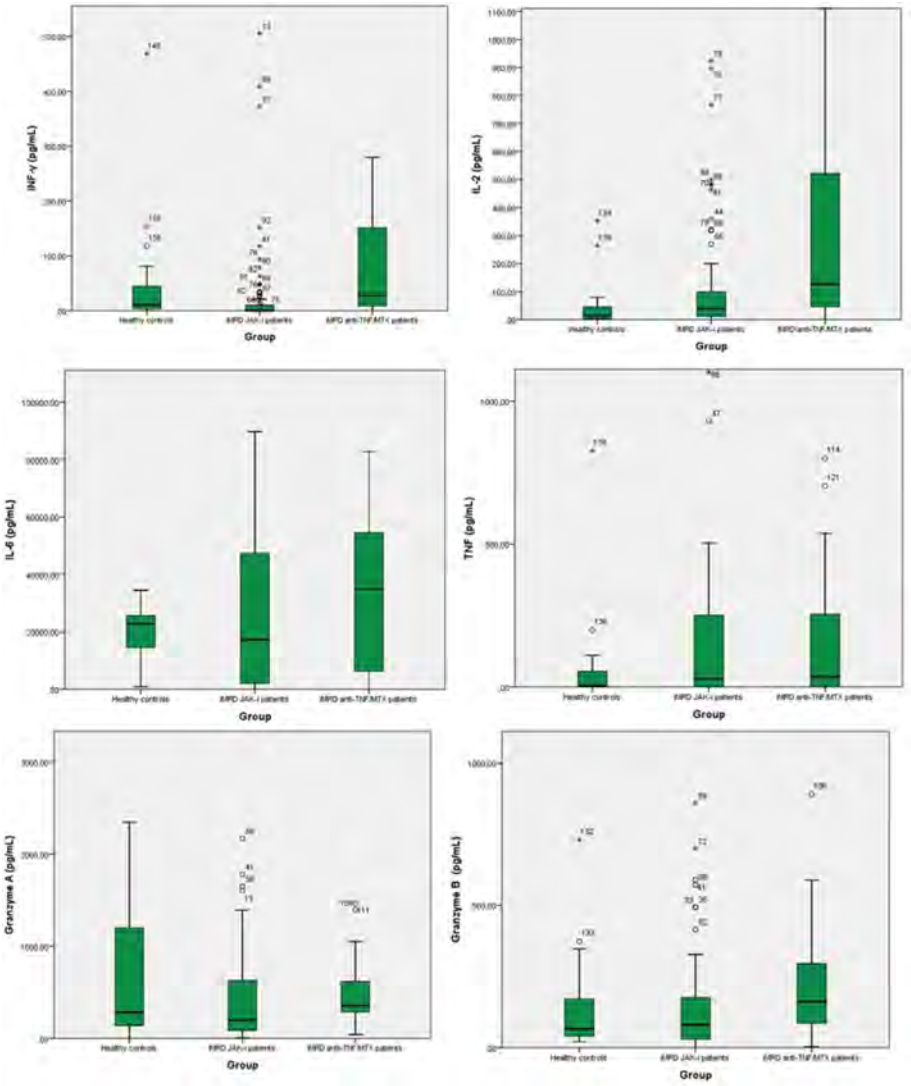
Cumulative MTX dose	**β =-0.28, p=0.002**	β =-0.1, p=0.24	**β =-0.25, p=0.002**
Cumulative GC dose	**β =-0.40, p=0.0002**	**β =-0.24, p=0.003**	**β =-0.36, p=0.0002**

Correlations between T-CD4 response, T-CD8 response, and VZV antibody concentration with JAK-I, anti-TNF/MTX, age, gender, disease duration, treatment with ≥2 DMARDs, treatment duration with JAK inhibitors, and cumulative doses of MTX and GC. Linear logistic regression coefficients (β) and p-values are presented, with significant parameters highlighted in bold.



Comparison of post-vaccination concentrations of granzyme A (2a), granzyme B (2b), TNF (2c) and IL-6 (2d) in healthy controls, IMRD JAK-I and IMRD anti-TNF/MTX patients. Higher levels of granzyme B (p=0.03), IL-6 (p=0.005) and IL-2 (p<0.0001) were observed in patients treated with anti-TNF/MTX as compared with baricitinib, tofacitinib and upadacitinib. Box-and-whiskers, 5–95 percentile, ANOVA test (3A–3D). P values are indicated above each graph.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 157 participants (mean age 58.2 years), JAK-i users had significantly lower immune responses. Seroconversion was 86% in JAK-i patients, compared to 97% in anti-TNF/MTX and 100% in controls (P = 0.03). VZV IgG titers were significantly lower in the JAK-i group (mean 1842 U/mL) versus anti-TNF/MTX and controls (both ∼3,000 U/mL, P < 0.0001). Only 28% of JAK-i patients had a full CD4+ Th1 response (vs. 74% anti-TNF/MTX, 93% controls), and CD8+ responses were similarly reduced (29% vs. 42% and 85%, respectively). Immunogenicity was negatively associated with cumulative MTX and glucocorticoid use, prior DMARDs, baricitinib and tofacitinib treatment, and longer JAK-i exposure. A positive correlation was seen between CD4+ and CD8+ responses (β = 0.36, P = 0.0002).

Conclusion: IMID patients treated with JAK inhibitors exhibit significantly reduced humoral and cellular immune responses to the HZ recombinant vaccine, suggesting lower protection against VZV reactivation. While some reduction was seen in the anti-TNF/MTX group, their immune responses remained relatively preserved. The findings underscore the impact of JAK inhibitors and cumulative immunosuppression on vaccine efficacy in this population.

Abstract Number: 0983

Detecting Autoreactive CD4+ T Cells Relevant to Mixed Connective Tissue Disease

Grace Frechette, Thamotharampillai Dileepan, Marc Jenkins and Shawn Mahmud, University of Minnesota, Minneapolis

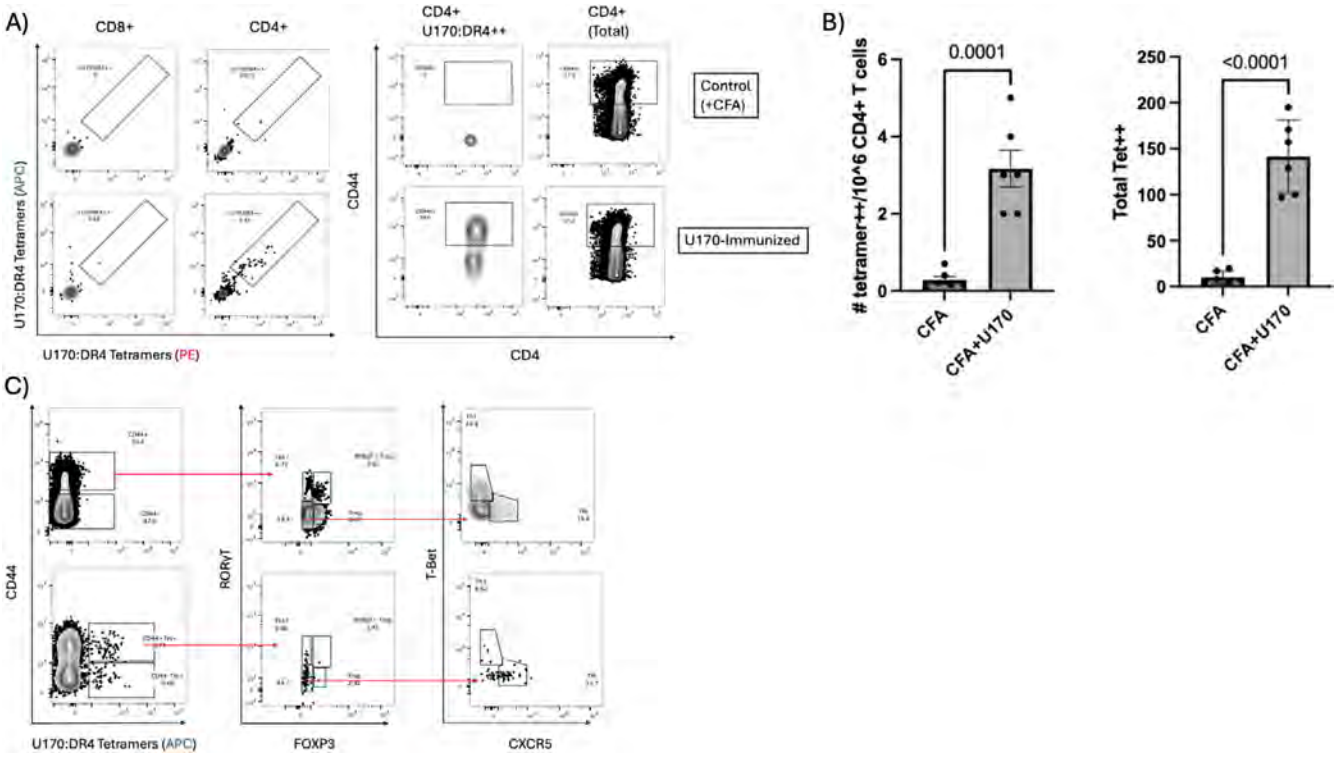
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Mixed connective tissue disease (MCTD) is a systemic autoimmune disorder marked by a U1-small nuclear ribonucleoprotein (U1-snRNP) autoantibody. The majority of U1-snRNP antibodies in MCTD target the 70 kD subunit of the protein complex (U170). How self-reactive T and B cells cooperate to drive autoantibody production in MCTD is unknown. Here, we use novel tetramers of U170 peptides bound to HLA-DRB1*0401 (U170:DR4) to detect self-reactive CD4+ T cells in a previously published mouse model of MCTD and diseased human patients. Our goals are to quantify and better characterize self-reactive CD4+ T cells in MCTD, which may eventually drive development of antigen-specific immunotherapy.

Methods: Because MCTD is linked to DR4, we use commercially available DR4 transgenic mice as previously published. We generated fluorophore-labeled DR4 tetramers with peptides bioinformatically predicted to bind DR4. We used these reagents to stain and magnetically enrich U170:DR4-specific CD4+ T cells from mice immunized with human U170 and separately from human peripheral blood mononuclear cells (PBMCs) from diseased patients. In mice, U170-specific antibodies and blood cells were quantified with a commercially available ELISA and flow cytometry, respectively.

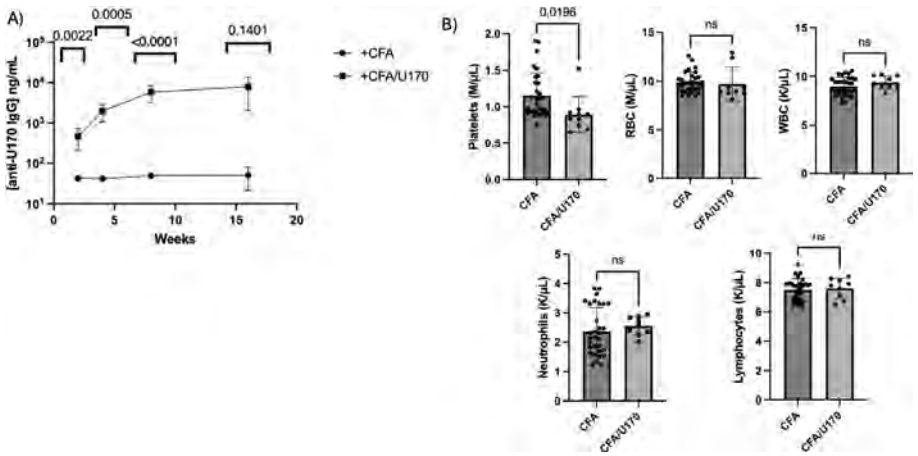
Results: Our novel U170:DR4 tetramers identified mouse CD4+ T cells expanding and upregulating CD44 and differentiating into Th1, Th17, and Tfh (Fig. 1). U170-specific antibody production in DR4 Tg mice accelerates until six weeks and plateaus (Fig. 2). Mice also develop a mild thrombocytopenia 8-10 weeks after immunization. Lastly, U170:DR4-specific tetramers detected rare CD45RA low (memory) cells in a DR4 positive MCTD patient (Fig. 3).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Expanding and activated mouse U170-specific CD4+ T cells primarily become Th1, Tfh, and Th17 cells in DR4-Tg mice immunized with recombinant U170 protein. DR4 Tg mice (both sexes, n=6 each group) were subcutaneously immunized with human recombinant U170 protein emulsified in CFA, and secondary lymphoid organs stained with U170:DR4 tetramers and surface markers as displayed in (a), and quantified in (b) (mean ±SEM, Mann-Whitney). (c) Analysis of phenotypes of bulk (top row) and tetramer+ cells (bottom row) with intracellular staining.

Conclusion: DR4 Tg mice produce autoantibodies in response to U170 immunization, and cognate U170-specific CD44+ T cells were detected alongside them using novel tetramers. U170-specific cells in mice were Th1, Th17, and Tfh. Mild thrombocytopenia, which is seen in MCTD, was also present at late time points in mice. Preliminary human data indicate these novel tetramers will be useful tools in longitudinal studies of humans with MCTD undergoing therapy and for development of specific treatments, such as chimeric antigen receptor (CAR) regulatory T cells.



DR4-Tg mice immunized with U170 develop U170-specific antibodies and mild thrombocytopenia. (a) DR4-Tg mice (n=14 each group at 2-8 weeks, n=5 each group at 16 weeks) were immunized with U170 protein. U170-specific antibodies were measured over time with ELISA modified to detect mouse IgG (mean ±95% CI). (b) Flow cytometry-based enumeration of platelets, red blood cells (RBC), leukocytes (WBC, neutrophils, lymphocytes) (n=9, 8-10 weeks post-immunization, mean ±SEM, Mann-Whitney).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Interleukin-21 as a driver of CD8 T cell tissue resident memory and pathogenesis in dermatomyositis

Heather Ren[1], havell Markus[2], Mackenzie Sennett[2], Acela Cristina Rosado[1], Matthew Helm[1], Aron Lukacher[2], Amanda Nelson[2] and Galen Foulke[1], [1]Penn State Health, Hershey, PA, [2]Penn State College of Medicine, Hershey, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Dermatomyositis is an autoimmune disease characterized by skin and muscle pathology and can feature significant morbidity and mortality from interstitial lung disease (ILD). Dermatomyositis is traditionally considered an antibody-mediated disease driven by pathogenic CD4 T cells and B cells as there are multiple myositis specific antibodies identified in dermatomyositis. These myositis-specific antibodies can have significant differences in disease progression. CD4 T cell-derived IL-21, a cytokine best known for its stimulation of B cells during the germinal center response, may be a driver of dermatomyositis. While IL-21 likely plays a role in stimulating myositis specific antibody production, IL-21 has also been identified as a CD4 T cell-derived driver of CD8 T cell differentiation to tissue resident memory cells (T_{RM}). T_{RM} are named for their abilities to be maintained independent of the circulation in non-lymphoid tissues and rapidly release effector molecules during antigen re-encounter which we hypothesized could be an important step in the pathogenesis of dermatomyositis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We performed immunofluorescence labeling for CD4, CD8, and IL-21 on skin biopsy samples from dermatomyositis patents. We also obtained single-cell RNAseq data from the lungs of a patient with MDA5+ dermatomyositis and subsequent ILD. Using the RNAseq data, we analyzed the CD8 T cells for IL-21 receptor expression and gene expression profiles of tissue resident memory.

Results: We show that IL-21 is present in active dermatomyositis skin lesions and that IL-21 is present in areas with high CD4 T cell and CD8 T cell infiltrates. We also show with the single-cell RNAseq data that lung CD8 T cells highly express the IL-21 receptor compared to CD8 T cells from the lungs of controls. Gene set enrichment analyses showed significant enhancement in the expression of T_{RM} genes in the CD8 T cells from the dermatomyositis lung.

Conclusion: These data suggest IL-21 could be an important, understudied driver of ILD in dermatomyositis, and a potential therapeutic target. Specifically, IL-21 may act on CD8 T cells to drive differentiation into long-lived T_{RM} in the tissues of dermatomyositis, likely contributing to tissue damage and clinical pathology.

Lupus Skin Shapes a Distinct Inflammatory Milieu that Drives the Skewing of Treg and inflammatory T cells

Hiroshi Kato[1], Lin Zhang[1], Mehrnaz Gharaee-Kermani[2], Amy Hurst[1], Rachael Bogle[3], Alex Tsoi[3], Johann Gudjonsson[2] and J. Michelle Kahlenberg[2], [1]Michigan Medicine, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, Holland, OH

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is a frequent manifestation of systemic lupus erythematosus (SLE) and remains an important contributor to morbidity in lupus patients. Despite its clinical significance, the underlying mechanisms of CLE and its pathophysiological links to SLE are poorly understood. Importantly, new data support a critical difference between cutaneous and peripheral immune subsets in the same patient. This study aimed to elucidate the shifts in T cell and natural killer cell subsets from blood to lupus-affected skin.

Methods: We performed single-cell RNA sequencing of non-lesional and lesional skin biopsies and paired PBMCs from 17 patients with active CLE/SLE and non-lesional skin and PBMCs from 5 healthy controls via 10x Genomics pipelines. Cellular clustering and annotation were conducted using the Seurat R package by matching cluster-defining marker genes with canonical subtype signatures. To uncover key upstream regulators, we applied Ingenuity Pathway Analysis (IPA) to differentially expressed genes (DEGs). Cytokines and transcription factors with an activation z-score ≥2 or ≤–2 were considered significant regulators. Pseudotime trajectory was constructed using the R package Monocle.

Results: Visualization using uniform manifold approximation and projection (UMAP) revealed 30 distinct cell clusters (Figure 1). We identified transcription factor NONO and proinflammatory cytokines including type I interferons (IFNs), IL-1, IL-27, TNF and prolactin as primary upstream regulators of transcripts enriched in regulatory T cells (Tregs), interferon-

UMAP plot of 92,405 cells colored by cluster

educated T (IFN-T) cells, and natural killer (NK) cells in lupus skin. These effects were observed when compared to both paired peripheral blood and healthy control skin (Figure 2), with the signaling being most pronounced in lesional as compared to non-lesional lupus skin. In contrast, the signaling of TGF-β, IL-4, MLXIPL, MYC, MYCN, SPEN, ETV3, and ETV6 was inhibited in Tregs in lupus skin compared to healthy controls. Furthermore, NONO and type I IFNs were important upstream regulators of gene expression in CD69^{lo} NK cells, while IL-1 and TGF-β were stronger regulators of gene expression in CD69^{hi} NK cells in skin. Trajectory analysis showed that circulating NK cells, IFN-T cells and Tregs upregulate CD69 whereas Tregs additionally acquire the expression of CTLA-4, GATA-3, heat shock protein, PD-1 and BATF as they infiltrate the skin.

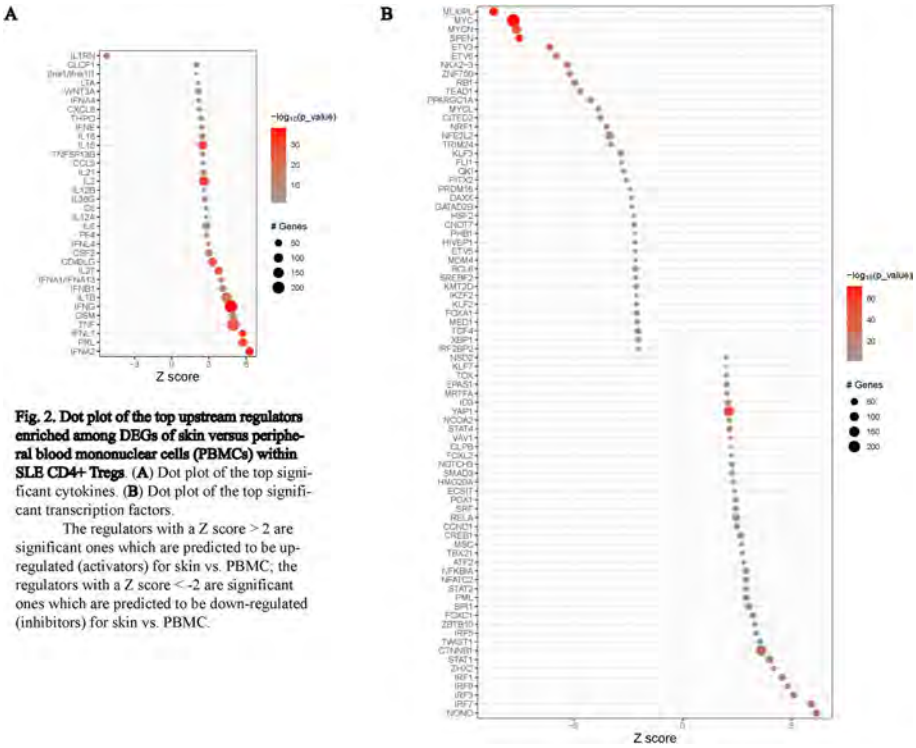

Fig. 2. Dot plot of the top upstream regulators enriched among DEGs of skin versus peripheral blood mononuclear cells (PBMCs) within SLE CD4+ Tregs. (**A**) Dot plot of the top significant cytokines. (**B**) Dot plot of the top significant transcription factors.

The regulators with a Z score > 2 are significant ones which are predicted to be up-regulated (activators) for skin vs. PBMC; the regulators with a Z score < -2 are significant ones which are predicted to be down-regulated (inhibitors) for skin vs. PBMC.

Dot plot of the top upstream regulators enriched among DEGs in Skin versus peripheral blood SLE Tregs

Conclusion: Our findings highlight the role of the skin in shaping an inflammatory profile in lupus Treg, IFN-T, and NK cell subsets. Treg development in lupus skin appears to shift from TGF-β- to type I IFN–mediated signaling. While NK cells, IFN-T cells and Tregs acquire activated phenotypes, Tregs additionally develop potentially exhausted phenotypes in SLE. NONO and type I IFNs contribute to the early programming of NK cells, while IL-1 drives their activation. These insights provide a deeper understanding of T cell–driven inflammation in CLE and may inform future therapeutic strategies.

LBL-053, A Novel Anti-TL1A/p40 Bispecific Antibody for the Treatment of Autoimmune Disorders.

Shuijun Hu[1], Fengxia Li[1], Aixia Liu[1], Hailin Wang[1], Xiaoxiao Liu[1], Jianming Sun[1], Yurong Qin[1], Guojin Wu[1], Jing Guan[1], Hui Yuwen[1], Jordan Zhu[2], Xiaoqiang Kang[1], Xiao Huang[1] and **Hong Ling**[1], [1]Nanjing Leads Biolabs Co., Ltd., Nan Jing, China (People's Republic), [2]Nanjing Leads Biolabs Co., Ltd., Nan Jing

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Inflammatory bowel disease (IBD) is a chronic, immune-mediated, inflammatory disease of the digestive tract. Several biological agents have greatly improved clinical course, remission, and complication rates in IBD patients. Ustekinumab, targeting p40 subunit, has demonstrated robust efficacy and approved for IBD. However, About 30% of patients are unresponsive to therapy , and 40% lose response over time,Therefore, more efficient therapies are needed. Recent studies showed that the Tumor necrosis factor-like cytokine 1A (TL1A) acts as a regulator of mucosal immunity and participates in immunological pathways involved in the IBD pathogenesis. Two anti-TL1A antibodies, MK-7240 and RVT-3101 have demonstrated excellent safety and effectiveness in patients with IBD. Therefore, a novel anti-TL1A/p40 bispecific antibody may hold promise in the treatment of autoimmune diseases including IBD.

Methods: An anti-TL1A monoclonal antibody was generated from mouse hybridoma and humanized by CDR grafting, then the anti-TL1A ScFv domain was fused to Ustekinumab using IgG1 Fc with LALAGA mutation. And YTE mutation was introduced to extend the half-life, creating the bispecific molecule: LBL-053. Binding affinity was assessed by Fortebio. The ligand-receptor interaction blocking capability of LBL-053 was evaluated by ELISA. The blocking efficacy of LBL-053 to TL1A and DR3 interaction was detected by reporter gene assay. The p40 and IL-12Rβ1 blocking efficacy was detected by ELISA and IFN-γ production inhibition assay .The synergistic effect of LBL-053 on TL1A and p40 was tested by IFN-γ production inhibition assay , which was conducted using $CD4^{+}$T cells cocultured with TL1A, IL-12 , IL-18 proteins and the drug. IL-23 and TL1A induced ear inflammation mouse model was used to test the in vivo efficacy of LBL-053 in which ear swelling symptoms alleviating degree was recorded. Single dose PK study was conducted in humanized FcRn mice.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: LBL-053 antibody exhibited high binding affinity to human TL1A and IL-23 protein. It selectively blocked TL1A-DR3 interaction, leaving TL1A-DcR3 unaffected. The effect of LBL-053 on inhibiting TL1A-DR3 downstream signaling pathway was comparabile to RVT-3101, but better than MK-7240 and PF-07261271.LBL-053 also significantly blocked IL-23/IL-12Rβ1 interaction. The synergistic effect of LBL-053 on IFN-γ Inhibition using $CD4^+$T cells with targeting IL-23 and TL1A pathway simultaneously demonstrated greater activity than each individual monoclonal antibody, their combination and PF-07261271.The effect of LBL-053 in relieving ear swelling symptoms was better than each individual monoclonal antibody and their combination. LBL-053 exhibited excellent PK profile in humanized FcRn mice.

Conclusion: LBL-053 showed dual immunosuppressive functions, simultaneously inhibiting TL1A-DR3 and IL-23/IL-12Rβ1 signaling pathway, indicating promising clinical applications for the treatment of autoimmune diseases.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: S-4321 is a novel antibody that agonizes the inhibitory PD-1 checkpoint receptor on T cells without competing for binding with its natural ligand, PD-L1, while selectively engaging and signaling through the inhibitory FcγRIIb on B cells/antigen presenting cells (APCs). S-4321 is expected to restore immune homeostasis in diseases such as RA, SLE, GCA, and IBD.

Methods: PD-1 expression was measured on activated T cells after culturing with S-4321 or benchmark PD-1 agonists. FcγRIIb selectivity of the S-4321 Fc domain was demonstrated via binding assays. The lack of proinflammatory activity of the S-4321 Fc domain was assessed using TNFα production from activated monocyte-derived dendritic cells or antibody-dependent cellular cytotoxicity (ADCC) of target Tregs by human NK cells. S-4321 was tested in *in vitro* Treg differentiation assays. S-4321 was assessed *in vivo* using the B6D2F1 model of GvHD and naïve mice and in cynomolgus monkeys.

Results: Treatment with S-4321 *in vivo* does not result in loss of PD-1 target expression, unlike first-generation PD-1 agonists. S-4321 enhances induced Treg (iTreg) differentiation ($p< 0.05$) *in vitro*. *In vivo*, S-4321 reduces T cell expansion and proinflammatory cytokine production ($p< 0.05$) in a murine model of GvHD and induces TIGIT expression on the surface of PD-1+ T cells in naïve mice. S-4321 demonstrates dose-proportional exposure and ∼70% bioavailability with subcutaneous dosing in cynomolgus monkeys.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In contrast to first-generation PD-1 agonists, treatment with S-4321 does not result in loss of PD-1 expression on T cells, induction of proinflammatory cytokines, or depletion of PD-1+ Tregs. S-4321 enhances TIGIT expression on PD-1+ T cells. S-4321 has the potential to restore immune homeostasis in cell-mediated autoimmune diseases and its high bioavailability will allow for convenient drug administration.

Background/Purpose: Autoreactive T cells play a crucial role in the autoimmune pathology of rheumatoid arthritis (RA). Activation of inhibitory receptors on T cells is a promising strategy to suppress RA immunopathology. However, the impact of various inhibitory receptors on pathogenic T cell functions in RA remains unclear. This study aimed to define the effects of three inhibitory receptors, PD-1, BTLA, and TIGIT, on activation and function of distinct synovial CD4 T cell populations.

Methods: To evaluate inhibitory receptor effects on cytokine production, we developed an artificial antigen presenting cell (APC)–T cell co-culture system delivering inhibitory signals to T cells. We used a murine fibroblast line engineered to express CD32 (Fc receptor), CD80 (a ligand for CD28) and CD58 (a ligand for CD2). We transduced PD-L2 (ligand for PD-1), HVEM (ligand for BTLA) or CD155 (ligand for TIGIT) into the APCs and assessed their impact on cytokine production by T cells or T cell subsets from RA synovial fluid or blood or tonsil. Additionally, we generated synovial organoids containing engineered fibroblast APCs co-expressing cadherin-11 and each inhibitor receptor ligand to study their functions in a 3D context.

Results: Among T cells from RA synovial tissue, PD-1, BTLA, and TIGIT were highly expressed on Tph and Tfh cells, with intermediate expression on other diverse synovial CD4 T cell populations. To functionally assess $CD4^+$ T cells from RA synovial fluid, we investigated the effects of inhibitory receptors on cytokine production by two populations: Tph cells ($PD\text{-}1^{hi}$

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Effects of inhibitory receptor activation on cytokine production by synovial fluid CD4$^+$ T cells. Cytokine production by Tph cells (CXCL13 and IL-21) and PD-1intCXCR5$^-$ memory CD4+T cells (TNF and IFN-γ) from RA synovial fluid, co-cultured with APCs expressing PD-L2, HVEM, CD155, or control. Cytokine levels were measured by ELISA (n = 5 RA donors). *=P<0.05 (Tukey's multiple comparison test).

CXCR5$^-$) and PD-1^{int} CXCR5$^-$ cells. Among B cell helper cytokines produced by Tph cells, IL-21 was suppressed by PD-L2 and HVEM, while CXCL13 was suppressed by PD-L2. Analysis of inhibitory receptor function on PD-1^{int}CXCR5$^-$ cells showed that IL-2 production was suppressed by PD-L2, HVEM and CD155, while IFN-γ and TNF production were only significantly suppressed by PD-L2. In contrast, no effect of inhibitory receptors on IL-10 production was observed in PD-1^{int}CXCR5$^-$. In memory CD4$^+$ T cells from blood, PD-L2 reduced the production of TNF, CXCL13, IFN-γ, IL-21 and IL-2. HVEM suppressed TNF, IFN-γ and CXCL13, while CD155 selectively reduced CXCL13 levels. We compared these results to effects on tonsil CD4$^+$ T cell subsets, where PD-1^{hi} CXCR5^{hi} cells were identified as the primary source of CXCL13, PD-1^{int} cells showed a preference for IL-10 production, and PD-1$^{-/low}$ CXCR5$^-$ cells primarily secreted IL-2, IFN-γ and TNF. In this context, PD-L2 significantly suppressed the production of IL-2, TNF, IFN-γ and CXCL13 which was consistent with results using blood T cells. In the 3D synovial organoids, PD-L2 suppressed T cell proliferation and decreased the production of IFN-γ and TNF. In organoid containing of memory CD4$^+$ T cells, B cells and cadherin-11$^+$ APCs, PD-L2 reduced the number of T cell-B cell aggregates.

Conclusion: Our study demonstrates that the effects of inhibitory receptors on cytokine production vary across distinct CD4$^+$ T cell populations. Activation of PD-1 in particular showed strong suppressive activity in RA synovial T cells, highlighting its potential as a key modulator of pathogenic T cell responses in RA.

Background/Purpose: Mucosal-associated invariant T (MAIT) cells represent a specialized subset of T cells that exhibit innate-like, effector functions and have been implicated in the pathogenesis of several autoimmune disorders, including IL-17-driven diseases such as ankylosing spondylitis and hidradenitis suppurativa. MAIT cells are activated through recognition of microbial and self-metabolites presented by MR1, a non-polymorphic, MHC class I-like molecule. Upon activation, they amplify inflammation by producing pro-inflammatory cytokines (e.g., IFN-γ, TNF-α) and cytotoxic molecules such as perforin and granzyme B. Notably, MAIT cells are a potent source of IL-17A and IL-17F.

Methods: In this study, we investigated the requirement for IL-23 and TL1A, known Th17 driving cytokines, in regulating IL-17 production by MAIT cells. Using human peripheral blood mononuclear cells (PBMCs), we validated that proagent of 5-A-RU (p5-A-RU), a known MR1 ligand, specifically activates MAIT cells, as indicated by the selective upregulation of CD69 within the MAIT cell population. This activation was dependent on antigen-presenting cells (APCs), as depletion of monocytes and B cells abolished CD69 expression on MAIT cells.

Results: Furthermore, we demonstrated that p5-A-RU synergizes with IL-12 and IL-18 to drive the production of inflammatory effector molecules, including perforin, granzyme B, TNF-α, IFN-γ, and IL-17. Interestingly, IL-17A and IL-17F production was not enhanced by exogenous IL-23, nor was it reduced by the application of clinically validated neutralizing antibodies against these cytokines. In contrast, MR1 blockade completely abrogated MAIT cell activation in both PBMCs and human skin explants.

Previous work has shown that MAIT cells play a significant role in tissue repair. To explore the potential role of MAIT cells in tissue repair, we assessed the effect of conditioned media from activated MAIT cells on wound healing in vitro using primary human lung fibroblasts. No enhancement in wound repair was observed, suggesting that inflammatory MAIT cells may not contribute to tissue regeneration.

Conclusion: Collectively, our findings highlight a key role for IL-12 and IL-18 in driving IL-17A and IL-17F production by MAIT cells, independently of IL-23 and TL1A. This MR1-dependent activation pathway could represent a novel therapeutic target, particularly for IL-17-mediated autoimmune diseases such as ankylosing spondylitis and hidradenitis suppurativa.

Background/Purpose: PD-1$^+$ T cells play a pivotal role in the pathogenesis of autoimmune diseases, including rheumatoid arthritis. Therapeutic antibodies targeting PD-1 with both depleting and agonistic functions have demonstrated the ability to selectively deplete T cells with high PD-1 expression, such as Tph and Tfh cells, and achieved notable clinical responses in patients with rheumatoid arthritis. However, PD-1 is expressed at varying levels across different pathogenic T cell subsets. Cells expressing low to intermediate PD-1 levels, such as cytotoxic CD8$^+$ T cell and Th1/Th17 subsets, also play pathogenic roles in autoimmunity. Therefore, therapeutic strategies capable of achieving broad depletion across this full spectrum of PD-1-expressing pathogenic T cells may offer superior benefits in treating autoimmune conditions. ANV200 is a novel, Fc-enhanced PD-1 agonistic antibody, engineered to drive robust and comprehensive depletion of PD-1-expressing pathogenic T cells.

Methods: The effects of ANV200 were assessed in human in vitro reporter cell assays and T cell activity functional assays. Then, the impact of ANV200 on circulating T cell subsets, including PD-1 expression levels, was evaluated in humanized PD-1 mice by flow cytometry. Finally, the efficacy of ANV200 was examined in a xenogeneic graft-versus-host disease (GvHD) model.

Results: ANV200 demonstrated enhanced engagement of FcγRIIIa compared to clinical benchmark antibodies while maintaining the ability to inhibit T cell receptor (TCR) signaling through PD-1 agonism. In addition, ANV200 exhibited a greater capacity to reduce human T cell activation relative to the benchmarks. In vivo, ANV200 selectively depleted PD-1$^+$ T cells without inducing a broad lymphopenia, resulting in a shift of the T cell compartment toward a more naïve state in humanized PD-1 mice. In the xenogeneic GvHD model, ANV200 effectively reduced the expansion of donor human T cells.

Conclusion: ANV200 is a novel, highly potent Fc-engineered anti-PD-1 agonistic antibody designed to deplete pathogenic T cells expressing high to low levels of PD-1. By targeting a broad spectrum of antigen-reactive T cells, ANV200 may potentially achieve deeper clinical response in autoimmune diseases.

Background/Purpose: Aberrant activation and persistence of adaptive immune responses play a central role in autoimmune pathogenesis. Where traditional immunosuppressive therapies offer a broad targeting approach, reprogramming the adaptive immune system at a metabolic level represents a novel therapeutic strategy to selectively modulate disease-driving populations. Methylenetetrahydrofolate dehydrogenase 2 (MTHFD2), a mitochondrial enzyme critical to the folate cycle is robustly expressed in inflammatory disease tissue and upregulated in activated lymphocytes, providing a unique

opportunity to target disease-relevant effector populations. We sought to develop MTHFD2-targeting inhibitors and to evaluate the effects of pharmacological MTHFD2 inhibition on key adaptive immune cell subsets and their therapeutic potential in models of autoimmunity.

Methods: The *in vitro* pharmacology of MTHFD2 inhibitors in specific lymphocyte subsets was tested in human primary immune cell cultures- key readouts included cell proliferation and cytokine production which were assessed using flow cytometry and HTRF. Human primary $CD4^+$ T cells were stimulated with anti-CD3 and anti-CD28 to assess impact on T helper function. Th17 polarization was performed using purified human memory $CD4^+$ T cells cultured under Th17-skewing conditions to assess effects on lineage commitment and effector cytokine production. Th1 antigen recall responses were explored in human PBMCs stimulated *ex vivo* using REVAXIS® (Diptheria, Tetanus and Poliomyelitis) antigens. B cell responses were analysed following BCR stimulation. *In vivo* efficacy was tested in a keyhole limpet hemocyanin (KLH)–induced delayed-type hypersensitivity (DTH) model and an adjuvant- induced arthritis (AIA) model in rat to assess impact of inhibition in autoimmune disease progression.

Results: MTHFD2 inhibition led to a marked reduction in the proliferation of $CD4^+$ T cells, accompanied by a decrease in Th1 and Th17 signatures, without affecting overall cell viability. During Th17 polarisation, IL-17 production was significantly diminished. Antigen recall assays showed reduced proliferation and IFNγ production upon MTHFD2 inhibition, indicating impaired memory Th1 cell function. In B cells, treatment suppressed proliferation and IgG secretion upon stimulation. *In vivo*, MTHFD2 inhibition reduced KLH-specific IgG levels and ear swelling in the DTH model. In the AIA model, treatment significantly decreased paw swelling, correlating with reduced inflammation and periosteal bone formation.

Conclusion: MTHFD2 inhibition modulates key adaptive immune pathways by targeting memory Th1/Th17 cells and B cell effector functions- suppressing pathogenic cytokine production and antibody responses central to autoimmune pathology. These findings highlight MTHFD2 as a promising metabolic checkpoint for therapeutic intervention in autoimmune disease, with dual action on both T and B cell arms of adaptive immunity.

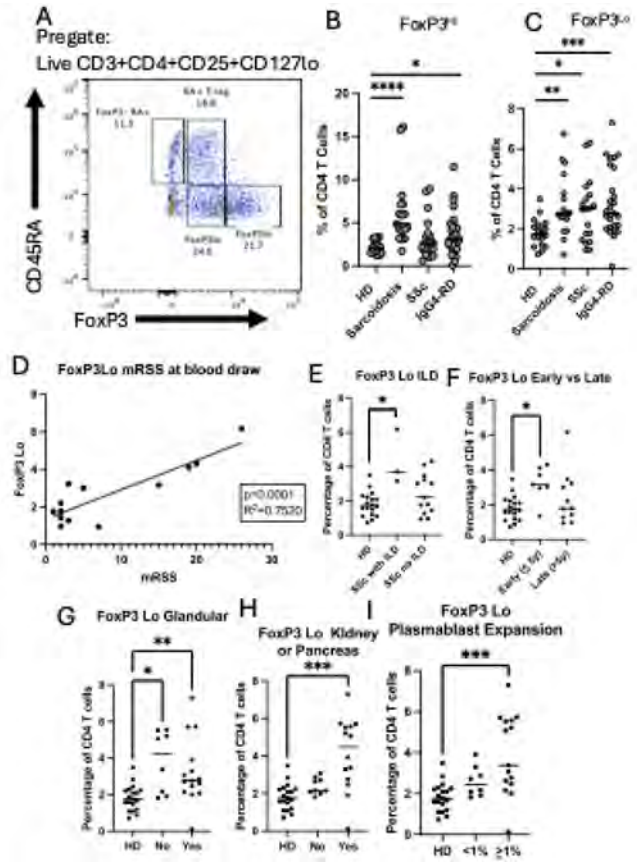
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

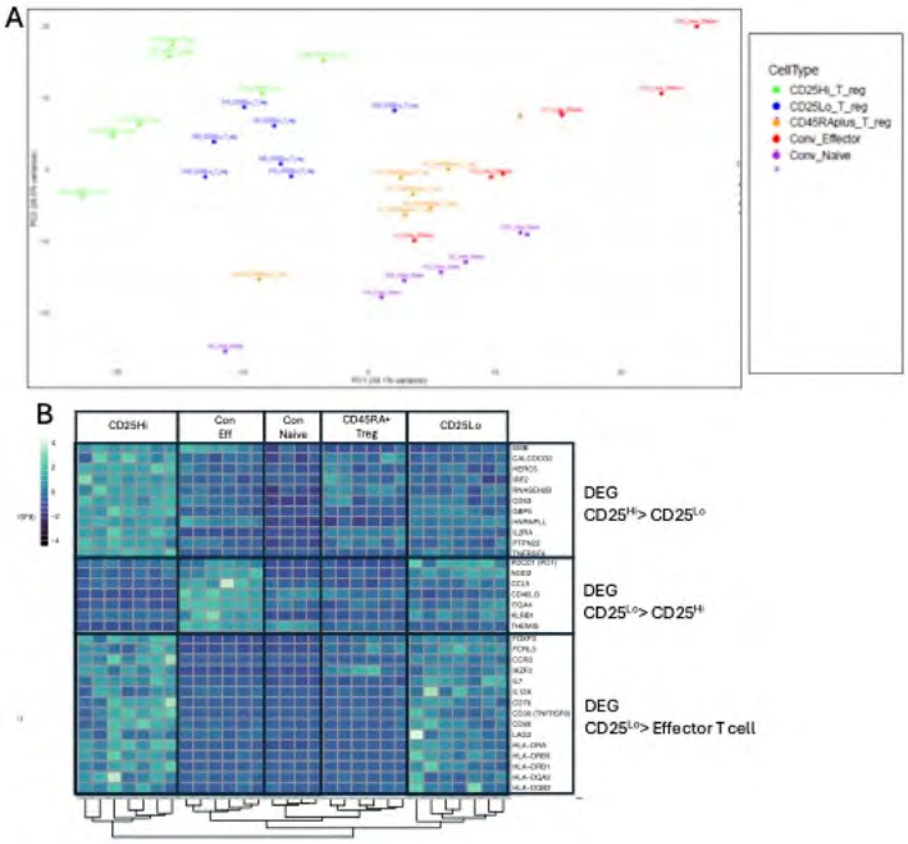
Background/Purpose: The absence of regulatory T cells (Tregs) results in multiorgan autoimmunity in the context of monogenic "Tregopathies," but their role in mediating polygenic autoimmune diseases remains less clearly defined. Antigen-experienced human T cells expressing FoxP3, a transcription factor driving regulatory function, can be divided into $FoxP3^{Lo}$ and $FoxP3^{Hi}$ subsets. $FoxP3^{Lo}$ T cells are expanded in the context of autoimmunity, but there is a paucity of data defining the function of $FoxP3^{Lo}$ T cells or their relevance to immune-mediated fibrosis. Previous studies suggest they are non-suppressive and primarily composed of activated effector T cells. We examined $FoxP3^{+}$ T cells across three different immune-mediated fibrotic diseases, systemic sclerosis (SSc), IgG4-related disease (IgG4-RD), and sarcoidosis.

Methods: We used spectral flow cytometry to examine circulating Treg subsets in PBMCs from patients with SSc (n=18, median age 55; 10 diffuse, 7 limited, 1 sine), IgG4-RD (n=27, median age 65, 15 head and neck, 10 pancreatobiliary, 2 retroperitoneal fibrosis, 6 kidney), sarcoidosis (n=17, median age 66, 7 only pulmonary, 10 extra-pulmonary involvement) and healthy donors (HD, n=17, median age 64). Bulk RNA sequencing of flow purified T cell populations was used to define



A representative flow plot of FoxP3/CD45RA subsets (pregated on live CD3+CD4+ CD25+CD127lo) are shown in (A). Graph of Treg subsets including FoxP3Hi (B, live CD3+CD4+ CD25+CD127lo CD45RA-FoxP3Hi) and FoxP3Lo (C, live CD3+CD4+ CD25+CD127lo CD45RA-FoxP3Lo). FoxP3Lo as a percentage of CD4+ T cells are graphed compared to modified Rodnan skin score (mRSS) (D). FoxP3Lo as a percentage of CD4+ T cells are graphed for SSc patients with and without ILD (E), and in early (<5 years from diagnosis)and late disease (>5 years from diagnosis) (F). FoxP3Lo as a percentage of CD4+ T cells are graphed for IgG4RD patients with and without parotid/salivary gland involvement (G), with and without kidney or pancreas involvement (H), and with and without plasmablast expansion, defined as >1% (I). For B-I: *p<0.05, **p<0.01, *** p<0.001, **** p<0.0001 by Mann-Whitney U test.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



T cell subsets from 7 healthy donors were sorted using flow cytometry by gating on live CD3+CD4+ cells. For Treg subsets: CD25+CD127Lo cells were gated on CD45RA+ population (CD45RA+Treg), CD45RA-CD25Lo(CD25Lo Treg; analagous to FoxP3Lo), and CD45RA- CD25Hi (CD25HiTreg; analagous to FoxP3Hi). For conventional T cell subsets, CD127+ and CD25-cells were gated on CD45RA+CCR7+ (Conv Naïve) or CD45RA-CCR7- (Conv Effector). RNA was isolated and bulk RNA sequencing was performed from different subsets. (A) A PCA plot was used to compare populations. (B) EBSeq was used to identify genes that are differentially expressed across the cell types with a posterior probability > 0.95. Select genes related to immune function are graphed for differentially regulated (DEG) upregulated in CD25Hi compared to CD25Lo(top), upregulated in CD25Lo compared to CD25Hi (middle), and upregulated in CD25Lo compared to Effector T cells.

the transcriptional differences between Treg subsets. Purified Treg subsets were used for *in vitro* assays to measure the capacity to suppress T cell proliferation.

Results: FoxP3^{Lo} T cells were preferentially expanded in SSc and IgG4-RD (Fig 1C). FoxP3^{Lo} T cell expansion correlated with disease severity, including early disease, skin score and interstitial lung disease in SSc and internal organ involvement in IgG4-RD (Fig 1 D-H). Expression of the transcription factor Helios reliably excluded IL2 and IFNg-producing effector T cell contaminants from the FoxP3^{Lo} gate, as has been previously suggested (Fig 3A). Helios^{+} FoxP3^{Lo} T cells are also expanded in SSc and IgG4-RD, indicating that the FoxP3^{Lo} expansion is not driven by activated effector T cells (Fig 3C). FoxP3^{Lo} T cells expressed decreased levels of the suppressive protein, CTLA4, and activation marker, ICOS, relative to FoxP3^{Hi} cells, as previously reported. Transcriptionally, CD127^{Lo}CD25^{Lo} (analogous to FoxP3^{Lo}) T cells expressed decreased levels of the activation markers *TNFRSF9* (CD137), *IL2R* (CD25), *TNFRSF8* (CD30), *CD70*, and *HLA-DR*, as well as *PTPN22*, relative to CD25^{Hi} cells, suggesting a difference in TCR binding affinity or activation state between these subsets (Fig 2B). The inhibitory receptor, *PDCD1* (PD1), was uniquely upregulated in CD25^{Lo} T cells. Despite differences in activation status and expression of CTLA4, CD127^{Lo}CD25^{Lo} T cells showed an equal ability to suppress T cell proliferation *in vitro* when compared to their CD25^{Hi} counterparts (Fig 3D).

Conclusion: We show that FoxP3^{+} T cells expressing low levels of FoxP3 are legitimate regulatory T cells but have reduced expression of certain markers of activation and Treg function. FoxP3^{Lo} T cells are expanded in the immune-mediated fibrotic diseases SSc and IgG4-RD and correlate with disease severity, suggesting either a pathogenic role in the context of fibrosis or an induced regulatory response.

Background/Purpose: Blau syndrome is a pediatric rheumatic disease characterized by dermatitis, arthritis, and uveitis. Blau syndrome is caused by inborn or *de novo* mutations in *NOD2*, the gene encoding the microbial sensing molecule NOD2. However, the cellular mechanism by which NOD2 causes sterile inflammation in Blau syndrome remains unknown. Recent studies have challenged the established dogma that Blau syndrome is caused by *NOD2* gain-of-function mutations to show Blau *NOD2* mutations result in a loss-of-function in NOD2 activation downstream of bacterial ligand stimulation. We previously demonstrated a novel T cell-intrinsic role for murine Nod2 in blocking pathogenic Th17/IL-17 responses and protecting against experimental autoimmune uveitis and arthritis in mice. Here we sought to determine how *NOD2* mutations in human patients with Blau syndrome alter T cell composition and function including Th17 responses.

Methods: Peripheral blood mononuclear cells (PBMCs) from patients with Blau representing 6 unique *NOD2* mutations, ages 2-64 (n=8) or controls (n=10) were analyzed before and after activation by anti-CD3 in combination with co-stimulatory agent, anti-CD28, or phorbol myristate acetate (PMA) and ionomycin (io). Cellular composition, T cell transcription factors, and cytokine expression were quantified by flow cytometry.

Results: Patients with Blau had comparable frequencies of peripheral blood CD4+ and CD8+ T cells to controls. However, these patients had a higher fraction of memory CD4+ T cells that expressed the Th17 lineage-defining transcription factor Rorgt, suggesting patients with Blau have enhanced baseline Th17 responses. Following T cell receptor (TCR)-independent stimulation (PMA/io) we found that cells from Blau patients had increased percentages of CD4+ T cells that produced IL-17A + or IL-17F+ compared to controls, yet no difference in percent of TNF+, IFNg+, or IL-2+ CD4 T cells. These data indicate that Blau patient T cells, regardless of individual *NOD2* mutations or age, have a predisposition to increased peripheral blood Th17 cells. To mimic antigen/cognate MHC-II interactions, T cells were then activated with a TCR-dependent stimulus (anti-CD3/CD28) over 5 days. On day 3 post-stimulation, PBMCs from Blau patients had increased IL-17F+, TNF+ and IL-2+ CD4 T cells with IL-17F+ CD4 T cells persistently increased through day 5 compared to controls. Cumulatively these data suggest that patients with Blau have primed Th17 immunity due to underlying *NOD2* mutations that enhance antigen-independent and -dependent T cell production of IL-17.

Conclusion: To our knowledge we are the first group to implicate T cells and Th17 immunity in Blau syndrome pathogenesis. These data provide foundational evidence for consideration of T cells and more specifically IL-17A and IL-17F as future targets for therapeutic intervention.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Current therapies inadequately restore immune homeostasis due to incomplete pathogenic cell clearance and limited multi-lineage targeting. UTAA91 integrates:

1) PD-1 agonist-targeted cytotoxicity: The PD-1 nanoantibody module directs Vδ1T cells to selectively eliminate PD-1+ pathogenic T cells via their potent killing capacity: includng follicular helper T cells (Tfh), peripheral helper T cells (Tph) and effectors;

2) CD19-targeted B-cell clearance: Concurrent CD19 nanoantibody-mediated B-cell depletion disrupts T-B cell collaboration;

3) Vδ1T cells for deep tissue penetration.

Methods: Manufacturing: Vδ1T cells from donor PBMCs were enriched via MACS, engineered with CD19/PD1-CAR (Chimeric antigen receptor), and Fas-knockout via CRISPR-Cas9 to mitigate HvGR;

In vitro: PD-1+ T-cell/B-cell depletion quantified in SLE/RA/SS patient PBMCs;

In vivo: Humanized NPG mice with CD19+ tumors assessed for HvGR suppression, PD1+ T-cell clearance, tumor inhibition (flow cytometry/IVIS), and safety.

Results: The cGMP-compliant manufacturing process for UTAA91 demonstrates exceptional industrial feasibility, achieving the following critical quality attributes: Vδ1T cell purity >90%, stable CAR molecule expression rate >30%, Fas gene-specific knockout efficiency >90%, expansion capability exceeding 10,000-fold, Tnaive subset proportion >90%, and sustained high expression of NKG2D/DNAM1 and chemokine receptors, establishing a robust cellular foundation for long-term immune regulation.

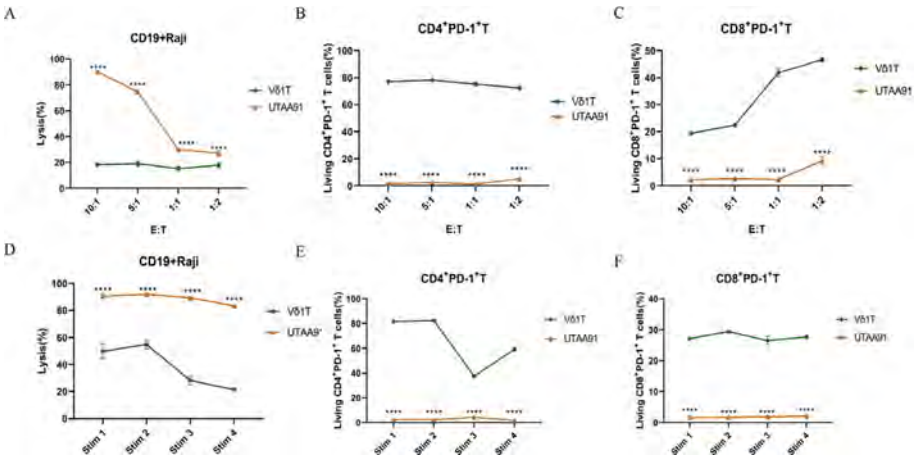

Figure 1: In vitro validation of dual-target specificity and functional persistence of UTAA91. (A) Targeted cytotoxicity of UTAA91 against $CD19^+$ Raji cells in vitro; (B) Targeted cytotoxicity of UTAA91 against $CD4^+PD1^+$ T cells in vitro; (C) Targeted cytotoxicity of UTAA91 against $CD8^+PD1^+$ T cells in vitro; (D) Persistent cytotoxicity of UTAA91 against $CD19^+$ Raji cells in vitro; (E) Persistent clearance capacity of UTAA91 against $CD4^+PD1^+$ T cells in vitro; (F) Persistent clearance capacity of UTAA91 against $CD8^+PD1^+$ T cells in vitro.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

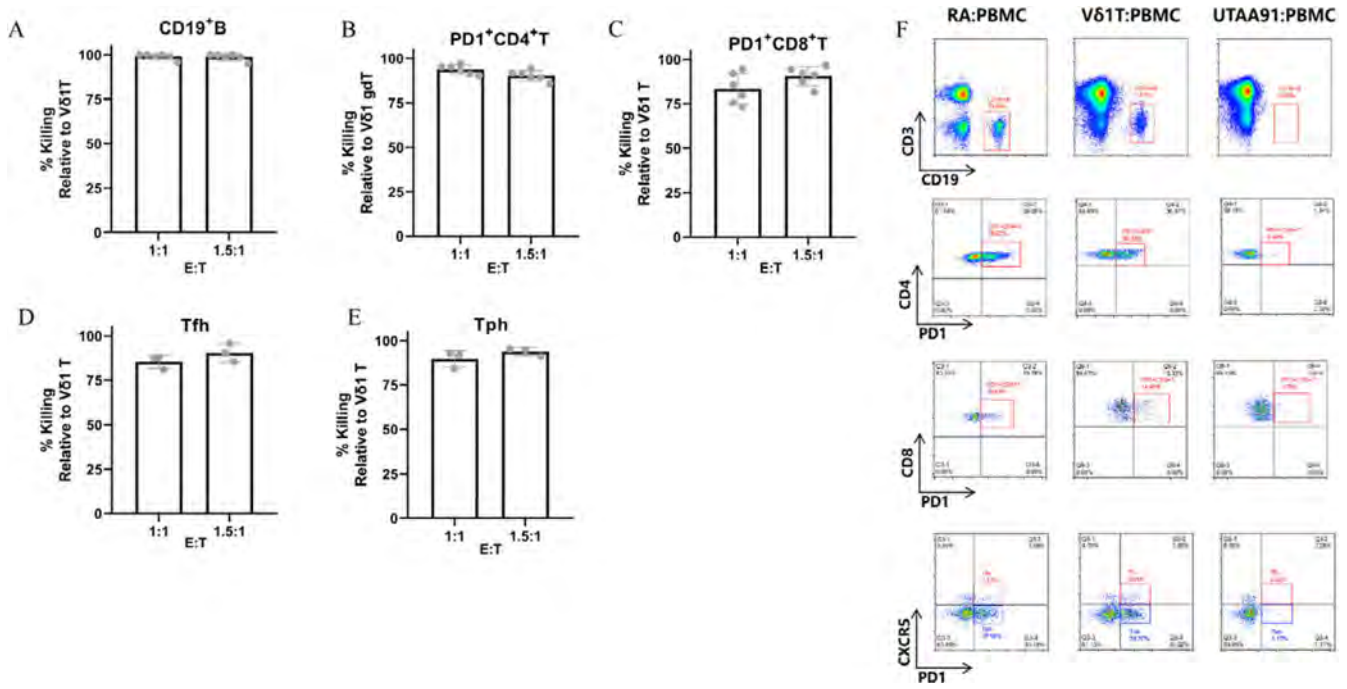

Figure 2: In vitro cytotoxicity of UTAA91 against peripheral PBMCs from autoimmune patients with various indications. (A) Clearance capacity against CD19$^+$ B cells; (B) Clearance capacity against PD1$^+$ CD4$^+$ T cells; (C) Clearance capacity against PD1$^+$ CD8$^+$ T cells; (D) Clearance capacity against Tfh cells in peripheral blood; (E) Clearance capacity against Tph cells in peripheral blood; (F) Raw flow cytometry data from one donor (RA). Notes: n=6, including patients with SLE, SSc, SS, RA, psoriasis, etc.

In vitro functional validation confirmed UTAA91's dual-targeted cytotoxicity against CD19+ and PD1+ cells, maintaining >90% specific killing efficiency through multiple rounds of antigen stimulation, which highlights its superior functional persistence. In humanized mouse models, UTAA91 effectively overcame allogeneic therapy barriers by significantly suppressing host-versus-graft reaction (HvGR), clearing peripheral PD1+ T cells, and inhibiting tumor growth, with no treatment-related toxicity observed.

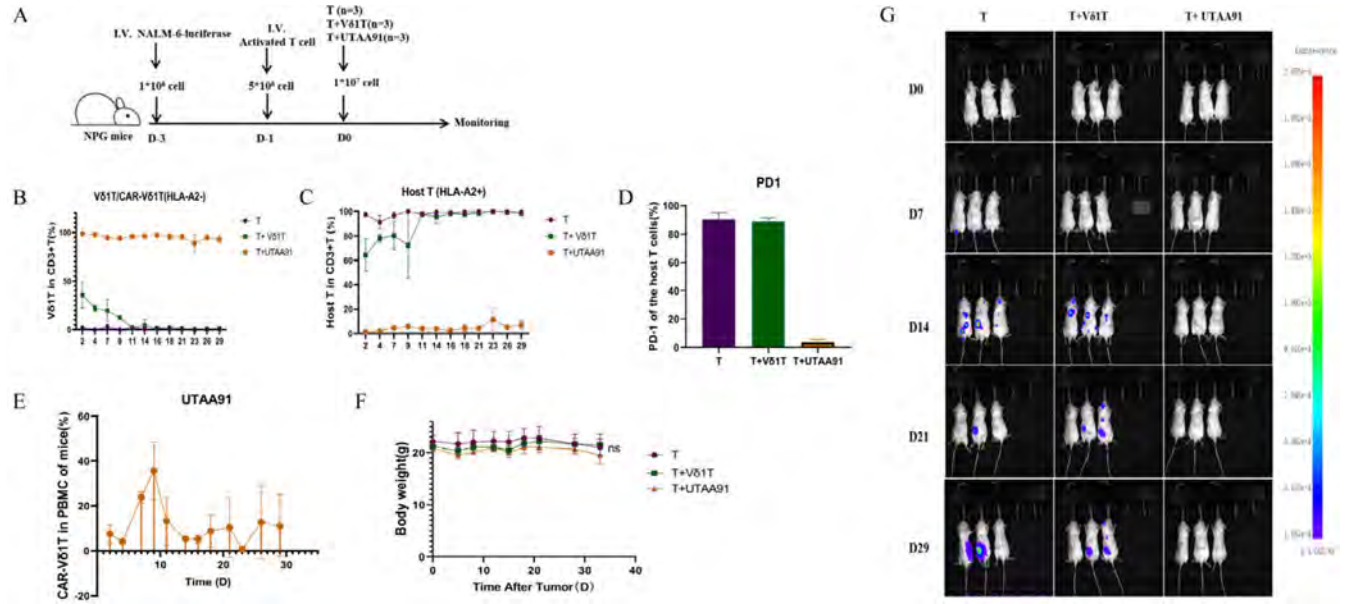

Figure 3: In vivo efficacy of UTAA91 in humanized tumor-bearing mice. (A) Preclinical in vivo experimental protocol; (B) Time-dependent monitoring of the proportion of Vδ1T/CAR-VδT cells in total CD3$^+$ T cells in peripheral blood; (C) Time-dependent monitoring of the proportion of host T cells in total CD3$^+$ T cells in peripheral blood; (D) Depletion of PD-1+ host T cell across experimental groups; (E) Pharmacokinetics of UTAA91 in peripheral blood; (F) Body weight monitoring across experimental groups; (G) Fluorescence imaging of tumor burden in mice.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Of significant translational value, UTAA91 exhibited precise and potent depletion of pathogenic cells in PBMCs derived from autoimmune disease patients (including SLE, RA, and SS), specifically eliminating CD19+ B cells and Tfh/Tph populations while selectively removing hyperactivated CD4+PD1+and CD8+PD1+T cells. Notably, functional PD1-T cell subsets were preserved post-treatment. This marks the first preclinical demonstration of UTAA91's unique capability to simultaneously target bidirectional T-B cell pathogenic pathways, offering a transformative therapeutic strategy for autoimmune diseases.

Conclusion: UTAA91, the first dual-targeting allogeneic UCAR-Vδ1T therapy, pioneers a "dual depletion" mechanism to eliminate B and Tfh/Tph cells, overcoming T-B interaction limitations and offering a groundbreaking solution for autoimmune diseases.

Abstract Number: 0995

Resident Memory T Cells Stimulate Pathogenic Activity in Fibroblast-like Synoviocytes

Madison Mangin[1], Yang Yang[2], Yusuke Miyashita[2] and Margaret Chang[2], [1]Boston Children's Hospital, St Simons Island, GA, [2]Boston Children's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by joint specific memory. We previously demonstrated that joint-specific memory is mediated by CD8+ synovial resident memory T (T_{RM}) cells that persist in arthritic joints during remission and can mediate arthritis flares. Further, we found that fibroblast-like synoviocytes (FLS) facilitate the formation of T_{RM} through IL-15 production. As cell-cell interactions can be bidirectional, we investigated the effects of T_{RM} on FLS pathogenicity.

Methods: T_{RM} were generated through two-week co-culture with FLS isolated from RA synovium in the presence of IL-15. T_{RM} development was validated by cell surface markers, gene expression profile and enhanced Bodipy free fatty acid uptake. T_{RM} were purified through multi-step magnetic nanobead sorting for CD62L-, CD25- and CD69+ cells. Purified T_{RM} cells were stimulated with anti-CD3/CD28 dynabeads for 24 hours then co-cultured with new unstimulated FLS. After 48 to 72 hours, FLS were collected and assayed for phenotypic markers of cellular activation by flow cytometry, for pathogenic gene expression by qPCR, and for protein expression by ELISA.

Results: T_{RM} generated through FLS co-culture displayed surface phenotype CD45RO+CD62L-CCR7-HLA-DR-CD25-CD69+ with variable CD103 and CD49a expression. These cells also displayed enhanced free fatty uptake and a gene expression signature consistent with T_{RM}. FLS co-cultured with purified T_{RM} upregulated surface expression of HLA-DR and ICAM-1 similar to FLS stimulated with TNF alone. T_{RM}-stimulated FLS also increased expression of inflammatory cytokines (IL-6, IL-8), chemokines (CCL5) and matrix metalloproteinases (MMP1, MMP3).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: We previously showed that FLS facilitate synovial T_{RM} development. We now demonstrate that T_{RM} also promote FLS activation, stimulating the expression of inflammatory cytokines, chemokines and matrix metalloproteinases by FLS, thus contributing to arthritis pathogenesis.

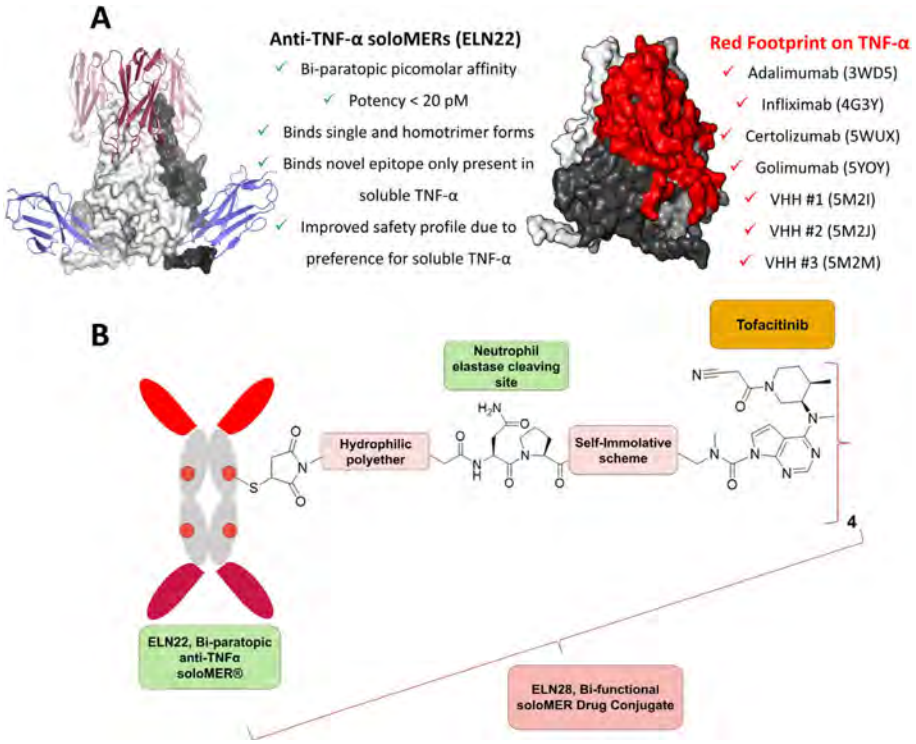
Breaking Inflammatory Pathways: ELN28, a Novel Dual TNFα/JAK Inhibitor Drug Conjugate for Chronic Inflammation

Obinna Ubah, Euan Murray, Stella Priyanka, Julia Martinez Fraile, Andrew Porter, Robert Boyd and Caroline Barelle, Elasmogen Limited, Aberdeen, United Kingdom

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite advances in therapies for chronic autoimmune diseases such as rheumatoid arthritis (RA), significant unmet needs persist, including therapeutic ceiling effects, adverse events, and suboptimal remission rates. We hypothesized that a rationally designed, dual-targeting molecule could enhance remission rates and reduce required dosing,



(A) X-ray structures of anti-TNF-α soloMERs expose novel TNF-α epitopes (left). On the right, crystallography data of existing anti-TNFα binding domains illustrating in red their overlapping footprint on TNF-α molecule (B) ELN28 SDC targets both soluble TNFα and Janus kinases. The overexpression of soluble TNFα in the inflamed tissues drives preferential accumulation of SDC at these sites. Tofacitinib payload is efficiently and safely released in the inflamed tissue by the action of human neutrophil elastase (HNE).

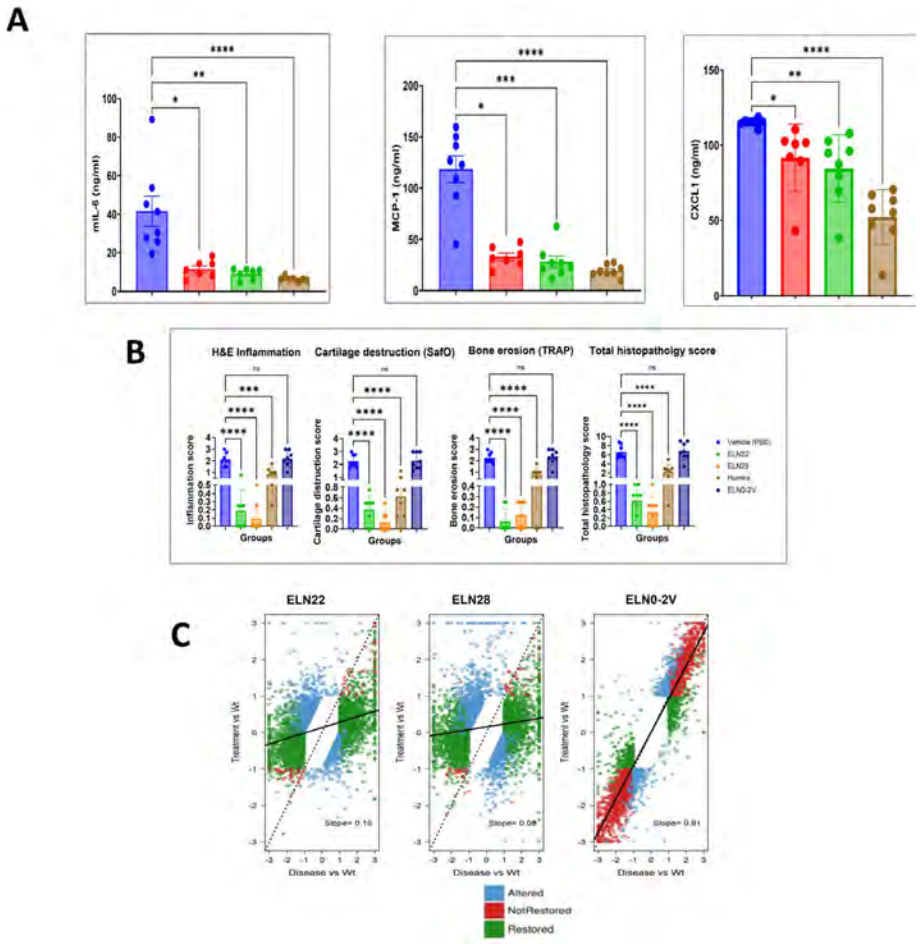
(A) Inhibition of TNF-α mediated cytotoxicity in L929 mouse fibrosarcoma cell line (left), and Anti-TNF-α independent inhibition of JAK/STAT phosphorylation signalling in human IL23-JAK/STAT HEK Blue™ Reporter cells (right). Functional Tofacitinib is released from ELN28 SDC in the presence of HNE. ELN0-2V is an isotype control soloMER (B) In the presence of HNE, ELN28 inhibited phytohemagglutinin (PHA) induced PBMC proliferation (donors A, C, D E). In a pooled PBMC sample, ELN28 +/- HNE demonstrated the additive (bifunctional) activity. ELN0-2V is an isotype control soloMER drug conjugate with a non-binding soloMER conjugated to Tofacitinib.

thereby improving the safety profile. ELN28 is a first-in-class bi-functional soloMER drug conjugate (SDC) targeting soluble TNFα and delivering the JAK inhibitor Tofacitinib directly to inflamed tissues. The payload is released in the presence of neutrophil elastase, which is enriched in inflammatory microenvironments. We evaluated ELN28's functional activity and compared it to mono-specific anti-TNFα therapies across multiple ex vivo and in vivo models of autoimmune inflammation.

Methods: Dual immunomodulatory activity of ELN28 was assessed in phytohemagglutinin (PHA)-stimulated healthy donor PBMCs. To model synovial inflammation, a 3D co-culture system was developed comprising primary RA synovial fibroblasts, endothelial cells, and monocytes (2:2:1 ratio). Organoids were treated with ELN28, followed by quantification of cytokine and chemokine production. In vivo efficacy was tested in an LPS-induced acute inflammation model (Tg1278TNFKOhTNFR1KI), where ELN28 was administered 2 hours pre-LPS exposure and cytokine levels measured after 5 hours. Chronic efficacy was evaluated in the Tg197 transgenic mouse model of polyarthritis, with biweekly ELN28 dosing over 7 weeks. Comparative treatments included Adalimumab and a mono-specific anti-TNFα soloMER (ELN22).

Results: ELN28 exhibited high-affinity (~100 pM) binding to soluble TNFα and potent neutralization in TNFα-stimulated L929 fibrosarcoma assays. Structural analysis via X-ray crystallography confirmed binding to a recessed epitope unique to soluble TNFα, enabling discrimination from membrane-bound TNFα. ELN28 inhibited PHA-induced PBMC proliferation and significantly reduced secretion of CXCL1, CXCL5, CXCL10, IL-6, and CCL2 in the RA synovial organoid model, outperforming mono-specific comparators. In vivo, ELN28 demonstrated dose-dependent, superior efficacy versus Adalimumab

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



(A) ELN28 attenuates the release of proinflammatory cytokines and chemokines in an LPS induced acute inflammation human TNF-α transgenic mouse model (Tg1278TNFKohTNFR1K1). In this acute inflammation model, LPS was administered 2 h after intraperitoneal administration of test articles, and terminal blood sampling 5 h post-LPS dosing (B) Test articles were dosed at 3 mg/kg twice weekly for 7 weeks. ELN28 and ELN22 were comparable in the clinical arthritis score assessment (left panel). Histopathology analysis demonstrated superior disease control by ELN28 (C) RNAseq analysis of disease associated genes (DAGs). Two dimensional scatterplots, regression lines show deviation of the treatment profile from disease group

and ELN22 in the LPS-induced Tg1278 model. In the Tg197 chronic arthritis model, ELN28 improved histopathological outcomes—including reductions in bone erosion, cartilage destruction, and inflammatory scores—and achieved twofold superiority in normalizing disease-associated gene expression (RNA-seq) toward a wild-type baseline.

Conclusion: ELN28 is a novel bi-functional drug conjugate that combines selective TNFα neutralization with inflammation-targeted JAK inhibition. Its unique targeting of soluble TNFα and elastase-triggered delivery mechanism offer a promising strategy for overcoming limitations of current RA therapies. ELN28 demonstrated robust dual activity and disease-modifying effects in preclinical models of autoimmune inflammation. IND-enabling studies are underway to advance ELN28 toward clinical development in RA and related autoimmune diseases, including Psoriatic Arthritis, Hidradenitis Suppurativa, and IBD.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Selective modulation of autoimmune responses through antigen-specific therapies represents a promising direction for improving treatment specificity and safety. Genetic associations with HLA class II alleles, combined with evidence of tissue-infiltrating T cells and T cell–mediated cytokine signatures, highlight the central role of $CD4^+$ T cells in driving autoimmune pathology. However, the targets of these pathogenic T cells remain poorly defined, limiting development of antigen-specific therapies. TScan's proprietary TargetScan platform offers an unbiased, high-throughput method to identify natural targets of disease-relevant T cell receptors and support development of antigen-specific tolerizing modalities.

Methods: To identify HLA class II T cell targets for $CD4^+$ T cells, the TargetScan platform was adapted to present genetically encoded peptide libraries on ectopically expressed HLA class II molecules. We initially applied this approach to scleroderma. $CD4^+$ T cells were isolated from affected skin biopsies of patients and analyzed using 10x Genomics single-cell RNA sequencing. A total of 764 TCRs were identified, with candidates selected for screening based on pathogenic gene expression profiles and CDR3 sequence clustering shared by TCRs found in more than one patient. 61 candidate TCRs were screened for antigen recognition in the context of disease-associated Class II HLA alleles, and identified targets were assessed for disease relevance using follow-up validation assays. Similarly, we used the TargetScan platform to evaluate TCRs from inflamed colon samples derived from patients with ulcerative colitis.

Results: Screening of the candidate TCRs using the Class II TargetScan platform identified eight novel targets presented by multiple HLA Class II alleles associated with scleroderma. These reactive TCRs belonged to shared $CD3^+$ clusters found in multiple patients and were characterized by high expression of activation and tissue-homing markers, as well as genes associated with Th2 and Th17 profiles. The identified targets exhibited expression patterns consistent with disease relevance and were validated through orthogonal assays, including functional T cell activation assays. In ulcerative colitis, two novel targets were identified with expression patterns consistent with disease pathology.

Conclusion: TScan's Class II TargetScan platform enables unbiased identification of novel autoantigens in $CD4^+$ T cell–driven autoimmune diseases where antigenic drivers have remained poorly defined. These discoveries may inform the development of antigen-specific therapeutic strategies, including tolerogenic approaches aimed at restoring immune homeostasis.

Preclinical Characterization of a Novel Bi-specific Antibody Targeting IL-23p19 and IL-36R for The Treatment of Autoimmune Diseases

Qianqian Yin[1], changqing run[1], kaili liu[1], xueqin cui[1], fanpeng Meng[1], yanru fan[1], yifei yang[1], wei ye[1], Lu Su[2], yuan lin[1] and cheng liao[1], [1]Jiangsu Hengrui Pharmaceuticals Co., Ltd, Shanghai, China (People's Republic), [2]Jiangsu Hengrui Pharmaceuticals, Shanghai, Shanghai, China

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IL-23 is a pivotal cytokine driving IL-17-mediated inflammation, and its inhibition has shown efficacy in Th17-associated autoimmune diseases. However, patient heterogeneity and compensatory pathways limit therapeutic responses. The IL-36/IL-36R pathway contributes to inflammation and barrier homeostasis, with its hyperactivity related to multiple autoimmune diseases and implicated in resistance to IL-23/IL-17 inhibitors in psoriasis. Here we developed an anti-IL-23/IL-36R bispecific antibody (BsAb) to block both pathways, aiming to improve clinical outcomes across autoimmune indications.

Methods: The synergistic effect of the two pathways was validated in an intradermal dual-cytokine (IL-23 plus IL-36)-challenging murine model. The binding to targets was evaluated by Surface Plasmon Resonance (SPR) and Fluorescence-Activated Cell Sorting (FACS). The blockade of IL-23 and IL-36 signaling was separately assessed by Ba-F3 cell proliferation assay and the assay of IL-8 secretion in A431 cells. The simultaneous blockade of both pathways was assessed in a PBMC/A431 co-culturing system. *In vivo* efficacy of BsAb was evaluated in an IL-23/IL-36 co-induced murine psoriasis model. The safety profile was evaluated in a 4-week repeated-dose Good Laboratory Practice (GLP) toxicology study in cynomolgus monkeys.

Results: Intradermal dual-cytokine challenge induced exacerbated psoriasiform pathology in mice, including epidermal hyperplasia and upregulated pro-inflammatory cytokines, suggesting the synergistic effect between IL-23 and IL-36 pathways. The anti-IL-23/IL-36R BsAb demonstrated high-affinity binding to both IL-23 and IL-36R, and inhibited IL-23-dependent Ba-F3 proliferation and IL-36R-mediated inflammatory responses, with activities comparable to those of the corresponding monospecific antibodies. In the PBMC/A431 co-culture assay, the BsAb surpassed monospecific antibodies in suppressing psoriasis-related cytokines. In a murine psoriasis model induced by IL-23/IL-36 co-stimulation, the BsAb outperformed monospecific antibodies in reducing ear thickness and suppressing multiple pro-inflammatory

cytokines and keratinocyte hyperproliferation markers. Non-human primate studies revealed no drug-related toxicity at all tested doses.

Conclusion: Our data highlight the enhanced therapeutic efficacy of the anti-IL-23/IL-36R BsAb through concurrent inhibition of two complementary signaling pathways, without compromising safety profile. This dual-targeting therapeutic shows promise for treating diverse autoimmune diseases, including psoriasis.

Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are a heterogeneous group of autoimmune disorders targeting muscle as well as extra-muscular organs. Among the most common autoantibodies associated with IIM is anti-histidyl-tRNA synthetase (HRS; Jo-1), which defines a distinct subset of IIM. Although pathogenic mechanisms of the anti-synthetase syndrome are incompletely understood, administration of recombinant HRS in mice has been shown to recapitulate histopathological features and robust anti-HRS antibody responses that are characteristic of human disease. In this study, we used an established murine model of HRS-induced myositis to evaluate the role of membranopathy in IIM pathogenesis and to investigate the therapeutic potential of regulatory T cells (Tregs).

Methods: BALB/C-Tg(NF-κB-RE-luc)-Xen mice harboring a firefly luciferase cDNA reporter gene under the regulation of κB-responsive binding sites or synaptotagmin VII (Syt VII) knockout (KO) mice (B6.129S1-Syt7tm1Nan/J) were injected intramuscularly with a recombinant amino-terminal fragment of murine HRS (mHRS). In NF-κB-RE-luc mice, bioluminescent signals were measured longitudinally. To evaluate suppression of disease pathology, Tregs isolated from wild-type (WT) mice were co-administered with mHRS injections. At experimental endpoints, histopathology of muscle tissue was analyzed and serum was collected to measure autoantibody production. In addition, nuclear extracts of muscle tissue cells were evaluated via EMSA to measure NF-κB activation. Sarcolemmal membrane repair capacity in skeletal muscle was assessed *ex vivo* by laser injury assays.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: NF-κB-RE-luc mice stimulated with mHRS developed an acute inflammatory response consisting primarily of lymphocytes and monocytes/macrophages, which correlated with NF-κB-associated bioluminescence and enhanced nuclear NF-κB binding activity in injected muscles. Despite a reduction in NF-kB activity at later time points, histopathology of mHRS-injected muscle tissue revealed persistent endomysial inflammatory infiltrates consisting of both lymphocytes (CD4+ and CD8+ T cells) and macrophages. Similar mHRS-induced muscle tissue pathology and anti-Jo-1 autoantibody production was observed in mice with a different genetic background (C57BL/6); inflammatory pathology was further amplified in SytVII KO mice that are characterized by inherent sarcolemmal membrane instability, but was ameliorated with concurrent adoptive transfer of WT Tregs. Moreover, WT C57BL/6 mice with mHRS-induced myositis demonstrated significantly compromised cell membrane repair *ex vivo*.

Conclusion: In summary, these data indicate that the initial inflammatory response in mHRS-induced myositis is NF-κB-regulated and exacerbated by membranopathy, suggesting that aberrant exposure of intracellular antigens, including HRS, can augment autoimmune-mediated pathogenesis. However, myositis pathology is suppressed by adoptive transfer of Tregs from healthy mice. Therefore, strategies engaging the immunosuppressive capacity of Tregs and/or sarcolemmal membrane stabilization represent novel areas of future therapeutic development for the treatment of IIM.

A Deep-learning Based Approach Uncovers Novel Mediators of Micro-rna Restraint of type-2 Immunity

Shaan Sekhon[1], Robin Kageyama[2], Neil Sprenkle[3], Hannah Happ[2], Eric Wigton[2], Heather Pua[3] and Mark Ansel[2], [1]University of California, San Francisco, Berkeley, [2]University of California, San Francisco, San Francisco, [3]Vanderbilt University, Nashville

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: MicroRNAs, such as miR-24 and miR-27, co-expressed within the Mirc11 and Mirc22 clusters, orchestrate a regulatory network critical to Th2 cell differentiation and cytokine production, notably Interleukin-4 (IL-4), with emerging roles in immune dysregulation in rheumatic diseases. To probe this network, we developed DeepRNA-Reg, a deep learning-based algorithm leveraging recurrent neural networks for high-fidelity comparative analysis of high-throughput sequencing of RNA isolated by crosslinking immunoprecipitation (HITS-CLIP) datasets.

Methods: The DeepRNA-Reg algorithm utilizes deep learning to predict differentially enriched sites in paired HITS-CLIP data sets, employing a recurrent neural network to infer differential enrichment status across the transcriptome. CD4+ T cells were isolated from spleen and lymph nodes and cultured under Th2 conditions. C57BL/6 male and female age and sex matched mice between 5 to 12 weeks of age were used for all experiments. To generate "miR-23, 24, 27 KO" T cells lacking expression of all *Mirc11* cluster miRNAs (miR- 23a, miR-24-2, and miR-27a) and *Mirc22* cluster miRNAs (miR-23b, miR-24-1, and miR-27b), we intercrossed previously generated conditionally mutant Mirc22$^{tm1.1Mtm}$ mice and Mirc11$^{tm1.1Mtm}$ mice and with *Cd4-Cre* transgenic mice (*Tg(CD4-cre)1Cwi*; 4196, Taconic) to induce Cre-mediated deletion in T cells.

Benchmarking predicted miRNA target site capture. (A) Schematic representation of the DeepRNA-Reg algorithm. (B-C) Seed binding sequence motif abundance in the Th2 differential AHC analysis (B) and the Th17 differential AHC analysis (C) by both DeepRNA-Reg and dCLIP. (D) Venn diagram quantifying overlap events between Targetscan 7.2 predicted miRNA target sites of miR-23, 24, and 27 and the sites called to be enriched in WT Th2 cells (relative to miR-23,24,27 KO Th2 cells) by both DeepRNA-Reg and dCLIP. (E) Venn diagram quantifying overlap events between Targetscan 7.2 predicted miRNA target sites of miR-29 and the sites called to be enriched in WT Th17 cells (relative to miR-29 KO Th2 cells) by both DeepRNA-Reg and dCLIP.

Ago2 HITS- CLIP was performed using an anti-Ago2 monoclonal antibody. Lastly, differential protein expression was evaluated in CD4+ T Cells harvested from mice bearing selective microRNA cluster knock-out.

Results: This analysis of miR-24, 27 targets uncovered a suite of transcriptional regulators that are known to affect IL-4 expression, including *Gata3* and *Ikzf1* but also *Rora, Tcf7, Runx1, Bcl11b, Foxo1, Nfat5, Tsc22d3* and *Klf11*. In addition, this study uncovered the cell surface costimulatory receptor CD28 as a novel target of miR-24 and miR-27. CD28 is a key regulator of T cell activation, differentiation and cytokine production. Flow cytometric analysis of CD28 protein expression confirmed that miR-23,24,27 KO Th2 cells express a larger quantity of CD28 on their cell surface, consistent with direct targeting by miR-24 and/or miR- 27.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Interrogating the Il-4 regulatory axis in the T Helper 2 Context. (A) A gene regulatory network showing the intersection of the IPA knowledge bank of known il-4 regulators and high-confidence DeepRNA-Reg predicted microRNA-24,27 targets. This high-confidence prediction set met the following conditions: a differentially enriched site with a DBE score above the median DBE score for the analysis that contains a canonical motif, with a negative response to the corresponding miRNA mimic between 15% and 85%. (B) A scatterplot of the degree of gene expression change between the miRNA mimic and control condition for microRNAs 24 and 27 on the horizontal and vertical axes, respectively. This plot represents the set of genes that lie at the intersection of the set of known upstream regulators of interluken-4 within the IPA knowledge-base and the set of high-confidence DeepRNA-Reg predictions of miR-24,27 targets. (C) A line plot representing the read depth across a section of the Cd28 3'UTR for both the WT and miR-23,24,27 KO condition HITS-CLIP experiments. Highlighted within this plot are two loci enriched in the WT condition relative to the miRNA KO condition, called and scored by DeepRNA-Reg, which overlap canonical seed sequences of miRNAs 24 and 27. (D) Flow cytometric analysis of CD28 protein expression showing that miR-23,24,27 KO Th2 cells express a larger quantity of CD28 on their cell surface, consistent with direct targeting by miR-24 and/or miR-27

Conclusion: These findings demonstrate that DeepRNA-Reg analysis of comparative Ago2 HITS-CLIP data can both confirm prior knowledge and uncover novel nodes in post-transcriptional regulatory networks. In tested data sets, DeepRNA-Reg uncovered novel mediators in the mechanism of microRNA-mediated restraint of type-2 immunity in T-Helper 2 cells, a pattern of immune response implicated in the pathophysiology.

LBL-057, a Novel ADCC Enhanced PD-1 Agonist VHH-Fc Antibody

Hongyan Shang[1], **Xiao Huang**[2], Duqing Jiang[1], Jianming Sun[2], Yurong Qin[2], Guojin Wu[2], Chengze Ni[1], Jing Guan[2], Jordan Zhu[3], Xiaoqiang Kang[2] and Hong Ling[2], [1]Nanjing Leads Biolabs Co., Ltd., nanjing, China (People's Republic), [2]Nanjing Leads Biolabs Co., Ltd., Nan Jing, China (People's Republic), [3]Nanjing Leads Biolabs Co., Ltd., Nan Jing

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Programmed cell death protein 1 (PD-1) is expressed on activated T cells and serves as a key co-inhibitory checkpoint molecule in immune regulation. Aberrant in PD-1 signaling increases human susceptibility to multiple autoimmune diseases, while insufficient PD-1 signaling can lead to dysregulated T cell responses. By targeting PD-1 regulatory mechanisms to modulate disease-driving T cells, LBL-057 aims to dampen the inflammatory cycle and restore immune balance. LBL-057 is an ADCC (antibody-dependent cellular cytotoxicity) enhanced PD-1 agonistic VHH-Fc antibody that stimulates the endogenous PD-1 inhibitory pathway, inhibits activated T cells, and reduces T cell proliferation and inflammatory cytokine secretion. In addition, the ADCC-enhanced design enables effective depletion of PD-1^+ T follicular helper cells and T effector cells, offering an attractive therapeutic approach for the treatment of PD-1^+ T cells driven autoimmune disorders such as rheumatoid arthritis (RA) and inflammatory bowel disease (IBD).

Methods: A panel of diverse VHH antibodies against PD-1 were developed via alpaca immunization and phage library screening. Candidates underwent rigorous *in vitro* evaluation, including PD-1^+ cell binding, PD-L1/PD-L2-PD-1 blockade, ADCC activity and PD-1 agonist activity. In addition, the inhibitory effect of LBL-057 on graft-versus-host disease (GvHD) was validated in a human PBMC transplantation mouse model.

Results: LBL-057 binds to PD-1 with an epitope distinct from pembrolizumab and enhances PD-1 interaction with to PD-L1/PD-L2 rather than blocking it. *In vitro* assays confirmed that LBL-057 significantly activates PD-1 pathway, suppresses PD-1^+ T-cell proliferation and activation in a dose-dependent manner. Furthermore, LBL-057 exhibits potent ADCC activity, effectively reducing PD-1^+ T cell populations. *In vivo*, LBL-057 demonstrated a better efficacy than benchmarks in inhibition of GvHD progression in mice.

Conclusion: LBL-057, a VHH-Fc antibody, specifically binds to a unique epitope on PD-1, with dual mechanisms of action. On the one hand it depletes PD-1^+ T cells with enhanced ADCC ability, on the other it enhances PD-1-PD-L1/PD-L2 interactions while activates PD-1 downstream signaling. Taken together, it potently suppresses T cell proliferation and activation *in vitro* and alleviates pathological damage in a GvHD mouse model. These findings support its therapeutic potential for PD-1^+ T cells driven autoimmune disorders.

ATF3 Inhibits Pulmonary Fibrosis via CD4+CD25−LAG3+ T Cells

Xiao Zhang[1], linmang Qin[2] and Yixuan Li[1], [1]The Eighth Affiliated Hospital of Sun Yat-sen University, Shenzhen, Guangdong, China (People's Republic), [2]Sun Yat-sen University, gaungzhou, Guangdong, China (People's Republic)

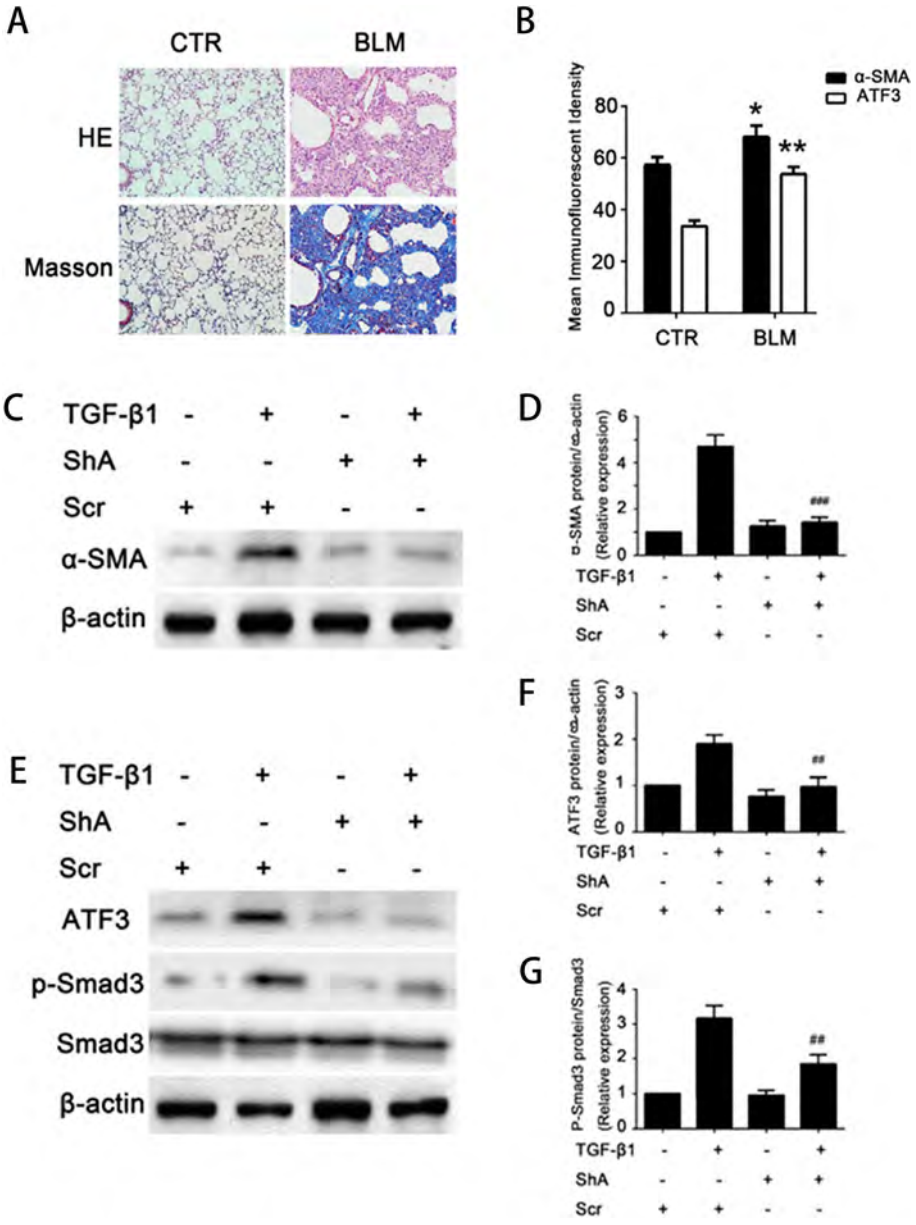
SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM



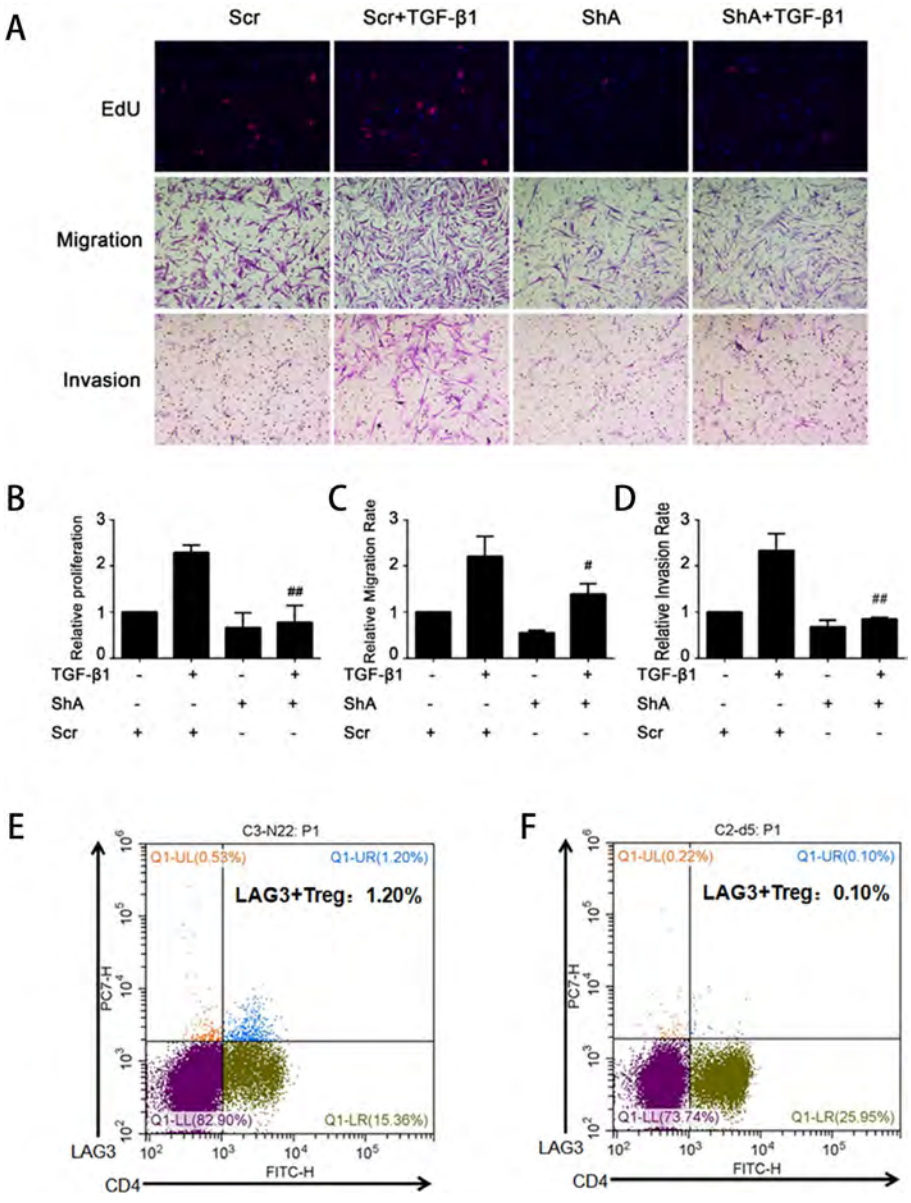
(A-B) Elevated expression of α-SMA and ATF3 in bleomycin-induced pulmonary fibrosis mouse model. (C-G) TGF-β1 induces ATF3 and Smad3 expression in human lung fibroblasts.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: The rising incidence of connective tissue disease-associated interstitial lung disease (CTD-ILD) significantly worsens patient prognosis. While its pathogenesis remains unclear, immune-inflammatory dysregulation—particularly enhanced immune responses and impaired suppression—may drive chronic inflammation and fibrosis. T cells regulate fibroblast activation and collagen synthesis, interacting with other immune cells to accelerate fibrosis. Notably, reduced LAG3+ T cell populations in CTDs suggest iTreg dysfunction. Our prior studies identified elevated ATF3, a leucine zipper transcription factor, in pulmonary fibrosis. ATF3 may modulate inflammation, fibrosis, and immune responses. We hypothesize that ATF3 promotes fibrosis, and its knockdown could attenuate progression, possibly by expanding LAG3+ T cells.

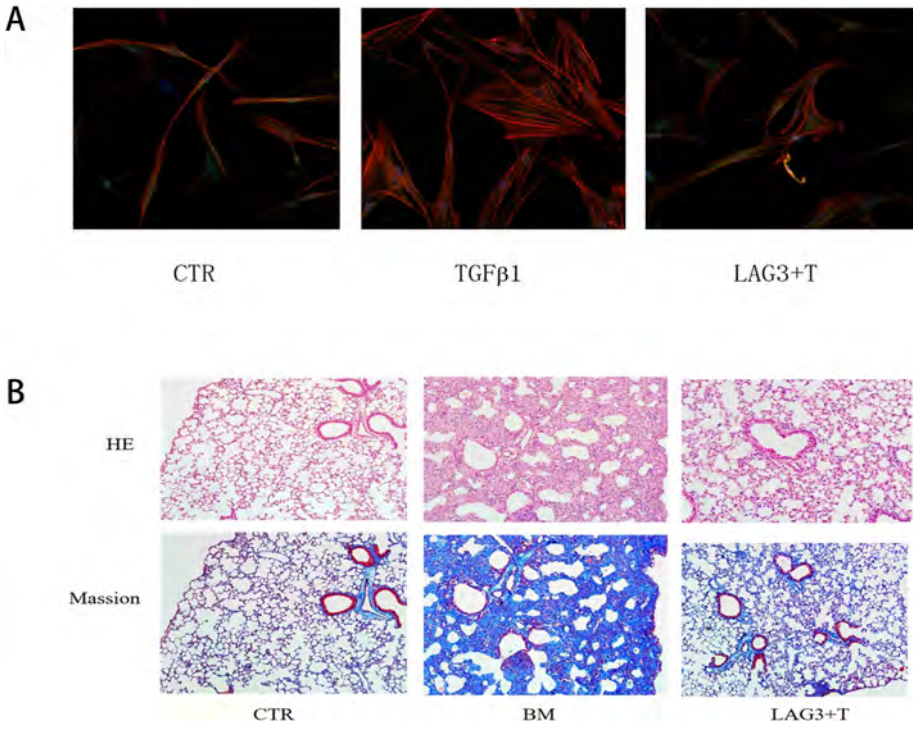
Methods: 1. Establish a bleomycin-induced pulmonary fibrosis mouse model and measure ATF3 expression levels.

2. Culture human lung fibroblasts in vitro and assess the effects of TGF-β1 induction on their proliferation, migration, and invasion capabilities.



(A-D) ATF3 knockdown suppresses TGF-β1-induced proliferation, myofibroblast differentiation, and invasion in human lung fibroblasts. (E-F) Significant reduction of CD4+CD25-LAG3+ regulatory T cells in peripheral blood of SSC-ILD patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



(A) Supernatants from LAG3+ Tregs inhibit TGF-β1-induced fibroblast-to-myofibroblast transition in human lung fibroblasts (20×) (Red: F-actin; Green: α-SMA; Blue: DAPI). (B) Adoptive transfer of LAG3+ T cells ameliorates pulmonary inflammation and fibrosis in murine models.

3. Construct siATF3 knockdown/overexpression in naive CD4+ T cells and examine their regulatory effects on lung fibroblast proliferation, migration, and invasion.

4. Quantify LAG3+ T cell populations in peripheral blood of SSC-ILD patients using flow cytometry with dual-labeling techniques. Isolated LAG3+ T cells will be cultured, and their supernatants will be added to in vitro cultured human lung fibroblasts to evaluate fibrosis markers (F-actin and α-SMA).

5. Evaluate spontaneous lung inflammation, collagen deposition, and LAG3+ T cell levels in ATF3-/- mice. Additionally, adoptive transfer of LAG3+ T cells from wild-type mice will be performed to assess their impact on lung pathology in bleomycin-induced pulmonary fibrosis models.

Results: 1. ATF3 expression is upregulated in bleomycin-induced pulmonary fibrosis mice.
2. TGF-β1 induces overexpression of α-SMA, Smad, and ATF3 in human lung fibroblasts in vitro.
3. ATF3 knockdown suppresses TGF-β1-induced proliferation, activation (myofibroblast transdifferentiation), and invasion of human lung fibroblasts.
4. Peripheral blood LAG3+ T cell counts are reduced in SSC-ILD patients compared to controls.
5. Supernatants from LAG3+ T cell cultures inhibit fibrotic marker expression (blocking TGF-β1-induced fibroblast-to-myofibroblast transition).Adoptive transfer of LAG3+ T cells ameliorates lung inflammation and fibrosis in murine models.

Conclusion: ATF3 promotes proliferation, migration, and invasion of lung fibroblasts, playing a critical role in pulmonary fibrosis progression. Knockdown of ATF3 significantly attenuates fibrotic progression, suggesting its utility as a therapeutic target. Adoptive transfer of LAG3+ T cells suppresses inflammatory responses and hyperproliferation of immune cells, demonstrating their protective role in fibrosis. These findings provide A novel strategy for treating CTD-ILD by targeting the ATF3/LAG3+ T cell axis, Translational potential for developing immunomodulatory or gene-based therapies.

Potent Engineering of Polyfunctional CD8+ T Cells by a Novel *In Vivo* CAR mRNA Product Candidate (CPTX2309) in a Targeted Lipid Nanoparticle (tLNP) Utilizing CellSeeker™ Technology

Yan Zhang[1], Brittany Ross[1], Aditi Upadhye[1], Diana Galvan[1], Shaun E Grosskurth[1], Yanjie Bao[1], Romina Riener[1], Annabel Wang[1], Aric Frantz[1], Gregor B Adams[1], Michael Rosenzweig[1], Ramin Farzaneh-Far[1], Priya Karmali[1], Adrian I Bot[1], Carl June[2] and Haig Aghajanian[1], [1]Capstan Therapeutics, San Diego, CA, [2]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: A major objective in autoimmunity is immune reset, requiring autoreactive B cell depletion in tissues. We designed an *in vivo* CAR product candidate (CPTX2309) utilizing a targeted lipid nanoparticle (tLNP) technology (CellSeeker™), comprising proprietary ionizable lipid-based LNP targeted to engineer CD8+ T cells from normal subjects or autoimmune disease patients, by delivering encapsulated mRNA CD19 CAR (ACR Convergence, 2024). Utilizing NHPs and a surrogate product, we defined a compact dose regimen of two infusions 72 hours apart that resulted in rapid engineering of CD8+ T cells and profound B cell depletion in peripheral blood and tissues (ASGCT, 2025). Herein, we report mechanistic data generated on human T cells *in vitro*, in support of clinical translation of CPTX2309.

Methods: CPTX2309 contains an mRNA encoding for an all human anti-human CD19 CAR, in a CD8-targeted tLNP. Transcriptomic analysis was performed on T cells upon incubating CPTX2309 with human peripheral blood mononuclear cells (PBMC). Additional analysis was performed by depletion of cell subsets from PBMC utilizing immunomagnetic beads, followed by cytotoxicity and cytokine production analysis.

Results: CPTX2309 incubation with human PBMCs *in vitro* resulted in rapid (< 24 hr) and selective engineering of CD8+ T cells to express a CD19 CAR. This resulted in rapid depletion of autologous B cells (24-72hr timeframe). The interaction with autologous B cells also resulted in activation of CAR+ CD8+ T cells, namely augmentation of cellular metabolic programs including cellular proliferation and ribosomal translational activity. Transcriptomic analysis demonstrated the activation of several immune programs known to induce immune cell effector polyfunctionality – including cytotoxicity and the type II IFN pathway. In contrast, mCherry mRNA-loaded tLNPs showed minimal effect. Depletion of CD8+ T cells but not of any other cell subset (CD4+ T cells, NK cells or myeloid cells) within the PBMC population, resulted in profound diminution of B cell depletion as well as IFNγ production in culture, demonstrating that the tLNP-engineered CD8+ CAR T cells are the primary driver of efficacy and on-target activity of CPTX2309.

Conclusion: CellSeeker™ technology affords a tunable CAR exposure without the risk of prolonged on target toxicities or genotoxicity. These novel data including transcriptomic analysis shed light on the cellular and molecular mechanism of action of CPTX2309, explaining the high engineering rate and pharmacodynamic activity afforded by this platform technology. Together with preclinical data generated in mouse and NHPs, this supports the translation of CPTX2309 to clinic.

Abstract Number: 1004

Single-Cell Analysis Reveals Tissue Resident Memory T Cells Heterogeneity in the Joint

Yang Yang[1], Yusuke Miyashita[2], Madison Mangin[3], Kellen Winden[1], Peter Nigrovic[2] and Margaret Chang[1], [1]Boston Children's Hospital, Boston, MA, [2]Boston Children's Hospital, Brookline, MA, [3]Boston Children's Hospital, St Simons Island, GA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by joint-specific memory, the phenomenon in which arthritis repeatedly flares in the same joints. We previously demonstrated that CD8 synovial resident memory T (T_{RM}) cells persist in arthritic joints and mediate joint-specific memory. There is increasing recognition of diversity among T_{RM} cells with distinct functional subsets described across tissues and diseases. Here, we evaluated the heterogeneity of CD8 T_{RM} cells within arthritic synovium in humans and mice and investigated their developmental precursors.

Methods: We evaluated the gene expression profiles of memory T cells isolated from human RA synovium through 10x single-cell RNA sequencing. As we previously demonstrated CD8 T_{RM} cells to be important for joint specific memory, we further evaluated subclusters of CD8 memory T cells from the synovium using Seurat and weighted gene co-expression network analysis packages. Cell clusters were annotated by the presence of known marker genes and comparison to published T_{RM} gene expression signatures. We further evaluated the gene expression profiles of CD8 T cells isolated from the synovium of a mouse model of arthritis of flare and remission. CD8 T cells were isolated from the synovium at several time points across the course of arthritis through acute joint inflammation and remission and sequenced by 10x single-cell RNA sequencing. Synovial T_{RM} cells were identified through transcriptomic profiles and presence in synovium during remission. Subclusters of CD8 T_{RM} cells were further refined, and trajectory of analysis and cell ancestry of these synovial CD8 T_{RM} cell clusters were computed with the Waddington Optimal Transport and Pseudotime analysis packages. We further confirmed the developmental progenitors of these T_{RM} cells using human synovial organoids.

Results: We identified diversity among CD8 memory T cells in human RA synovium, including several subclusters of cells exhibiting transcriptomic profiles consistent with T_{RM}. Gene Ontology enrichment analysis of highly expressed genes among T_{RM} subclusters reveals pathways in T cell differentiation, granzyme-mediated programmed cell death signaling, and negative regulation of T cell apoptosis, suggesting distinct functions in cytotoxicity and tissue-adaptive programming. We identified similar T_{RM} subpopulations in the synovium of murine arthritis during remission. Trajectory analysis revealed different timing in the emergence of these T_{RM} subpopulations during arthritis, further implicating distinct roles in disease.

Conclusion: Our findings reveal heterogeneity within CD8 T_{RM} cells in both murine and human synovial tissue. This diversity in function and timing of these T_{RM} subpopulations suggests different roles in arthritis pathogenesis.

CD49a Contributes to Binding and Survival of Synovial Resident Memory T cells

Yusuke Miyashita[1], Yang Yang[2], Madison Mangin[3], Maryrose Hahn[2] and Margaret Chang[2], [1]Boston Children's Hospital, Brookline, MA, [2]Boston Children's Hospital, Boston, MA, [3]Boston Children's Hospital, St Simons Island, GA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease featured with recurrent inflammation in the same joints, a characteristic termed joint-specific memory. We previously demonstrated that joint-specific memory in arthritis is mediated by resident memory T (T_{RM}) cells in the synovium. T_{RM} cells remain in the synovium of previously inflamed joints and activation of T_{RM} cells can drive recurrent arthritis flare. However, the factors that mediate the persistence of T_{RM} cells in the synovium are unclear. Here, we investigate the role of CD49a in the retention and survival of T_{RM} in synovial tissue.

Methods: We generated synovial organoids with CD8 memory T cells isolated from peripheral blood mononuclear cells, fibroblast-like synoviocytes (FLS) isolated from RA synovium, and human umbilical vein endothelial cells (HUVEC) encapsulated in Matrigel. T_{RM} cells form within the synovial organoid after 3 weeks of culture. To evaluate whether CD49a mediates binding of T_{RM} cells to FLS, isolated T_{RM} cells were incubated with isotype or CD49a neutralizing antibodies, then added to a microfluidic slide (μ-Slide I Luer) seeded with FLS. The strength of cell binding was assessed through live cell imaging of bound T_{RM} cells under increasing velocities of laminar flow. Cell survival was assessed in CD49a positive T_{RM} cells through viability dye and Annexin V staining in cells remaining within the synovial organoids and those that migrated out of the Matrigel. Cell proliferation was assessed in CD49a positive T_{RM} cells through intracellular staining for Ki67.

Results: We found that T_{RM} cells incubated with CD49a neutralizing Ab had lower binding affinity to FLS. Further, CD49a positive T_{RM} cells had less cell death compared to CD49a negative T_{RM} cells, and viability of T_{RM} cells also increased in cells remaining within the synovial organoids. Moreover, there is increased Ki67 expression in CD49a positive T_{RM} cells compared to CD49a negative T_{RM} cells at 21 days of culture.

Conclusion: We showed that CD49a contributes to binding of T_{RM} cells to FLS. Further, CD49a positive T_{RM} cells have increased viability particularly within the organoid structure and a higher proliferative capacity even after 21 days of culture, suggesting a possibility for self-renewal. Our findings implicate CD49a in the persistence and survival of T_{RM} cells in synovial tissue. Targeting T_{RM} cell anchoring could provide a novel therapeutic approach to joint-specific memory and chronic arthritis.

Abstract Number: 1006

Ai-guided Generation and Preclinical Evaluation of an OX40L-IL31 Bispecific Antibody

Yun Zhang, Hao Ran, Tianhong Li, Liguo Dong, Chenpeng Su, Chuan Chen, Lisha Dong, Dandan Liu, Yi Pan, Xiaoou Xu, Xiaoqian Chen, Liang Tian, Jian Peng and **Zhenping Zhu**, Helixon Therapeutics, New York

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (0978–1006) T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The itch-scratch cycle in atopic dermatitis (AD) is closely linked to skin inflammation exacerbation, which not only accelerates disease progression but also significantly impacts patients' quality of life. IL31 is a key factor in promoting itching, and antibodies targeting IL31Ra have shown promising therapeutic effect in AD patients in alleviating the disease symptoms, but with limited activity on the underlying skin inflammation and overall disease progression. In this study, we developed a bispecific antibody (bsAb), HXN-1022, that binds to and neutralizes both IL31 and OX40L, aiming to simultaneously inhibit OX40L and IL31 activities, thus providing a faster, deeper and more durable therapeutic efficacy to patients with AD and other autoimmune skin disorders.

Methods: The binding affinity of bsAb to each target was evaluated using SPR, while its interaction with membrane-bound OX40L was measured with flow cytometry. The biological activity of HXN-1022 was examined through various *in vitro* assays, including IL31R-STAT reporter assay and HaCaT cell activation assay for IL31, and OX40-NFκB-Luc reporter assay and Th2-differentiation assay for OX40L. *In vivo* efficacy was demonstrated in human PBMC-reconstituted GvHD (graft-versus-host disease) mouse model.

Results: We generated a highly potent anti-IL31 antibody through an internal AI-guided design and optimization platform. This antibody significantly inhibits IL31 biological activity, as demonstrated in the IL31R-STAT reporter assay and HaCaT cell activation assay, outperforming the benchmark antibodies Nemolizumab and NM26-2198 analogs. Using this anti-IL31 antibody and an anti-OX40L antibody as the building blocks, we engineered HXN-1022, a tetravalent bispecific antibody capable of simultaneously binding IL31 and OX40L with high affinity. HXN-1022 effectively blocks both IL31 and OX40L from interacting with and activating their respective receptors, with potency comparable to each of the parent antibodies. Moreover, HXN-1022 demonstrated a strong therapeutic efficacy in a human PBMC-reconstituted GvHD (graft-versus-host disease) mouse model. The bsAb significantly inhibited T cell proliferation, alleviated key GvHD symptoms, and prolonged the survival of the animals.

Conclusion: HXN-1022 is a first-in-class bsAb that simultaneously targets IL31 and OX40L, two major pathogenic factors associated with skin inflammation and itch. The bsAb holds great potential as a more effective therapeutic option for patients with a variety of autoimmune skin disorders.

Accelerometry-derived Activity and Sleep Patterns in the NIH All of Us Cohort: Insights and Predictive Potential for Inflammatory Arthritis

Adeep Kulkarni[1], Jose Scher[2], Rebecca Haberman[3] and Souptik Barua[1], [1]New York University Grossman School of Medicine, New York, NY, [2]New York University School of Medicine, New York, NY, [3]NYU Langone Health, New York, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with inflammatory arthritis (IA) report reduced physical activity and poor sleep, However, much remains unknown about the extent and impact of this relationship. Using accelerometry data from the NIH All of Us Research Program, we investigated (1) physical activity and sleep patterns in those with and without IA, and (2) the association of activity and sleep with risk of incident IA.

Methods: Participants who consented to share electronic health records and had at least one year of Fitbit accelerometry data in All of Us were included. IA was defined as ICD-10 codes for rheumatoid (RA) or psoriatic arthritis (PsA). Incident IA was defined as new IA diagnosis from the completion of accelerometry data up to 10 years. Daily step count, weekly moderate-vigorous physical activity (MVPA), daily sedentary time, and nightly sleep duration were assessed. Between group differences were tested using Kruskal-Wallis and Bonferroni-adjusted Dunn's tests. Associations between accelerometry metrics with incident IA were identified using Cox proportional hazards models adjusting for age, sex, and race/ethnicity.

Characteristic	All (n=24,808)	Inflammatory Arthritis (n=206)	No Arthritis (n=24,602)	p-value
Age - mean (SD)	51.86 (15.32)	58.04 (12.59)	51.81 (15.33)	<0.001
Female - n (%)	17,268 (69.6%)	168 (81.6%)	17,100 (69.5%)	<0.001
Race - n (%)				0.011
- White	19,569 (78.9%)	173 (84.0%)	19,396 (78.8%)	
- Black	1,426 (5.7%)	11 (5.3%)	1,415 (5.8%)	
- Asian	856 (3.5%)	1 (0.5%)	855 (3.5%)	
- Other	0 (0.0%)	0 (0.0%)	0 (0.0%)	
Number of days - mean (SD)	319.57 (54.53)	317.15 (52.26)	319.59 (54.55)	<0.05
BMI - median (IQR)	28.31 (27.12–30.09)	29.41 (26.48–34.69)	28.30 (27.12–30.07)	<0.001
Hypertension - n (%)	8,196 (33.0%)	173 (84.0%)	8,023 (32.6%)	<0.001
Diabetes - n (%)	3,224 (13.0%)	85 (41.3%)	3,139 (12.8%)	<0.001

Cohort Characteristics

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

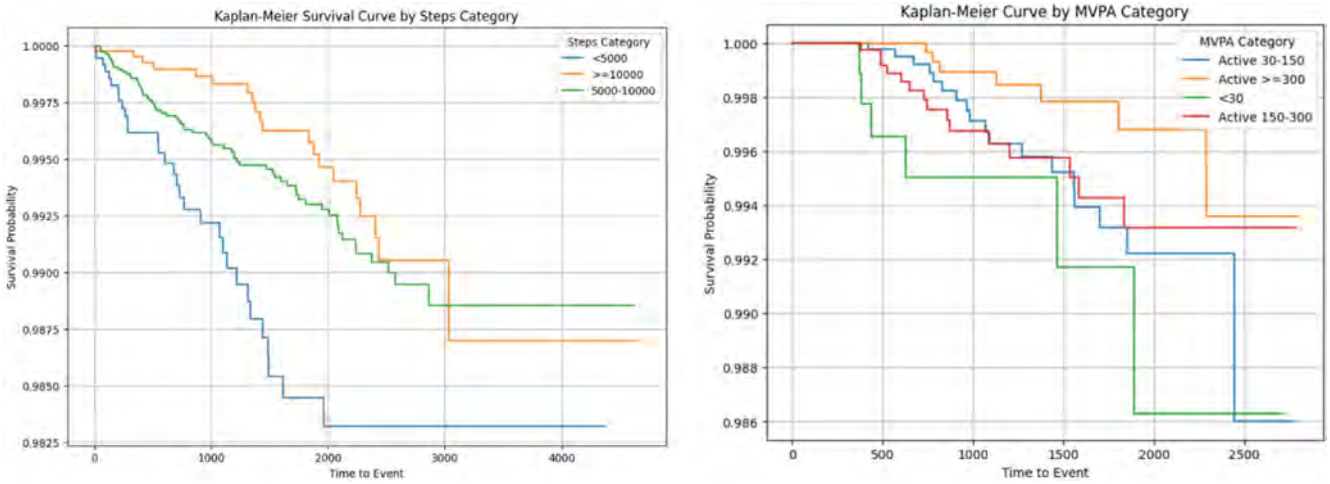
Results: 24,808 individuals were included (mean age 51.9 [15.3] years, 70% female, 79% White); 206 had IA (177 with RA and 29 with PsA). Compared to those without IA, participants with IA were older (58.0 vs 51.8 years, p< 0.001), female (81.6% vs 69.5%, p< 0.001), and had higher rates of hypertension (84.0% vs 32.6%, p< 0.001) and diabetes (41.3% vs 12.8%, p< 0.001). Participants with IA had lower median daily step counts (6,742 [5,093–9,327] vs 7,360 [5,386–9,693]; p< 0.001), lower weekly MVPA (147.0 [62.7–271.2] vs 185.3 [88.8–330.9] minutes; p< 0.001), and higher sedentary time (900.7 [759.3–981.3] vs 799.0 [704.8–961.1] minutes; p< 0.001). Sleep duration was similar between the two groups (371 [312, 418] vs 385 [332, 426] minutes; p=0.78).

125 individuals developed incident IA. Adjusting for age, sex, and race/ethnicity, each additional 1,000 steps/day was associated with an 8% lower risk of IA (HR 0.92; p=0.012). Compared to < 5,000 steps/day, 5,000–10,000 steps/day was associated with a 45% lower risk (HR 0.55; p=0.007) and >10,000 steps/day with a 57% lower risk (HR 0.43; p=0.004). MVPA showed that participants engaging in ≥300 minutes/week of MVPA had a significantly lower risk of IA (HR 0.27; p=0.022) compared to those with < 30 minutes/week. There was no significant association between incident IA and sedentary time (HR 1.00 per minute; p=0.294) or nightly sleep duration (HR 1.04 per hour; p=0.388).

Conclusion: Accelerometers provide more objective and granular measurement of physical activity and sleep compared to self-reported data. Using 1-year accelerometry data from the NIH All of Us cohort, we observed lower physical activity and higher sedentary time in those with IA. Further, higher step counts and MVPA were significantly associated with reduced 10-year risk of incident IA, highlighting the crucial role of physical activity in IA prevention. Wearable technologies may offer valuable insights into the complex interplay between activity, sleep, and arthritis, and further studies in well-phenotyped cohorts are warranted.

Variable	HR	p-value
Age (per 10 years)	1.09	0.1856
Sex (reference: Female)	0.50	0.0050
Race (reference: White)	1.41	0.1539
Ethnicity (reference: Not Hispanic)	1.15	0.7155
5000–10000 steps (reference: <5000)	0.55	0.0067
≥10000 steps (reference: <5000)	0.43	0.0040

Cox regression results showing the association between accelerometry-derived steps categorized by WHO guidelines and incident inflammatory arthritis.



Kaplan Meier Survival Probability Curves for Categorical Steps and Categorical MVPA v Incident IA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: While two trials with colchicine have demonstrated its efficacy in reducing the risk of cardiovascular events, a more recent study showed no significant impact on the composite primary outcome over three years. This study aims to evaluate the cardioprotective effects of colchicine on the incidence of myocardial infarction requiring bypass surgery or stent placement, utilizing a nationwide historical cohort.

Methods: The electronic medical registry system of Turkiye was retrospectively analyzed for the period between January 1, 2015, and December 31, 2024. Individuals aged 50 or older who regularly used colchicine (defined as being prescribed at least 3 times per year) between January 1, 2018, and December 31, 2024, were identified as the study group, which consisted mainly of patients with familial Mediterranean fever (FMF) and gout. A control group, matched 1:1 for age, gender, and history of diabetes mellitus (DM), hypertension, hyperlipidemia, and chronic renal failure, was selected. Additionally, a second set with a case-to-control ratio of 1:2 was prepared, matching participants based on geographical region. Subgroup analyses were conducted on statin users and on a third set with a 1:2 ratio, matched for a history of gout. The primary outcome was defined as the first myocardial infarction (MI) requiring bypass surgery or stent placement. The association of colchicine use with the likelihood of cardiovascular endpoint was investigated through logistic regression models.

Results: A total of 41,971 individuals who regularly used colchicine during the defined period were identified, along with a matched control group of 41,833 individuals. During the study, 5,278 participants were diagnosed with myocardial infarction (MI) requiring bypass surgery or stent placement. Multivariate logistic regression analysis showed a significantly lower rate of cardiovascular events in the colchicine group compared to the control group (OR=0.769, 95% CI: 0.724–0.816, p< 0.001). A similar analysis using a larger, geographically matched control group at a 1:2 ratio yielded comparable results (OR=0.770, 95% CI: 0.731–0.812, p< 0.001). In a subgroup analysis with a control group matched for gout, the protective effect of colchicine persisted, albeit to a lesser extent (OR=0.882, 95% CI: 0.836–0.930, p< 0.001). Interestingly, colchicine's protective effect was evident in individuals not using statins (OR=0.741, 95% CI: 0.694–0.790, p< 0.001), but no significant difference was observed among regular statin users. Additionally, there was no statistically significant difference in cardiovascular event risk between controls using statins and individuals on colchicine who were not using statins (OR=0.976, 95% CI: 0.860–1.109, p=0.0906).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This nationwide health record study represents the largest cohort of patients and controls to date, reinforcing earlier clinical trial findings by demonstrating a reduction in cardiovascular event rates associated with colchicine use. The relatively lower protective effects observed in gout patients may be linked to higher cardiovascular risks, lower colchicine dosages, and potentially greater non-compliance compared to patients with FMF.

Abstract Number: 1009

Pregnancy Outcomes and Comorbidities Among Individuals with Systemic Lupus Erythematosus: A Nationwide Study Using Publicly Funded Health Insurance Claims Data

Amadeia Rector[1], Sadaf Sediqi[2], Alyssa Howren[2] and Julia F Simard[3], [1]Stanford University, San Francisco, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford Medicine, Stanford, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Individuals with SLE are at increased risk for pregnancy complications such as preeclampsia and preterm delivery. As SLE is commonly diagnosed and active during the childbearing years—and more individuals are pursuing pregnancy due to improved management—there is a growing need to better understand pregnancy outcomes in this population. To address this, we describe pregnancy characteristics and outcomes among individuals enrolled in Medicaid, a publicly funded health insurance program available nationwide.

Methods: Using data from Medicaid T-MSIS Analytic Files (TAF), we identified all pregnancies for patients with SLE from 2014 to 2019. SLE was defined as ≥2 ICD coded outpatient visits occurring less than 30 days apart or ≥1 ICD coded inpatient visit (ICD9: 710.0, ICD10: M32.1X, M32.8, M32.9) occurring before or during pregnancy. We described demographic factors (age, race and ethnicity, and income relative to federal poverty level) and pregnancy characteristics (parity, delivery type, complications, comorbidities occurring during and before pregnancy, and pregnancy outcomes). Additionally, we stratified the pregnancy outcomes by race.

Results: This diverse cohort consisted of 9391 pregnancies among 8201 individuals with SLE , with 2% identifying as Asian, 29% as Black, 17% as Hispanic, and 32% as white. Forty-four percent were below the federal poverty level. Most pregnancy were livebirths (93%). Approximately 16% of pregnancies were complicated by preeclampsia and 18% resulted in preterm delivery. (Table 1). When stratified by race, Black individuals had the highest prevalence of preeclampsia (19%) and preterm delivery (22%). (Table 2)

Conclusion: Pregnancies among patients with SLE had a high frequency of preeclampsia and preterm delivery compared to estimates in the general population (3-7% preeclampsia and 10% preterm). Black individuals had the highest prevalence of complications. These findings offer contemporary, national estimates of pregnancy complications and outcomes among publicly-insured individuals with SLE, highlighting variations by parity and comorbidity burden, and provide patients and providers with further data to inform pregnancy planning and risk counseling.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Observational studies investigating glucocorticoids (GCs) and related adverse events (AEs) in patients with rheumatoid arthritis (RA) can suffer from bias by indication if confounders such as disease activity or systemic inflammation are not adjusted for in the statistical analyses. We assessed whether observational studies in RA which investigate the relationship between GC use and AEs regularly adjust for disease activity or systemic inflammation.

Methods: We conducted a protocolized (https://doi.org/10.17504/protocols.io.bp2l6x955lqe/v1) systematic literature review. MEDLINE was searched for observational studies published since 2008 in patients with RA that investigated the association between GCs and certain AEs. GCs had to be mentioned in the study abstract. We calculated the proportion of studies that statistically adjusted for validated disease activity scores (e.g., RAPID3) and/or systemic inflammation (e.g., serum CRP levels) and/or both (e.g., both RAPID3 and CRP or combined scores such as DAS28-CRP). Joanna Briggs Institute's critical appraisal checklists were used for quality appraisal. Analyses were further stratified by study characteristics (year of publication, study type, type of AE, critical appraisal checklist score percentages, and 2022 Journal Impact Factor®). Statistical comparisons were made with Chi-squared tests.

Results: Out of 609 initial search results, 47 observational (mostly cohort) studies were finally included (**Table 1**). Most studies had a cohort design, were from North America or Europe, and assessed oral GCs. The most commonly investigated AEs were bone-related such as bone mineral density or fractures, followed by cardiovascular and infectious AEs. Almost one third of all included studies were published in either *Annals of the Rheumatic Diseases* or *Rheumatology (Oxford)*. Most studies (57%) *neither* adjusted for validated disease activity scores *nor* markers of systemic inflammation, regardless of study

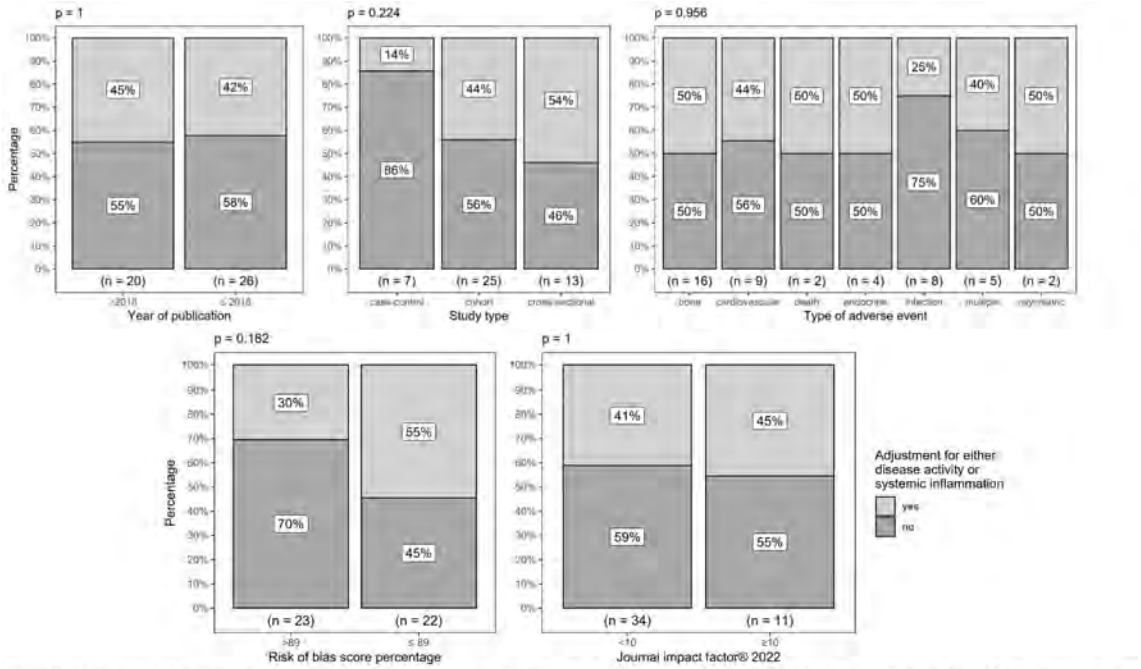

Figure 1. Proportions of studies adjusting for disease activity or systemic inflammation, stratified by year of publication, study type, type of adverse event, risk of bias score percentage and 2022 Journal Impact Factor®.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

characteristics (**Figure 1**). Even in the subsets of studies that were published in a journal with a Journal Impact Factor® of ≥10 or that had critical appraisal checklist score percentages of ≥90%, the majority of studies did not statistically adjust for disease activity or markers of inflammation.

Conclusion: Confounding by indication is likely present in most observational studies investigating the relationship between GC use and AEs. Even studies published in "high-ranking" scientific journals did not regularly adjust for disease activity or markers of systemic inflammation. Observational studies may attain relatively high quality appraisal scores according to a highly regarded, commonly used critical appraisal tool despite not accounting for the possibility of confounding by indication.

Model-based Evaluation of the Potential Public Health Impact of Expanding Medicare Coverage for Weight Loss Medications for Beneficiaries with Knee Osteoarthritis and Obesity in the US.

Ethan Eickmann[1], Daniel Betensky[1], Karen Smith[1], Candace Feldman[1], Jason Kim[2], Ankur Pandya[3], Jeffrey Katz[4] and Elena Losina[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Arthritis Foundation, Atlanta, GA, [3]Harvard School of Public Health, Boston, [4]Brigham and Women's Hospital, Brookline, MA, [5]BWH, Boston, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: US federal law currently does not allow Medicare Part D coverage for weight loss medications without additional indications, such as diabetes. Several glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have been approved for weight loss alone. GLP-1 RAs are prohibitively expensive, and only about 1% of Medicare beneficiaries report taking GLP-1 RAs for weight loss. The substantial clinical benefits associated with GLP-1 RAs in RCTs, coupled with their high cost, have led to discussions about adding Medicare coverage for weight loss indications. We examined the potential public health impact of expanding coverage of GLP-1 RAs for weight loss among Medicare Part D beneficiaries with knee osteoarthritis (OA) and obesity.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Potential public health impact of GLP-1 RA coverage by Medicare for weight loss in persons with knee OA and concomitant obesity

	Life Years	Quality-Adjusted Life Years	# of new T2DM cases	# of MACEs	# CVD-attributable deaths	# of TKRs
No coverage for GLP-1 RAs for weight loss	6,314,531	4,467,493	100,866	66,337	24,611	30,237
Maximum health benefit of Medicare coverage for GLP-1 RAs for weight loss (100% uptake)	+319,824	+341,827	-39,893	-6,745	-2,173	-6,380
Realistic health benefit of Medicare coverage for GLP-1 RAs for weight loss (20% uptake)	+93,002	+88,797	-7,577	-5,754	-2,018	-1,023

GLP-1 RAs = Glucagon-Like Peptide-1 Receptor Agonists, T2DM = Type 2 Diabetes Mellitus, MACEs = Major Adverse Cardiovascular Events, CVD = Cardiovascular Disease, TKRs = Total Knee Replacements

Methods: We used the data from OAI (the Osteoarthritis Initiative), the United States Census, NHANES (National Health and Nutrition Examination Survey) and published literature to estimate the proportion of the US population ≥65 years of age with obesity (BMI ≥30 kg/m^2) and knee OA, without type 2 diabetes mellitus (T2DM), and enrolled in Medicare Part D. Using the Osteoarthritis Policy Model (OAPol), a widely published and validated microsimulation of OA, we estimated the maximum potential clinical benefits of GLP-1 RAs coverage for weight loss among Medicare beneficiaries with knee OA and obesity as the difference in clinical outcomes with and without GLP-1 RA use. The clinical benefits included gains in life expectancy and gains in quality-adjusted life expectancy along with reductions in incident cases of MACE, T2DM, and total knee replacement (TKR). We modeled GLP-1 RA weight loss efficacy, toxicity and discontinuation rates from the SURMOUNT trials. We derived knee pain reduction using data from the STEP-9 trial, which focused on a population with knee OA. To recognize that not all eligible Medicare beneficiaries would use GLP-1 RAs for weight loss, we used data for GLP-1 RA uptake among people with GLP-1 RA insurance coverage to estimate realistic clinical benefits (~20% uptake among those who are eligible).

Results: We estimated that 591,550 Americans have obesity, symptomatic knee OA, no T2DM, and are enrolled in Medicare Part D. Cumulatively, affordable access to GLP1RA among this entire population would add 319,824 years to life expectancy (0.54/person) and 341,827 years to quality-adjusted life expectancy (0.58/person), if every eligible individual would use GLP-1 RAs. Additionally, expanded GLP-1 RA coverage could avert 39,893 cases of T2DM, 6,745 major adverse cardiovascular events (MACEs, including 2,173 CVD-attributable deaths), and 6,380 TKRs. Table 1 shows maximum and realistic health gains for scenarios of GLP-1 RA uptake.

Conclusion: Adding GLP-1 RA coverage for weight loss alone to Medicare Part D may lead to substantial health benefits in the US, increasing survival and improving quality of life, while also averting costly and morbid chronic diseases and reducing the need for TKR, even if only parts of this population would be willing to use these medications. These estimates may be useful when discussing how to balance the health benefits of expanded access to GLP-1 RAs with the potential budgetary impacts.

Racial and Gender Disparities in Gout Clinical Trials

Fizza Zulfiqar[1], Dania Kaur[2], Meaghan Bethea[3], Taylor Spencer[4], Samhitha Bitla[5], Abhinav Vyas[6] and Camelia Arsene[7], [1]Trinity Health Oakland/Wayne State University, Pontiac, MI, [2]North Alabama Medical Center, Muscle Shoals, AL, [3]Trinity Health Oakland Hopsital, Pontiac, MI, [4]Trinity Health Oaklnd Hospital, Pontiac, MI, [5]Trinity Health Oakland Hospital, Pontiac, MI, [6]Vanderbilt University, Nashvile, TN, [7]Trinity Health Oakland Hospital, Pontiac

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: To develop effective novel treatment strategies for Gout disease that cater to patients from diverse backgrounds, it is crucial that all racial groups, without exception, have equal opportunities to participate in clinical trials. This inclusivity is not just a matter of fairness, but a necessity for the advancement of medical research.

Methods: Using ClinicalTrials.gov, a web-based resource that registers all studies meeting the definition of a clinical trial according to the International Committee on Medical Journal Editors,we identified all phase 1 to phase 4 Gout disease clinical trials. We manually abstracted data on the racial distribution of enrolled participants, sex distribution, trial phase, location, and year of trial reporting. Additionally, we conducted subgroup analyses of racial distribution based on trial phase and location and evaluated trends in racial disparity within clinical trial enrollment over the years. SPSS software version 28 was used for analysis. P value of < 0.05 was considered statistically significant.

Results: We identified 78 clinical trials related to Gout, of which 91.7% were done in Europe or the United States. Most of these were phase 2 or 3 clinical trials (70.4%). The racial distribution of enrolled participants was publicly available in 44 (56.4%) clinical trials. The race distribution of enrolled subjects was reported in 33.3% of Phase 1, 60.9% in Phase 2, 48.1% in Phase 3 and 53.3% in Phase 4. The race distribution among 29,166 study participants in 78 clinical trials was: 61.3% White race (14522), 15.8 % Black race (3738), 6.1% Asians descent (1450), 9.2% Hispanics origin (2189), 2.4% American Indian/Alaskan Native (559), 0.8% Native Hawaiian/Other Pacific Islander (198), and 4.3% other races (1029). A similar race distribution trend was observed across all subgroups of clinical trials based on phase. There was a statically significant difference between trail phases regarding racial groups with $p < 0.001$. The sex distribution, as seen throughout the

		% within Phase	100.0%	100.0%	100.0%	100.0%	100.0%

Gender Distribution of Participants Across Clinical Trial Stages (Stage 1 to 4)

trials, was 87.7% in males (25572) and 12.3% in females (3594). There was a statistically significant difference between trial phases regard toregarding sex at birth with $p < 0.001$.

Conclusion: Our research revealed that only 56.4% of Gout studies reported racial distribution. The Black race was underrepresented despite a higher prevalence of Gout in this population per the literature evidence. Strategies to ensure equitable representation in Gout clinical trials are needed to address disparities and improve treatment outcomes across diverse populations.

All Roads Lead to Rheum? Modeling Scenarios of New Patients-to-pediatric Rheumatologist Ratios in Different US States

Gabriela Accetta Rojas[1], Evan Mulvihill[2], Salma Siddique[1] and Annemarie Brescia[1], [1]Nemours Children's Hospital of Delaware, Wilmington, DE, [2]Nemours/A.I.duPont Hospital for Children, Wilmington, DE

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology is among the pediatric subspecialties with the lowest workforce density in the US[1]. Initial management of most of the pediatric rheumatologic conditions relies exclusively on rheumatologist assessment. Pediatric rheumatologists might be responsible for a high patient load in some states of US.

Methods: The number of active certified pediatric rheumatologists in 2024 per state was determined by the American Board of Pediatrics (ABP)[2] and the pediatric state population < 18 years by US Census Bureau Population Estimates[3]. We estimated the number of new patients-to-pediatric rheumatologist in 1-year interval applying reported incidence rates of the main rheumatic conditions - juvenile idiopathic arthritis[4], pediatric lupus[5], juvenile dermatomyositis[6], and others[7-9] - equally to each pediatric state population under the assumption that children living in different states are at the same risk of developing a rheumatologic condition. Using Monte Carlo simulations[1,10] we then created 1,000 scenarios of varying incident cases/100,000 children at the state level in a 1-year interval ranging from the minimum to the maximum reported incidence. In a sensitivity analysis, states reported to have zero active certified pediatric rheumatologist were considered to have 0.5.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

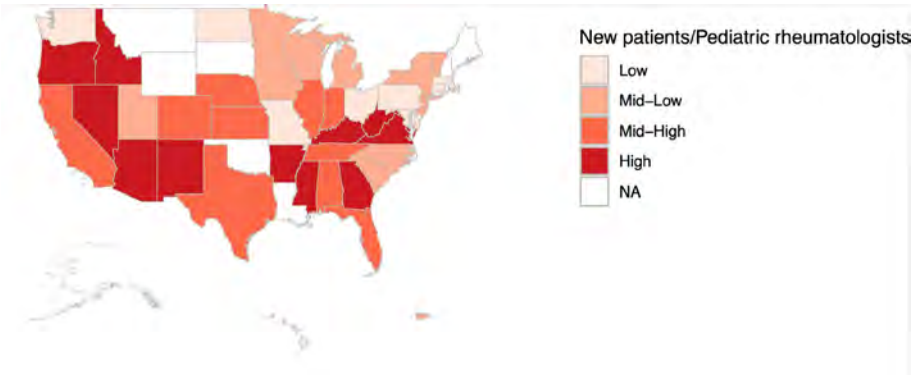

Figure 1. New patients-to-pediatric rheumatologist in each state in a scenario of lowest incidences of pediatric rheumatic conditions

Results: In the scenario of lowest incidences of all rheumatic conditions, the ratios of new patients-to-pediatric rheumatologist were categorized in quartiles, as shown in Figure 1. The states with highest ratios of new patients-to-pediatric rheumatologist were found in Arizona (189, 95%CI 176-301), Idaho (176, 95%CI 145-247), and New Mexico (165, 95%CI 143-245). States the with lowest ratio of new patients-to-pediatric rheumatologist were Delaware (24, 95%CI 14-31) and Massachusetts (26, 95%CI 18-35). In the sensitivity analysis, states with the highest ratios of new patients-to-pediatric rheumatologist were Louisiana and Oklahoma.

Conclusion: There are striking differences in the ratios of new patients-to-pediatric rheumatologist across the US. Children living in states with very high patient- to-pediatric rheumatologist might be at risk for delay in care. Further studies to examine the implications of workforce availability and pediatric access to rheumatology care are warranted.

Factors Associated with Fibromyalgia Diagnosis amongst People Meeting Criteria: Results from UK Biobank

Sung-A Kim, **Gary Macfarlane**, Marcus Beasley and PACFiND study group, University of Aberdeen, Aberdeen, United Kingdom

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The diagnosis of fibromyalgia (FM) is challenging due to its reliance on patient-reported symptoms, the absence of definitive biomarkers, and numerous overlapping comorbidities. Discrepancies between diagnostic criteria and clinical practice imply the possibility of diagnostic biases, complicating timely and accurate identification. This study aimed to identify factors associated with receiving a FM diagnosis, among individuals who met 2016 criteria, and explore potential barriers to diagnosis.

Methods: Using data from UK Biobank, a total of 27 potential factors across four biopsychosocial domains were analysed for differences between diagnosed and undiagnosed individuals. Multivariate log-binomial regression was used within and across domains to evaluate prevalence ratios (PR) regarding the independent association of factors with receiving a FM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Diagnosis status among people meeting the 2016 fibromyalgia criteria

diagnosis. To avoid potential selection bias, we conducted a sensitivity analysis including all UK Biobank participants who completed the Experience of Pain question, regardless of whether they met the 2016 FM criteria.

Results: Among the 4,197 individuals meeting FM criteria, 72.6% reported not having received a diagnosis. We identified eight factors significantly associated with not being diagnosed: being male (fully adjusted PR 0.47, 95% confidence interval 0.41-0.56), older age (0.85, 0.75-0.96), self-reported concomitant diagnosis of neuropathy (0.91, 0.83-0.99), shorter pain duration (0.56, 0.41-0.76), lower polysymptomatic distress scores (0.56, 0.51-0.62), and less frequent fatigue (0.85, 0.76-0.96). In contrast diagnosis was more likely amongst people who also reported a diagnosis of chronic fatigue syndromes (1.65, 1.50-1.82) and complex regional pain syndrome (1.13, 1.03-1.25). The sensitivity analysis conducted on the whole population sample demonstrated results generally consistent with the main analysis.

Conclusion: Our research has identified significant disparities in the diagnosis of FM at the population-level in the UK, particularly among patients without stereotypical characteristics, with less severe symptoms, or the existence of concomitant chronic pain conditions. Understanding these diagnostic patterns can help improve alignment between criteria for identifying FM and real-world practice.

Refining Administrative Algorithms For Accurate Identification of Patients with Systemic Sclerosis In Trinetx Research Network

Gulsen Ozen[1], Michael O'Rorke[2], Paul Romitti[2] and Robyn Domsic[3], [1]University of Iowa, Carver College of Medicine, Division of Immunology, Coralville, IA, [2]University of Iowa College of Public Health, Department of Epidemiology, Iowa City, IA, [3]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Large data-driven medical research is invaluable in answering questions about epidemiology, genetics, therapeutics, and outcomes of rare diseases. Systemic sclerosis (SSc) is rare yet the deadliest autoimmune disease with limited treatment options available to alter the disease course. Despite the availability of large administrative datasets, there are only a few studies on SSc using these datasets, most of which define SSc cases based on one diagnostic code. Optimal use of these datasets, however, requires accurate SSc case determination, which has yet to be studied. We aimed to evaluate algorithms to identify SSc cases in an administrative dataset and to describe the performance characteristics of these algorithms.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. **Excluding non-melanoma skin cancers.*

Methods: Patient records in a large, global multicenter electronic medical record dataset (TriNetX Research Network) were screened for SSc using the International Classification of Diseases, Ninth and Tenth Revisions (ICD-9 and ICD-10). The patient identifiable data were available only from one center. A medical record review was performed from a simple random sample of this cohort using a standardized data abstraction form (GO) to confirm the SSc diagnosis. All outpatient and inpatient ICD codes and dates assigned were extracted from the TriNeTx Research Network. Using data for confirmed cases, the performance of different administrative algorithms was assessed by sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and receiver operator curve analyses.

Results: To date, medical records for a random sample of 480 of the 1126 patients with at least one ICD9/10 code for SSc were reviewed. Overall, 342 of the 480 (71.2%) patients were confirmed to have SSc, predominantly limited cutaneous SSc (*Table 1*). Among the tested administrative algorithms, "≥ 2 outpatient ICD9/10 codes at least 30 days apart without an alternative diagnosis code (algorithm 4)" showed the best performance with a sensitivity of 95.6%, specificity of 70.3%, PPV of 89.8%, NPV of 86.6% and area under the curve of 0.906 (*Table 2*). Although ≥1 inpatient ICD9/10 code had a high specificity (90.6%) and PPV (92.1%), its sensitivity (44.4%) and NPV (39.7%) were low. When "≥1 inpatient ICD9/10 code" was added to the algorithm 4, the performance of the algorithm did not change significantly (*Figure*). When patients with overlap syndromes were excluded, algorithm 4 still performed the best (sensitivity 96.8%, specificity 70.6%, PPV 85.9%, NPV 92.3%).

Conclusion: The administrative algorithm ("≥ 2 outpatient ICD9/10 code at least 30 days apart without an alternative diagnosis code) reliably identifies SSc cases. This algorithm can be applied to large administrative datasets to conduct clinical and epidemiologic studies with a higher validity in SSc patients. External validation of this algorithm in different datasets can further strengthen its utility.

Session Date: Monday, October 27, 2025

Session Title: (1007–1037) Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Heart failure (HF) is a major cause of morbidity and mortality in rheumatoid arthritis (RA). Prior work has suggested that higher levels of inflammation is associated with increased future risk of HF. Several inflammatory pathways are hypothesized to play a role in both RA and HF including interleukin-1-beta (IL-1b), interleukin-6 (IL-6), and soluble tumor necrosis factor-2 (sTNFR2). The Predicting Risk of Cardiovascular Disease Events (PREVENT) risk equation published in 2023 includes a validated risk estimator for predicted 10-year HF risk (PREVENT-HF). The objective of this study was to determine the cross-sectional association between inflammatory biomarkers and predicted HF risk in RA to identify potential markers of HF risk in RA.

Methods: We studied patients from the LiiRA (Lipids, Inflammation and Cardiovascular risk in RA) study, who had active RA with a plan to initiate tumor necrosis factor inhibitor (TNFi) therapy. All patients underwent measurements for high-sensitivity C-reactive protein (hsCRP), erythrocyte sedimentation rate (ESR), IL-1b, IL-6, sTNFR2, NT-pro-BNP, and high sensitivity cardiac troponin (hs-cTnT) at the baseline visit. We calculated the estimated risk of HF for each patient at baseline using PREVENT-HF risk equations. Spearman's correlation was calculated for each biomarker value and the PREVENT-HF score. We performed a univariable linear regression to determine the association between detectable hs-cTnT (>6ng/L) and PREVENT-HF score. Biomarkers significantly correlated with PREVENT-HF score ($p< 0.05$) in the univariable analyses were considered in a multivariable linear regression testing the association with PREVENT-HF score, adjusting for RA disease duration and disease activity (PREVENT-HF includes age and sex).

Results: We studied 73 patients, 82% female, median age 56 years (Table 1). The median RA duration at baseline was 3.6 years and median CDAI was 22 (moderate disease activity). The median PREVENT-HF 10-year estimated HF risk was 2.1% (IQR 0.7, 5.1), and 21% of the cohort had a detectable hs-cTnT. Higher levels of hsCRP, ESR, IL-6, and sTNFR2 were correlated with higher PREVENT-HF estimated HF risk, and detectable hs-cTnT was associated with higher PREVENT-HF estimated HF risk

(Table 2). Starting with a model including inflammatory markers measured in clinic (ESR and hsCRP), sTNFR2 was associated with PREVENT-HF risk after adjustment for these inflammatory biomarkers, RA duration, and disease severity (Table 3). The addition of hs-cTnT to the model attenuated the association between sTNFR2 and estimated HF risk, and ESR maintained a significant association with estimated HF risk. Adjusting for NT-pro-BNP did not change the associations.

Conclusion: In this RA cohort with moderate disease activity, among candidate inflammatory markers, ESR and sTNFR2 were most correlated with higher PREVENT-HF risk scores. Moreover, detectable hs-cTnT was most strongly associated with higher PREVENT-HF risk scores. More studies are needed to further examine specific inflammatory pathways, e.g., TNF, and subclinical myocardial injury as potential markers of HF risk in RA.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of developing herpes zoster (HZ). This study aimed to assess the effectiveness of recombinant zoster vaccine (RZV) in reducing both the incidence of HZ and all-cause mortality among individuals with RA.

Methods: We conducted a retrospective cohort study using data from the TriNetX U.S. Collaborative Network between October 1, 2017, and March 31, 2024. The study population consisted of RA patients who received RZV (RA-RZV cohort) and those who did not (RA control cohort). Propensity score matching (PSM) was employed to balance baseline characteristics between the groups, accounting for demographics, social economic status, lifestyles, medical utilization, comorbidities, and medications. The primary outcomes were the risk of HZ and all-cause mortality. PSM-adjusted hazard ratios (HRs) were calculated using Cox proportional hazards regression models. Kaplan-Meier curves and Log-Rank tests were used to evaluate survival differences.

Results: After PSM, each cohort included 21,046 individuals. The RA-RZV group demonstrated significantly lower risks of HZ (HR: 0.836, 95% CI: 0.738–0.947) and all-cause mortality (HR: 0.606, 95% CI: 0.561–0.654). The HZ risk reduction was more pronounced in patients aged 50-64 years (HR: 0.731, 95% CI: 0.610–0.876), females (HR: 0.791, 95% CI: 0.684–0.915), White (HR: 0.808, 95% CI: 0.696–0.937), and Black/African American participants (HR = 0.685; 95% CI = 0.481–0.976).

Conclusion: RZV vaccination is associated with a reduced risk of HZ and mortality among RA patients aged 50 years and older. RZV vaccination should be prioritized among eligible RA patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The differences in lupus-related mortality reported in population studies are partly explained by racial disparities and access to healthcare. However, population-based data from universal healthcare systems are less well known.

Our objective was to determine factors related with mortality in SLE patients in Catalonia (Spain) during the period from January 1, 2006, and December 31, 2021.

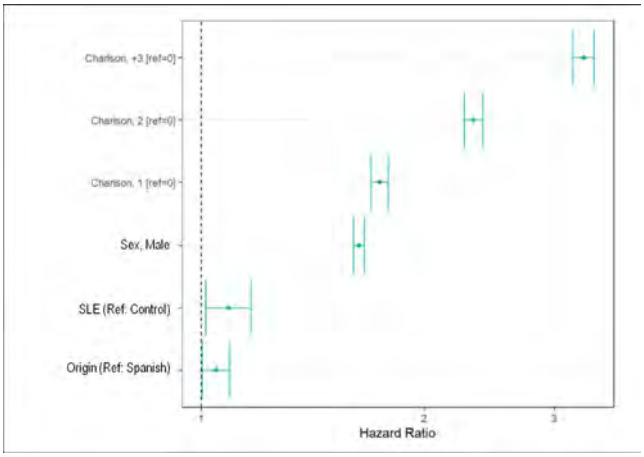
Methods: We conducted a population-based cohort study (CAPTURED study, **C**at**A**lonia e**P**idemiology s**TU**dy in **R**h**E**umatic **D**iseases) of all existing Catalonian cases who received SLE diagnosis from 2006 to 2021 by using ICD-10-CM codes from the Information System for the Development of Primary Care Research (SIDIAP). A database of primary care electronic health records that includes data from 328 primary care practices covering 5.8 million people, 75% of the Catalan population.

Patients with SLE were matched 1 with individuals from the Catalonia general population and estimate hazart ratio (HR) for mortality using a cox regression model adjusting by potential coufounding factors including sex, age, origin (Spanish vs non-Spanish), socioeconomic status (MEDEA*, Gotsens M et al. Accid Anal Prev. 2011 Sep;43(5):1802-10) and comorbidities (charlson score, CS).

Results: We identified 10,687 prevalent cases of SLE, with a mean age of 47.5 years (SD 16.3). Of these patients, 8,851 (83.4%) were female, and 6,885 (64.9%) had Spanish nationality. General characteristics are summarized in Table 1.

During the study period, we identified 1,175 deaths among SLE cases (12.5%) and 11,499 (15.6%) among 824,028 controls. Age (HR 1.05, 95% CI 1.02–1.08), male sex (HR 1.60, 95% CI 1.58–1.63), and Charlson score (CS=1 HR 1.75, 95% CI 1.70–1.80; CS=2 HR 2.38, 95% CI 2.31–2.45; CS≥3 HR 3.50, 95% CI 3.38–3.62) were associated with increased mortality risk, while patients of Spanish origin had a lower risk of death (HR 0.94, 95% CI 0.90–0.98).

After adjusting for confounding factors, patients with SLE had a slightly higher mortality rate compared to the general population (HR 1.09, 95% CI 1.01–1.17) (Figure 1).



Adjusted HR for mortality in SLE in Catalonia (Spain)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In our population-based study conducted within a universal healthcare system, we observed a slight increase in mortality among patients with SLE. Socioeconomic status did not significantly impact mortality in these patients.

Abstract Number: 1019

Associations Between Mental Health Diagnoses and Acute Care Use Among Individuals with Systemic Lupus Erythematosus in the All of Us Research Program

Karen H. Costenbader[1], Jeong Yee[2], Hongshu Guan[3], Emily Oakes[4], Jing Cui[3], Leah Santacroce[4], Elizabeth Karlson[4], Karestan Koenen[5], Laura Kubzansky[5] and Candace Feldman[3], [1]Harvard Medical School and Brigham and Women's Hospital, Boston, MA, [2]Sungkyunkwan University, Suwon, MA, South Korea, [3]Brigham and Women's Hospital/ Harvard Medical School, Boston, [4]Brigham and Women's Hospital, Boston, MA, [5]Harvard T.H Chan School of Public Health, Boston

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Mental health disorders, including depression, anxiety, and post-traumatic stress disorder, are prevalent among people with SLE. In other disease populations, these disorders have been associated with increased acute care use. We quantified the association between mental health conditions and recurrent acute care use (emergency department [ED] visits, hospitalizations) among patients with SLE.

Methods: We used data from the nationwide All of Us Research Program (version 8), an NIH cohort of >393,000 U.S. adults who enrolled and consented for linkage to their electronic health records. We identified those with ≥2 ICD-10 or SNOMED codes for SLE in the 2 years pre-enrollment. We assessed for mental health diagnoses in that time, identified by ≥2 ICD-10 or SNOMED codes for major depression, anxiety, or PTSD. The outcome was number of emergency department visits (only) and hospitalizations (including from emergency department) after enrollment. Incidence rates for acute care use among patients with and without mental health diagnoses were calculated. Multivariable negative binomial regression models calculated incidence rate ratios (IRRs), adjusting for age, sex, race, ethnicity, enrollment year, baseline sociodemographic factors and comorbidities.

Results: We identified 2,160 with SLE, of whom 1,333 (61.7%) had depression, anxiety, and/or PTSD (**Table 1**). Mean age overall was 49.8 (14.3) and 90.2% were female. Those with ≥1 mental health condition were more likely to be less educated, in a low-income group, to have ever smoked, and to have more comorbidities. Patients were followed for a mean 36.2 months (SD 20.9) after enrollment. Incidence rates for all acute care were much higher in those with mental health disorders (**Table 2**). In adjusted analyses (**Table 2**), we found strong associations between having mental health diagnoses and

higher rates of acute care use, both emergency department visits (adj IRR 2.12, 95%CI 1.79-2.52) and hospitalizations (adj IRR 1.95, 95%CI 1.59-2.41). This was true both for all emergency visits and hospitalizations for SLE (adj IRR 1.80, 95%CI 1.50-2.16) and for all diagnoses (adj IRR 1.92, 95% CI 1.60, 2.30).

Conclusion: In this large US-wide population of patients with SLE, mental health diagnoses were extremely prevalent and those with them had much higher rates of recurrent acute care use compared to those without these diagnoses. As patients with frequent acute care use are less likely to receive standard-of-care long-term medications and preventive care, contributing to inequities, further work is needed to develop interventions to decrease this recurrent acute care use for patients with SLE and mental health disorders.

Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyalgia rheumatica (PMR) is one of the most common inflammatory rheumatic diseases among older women, but little is known of its etiology, and there are few established risk factors. We aimed to prospectively investigate the association between European ancestry, geographic region, ambient erythemal ultraviolet B light (UV) irradiance and PMR risk among women.

Methods: We used data from the Nurses' Health Study (NHS), an ongoing longitudinal cohort of US female registered nurses (1980-2020; aged 34-59 years in 1980). Participants provided updated information on ancestry, residential information, lifestyle factors and newly diagnosed health conditions, such as PMR, on biennial questionnaires. Two board certified rheumatologists confirmed PMR self-reported diagnoses and dates of onset with medical records. Eligible participants were women aged 50 years or older and were free of PMR. Cox proportional hazards regression models, stratified by 2-year risk period and age, were used to estimate multivariable-adjusted hazard ratios (HRs) with 95% confidence intervals (95%CIs) for ancestry, region of residence and residential erythemal ambient UV irradiance in models that simultaneously adjusted for these factors and other covariates in relation to incident PMR.

Mean alcohol intake ± SD, g/day	4.9± 8.1	5.2± 8.2	6.1± 8.9	6.5± 9.8
Mean caffeine intake ± SD, mg/day	287.2± 195.2	280.6± 189.7	292.3± 190.5	285.7± 197.2
Alternate Health Eating Index, without alcohol ± SD‡	46.3± 8.5	46.8± 8.5	47.2± 8.5	49.4± 8.9
Highest quartile of physical activity, %	23.8	24.6	25.4	27.8
Age at menopause <45 years, %	9.9	9.8	10.6	10.9
Current use of postmenopausal hormones, %	19.0	19.8	19.3	30.7

Values are means ± SD or percentages and are standardized to the age distribution of the study population.
* Value is not age-adjusted
† This score is based on the sum of the z-scores of census tract indicators based on participants' zip codes (median household income, home value, percentage with college degree, percentage of families with interest or dividends, percentage occupied housing, percentage living in poverty, percentage White).
‡ Alternate Health Eating Index without alcohol is a score (range 0-100) that measures adherence to a diet pattern based on 10 foods and nutrients most predictive of disease risk in the literature, with higher scores representing better adherence.

Results: We followed 111,874 NHS women and accrued a total follow-up of 2,990,295 person-years (**Table 1**). Among them, 129 incident PMR cases were identified, and the mean age at diagnosis was 75.6 (SD=6.5) years. In multivariable-adjusted analyses (**Table 2**), having Scandinavian ancestry, compared to other European ancestry, was associated with more than a doubling of risk (HR: 2.35; 95%CI: 1.37, 4.05). Compared to living in the Midwest region, living in the Northeastern region was associated with a higher risk (HR: 1.89; 95%CI: 1.07, 3.34), while living in the Southern or Western regions were not significantly different (p >0.58). Greater ambient erythemal UV exposure based on residence was associated with a lower risk, with every 1 mW/m^2 increase in UV being significantly associated with a 2% lower risk (p=0.0045; HR=0.98; 95%CI: 0.96, 0.99; **Figure 1**). Those in the highest versus lowest UV quartile had a 73% lower risk (HR=0.27; 95%CI: 0.10, 0.72).

Conclusion: Scandinavian ancestry and living in Northeastern US were associated with a higher risk, while greater ambient UV erythemal irradiance was associated with a lower risk of PMR, indicating the important role of genetic and environmental factors in PMR etiology.

Abstract Number: 1021

Recent Trends in Cannabis Use Among Individuals with Rheumatic Diseases

Kristin Wipfler[1] and Kaleb Michaud[2], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Cannabis use has increased substantially in the general population over the past decade, driven by changing legal landscapes and expanding public interest in its therapeutic potential. Among individuals with rheumatic and musculoskeletal diseases (RMDs), pain management remains a persistent challenge, prompting interest in alternative therapies such as cannabis. Our prior work documented a dramatic rise in cannabis use among people with RMDs between 2014 and 2019.[1] However, updated recent estimates are lacking, and the clinical landscape has evolved rapidly with changing laws and new formulations available. We aimed to describe trends in cannabis use from 2020 to 2024 among individuals with RMDs, including patterns of THC vs CBD product use, routes of administration, and reasons for use.

Table 1. Characteristics of study participants by cannabis use status.

Characteristic	Cannabis Nonusers n=3704	Cannabis Users (ever) n=2969
*Age, years, mean (SD)	69.5 (11.8)	65.2 (11.4)
*Female, %	82.4	85.1
White race, %	90.5	90.8
BMI, kg/m^2, mean (SD)	28.9 (7.3)	29.2 (7.2)
*Hx smoking cigarettes, %	41.1	51.4
*Primary Diagnosis, %		
Rheumatoid Arthritis	63.7	60.8
Osteoarthritis	14.1	16.2
Systemic Lupus Erythematosus	5.4	5.7
Fibromyalgia	4.5	6.5
Psoriatic Arthritis	2.8	3.1
Other	9.5	7.8
*Pain VAS, 0-10, mean (SD)	3.7 (2.8)	4.3 (2.8)
*Patient global VAS, 0-10, mean (SD)	3.7 (2.6)	4.0 (2.6)
HAQ-II, 0-3, mean (SD)	0.95 (0.73)	0.93 (0.68)
*Rheumatic Disease Comorbidity Index, 0-9, mean (SD)	2.0 (1.6)	2.2 (1.7)
*DMARD use, %	64.1	61.0
Non-opioid analgesic use, %	42.7	45.0
*Opioid use, %	18.7	24.1

*p<0.05; significance testing by X^2 or Student's t-tests, as appropriate

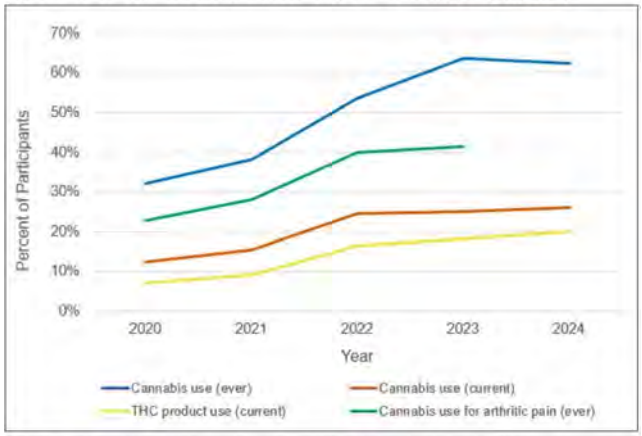
Table 2. Reasons for use and routes of administration among cannabis users (2020-2024).

	All Users n=2969	THC Product Users n=1725	CBD-Only Users n=1244
Reason for use			
Anxiety/relaxation	725 (24.4)	568 (32.9)	157 (12.6)
Arthritic pain	2024 (68.2)	990 (57.4)	1034 (83.1)
Depression	207 (7.0)	160 (9.3)	47 (3.8)
Insomnia	362 (12.2)	365 (21.2)	148 (11.9)
Recreational only	498 (16.8)	358 (20.8)	4 (0.3)
Other	234 (7.9)	124 (7.2)	110 (8.8)
Route of administration			
Smoked	891 (30.0)	882 (51.1)	9 (0.7)
Vaped	208 (7.0)	197 (11.4)	11 (0.9)
Ingested	1356 (45.7)	826 (47.9)	530 (42.6)
Topical	1181 (39.8)	510 (29.6)	671 (53.9)

Values are n (%). Participants could report multiple reasons for use and multiple routes of administration. Users are "ever" (both past and current).

Figure 1. Trends in cannabis use for the treatment of arthritis-related pain (2020-2024).



N=6673; 2020 n=4485; 2021 n=5342; 2022 n=3115; 2023 n=1728; 2024 n=1429
Reason for use data are not yet available for 2024

Methods: The study population included adults with RMDs in the FORWARD Databank who answered questions related to cannabis use between 2020 and 2024. Participants who reported use of cannabis or cannabis-derived products (hereafter "cannabis") were categorized by whether the products they used contained THC or not (CBD only) and whether their use was past or current. Descriptive statistics were calculated for characteristics of these subgroups as well as for self-reported reason(s) for cannabis use and route(s) of administration. Temporal trends for cannabis use in general, for THC-containing products, and for use related to arthritic pain were examined.

Results: A total of 6,673 participants were included in the study, 2,969 (44%) of whom reported past or current cannabis use (Table 1). Among users, 1,725 (58%) reported use of a THC-containing cannabis product, while the remainder reported use of CBD-only products (Table 2). Most cannabis users (68%) reported use of cannabis products for the purpose of treating arthritis-related pain, particularly those who reported use of CBD-only products. Ingestion and topical use were the most common routes of administration in general, although smoking was more common among users of THC-containing products. From 2020 to 2024, frequency of cannabis use in this population doubled; "ever" use increased from 32% to 62%, while current use increased from 13% to 26% (Figure 1). Each year, most current users (57-77%) were using THC-containing products.

Conclusion: Cannabis use has increased substantially among individuals with RMDs since 2020. This finding underscores the need for clinician awareness and guidance in this area, as well as the need for an understanding of any

therapeutic impact of cannabis use in this population. Ongoing work will explore associations between cannabis use and disease activity, physical function, and patient-reported outcomes, as well as perceived effectiveness of treatment with cannabis products and reasons for discontinuation.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Exposure to a hostile environment may negatively impact disease outcomes in patients with RD, particularly by affecting their mental health and overall quality of life. We aimed to evaluate the prevalence of abuse among patients with RD and to identify their associated factors.

Methods: We conducted a cross-sectional study at an academic rheumatology clinic, including adult patients with a clinical diagnosis of RD. A modified version of the Geriatric Mistreatment Scale was used to assess physical, psychological, neglect, economic, and sexual abuse. Psychological symptoms (DASS-21 tool), personality traits (BFI-10), functional capacity (HAQ-DI) disease activity (RAPID-3), family function (APGAR questionnaire), resilience (BRCS), and quality of life (WHOQOL-BREF) were all assessed. Patients were grouped based on reported abuse. Group comparisons were performed using X^2 and Mann–Whitney U tests. Univariable logistic regression was conducted to explore associations between abuse and clinical or psychosocial factors. Multivariable logistic regression was used to account for age, sex, education level, and marital status. $P < 0.05$ was statistically significant.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Hyperlipidemia	9 (9.2)	17 (11.1)
Hypothyroidism	--	1 (0.7)
Osteoporosis	3 (3.1)	8 (5.3)

Results: We included 250 patients with RD. Median age was 52 years (IQR 44–61), and 232 (92.8%) were female. Most patients had RA (124, 49.6%), followed by SLE (50, 20.0%), and SS (20, 8.0%). The prevalence of abuse/mistreatment was 39.8% (n= 98). There were no differences in age, sex, educational level, economic status, or employment status between patients with or without abuse (**Table 1**).

Patients with abuse had more functional disability (34.0%) than non-abuse patients (13.2%; p< 0.001), and fewer patients with RA and abuse were on remission according to RAPID3 (46.9% vs. 65.8%, p< 0.005). Quality of life was lower among patients with abuse in the psychological, social, and environmental domains; but not in the physical domain (**Table 2**).

In univariable logistic regression, mistreatment was associated with higher levels of depression (OR 1.10, 95% CI 1.05–1.14), anxiety (OR 1.09, 95% CI 1.05–1.13), stress (OR 1.09, 95% CI 1.06–1.13), and disability (OR 2.10, 95% CI 1.40–3.10). It was also associated with lower quality of life (psychological, social, and environmental), higher neuroticism, and reduced coping and family function (**Table 3**).

Environment	56 (41–66.7)	63 (50–75)	0.003

DASS-21: Depression Anxiety Stress Scales–21; HAQ: Health Assessment Questionnaire. WHOQOL-BREF: World Health Organization Quality of Life - Brief. BFI-10: Big Five Inventory-10.

After accounting for age, sex, education and marital status, abuse/mistreatment remained associated with higher levels of depression (aOR 1.10, 95% CI 1.05–1.15), anxiety (aOR 1.09, 95% CI 1.05–1.13), stress (aOR 1.10, 95% CI 1.06–1.13), and disability (aOR 2.10, 95% CI 1.40–3.10). In contrast, better quality of life (psychological, social, and environmental), along with lower neuroticism (aOR 0.83, 95% CI 0.72–0.96), adaptive coping (aOR 0.89, 95% CI 0.81–0.97), and stronger family support (aOR, 95% CI 0.67–0.87), were protective (**Table 3**).

Conclusion: Abuse in patients with RD is associated with greater psychological distress, disability, and disease activity, while better quality of life, coping, and family support are protective. Screening for abuse should be considered in patients care to improve outcomes.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Oral health impairment is common in patients with immune-mediated rheumatic diseases (IMRDs) due to chronic inflammation and immune dysregulation. These complications can worsen systemic inflammation, potentially influencing disease activity and quality of life. Although previous studies have explored oral health in rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjögren's syndrome (SS), few have compared oral health status and dental care practices between IMRDs and non-immune-mediated rheumatic diseases (NIMRDs). Understanding these differences may help optimize integrated care strategies for rheumatic patients.

Methods: We conducted a cross-sectional study including 670 patients: 569 with IMRDs and 101 with NIMRDs. Patients were consecutively enrolled from rheumatology outpatient clinics at a tertiary care center between December 2021 and May 2025, based on confirmed diagnoses according to international classification criteria. The IMRD group included patients with RA, SLE, and SS, while the NIMRD group included patients diagnosed with osteoarthritis and osteoporosis. Clinical, demographic, and treatment characteristics were recorded. A structured survey evaluated awareness of dental impact, rheumatologist advice, referral desire, dental visits, and toothbrushing habits. Primary comparisons were made between IMRDs and NIMRDs, with additional subgroup analyses comparing RA, SLE, and SS individually to the NIMRD group. Comparisons were performed using the Student's t-test and Chi-square test, with $p < 0.05$ considered statistically significant.

Results: We included 670 patients (569 IMRDs: RA n=400, SLE n=101, SS n=68; 101 NIMRDs). IMRD patients were predominantly female (93.14%) with a mean age of 50.70 ± 14.68 years. Awareness of the oral impact of rheumatic disease was higher in IMRDs vs. NIMRDs (48.85% vs. 28.71%; p< 0.001), as was rheumatologist dental advice (40.77% vs. 26.73%; p=0.008). Referral desire was high across both groups (79.96% vs. 80.19%; p=0.957).

Time since last dental visit						0.659	0.379	0.995	0.735
Within the past year, n (%)	53 (56.14)	297 (52.19)	199 (49.75)	57 (56.43)	41 (60.29)				
1-5 years ago, n (%)	24 (23.76)	151 (26.53)	114 (28.50)	22 (21.78)	15 (22.05)				
Over 5 years ago, n (%)	9 (8.91)	33 (5.80)	20 (5.00)	8 (7.92)	5 (7.35)				
Never, n (%)	15 (14.85)	88 (15.46)	67 (16.75)	14 (13.86)	7 (10.29)				
Dental visit frequency						0.142	0.061	0.381	0.495
Once a year, n (%)	20 (19.80)	71 (12.52)	44 (11.00)	12 (12.00)	15 (22.38)				
Twice or more per year, n (%)	28 (27.72)	177 (31.21)	124 (31.00)	30 (30.00)	23 (34.32)				
Never, n (%)	53 (52.47)	319 (56.26)	232 (58.00)	58 (58.00)	29 (43.28)				
Daily toothbrushing frequency						0.519	0.618	**0.027**	0.971
Once	13 (12.87)	65 (11.46)	53 (13.25)	4 (3.96)	8 (12.12)				
Twice	38 (37.62)	248 (43.73)	170 (42.50)	52 (51.48)	26 (39.39)				
Three or more	50 (49.50)	254 (44.79)	177 (44.25)	45 (44.55)	32 (48.48)				

GOHAI total scores were 50.20 ± 8.44 in IMRDs and 47.98 ± 7.95 in NIMRDs (p=0.014), with significant differences also observed in the physical function domain (17.54 ± 4.01 vs. 16.44 ± 3.22; p=0.009). No significant differences were found in psychosocial function or pain/discomfort. Subgroup analysis showed that SS patients had the lowest GOHAI total score (47.63 ± 9.12) and the lowest pain/discomfort score (11.54 ± 1.93). Dental visit frequency and toothbrushing habits showed no significant differences between groups.

Conclusion: Patients with IMRDs demonstrated greater awareness of oral health and received more dental advice than those with NIMRDs; however, significant oral health impairment persists, particularly among SS patients. These findings highlight the unmet need for integrated rheumatology-dental care to improve oral health outcomes across all rheumatic disease populations.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1007–1037) Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune interstitial lung disease (ILD) may arise in various autoimmune rheumatic diseases (ARD). Some patients develop ILD with systemic symptoms and autoantibodies without fulfilling ARD criteria, as in interstitial pneumonia with autoimmune features (IPAF) and unclassifiable autoimmune ILD (ILD-UA). Autoinmune-ILD can progress to progressive pulmonary fibrosis (PPF), characterized by irreversible lung damage and high mortality. Real-world data on these patients, particularly cause-specific mortality, are still limited. This study evaluates ILD-related mortality rate over time in patients with autoimmune ILD from the onset of PPF.

Methods: A multicenter longitudinal study was conducted on patients with autoimmune origin ILD (ARD-ILD, IPAF, and ILD-UA), from Madrid, enrolled from Jun 2006 to Jun 2023 and followed up until Sept 2024. Autoimmune-ILD patients were included in a registry [pNEumology RhEumatology Autoinmune diseases (NEREA)]. Patients were required to meet progressive pulmonary fibrosis (PPF) criteria based on the ATS/ERS/JRS/ALAT Guideline. Main outcome was specific-cause mortality related to ILD. Covariables included sociodemographic, clinical, radiological, pulmonary function tests, and therapy. Time of observation comprised the period from the PPF starting until loss of follow-up, main outcome or end of study. Survival techniques were used to estimate the specific-cause mortality rate related to ILD (MR), expressed per 100 patients-year with their respective 95% confidence interval [CI].

Results: A total of 158 patients with PPF were included, of whom 62% were women (n=98). Autoimmune diseases were present in 71.5%, with rheumatoid arthritis being the most common (39.9%) followed by systemic sclerosis (12.0%). Regarding treatments at baseline, 70.9% received corticosteroids, 70.3% disease-modifying antirheumatic drugs (DMARDs) (csDMARDs: 54.4%, b/tsDMARDs: 31.7%), and 14.6% antifibrotic therapy. During follow-up, a total of 47 deaths were recorded. Of these, 37 (78.7%) were attributed to ILD-related causes, with respiratory failure being the most common (16.2%). Additional causes included cancer (n=4), sepsis(n=2), cardiovascular(n=1), neurological(n=2), and unknown(n=1). The ILD-specific mortality rate was 6.2 [4.5-8.5], with a median survival time of 7.8 years. The MR was similar between genders and higher at older ages. Regarding radiographic patterns it was higher in UIP (9.9 [7.0-14.2]) compared to NSIP (MR: 0.47 [0.06-3.4]); in diagnosis MR was higher in IPAF/UA (MR: 7.7 [4.2-13.9]), RA (MR: 9.2 [6.0-14.2]) and lower in others (scleroderma MR:1.5 [0.4-6.3]). Concerning therapy, MR was lower in those on DMARDs during the follow-up compared to those with none (MR: with 4 [2.5-6.4]; without 9.0 [5.7-14.3]).

	HPH	8 (5.1)
	HULP	1 (0.6)
	RyC	6 (3.8)
Autoimmune diagnosis, n (%)	Rheumatic diagnosis:	113 (71.5)
	Rheumatoid arthritis	63 (39.9)
	Sjögren's disease	7 (4.4)
	Scleroderma	19 (12.0)
	Mixed connective tissue disease	5 (3.2)
	Polymyositis, dermatomyositis,	6 (3.8)
	Antisynthetase syndrome	5 (3.2)
	Overlap syndrome	2 (1.2)
	Others (Still disease, vasculitis)	6 (3.8)
	IPAF	33 (20.9)
	ILD-UA	12 (7.6)
Comorbidity, n (%)	Hypertension	70 (44.3)
	Cholesterol	54 (34.2)
	Diabetes Mellitus	14 (8.8)
	Ischemic heart disease	10 (6.3)
	Cerebrovascular disease	13 (8.2)
	Peripheral vascular disease	16 (10.2)
	Liver disease	15 (9.5)
	History of cancer	22 (13.9)
	Renal failure (dialysis)	1 (0.6)
	GER	28 (17.7)
	Sleep apnea	10 (6.3)
ILD associated (HRCT), n (%)	Emphysema (n=148)	59 (39.8)
	PHT (n=132)	19 (14.4)
PTF parameters, median [p25-75]	FVC% (n=155)	81.5 [67 – 98.0]
	DLCO% (n=144)	57 [43 – 72]
Radiographic ILD pattern (HRCT), n (%):	NSIP	45 (28.4)
	UIP	87 (55.1)
	Indeterminate UIP	6 (3.8)
	Others	20 (12.7)
Laboratory: antibodies, n (%)	ANA >1/360, (n=125)	47 [37.1]
	Anti-Ro +, (n=91)	24 (26.4)
Laboratory , median [p25-75]	ESR	26 [13-45]
Concomitant therapy, n (%)	Oxygen therapy	21 (13.3)
	Glucocorticoids	112 (70.9)
	Anti-fibrotic	23 (14.6)
	DMARDS	111 (70.3)
	csDMARDs	86 (54.4)
	b/tsDMARDs	50 (31.7)

Conclusion: This study provides real-world evidence on the clinical course and cause-specific mortality in patients with autoimmune PPF-ILD. The findings underscore the substantial mortality rate directly attributable to ILD. Moreover, the results suggest a potential survival advantage in patients receiving immunomodulatory therapy, supporting its role in the management of this patient population.

Abstract Number: 1025

Association Between Rural-urban Clinics and the Management of Adult Rheumatoid Arthritis in the United States

Megan Lorenz, Paxten Wahlund, Henry Elsenpeter, Abe Sahmoun and James Beal, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Disease modifying anti-rheumatic drugs (DMARDs) improve symptom management and outcomes in rheumatoid arthritis (RA). While residence may influence management strategies and access to care, limited research exists on how rural vs. urban residence affects use of DMARDs and glucocorticoids. This study aimed to determine the association between rural and urban clinics and management of rheumatoid arthritis in the U.S.

Methods: We conducted a retrospective analysis of adults, 18-80 years old, rheumatoid arthritis visits utilizing the 2011-2019 National Ambulatory Medical Care Survey datasets. We compared demographic, clinical, and management factors of adult rheumatoid arthritis visits between rural and urban clinics. SPSS Complex Samples 30.0 for Windows was used to analyze the data to account for the NAMCS complex sample survey design. Chi-square and GLM means tests were performed with two-sided test and $p < .05$. This study was approved by the Institutional Review Board of the University of North Dakota.

Results: Of the estimated 35 million adult RA visits, 5.4% were in rural clinics. Rural RA visits were less likely to be female (57.9% vs 77.7%, p=.000) and more likely to occur in the Midwest (46.8% vs. 14.1%, p=.002). There was no association between rural-urban clinics and age, race, and insurance.

Rural RA patients were less likely to see a medical specialist (41.7% vs 74.7%, p=.011) and more likely to see their own primary care physician (62.8% vs 22.5%, p=.000). Rural and urban RA patients had a similar number of comorbidities (2.3 vs 2.6, p=.090). However, rural RA patients had higher rates of hypertension (43.9% vs 27.8%, p=.004) and end stage renal disease (10.4% vs 1.4%, p=.006).

Rural and urban patients received similar laboratory tests and health education. Rural RA patients were on more medications than their urban counterparts, (7.2 vs 5.3, p=.031), and had a higher rate of opioid therapy (43.1% vs. 23.2%, p=.020). However, rural and urban RA patients had similar rates of DMARD therapy (49.8% vs 51.5%, p=.841) and glucocorticoids (29.9% vs 34.0%, p=.575).

Conclusion: Rural and urban clinics had similar utilization rates of DMARD therapy and glucocorticoids in adult RA patients, despite rural RA patients being more likely to be managed by primary care physicians and urban patients by medical specialists. However, rural RA patients had higher rates of opioid therapy than their urban counterparts.

Abstract Number: 1026

Seasonal Variation in Public Interest in Gout Made More Crystal-Clear: A Longitudinal Infodemiology Study Using Google Trends.

Naomi Schlesinger[1] and Ioannis Androulakis[2], [1]Spencer Fox Eccles School of Medicine, University of Utah, Salt Lake City, UT, USA, Salt Lake City, UT, [2]Rutgers University, Piscataway, NJ

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Understanding public interest in gout, as reflected by online behavior, can offer valuable insights into its perception and management. Infodemiology, which examines the distribution and determinants of information on the internet, offers insights into public health trends that are often challenging to capture through traditional epidemiological methods. This approach is especially relevant for analyzing interest patterns over time and across different regions.

Our objective was to explore whether public interest in gout, as measured by Google Trends data, shows seasonal patterns across countries, US states, and major metropolitan areas.

Methods: This study utilizes Google Trends data from January 1, 2014, to October 1, 2024, to analyze the frequency of gout-related search queries. Data were collected from 70 countries, 50 US states, and 36 major cities in the US and Canada. The analysis included both direct searches for "gout" and searches based on symptoms and covered queries in multiple languages.

The primary outcome was the seasonal variation in gout-related search queries, measured using a cosinor model to identify cyclic patterns in search behavior throughout the year. The secondary outcome assessed the influence of language-specific search terms on the seasonality of these queries.

Results: The analysis showed significant seasonal variation in gout-related search interest in 40 US states and 20 of the 70 countries analyzed, with peaks in the late spring/early summer for the Northern Hemisphere and corresponding shifts in the Southern Hemisphere (**Figures 1 and 2**). Symptom-based queries also displayed strong seasonality, aligning with

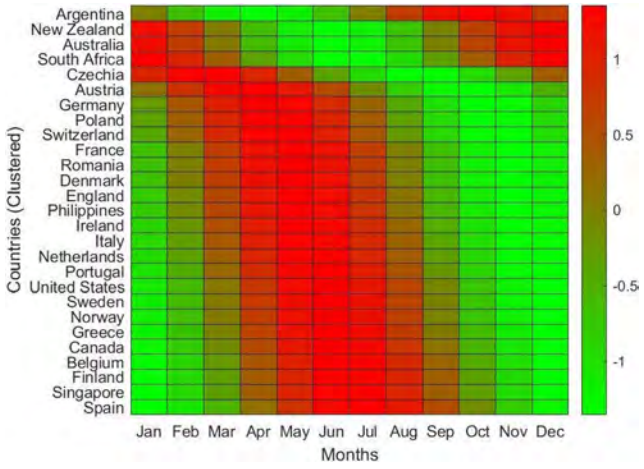

Figure 1 Frequency of query distribution using language-specific terms for "gout" across the globe. A clear separation between countries in the northern and the southern hemispheres was noted.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2 Typical monthly distribution of "gout" Google queries in Australia (AU), Canada (CA), and Hong Kong (HK). The presence of "***" indicates a statistically significant pattern in queries throughout the year (p_val<0.01).

known clinical patterns of gout flares. Using language-specific search terms further refined the detection of seasonal patterns, strengthening the findings.

Conclusion: Public interest in gout, as reflected by Google search behavior, follows a clear seasonal pattern, mirroring the clinical seasonality of gout flares. This study highlights the utility of infodemiology as a supplementary tool for understanding public behavior and informing health communication strategies. Accounting for linguistic nuances enhances the precision of seasonality analysis, offering valuable insights for public health initiatives to improve disease management and patient education.

No definitive RMD	1,249,703 (45.6)	9,754 (0.8)	3,463 (0.3)	13,217 (1.1)

Abbreviations: BMI, body mass index; RMD, Rheumatic and Musculoskeletal Diseases; WLT, weight loss treatment; RAPID-3, Routine Assessment of Patient Index Data 3; MDHAQ, Multi-Dimensional Health Assessment Questionnaire. a. Baseline is defined as any diagnosis, laboratory result, or medication exposure occurring on or before the index date. For new users (those with an evaluation and management [E/M] visit prior to GLP-1 initiation), the index date is the most recent E/M visit. For prevalent users (those without a prior E/M visit), the index date is the date of first GLP-1 prescription. b. Patients who use both semaglutide and tirzepatide are classified in the tirzepatide group. Among tirzepatide users, 24% also received semaglutide; among semaglutide users, 8.5% also received tirzepatide. c. For new users, the index date is the nearest prior E/M visit; for prevalent users, it is the date of first GLP-1 use (i.e., no prior E/M visit was found). d. A diagnosis (Dx) of diabetes at baseline is defined using an algorithm: presence of diabetes ICD-9 or ICD-10 codes OR antidiabetic medications (RxCUI-defined) OR hemoglobin A1c > 6.5% at any time, OR random glucose > 200 mg/dL at any time. e. Other RMD includes select inflammatory or musculoskeletal conditions not listed separately, such as fibromyalgia, ankylosing spondylitis, gout, myositis, vasculitis, psoriasis, juvenile idiopathic arthritis, and others and required 2+ diagnoses from a rheumatology provider. Patients without these diagnoses, or who only had a single diagnosis, were classified in the 'No definitive RMD' category. f. IL-17 use includes use of secukinumab, ixekizumab, or bimekizumab. Patients may have received more than one IL-17 inhibitor concurrently or sequentially. g. Patients who used both semaglutide and tirzepatide are included in both user groups. As a result, the semaglutide and tirzepatide user counts are not mutually exclusive and reflect any documented use, regardless of concurrent or sequential initiation.

Table 2. Baseline[a] Characteristics and Weight Change Among New Users of Semaglutide[b] (SEM) or Tirzepatide[b] (TIR), Stratified by Diabetes Status (N = 40,006)

Characteristic	N (%)	SEM[b] 27,535 (68.8%)		TIR[b] 12,471 (31.2%)		Total 40,006 (100%)

a. Baseline is defined as any diagnosis, laboratory result, or medication exposure occurring on or before the index date. For new users (those with an evaluation and management [E/M] visit prior to GLP-1 initiation), the index date is the most recent E/M visit. b. Patients who use both semaglutide and tirzepatide are classified in the tirzepatide group. Among tirzepatide users, 24% also received semaglutide; among semaglutide users, 8.5% also received tirzepatide. c. A diagnosis of diabetes at baseline is defined using an algorithm: presence of diabetes ICD-9 or ICD-10 codes OR antidiabetic medications (RxCUI-defined) OR hemoglobin A1c > 6.5% at any time, OR random glucose > 200 mg/dL at any time. d. For new users, the index date is the nearest prior E/M visit. e. Weight and BMI change are defined as the difference between the baseline measurement (on or before the index date) and the follow-up measurement closest to the target window (6, 12, or 18 months). Follow-up ends at the last observed WLT record. Change is calculated as follow-up minus baseline. f. Other RMD includes select inflammatory or musculoskeletal conditions not listed separately, such as fibromyalgia, ankylosing spondylitis, gout, myositis, vasculitis, psoriasis, juvenile idiopathic arthritis, and others and required 2+ diagnoses from a rheumatology provider. Patients without these diagnoses, or who only had a single diagnosis, were classified in the 'No definitive RMD' category. g. IL-17 use includes use of secukinumab, ixekizumab, or bimekizumab. Patients may have received more than one IL-17 inhibitor concurrently or sequentially.

loss treatment (WLT). Given the potential for weight loss to improve disease activity, function, and patient-reported outcomes (PROs) in rheumatic and musculoskeletal diseases (RMDs), understanding GLP-1 use patterns and effects is crucial.

Methods: We conducted a retrospective analysis using Q3 2024 (1/05–9/24) data from the ACR Rheumatology Informatics System for Effectiveness (RISE) registry, among RMD patients treated with SEM or TIR. Patients were categorized as new users (with ≥1 evaluation and management [E/M] visit prior to GLP-1 initiation) or prevalent users (without a prior E/M visit). Baseline included data on or before the index date. We examined baseline characteristics, RMD diagnoses, concurrent medications, and weight changes at 6, 12, and 18 months, stratified by GLP-1 type and diabetes. GLP-1 exposure was characterized as intent-to-treat (ITT). Multivariable linear regression assessed 12-month weight loss by GLP-1 type, adjusted for baseline weight, age, sex, and diabetes.

Results: Among 60,206 RMD patients treated with SEM or TIR, 67% had diabetes and 70% used SEM. Uptake was highest among patients with RA (20.7%) and OA (12.8%), with SEM more common in both. The most rapid increase occurred in 2023, accounting for 32% of all SEM and 41% of TIR use. Patients' mean (SD) baseline BMI was 36.3 (7.9), and ~20% were on oral glucocorticoids. Across all RMD cohorts, the highest proportion of WLT use was observed in PsA patients (6.4% of all RISE PsA patients, n=117,965), followed by AS (5.0%) and RA (3.7%).

Abbreviations: CI, confidence interval; lbs., pounds
** Significant at p ≤ .01; *** Significant at p ≤ .001
a. Baseline is defined as any diagnosis, laboratory result, or medication exposure occurring on or before the index date. For new users (those with an evaluation and management [E/M] visit prior to GLP-1 initiation), the index date is the most recent E/M visit. For prevalent users (those without a prior E/M visit), the index date is the date of first GLP-1 prescription. b. Patients who use both semaglutide and tirzepatide are classified in the tirzepatide group. Among tirzepatide users, 24% also received semaglutide; among semaglutide users, 8.5% also received tirzepatide. c. Reference group is semaglutide users. d. Reference group is female. e. A diagnosis of diabetes at baseline is defined using an algorithm: presence of diabetes ICD-9 or ICD-10 codes OR antidiabetic medications (RxCUI-defined) OR hemoglobin A1c > 6.5% at any time, OR random glucose > 200 mg/dL at any time. f. Reference group is yes.

Weight trajectories were evaluated among 40,006 new users of SEM or TIR. At baseline, PROs were similar across GLP-1 RA types, but diabetic users had greater disease burden, with higher RAPID-3 (mean 11.6 [SD 6.6] vs. 10.7 [SD 6.3]) and MDHAQ scores (mean 4.7 [SD 2.9] vs. 4.4 [SD 2.8]) than non-diabetic users. At 12 months, non-diabetic TIR users lost 8.0% (SD 11.3) of body weight, compared to 6.0% (SD 9.2) with SEM. Diabetic users showed a similar pattern, with TIR consistently outperforming SEM. Across GLP-1 RA types, non-diabetic users lost more weight than diabetic users. Weight loss plateaued after 12 months, with 1.0% weight regain in non-diabetic TIR users by 18 months. In models adjusting for baseline weight, age, sex, and diabetes, TIR users lost approximately 1.7% ($p< 0.001$) more weight at 12 months than SEM users. Patients without diabetes lost about 1.5% ($p< 0.001$) more weight than those with diabetes, regardless of GLP-1 RA type. No significant interactions were observed among models' variables.

Conclusion: In this national registry of RMD patients, SEM and TIR were increasingly used and effective weight loss treatments for individuals with and without diabetes. Across both GLP-1 RAs, non-diabetic users lost more weight than diabetic users, with TIR showing greater reductions than SEM over time. Ongoing work evaluates the impact of GLP-1 therapy on disease activity, function, and PROs in RMD populations.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The clinical Disease Activity in Psoriatic Arthritis (cDAPSA) score is widely used to assess PsA disease activity and its trajectory. cDAPSA sums four measures: 2 patient-reported outcomes (PROs), pain and patient global visual analog scales, and 66 swollen/68 tender joint counts (66SJC, 68TJC) into a single score despite their different scales. It therefore may obscure clinically important patterns, especially when inflammation and symptoms are discordant. To address this, we (1) analyzed the contributions of individual cDAPSA components, (2) developed a two-score measure (cDAPSA2), and (3) evaluated its utility in predicting patient outcomes.

Methods: To perform Principal Components Analysis (PCA), we obtained cDAPSA-adjusted residuals for pain, patient global, 66SJC, and 68TJC at baseline. These residuals were generated by regressing each variable on a smooth function of cDAPSA to account for nonlinear associations; they collectively represent available information about the patient's disease state and trajectory over and above what is described by cDAPSA. PCA was then applied to the residuals to find a single measure (the dominant principal component) that explains the largest fraction of remaining variation. To assess whether this first PC can risk-stratify patients, we modeled longitudinal cDAPSA trajectories using linear mixed-effects models with a smooth function of time for each quartile of the 1st PC, adjusting for age, sex, race, BMI. We further fit a Cox proportional hazard model to study the associations between PC quartiles and time to remission (cDAPSA $\leq$ 4), adjusting for age, sex, BMI, and baseline cDAPSA.

Results: Among 752 PsA patients fulfilling the PsA CASPAR classification (median age 52.8 years; BMI 29.4 kg/m^2; follow-up 2.0 years), PCA identified what we call the PROs-Joint Contrast (PJC), that is, approximately the mean PRO scores minus the mean joint count scores. For a given cDAPSA level, PJC measures whether most of the cDAPSA is due to the PRO components or to the joint counts. PJC accounts for 49.5% of the residual variance beyond what can be described by cDAPSA itself (Table 1). All PROMIS Profile measures, enthesitis, and sex significantly differed across the PJC quartiles (Table 2).

Longitudinal analysis showed the 1st and 4th quartiles of the PJC start at the same level, higher than Q2/Q3 and that Q1 has a steeper decline while Q4 remains at higher levels over a 5-year follow-up (Figure 1). Remission rates were statistically significantly associated with PJC, (HR per 1 SD: 0.88; 95% CI: 0.77–0.99). The 4th quartile had a significantly lower remission rate than the 1st quartile (HR: 0.49; 95% CI: 0.27–0.88).

Conclusion: Based on these findings, we propose cDAPSA2 as a two-score measure combining traditional cDAPSA with PJC. For example, patients with high cDAPSA and low PJC may benefit from escalating DMARDs targeting inflammation,

* NRS: numeric rating scale ; BMI: body mass index; IQI: interquartile interval ** Percentage may not add up to 100% due to rounding. *** The Kruskal–Wallis test and Fisher's exact test were used to compare differences across quartiles for continuous and categorical variables, respectively, due to non-normality of the data.

while those with similar cDAPSA and high PJC may require symptom-focused management and additional diagnostics before altering DMARD therapy. cDAPSA2 captures both overall severity and underlying heterogeneity of PsA, supporting a more nuanced assessment of PsA activity and individualized treatment.

Abstract Number: 1029

Cervical cancer screening rates in Korean women of childbearing age with systemic lupus erythematosus

PIL GYU PARK[1], Jisoo Lee[2], JIN SU PARK[3], Hyunsun Lim[3], In-Woon Baek[4], Min Kyung Chung[4] and Chan Hee Lee[5], [1]National Health Insurance Service Ilsan Hospital, Seodaemun-gu, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Ewha Womans University College of Medicine, SEOUL, Republic of Korea, [3]National Health Insurance Service Ilsan Hospital, Goyang-si, Republic of Korea, [4]Ewha Womans University College of Medicine, Seoul, Republic of Korea, [5]Desert Regional Medical Center, Palm Springs, CA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Cervical cancer remains a leading cause of death among women of childbearing age despite the proven efficacy of screening in reducing mortality rates. Women with systemic lupus erythematosus (SLE) are at a higher risk for cervical cancer but tend to have lower screening rates. This study aimed to assess Papanicolaou (Pap) test uptake and identify factors influencing participation in cervical cancer screening among women of childbearing age with SLE.

Methods: Women aged 20-49 with SLE and age matched controls, randomly selected at a 1:5 ratio, were identified from the 2016-2017 National Health Insurance Service-National Health Information Database (NHIS-NHID). Data from 10,981 women with SLE and 54,905 controls eligible for national cervical cancer screening in 2018-2019 were analyzed. Pap test

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

rates were calculated, and logistic regression was used to estimate odds ratios (ORs) for factors associated with Pap test uptake.

Results: The Pap test uptake rate was significantly lower in women with SLE compared to controls (49.6% vs. 52.1%, $P <$ .0001). Logistic regression revealed that younger age, lower income, self-employment or medical aid insurance, and rural residence were associated with reduced screening rates in both groups. The highest screening uptake occurred in the 40-44 age group for both women with SLE (OR 5.09, 95% CI 4.17-6.22) and controls (OR 4.65, 95% CI 4.26-5.07). Comorbidities increased screening uptake among controls (OR 1.18, 95% CI 1.13-1.23), but were associated with mild non-significant decrease in uptake among women with SLE (OR 0.96, 95% CI 0.87-1.04).

Conclusion: Cervical cancer screening is often underutilized by women of childbearing age with SLE, particularly those with comorbid conditions. Targeted interventions are needed to improve screening rates and address the unique challenges faced by this high-risk population.

Background/Purpose: Rheumatoid arthritis (RA) has been associated with an increased risk of developing atrial fibrillation (AF). However, recent data on trends in incidence of AF and risk factors associated with AF in RA from population-based cohorts are lacking. This study seeks to assess the risk of AF in patients with RA compared to the general population and identify predictors of AF in patients with RA.

Methods: Retrospective medical records review was completed to form an inception cohort of all patients with RA in 1990-2019, among residents of a geographically defined area, aged ≥18 years. The incidence date of RA was defined as the earliest date at which the patient fulfilled the 1987 or 2010 classification criteria for RA. Each patient with RA was matched on age, sex, year, and county to a randomly selected comparator without RA (using the date of RA as the index date for the matched referent without RA). Patients were followed until diagnosis of new-onset AF, death, migration, or 12/31/2023. AF was defined using a previously published electronic algorithm. Descriptive statistics and Cox models adjusted for age, sex, and calendar year of RA incidence were conducted.

Results: 3798 patients were included, with 1899 patients with RA and 1899 patients without RA (mean age 55.9 years, 68% female). RA status was not found to be a significant risk factor to predict AF (adjusted for age, sex, calendar year, smoking status, and obesity) (HR 1.10; 95% CI 0.92-1.33). Among patients with RA, significant risk factors associated with incident AF included age (HR:2.29 per 10 year increase; 95%CI:2.05-2.56), male sex (HR:1.57; 95%CI:1.22-2.03), former smoking (HR:1.35; 95%CI:1.01-1.81), current smoking (HR:2.16, 95%CI:1.51-3.09), obesity (HR:1.83, 95%CI:1.42-2.37), diabetes (HR:1.54, 95%CI:1.09-2.17), and hypertension (HR:1.60, 95%CI:1.20-2.13). Additionally, for patients with RA the following disease characteristics were associated with increased risk of AF: radiographic joint erosions or destructive changes (HR 1.36; 95% CI 1.03-1.79), rheumatoid nodules (HR 1.70; 95% CI 1.19-2.43), large joint swelling (HR 1.35; 95% CI 1.04-1.76), and severe extra-articular manifestations (HR 2.03; 95% CI 1.31-3.14).

Conclusion: While RA was not a risk factor for AF, adverse cardiovascular risk profile and RA disease severity significantly increased the risk of AF among patients with RA. Future studies will inform to what extent early recognition and management of these risk factors can help improve AF outcomes in RA.

Abstract Number: 1031

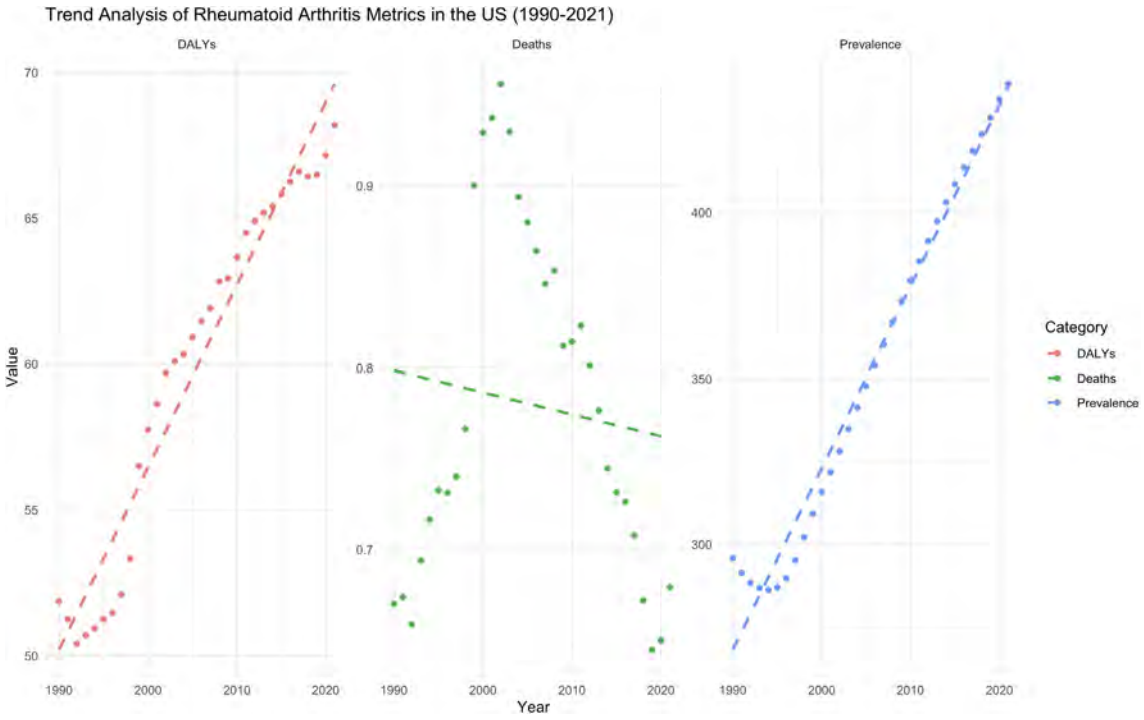
Trends and Gender Disparities in Rheumatoid Arthritis Burden in the United States: A Population-Based Time-Trend Analysis Using the Global Burden of Disease Database, 1990–2021

Satani Sharkas[1], Dina Murad[2] and Dariush Jahandideh[3], [1]Boston Medical Center - Brighton, Brighton, MA, [2]Tufts Medical Center, Boston, MA, [3]Boston Medical Center - Brighton, Boston

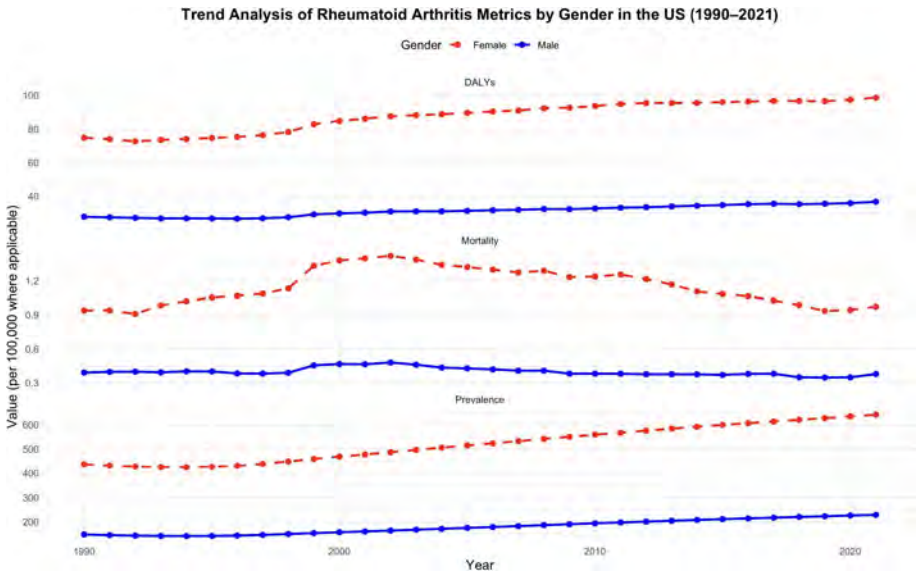
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a growing public health concern in the United States, with increasing prevalence and disease burden over recent decades. This study evaluates national time trends in RA prevalence, mortality, and Disability-Adjusted Life Years (DALYs) from 1990 to 2021, with a focus on gender-specific differences.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Temporal Trends in RA Prevalence, DALYs, and Mortality in the US (1990–2021) Line plots with scatter points showing annual values for RA prevalence (per 100,000), DALYs (per 100,000), and mortality (per 100,000) from 1990 to 2021. Each metric is displayed in a separate panel, highlighting the upward trends in prevalence and DALYs, and the stable mortality trend.



Gender Disparities in RA Prevalence, DALYs, and Mortality in the US (1990–2021) Faceted line plots with scatter points comparing RA metrics between males (blue solid lines) and females (red dashed lines) from 1990 to 2021. Panels for prevalence, DALYs, and mortality illustrate the steeper increases in prevalence and DALYs for females, alongside a slight decline in male mortality and stable female mortality.

Methods: Data were extracted from the Global Burden of Disease (GBD) 2021 database. Linear regression models were used to assess time trends in RA-related prevalence, mortality, and DALYs per 100,000 population, with the year as the independent variable. Analyses were stratified by gender, and trends were evaluated using slope estimates, 95% confidence intervals (CIs), p-values, and R-squared (R^2) values.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Nationally, RA prevalence increased significantly from 286.2 to 438.8 per 100,000 between 1990 and 2021 (slope = 5.5/year, 95% CI: 5.0–6.0, $p < 0.0001$, $R^2 = 0.98$). DALYs rose from 50.4 to 68.2 per 100,000 (slope = 0.6/year, 95% CI: 0.5–0.7, $p < 0.0001$, $R^2 = 0.94$). Mortality remained stable (0.67 to 0.68 per 100,000; slope = -0.001/year, 95% CI: -0.005 to 0.003, $p = 0.52$, $R^2 = 0.01$). Stratified analysis revealed that females bore a higher RA burden. Female prevalence rose from 436.8 to 641.5 per 100,000 (slope = 7.8/year, 95% CI: 7.4–8.2, $p < 0.0001$, $R^2 = 0.98$), compared to males (148.3 to 229.0; slope = 3.1/year, 95% CI: 2.9–3.3, $p < 0.0001$, $R^2 = 0.97$). DALYs for females increased from 74.8 to 98.6 per 100,000 (slope = 0.9/year, 95% CI: 0.8–1.0, $p < 0.0001$), while males increased from 27.8 to 36.7 (slope = 0.3/year, 95% CI: 0.3–0.4, $p < 0.0001$). Mortality declined slightly in males (0.39 to 0.38; slope = -0.002/year, $p = 0.0068$), while remaining unchanged in females (0.94 to 0.97; $p = 0.863$).

Conclusion: Rheumatoid arthritis continues to impose a rising and disproportionate burden on the U.S. population, with sharp increases in both prevalence and disability over the past three decades—particularly among women. While mortality has stabilized or modestly declined, the persistent rise in DALYs reflects significant unmet needs in disease control, long-term management, and quality of life. These findings signal a critical need for renewed public health attention and tailored intervention strategies to reduce disease burden and improve outcomes.

Exploring the role of the gut microbiome in gout: Prospective analysis of dietary fiber intake and the risk of gout

Sharan Rai[1], Natalie McCormick[2], Chio Yokose[3], Robert Terkeltaub[4], Dylan Dodd[5], Lama Nazzal[6], Huilin Li[6], Qi Sun[7] and Hyon K. Choi[8], [1]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital, Waltham, MA, [4]Retired, San Diego, CA, [5]Stanford University, Palo Alto, CA, [6]NYU Langone, New York, NY, [7]Harvard T.H. Chan School of Public Health, Boston, [8]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The role of the gut microbiome has been increasingly implicated in the pathogenesis of gout. For instance, gout patients have shown depletions of bacteria that lower urate levels or produce anti-inflammatory short-chain fatty acids (SCFAs). Dietary fiber is fermented by the gut microbiota and produces beneficial microbial metabolites, including SCFAs (1). Accordingly, greater dietary fiber (particularly cereal fiber) intake is also associated with lower levels of inflammatory biomarkers (2), which may be particularly relevant to gout. Indeed, prior work has found that a pro-inflammatory diet that is low in dark leafy and yellow vegetables as well as high in refined grains is associated with a nearly two-fold increased risk of gout among women (3). Taken together, these data suggest that dietary fiber may play a role in gout prevention through the modulation of gut microbiota and corresponding inflammatory pathway. We aimed to prospectively examine whether long-term dietary fiber intake is associated with the risk of gout among women over 34 years of follow-up.

Methods: We analyzed data from 80,175 women in the Nurses' Health Study with complete dietary data who were free from gout at baseline. We used a validated food frequency questionnaire to collect repeated measures of usual intake of

Multivariable-adjusted model	1.0 (Reference)	0.98 (0.80, 1.19)	1.14 (0.94, 1.39)	1.04 (0.85, 1.27)	1.06 (0.87, 1.30)	0.53
Legume fiber						
Median intake (g/day)	0.3	0.6	0.8	1.1	1.8	–
No. of gout cases	232	247	231	218	189	–
Person-years	442,640	449,383	441,574	439,930	445,001	–
Age-adjusted model	1.0 (Reference)	1.03 (0.86, 1.23)	0.96 (0.80, 1.15)	0.89 (0.74, 1.07)	0.76 (0.62, 0.92)	<0.001
Multivariable-adjusted model	1.0 (Reference)	1.03 (0.86, 1.23)	0.99 (0.82, 1.19)	0.95 (0.79, 1.15)	0.87 (0.72, 1.06)	0.12

All models were stratified by age and calendar time. All multivariable models were adjusted for energy intake, body mass index, hypertension status, diuretic use, physical activity, alcohol intake, postmenopausal status, postmenopausal hormone use, dairy intake, meat intake, and fish intake.

130+ food and beverage items every four years. We calculated dietary fiber intakes for all participants using the Harvard University Food Composition Database. In addition to total fiber, we calculated individual intakes of fiber sourced from cereals, fruits, vegetables, and legumes. Every two years, we collected updated data on relevant covariates as well as new confirmed cases of incident gout. We used multivariable Cox proportional hazard models to evaluate the associations between quintiles of dietary fiber intake and incident gout.

Results: We documented 1117 gout cases over 2,218,527 person-years of follow-up. At baseline, women consuming more total fiber tended to be older (Q1 vs. Q5: 49.3 vs. 53.3 years), more physically active (Q1 vs. Q5: 10.5 vs. 19.0 metabolic equivalent of task hours/week), and consume less alcohol (Q1 vs. Q5: 11.5 vs. 4.2 grams/day). After multivariable adjustment, greater intake of total dietary fiber was associated with a 31% lower risk of incident gout comparing extreme quintiles (hazard ratio [HR]=0.69 [95% confidence interval: 0.56 to 0.87]; P for trend=0.001) **(Table)**. This protective association was primarily driven by cereal fiber (from food sources such as cold cereals, dark breads [e.g., rye, pumpernickel, wheat, oatmeal, or other whole grain breads], cooked oatmeal, and added bran) (multivariable HR comparing extreme quintiles=0.61 [0.50 to 0.76]; P for trend< 0.001) and fruit fiber (multivariable HR comparing extreme quintiles=0.81 [0.65 to 1.00]; P for trend=0.009) **(Table)**.

Conclusion: Long-term dietary intake of fiber, particularly fiber sourced from cereals and fruits, is independently associated with a lower risk of incident gout among women. These findings support a role for fiber in the pathogenesis of gout, potentially by modulating the gut microbiome.

Abstract Number: 1033

Rethinking ANA in Rheumatoid Arthritis: ICAP Pattern Insights from a Large-Scale Taiwanese Cohort

Tien-Ming Chan, Chang Gung Memorial Hospital, Taoyuan, Taiwan (Republic of China)

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: ANA prevalence and patterns vary in RA. Using ICAP nomenclature, this study aimed to determine the prevalence of RA across different ANA patterns and the distribution of these patterns in RA patients within a large Taiwanese cohort.

Methods: This cross-sectional study used the Chang Gung Research Database (2019-2021). Patients undergoing ANA IIF testing (HEp-2 substrate, ≥1:100 positive) were included. Patients with inconsistent/mixed patterns were excluded from

Table 2. Prevalence of Rheumatoid Arthritis (RA) Across Different Pure ANA Staining Patterns Compared to ANA-negative Patients

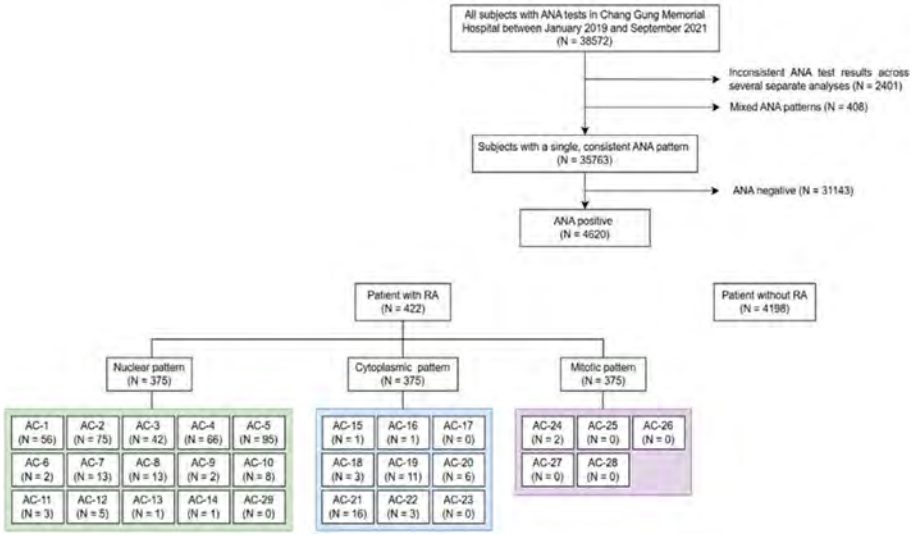

Figure 1. Flowchart illustrating the distribution of ANA patterns (AC-1 to AC-29) among rheumatoid arthritis patients tested at Chang Gung Memorial Hospital (2019–2021)

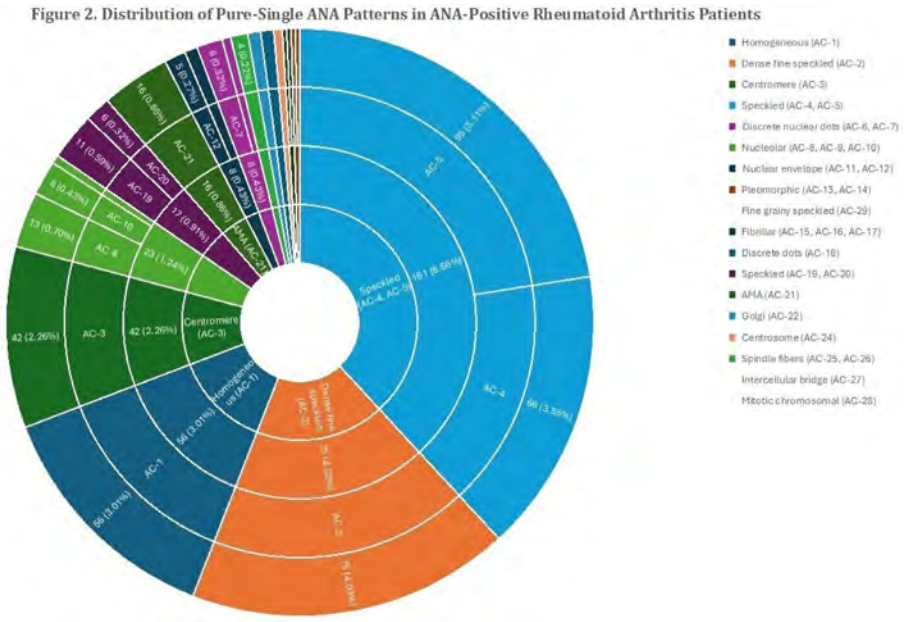

pure pattern analysis. RA diagnosis used ICD codes confirmed by rheumatologists. RA prevalence and odds ratios (ORs) were calculated for each ANA pattern (AC-1 to AC-29) versus ANA-negative (AC-0). ANA pattern/titer distributions were compared between RA and non-RA cohorts.

Results: Among 35,763 patients with single, consistent ANA patterns, 4,612 (12.9%) were ANA-positive. RA prevalence in the AC-0 group was 4.62%. Significantly higher RA prevalence occurred with AC-2 (Dense fine speckled, 11.92%, OR 2.80), AC-1 (Homogeneous, 10.02%, OR 2.30), AC-4 (Fine speckled, 9.85%, OR 2.26), and AC-5 (Coarse speckled, 8.95%, OR 2.03) patterns (all $p < 0.001$). In the RA cohort (n=1,860 with pure patterns), ANA positivity was 22.69% (vs. 12.38% in non-RA, $p < 0.0001$), with higher titers. The most frequent patterns in ANA-positive RA were Speckled (AC-

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 4/AC-5, 8.66%), Dense fine speckled (AC-2, 4.03%), Homogeneous (AC-1, 3.01%), and Centromere (AC-3, 2.26%).

Conclusion: Specific ANA patterns (AC-1, AC-2, AC-4, AC-5) are significantly associated with increased RA prevalence in this Taiwanese cohort. RA patients show higher ANA positivity and titers, favoring speckled, dense fine speckled, and homogeneous patterns. Detailed ICAP pattern reporting is clinically relevant for RA assessment.

Healthy Dietary Patterns and Risk of Rheumatoid Arthritis: A Systematic Review and Meta-Analysis

Elena Joerns[1], Jeffrey Sparks[2], Cynthia Chelf[1], Cynthia Crowson[3], John Davis[1] and **Vanessa Kronzer**[1], [1]Mayo Clinic, Rochester, MN, [2]Brigham and Women's Hospital, Boston, MA, [3]Mayo Clinic, Stewartvillle, MN

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1007–1037) Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

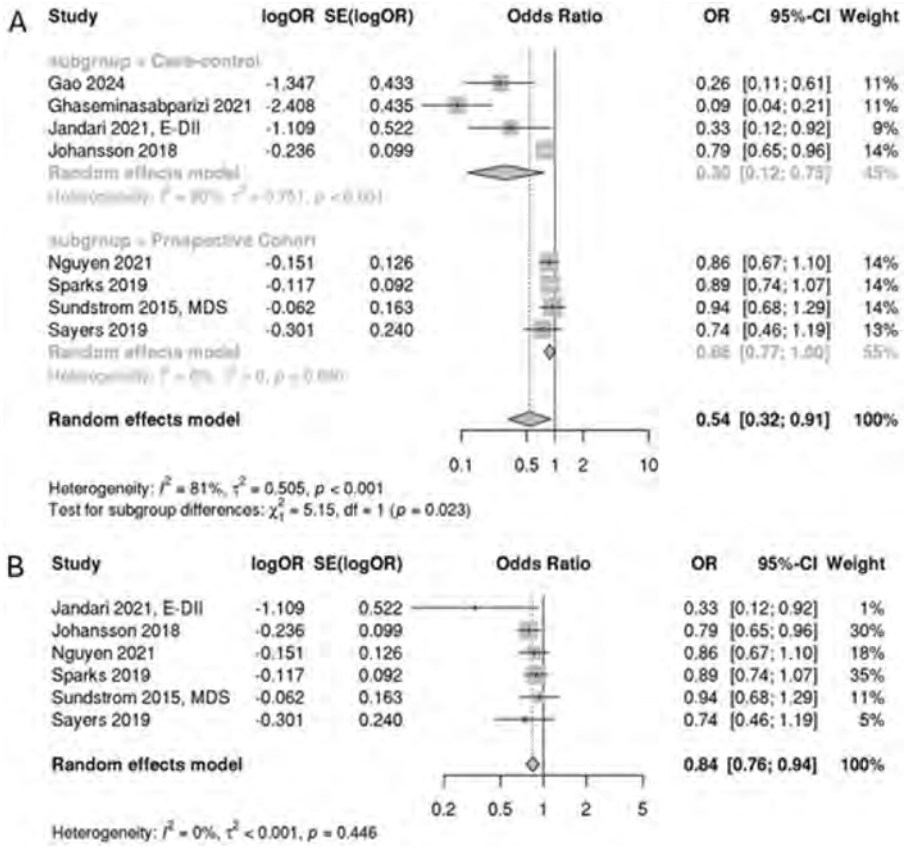

Figure 1. Association between healthy overall dietary pattern and incident RA among (A) all studies and (B) in the subset of studies with the lowest risk of bias

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

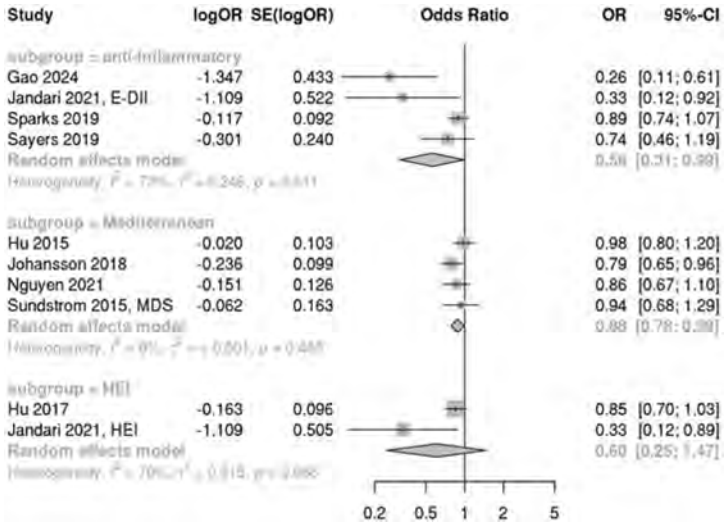

Figure 2. Association between individual healthy dietary pattern types and incident RA

Background/Purpose: Healthy dietary patterns are associated with many health benefits, including lower cardiovascular disease, mortality, and rheumatoid arthritis (RA) disease activity. Therefore, we aimed to determine the degree to which a healthy dietary pattern is associated with incident RA.

Methods: We registered this systematic review and meta-analysis in PROSPERO (CRD42025645056). Inclusion criteria were validated diet (anti-inflammatory, Mediterranean, Dietary Approaches to Stop Hypertension (DASH), and/or healthy eating index [HEI]); validated RA definition; dietary exposure preceding RA; and randomized controlled trial, cohort, or case-control design. We searched CENTRAL, Embase, MEDLINE, Scopus, Web of Science, and grey literature as of 2/3/2025. Two reviewers independently screened each reference and abstracted all data, with agreement reported using Cohen's κ. We assessed each study's risk of bias using the Newcastle-Ottawa Scale. Meta-analyses combined adjusted odds ratios (OR) with 95% confidence interval (CI) for incident RA using random effects models. For heterogeneity, we calculated I^2 and performed subgroup analyses including only the studies with lowest risk of bias and stratifying results by dietary pattern type. We assessed certainty of evidence using GRADE.

Results: The two reviewers screened a total of 796 independent references for inclusion with almost perfect agreement (Cohen's κ 0.89, 95% CI 0.81-0.97). Ultimately, we included 12 case-control and cohort studies spanning 270,121 unique individuals in the review. Three studies were low risk of bias, 3 moderate, 3 high, and 3 very high. Among the 8 independent studies included in the meta-analysis, healthy overall dietary pattern was associated with lower risk of incident RA (OR 0.54, 95% CI 0.32-0.91, I^2=81%, **Figure 1A**). Including only the 6 studies with the lowest risk of bias was also associated with lower RA risk (OR 0.84, 95% CI 0.76-0.94, I^2=0%, **Figure1B**). Anti-inflammatory (OR 0.56, 95% CI 0.31-0.99), Mediterranean (OR 0.88, 95% CI 0.78-0.99), and HEI (OR 0.60, 95% CI 0.25-1.47) patterns all showed lower point estimates for RA (**Figure 2**). Overall level of certainty in these results was moderate due to the studies' observational nature.

Conclusion: In observational studies, healthy dietary pattern is associated with reduced risk of incident RA. Therefore, individuals at risk for RA should consider observing a healthy dietary pattern to potentially reduce their risk of disease. In addition, these findings support inclusion of healthy dietary patterns in RA guidelines.

Abstract Number: 1035

Demographic and Clinical Correlates of 30 day Re-admission or Death During Admission in Patients With Rheumatologic Conditions : A Retrospective Cohort Analysis in a Single Academic Center

Waleed Ali[1] and Deepali Sen[2], [1]Wash U/BJH, St. Louis, MO, [2]Washington University in St Louis, Chesterfield, MO

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatology consults are often obtained in hospitalized patients with known or suspected rheumatologic disease. Identifying factors linked to poor short-term outcomes may improve risk stratification during hospitalization and post-discharge planning. This study aimed to characterize demographic, clinical, and social factors associated with 30-day readmission or in-hospital death in patients receiving a rheumatology consult.

Methods: We conducted a retrospective cohort study of patients hospitalized at Barnes Jewish Hospital (Saint Louis, MO) from 4/1/2024-9/30/2024 who received an inpatient rheumatology evaluation for confirmed or suspected rheumatologic conditions. Variables of age, sex, Area Deprivation Index (ADI), disabilty status were collected. Clinical data such as rheumatologic diagnosis, comorbidities (infection, CAD, hypertension) and length of stay (LOS) were collected. The primary outcomes were in-hospital mortality and 30-day all-cause readmission. Associations were assessed using chi-square tests, and independent predictors were evaluated via binary logistic regression. Statistical significance was set at $p < 0.01$ for chi-square and < 0.02 (Bonferroni-Hochberg adjusted) for regression.

Table 1: Summary of Associations with 30-Day Readmission and In-Hospital Death

Outcome	Predictor	Test	Statistic (χ^2 / OR)	95% CI	p-value
30-Day Readmission	Disability	Chi-squared	χ^2 = 11.389	—	< .001
	CAD	Chi-squared	χ^2 = 2.648	—	.104
	Disability	Logistic Regression	OR = 4.16	[1.73 – 10.02]	.001
	Male Sex	Logistic Regression	OR = 1.97	[0.87 – 4.45]	.105
In-Hospital Death	Infection	Chi-squared	χ^2 = 7.449	—	.006
	Male Sex	Chi-squared	χ^2 = 2.714	—	.099
	Length of Stay (LOS)	Logistic Regression	OR = 1.108	[1.017 – 1.208]	.020
	Age	Logistic Regression	OR = 1.059	[1.008 – 1.112]	.022
	Infection	Logistic Regression	OR = 1.197	[0.855 – 14.678]	.081
	Area Deprivation Index (ADI)	Logistic Regression	OR = 0.309	[0.083 – 1.149]	.080

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 268 rheumatology consult patients, 36 (13.4%) were readmitted within 30 days and 19 (7.1%) died during admission. Analyses showed higher readmission rates among those with disability ($\chi^2 = 11.389$, $p < .001$ [all listed are unadjusted]) and a trend with CAD ($\chi^2 = 2.648$, $p = .104$). Infections were more common among patients who died ($\chi^2 = 7.449$, $p < .006$), with a trend toward male predominance ($\chi^2 = 2.714$, $p = .099$). Logistic regression confirmed disability as the only significant predictor of readmission (OR = 4.16, $p = .001$), with male sex trending toward significance (OR = 1.97, $p = .105$). Death during admission was significantly associated with longer length of stay (OR = 1.11, $p = .020$), while age was borderline, just falling outside the corrected cut-off of $p < 0.02$ (OR = 1.06, $p = .022$). Infection (OR = 1.20, $p = .081$) and lower ADI (OR = 0.31, $p = .080$) also showed non-significant trends towards death during admission.

Conclusion: In this cohort, disability status was associated with more than a four-fold risk of 30-day readmission. Other factors such as male sex, known CAD also trended towards higher readmission risk. When looking at deaths during the index admission, LOS and age, alongside presence of infection, was more relevant. Notably, a lower ADI was linked (not significantly) with increased odds of death. This preliminary study highlights the importance of targeted post-discharge planning for patients with disabilities to reduce possible early rehospitalization alongside further research regarding comprehensive mortality risk stratification.

Factors Associated With Long-term Remission After Drug Discontinuation In IgG4-related Disease: A 3-Year Rule

Yifei Wang[1], Yuxue Nie[2], Jingna Li[3], Jialei Zhang[4], Qinhuan Luo[1], Xinli Yang[5], Jialing Jiang[1], Nianyi Zhang[6], Linyi Peng[7], Yunyun Fei[6], Jiaxin zhou[4] and Wen Zhang[8], [1]Peking Union Medical College, Beijing, China (People's Republic), [2]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China, Dong Cheng Qu, China (People's Republic), [3]Peking Union Medical College, Dong Cheng Qu, Beijing, China, [4]Peking Union Medical College Hospital, Beijing, China (People's Republic), [5]Peking Union Medical College, Dong Cheng Qu, China (People's Republic), [6]Peking Union Medical College Hospital, Beijing, Beijing, China (People's Republic), [7]PEKING UNION MEDICAL COLLEGE HOSPITAL, Beijing, Beijing, China, [8]Peking Union Medical College Hospital, Dong Cheng Qu, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic fibroinflammatory disorder with multi-organ involvement and elevated serum IgG4 levels. Glucocorticoids (GC) with or without immunosuppressants (IM) are the first-line treatment. GC/IM discontinuation carries a 23-41% relapse risk, but prolonged use increases infection risk, making cessation timing crucial. However, identifying patients who can achieve long-term remission remains challenging. This study aimed to investigate the characteristics of patients with and without relapse, identifying factors associated with long-term remission.

Methods: We conducted a retrospective study in China, screening 808 patients diagnosed with IgG4-RD. Eighty patients who achieved clinical remission before drug discontinuation were included in the study. Based on relapse records from the third year after drug cessation, patients were classified into no-relapse group (n = 37) and relapse group (n = 43). All patients fulfilled the 2019 ACR/EULAR classification criteria for IgG4-RD. We analyzed demographic characteristics, laboratory results, clinical symptoms, and treatment data at baseline and during follow-up.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Hazard ratios for clinical variables in IgG4-RD relapse prediction

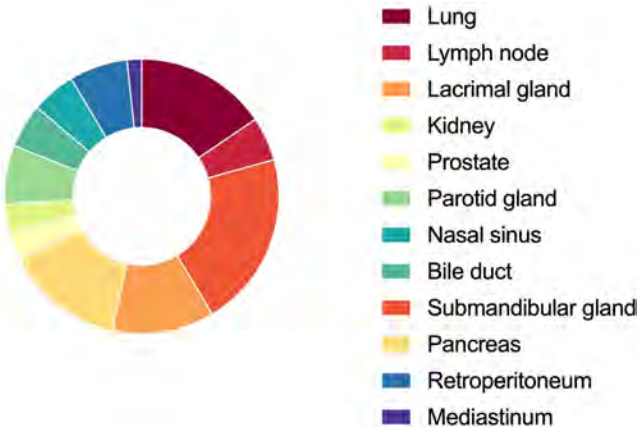

Figure 2. Distribution of relapsed organs

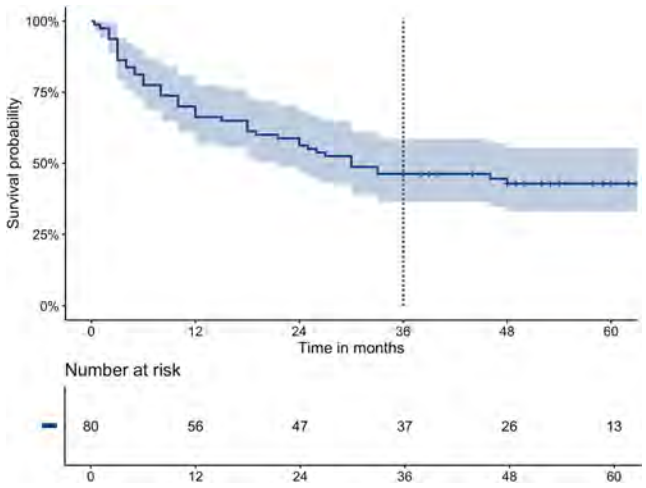

Figure 3. Kaplan-Meier curve of relapse-free survival in IgG4-RD patients

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Univariate analysis indicated that the no-relapse group had a lower number of affected organs (p=0.014), family history of allergy (p=0.017), and family history of malignancy (p=0.042). Laboratory findings revealed lower serum levels of eosinophils (p=0.001) and IgG4 (p=0.006) in the no-relapse group at baseline. Patients from the relapse group exhibited higher rates of submandibular (p = 0.009) and parotid glands involvement (p = 0.001).

Additionally, the relapse group had more patients without IM prescriptions (p = 0.006). Before complete medication withdrawal, the relapse group exhibited higher serum IgG4 levels (2190 g/L) than the no-relapse group (1250 g/L, p = 0.037).

Cox regression analysis identified no salivary gland involvement (HR 3.26, 95% CI: 1.32-8.06, p = 0.012) and initial IM use (HR 0.41, 95% CI: 0.20-0.84, p = 0.017) as significant protective factors (Figure 1). Figure 2 visualized the distribution of relapsed organs. Kaplan-Meier analysis revealed a biphasic relapse pattern following treatment discontinuation, characterized by a plateau after 36 months (Figure 3). These findings suggest that patients remaining relapse-free for 3 years tend to attain durable remission.

Conclusion: IgG4-RD patients without salivary gland involvement and receiving an IM prescription at baseline demonstrated a reduced likelihood of disease relapse following treatment cessation. Furthermore, patients maintaining relapse-free status for 3 years post-treatment exhibited a 94.6% probability of achieving long-term remission, suggesting this timepoint as a meaningful predictor of sustained treatment efficacy.

Session Title: (1007–1037) Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Myopathy in SSc significantly increases disability, reduces quality of life, and elevates mortality risk, yet remains understudied. Most identified risk factors derive from cross-sectional studies, limiting insights into longitudinal patterns and hindering time-varying risk prediction of myopathy at the individual patient level.

Methods: We analyzed longitudinal data from a cohort of over 2,800 SSc patients in a SSc research registry, totaling approximately 24,000 visits. Among included patients, 97.6% met 1980 or 2013 ACR/EULAR classification criteria. To examine clinical risk factors for incident muscle involvement (new onset between consecutive visits), we used multivariable logistic regression models separately across three dichotomized outcomes: proximal muscle weakness (Medsger Muscle Severity Score [MSS] ≥ 1), elevated creatine phosphokinase (CPK ≥ 200 U/L), and their co-occurrence as a myopathy surrogate (MSS/CPK-defined myopathy). To support individualized risk prediction, we developed a Bayesian generalized linear mixed model for cross-validated sequential prediction, using MSS as an example outcome to showcase and validate our

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

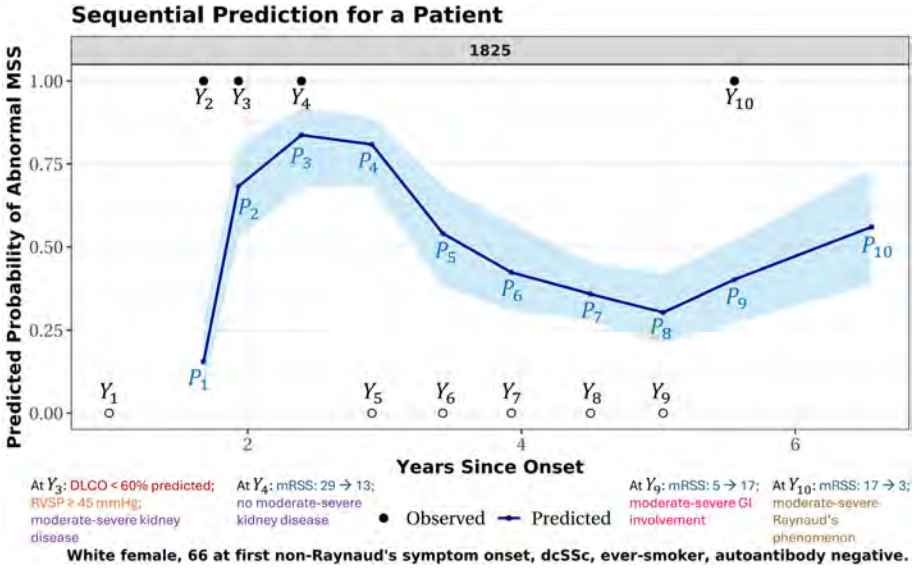

Figure 1. Predicted probability trajectory of abnormal MSS (proximal muscle weakness) for one patient. X-axis: years since the onset of first non-Raynaud's SSc symptom. Observed MSS outcomes labeled Y1-Y10: solid dots = abnormal MSS, empty circles = normal MSS. This patient initially presented with normal MSS, followed by three visits with abnormal MSS, then five consecutive visits with normal MSS, and a final visit with abnormal MSS. Predicted probabilities of abnormal MSS (P1-P10) are shown in dark blue, with 95% confidence intervals in light blue. Each prediction estimates the risk of abnormal MSS for the next visit using all available clinical information up to the current point. For example, prediction P1 estimates the risk for visit 2 (where outcome Y2 is to be observed), using only data from visit 1 (i.e., the measured outcome Y1 and associated clinical measurements). Similarly, P2 predicts the risk for visit 3 (where outcome Y3 is to be observed), using data from visits 1 and 2 (i.e., outcomes Y1-Y2 and associated clinical measurements). And P3 predicts the risk for visit 4 using earlier data from visits 1-3. This one-step-forward prediction process continues sequentially through all visits, with the final prediction, P10, estimating risk one year after the last observed visit using data from all 10 visits. Colored text annotations appear at selected visits and summarize clinical changes observed at that visit, relative to the previous one. These changes inform the next prediction (e.g., changes at visit 3, when outcome Y3 is measured, inform P3, the predicted risk for the following outcome Y4 to be observed at visit 4). DLCO: diffusing capacity for carbon monoxide (percent predicted); RVSP: right ventricular systolic pressure (≥ 45 mmHg indicates echocardiographic evidence of pulmonary hypertension); moderate-severe kidney disease: serum creatinine ≥ 1.7 mg/dL, 3-4+ proteinuria, or history of SSc renal crisis; moderate-severe GI involvement: high-dose GERD treatment, antibiotics for bacterial overgrowth, malabsorption syndrome, pseudo-obstruction, or total parenteral nutrition; moderate-severe Raynaud's phenomenon: Raynaud's with digital pitting scars, digital ulcers, or digital gangrene.

approach. The model incorporated baseline and time-varying characteristics, along with patient-specific medical history, to produce individualized risk trajectories. Cross-validation was used for efficiency and proper performance evaluation, and LASSO logistic regression model was used for variable selection.

Results: Several demographic, autoantibody, and comorbidity-related factors were associated with increased odds of incident MSS/CPK-defined myopathy. Notable predictors included diffuse subtype (OR=2.36 [1.68, 3.32]), Black race (OR=2.08 [1.49, 2.92]), anti-PM/Scl (positivity for both subunits, OR=3.42 [1.80, 6.51]), anti-Ku (OR=2.99 [1.95, 4.60]), anti-Fibrillarin (OR=1.95 [1.31, 2.91]), restrictive lung disease (ppFVC ≤ 70%) (OR=2.03 [1.46, 2.82]), tendon friction rubs (OR=1.97 [1.22, 3.17]), and moderate-severe GI involvement (OR=1.37 [1.04, 1.80]). Anti-Scl70 (OR=0.46 [0.31, 0.67]), anti-RNA polymerase III (OR=0.62 [0.41, 0.94]), and anti-U1RNP (OR=0.67 [0.46, 0.99]) were linked to lower odds of incident myopathy. Our prediction model for MSS (AUC: 0.867 [0.864, 0.869]) outperformed standard regression and random forest models, which did not capture the complete patient-specific history. With new data emerging at each visit, our method generates updated, real-time individualized predicted risk of abnormal MSS for the next visit (Figure 1).

Conclusion: This study identified key baseline and time-varying risk factors linked to SSc-associated myopathy and, to our knowledge, introduced the first longitudinal, real-time, individualized prediction model for a myopathy-related outcome (MSS). Our approach addresses unmet needs in monitoring SSc-associated myopathy by combining population-level risk

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: LN is a severe manifestation of SLE requiring intensive management. We aimed to characterize real-world treatment patterns in newly diagnosed patients with LN within the United States (US), focusing on use of immunosuppressants (ISTs) and advanced therapies including belimumab and voclosporin.

Methods: This retrospective cohort study utilized US healthcare claims data from the IQVIA PharMetrics® Plus database from January 1, 2017 to December 31, 2023. Adults with LN were identified using ICD-10-CM code M32.14, requiring at least one inpatient or two outpatient claims ≥30 days apart between January 1, 2018 to June 30, 2023. The first LN diagnosis was the index date. Patients needed ≥12 months pre-index and ≥6 months post-index continuous enrollment with no prior LN diagnoses. Exclusions included claims for renal transplant, dialysis, end-stage renal disease, malignancy, HIV, hepatitis B/C, and/or tuberculosis. LN treatments (ISTs, systemic glucocorticoids, antimalarials and antihypertensives) were examined, focusing on IST treatment patterns: initiation, switching, discontinuation (≥90-day supply gap), restarting, and duration of use. First and second lines of therapy (LoT) with ISTs were descriptively assessed, along with concomitant use of other LN treatments. Transitions to the second LoT involved adding or switching ISTs in ≤30 days of the first LoT ending or a ≥90-day treatment gap with or without restarting treatment.

Table 2. Treatment Regimens in the First Line of Therapy by Immunosuppressants

First IST LoT[a]	Number of patients	Proportion of patients on other drug classes during first IST LoT			Days on first LoT, median (Q1, Q3)
		Glucocorticoid overall, % (injection/oral)[b,c]	Antimalarial,[d] %	Antihypertensive,[e] %	
Any IST	946	79.7 (24.1/76.1)	64.7	54.1	219 (66, 485)
MMF	620	82.7 (18.1/81.5)	69.2	60.3	257 (96, 501)
AZA	95	61.1 (16.8/57.9)	62.1	44.2	254 (48, 560)
Belimumab	59	67.8 (52.5/49.2)	61.0	42.4	322 (59, 726)
Cyclophosphamide	39	94.9 (43.6/89.7)	56.4	38.5	106 (74, 136)
MMF, belimumab	32	84.4 (21.9/84.4)	81.2	65.6	288 (104, 606)
Rituximab	27	96.3 (77.8/63.0)	22.2	22.2	43 (42, 53)
CNI	20	55.0 (20.0/55.0)	40.0	35.0	240 (98, 610)
MMF, CNI	18	55.6 (11.1/55.6)	55.6	61.1	252 (72, 432)

CNI, calcineurin inhibitors (cyclosporine, tacrolimus, voclosporin); IST, immunosuppressant; LoT, line of therapy; MMF, mycophenolate mofetil; Q, quartile.
[a]Regimens with n<10 are not shown; [b]Injection and oral steroid percentages are based on total patients in each row, not a percentage of overall steroid use; [c]Steroid injections may include pre-infusion injections or pulse therapy; [d]Antimalarial included hydroxychloroquine; [e]Antihypertensive included angiotensin-converting enzyme inhibitors and angiotensin II receptor blockers.

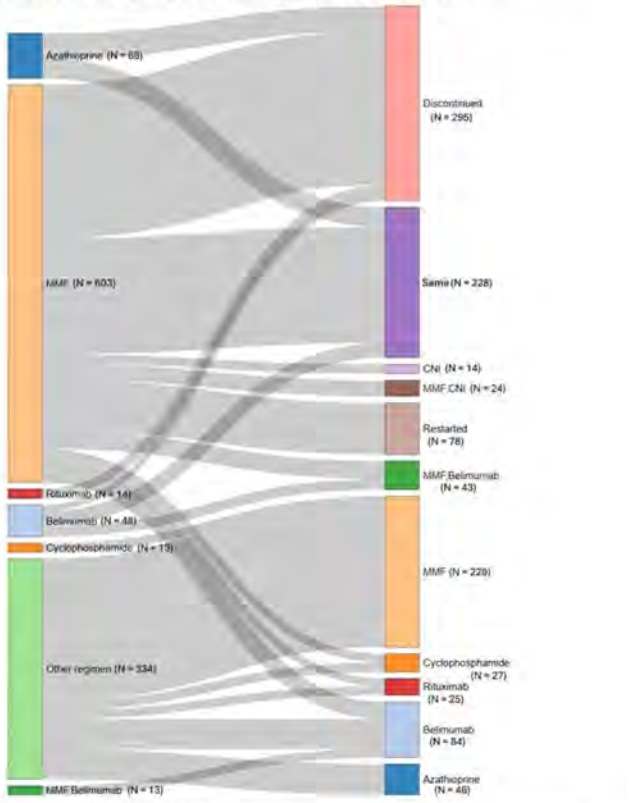
Figure 1. Sankey Diagram of First and Second Lines of Immunosuppressant Therapy Among Newly Diagnosed Lupus Nephritis Patients



Regimen transitions with n<10 are not shown.
Discontinued, dropped IST with a gap of ≥90 days and did not restart throughout study follow-up; Other regimen, including glucocorticoids, antimalarials, and antihypertensives, represents those who did not initiate IST in the first LoT but had it added later in the follow-up; Restarted, dropped IST with a gap of ≥90 days but reinitiated new or same IST later during study follow-up. Mean days until reinitiation ranged from 121 (CYC) to 392 days (CNI); Same: censored i.e., remained on first IST LoT throughout study follow-up.
Of the patients on MMF and belimumab as the first LoT, 41% withdrew MMF in the second LoT.
CNI, calcineurin inhibitors (cyclosporine, tacrolimus, voclosporin); LN, Lupus nephritis; LoT, line of therapy; MMF, mycophenolate mofetil.

Results: A total of 2052 newly diagnosed patients with LN were identified, with an average follow-up time of 2.5 years. The cohort was 82% female, with a mean (SD) age of 44 (15) years; 94% had private insurance, 74% had a prior SLE diagnosis and 35% had used ISTs pre-index (**Table 1**). During the post-index period, 1959 patients (95%) received any of the studied LN treatments. Of these, 946 patients (48%) received an IST as their first LoT, primarily mycophenolate mofetil (MMF, 66%), azathioprine (AZA, 10%) and/or belimumab (6%). Median treatment duration (in days) in the follow-up period varied: 257 for MMF, 254 for AZA, and 322 for belimumab. Among patients who received an IST as the first LoT, 80% were given systemic glucocorticoids (oral: 76%, injection: 24%, both: 21%), 65% antimalarials, and 54% antihypertensives (**Table 2**). By the end of their follow-up, 27% of these patients remained on their initial IST for a median of 456 days, while 19% added or switched to a second LoT with a different IST (primarily MMF, belimumab, or AZA), 16% dropped and restarted an IST after >90 days, and 37% discontinued IST treatment. Additionally, 18% (356/1959) of patients, with any LN treatment post-index, initiated non-IST treatment in the first LoT but switched to an IST during follow-up (**Figure 1**).

Conclusion: This health insurance claims-based study identified diverse treatment use in newly diagnosed patients with LN, with nearly half receiving an IST in the first LoT. Variability in treatment duration and regimens reflects dynamic patient needs and treatment practices. Understanding these patterns is essential for optimizing LN care and informing future monitoring of treatment changes following practice guideline updates and availability of newer therapies.

Abstract Number: 1039

CAR-T Therapy in Rheumatoid Arthritis: A Health Systems Analysis of Cost and Global Equity

Asrith Reddy Gandu[1] and Kolluri Prathyusha[2], [1]Davao medical school foundation, Hyderabad, India, [2]University of delaware, Newark, DE

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Refractory rheumatoid arthritis (RA) affects 30–40% of patients with limited therapeutic options and high disability burdens. Although CAR-T therapy has been transformative in oncology and lupus, its prohibitive cost (> $500K per patient) and limited accessibility in low- and middle-income countries (LMICs) constrain its application in RA. This systematic review evaluates CAR-T's cost-effectiveness, global equity challenges, and proposes actionable strategies for sustainable integration into rheumatology practice, aligning with ACR Convergence 2025's focus on healthcare delivery innovation.

Methods: Following PRISMA guidelines, we systematically reviewed 418 studies from PubMed and Embase (2000–2024) on CAR-T costs, access, or policy in RA/autoimmunity. Two reviewers independently screened studies using predefined inclusion/exclusion criteria. Thematic analysis categorized findings into cost-effectiveness, LMIC access barriers, and health system solutions, while study quality was assessed using AMSTAR-2.

Results: Eighteen studies met inclusion criteria (12 preclinical, 6 clinical).

In preclinical models, CD19 CAR-T cells resolved synovitis in 80% of RA mice ($p < 0.001$ vs. controls), correlating with a 90% reduction in B cells and a 3-fold increase in regulatory T cells ($p=0.002$). Early clinical trials reported 40–60% ACR50 response rates; however, 50% of patients experienced grade 1–2 cytokine release syndrome, which resolved with tocilizumab. CAR-T costs ($750K/QALY) exceed WHO-recommended thresholds (150K/QALY), with < 5% of trials including LMIC sites, while tiered pricing models in pilot programs reduced costs by 60%.

Conclusion: CAR-T therapy offers transformative potential for refractory RA but requires systemic reforms to address cost and equity challenges. Studies in oncology have demonstrated CAR-T's significant impact; adapting these cost-effectiveness models to RA supports the need for tiered pricing and LMIC-centric trials to ensure sustainable, equitable access. Implementing tiered pricing, initiating LMIC-centric trials, and developing engineered safety switches (e.g., ON/OFF CAR-T) are recommended strategies to democratize access.

Abstract Number: 1040

Impact of Clinical Pharmacist-Directed Patient Education on Medication Adherence and Clinical Outcomes in Patients with Inflammatory Arthritis

Cristina Hurley[1], Megha Kotha[2], Jisna Paul[3] and Jeff Barbee[4], [1]Carilion Clinic, Roanoke, VA, [2]Ohio State University, Columbus, OH, [3]Division of Rheumatology and Immunology, Department of Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH, Columbus, OH, [4]Ohio State University Wexner Medical Center, Columbus

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1038–1054) Health Services Research Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: This study assesses the impact of a clinical pharmacist-directed intervention on medication adherence and clinical outcomes in patients with rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis receiving non-infusion disease-modifying antirheumatic drugs (DMARDs). Previous studies on patient education interventions in rheumatology have yielded mixed results due to variability in study populations and educational methods. Pharmacist-led interventions in other chronic diseases, such as hypertension and diabetes, have demonstrated improved disease management and adherence, but data on their effectiveness in inflammatory arthritis remains limited.

Methods: A prospective, controlled study was conducted from July to December 2024 at Ohio State University (OSU) Rheumatology. Fifty adult patients were enrolled and assigned to either a pharmacist-directed intervention group or a usual care control group. The intervention group received pharmacist-led education, drug toxicity monitoring, and follow-up. Surveys administered at baseline and follow-up included the Morisky Medication Adherence Scale (MMAS), the Routine

Assessment of Patient Index Data 3 (RAPID3), and three medication knowledge questions. Statistical analyses included Pearson's chi-square test for categorical variables and Wilcoxon rank sum test for continuous variables. The primary outcome was MMAS score, with RAPID3 and medication knowledge responses as secondary outcomes.

Results: Baseline characteristics were similar between groups, except for a higher prevalence of tobacco use in the intervention group ($p = 0.03$). No significant differences were found in MMAS scores ($p = 0.84$), RAPID3 dichotomous outcomes ($p = 0.04$), or medication knowledge responses. Participants with higher education levels were more likely to report confidence in their medication knowledge. While the intervention group showed a trend toward improved disease control based on RAPID3 scores, this difference did not reach statistical significance. Correlation analysis revealed associations between gender and DMARD failure ($r = 0.37$, $p < 0.01$), race and anti-CCP positivity ($r = 0.31$, $p < 0.05$), and tobacco use with education level ($r = -0.41$, $p < 0.01$). The strongest correlation was between RF and CCP positivity ($r = 0.83$, $p < 0.001$).

Conclusion: Pharmacist-led patient education did not significantly improve medication adherence or clinical outcomes in this small cohort. However, trends in RAPID3 scores suggest a potential benefit in disease control. Confidence in medication knowledge was higher in those with greater educational attainment. Further large-scale studies are warranted to determine the impact of pharmacist-led education in inflammatory arthritis, similar to its demonstrated benefits in other chronic conditions such as hypertension and diabetes.

Abstract Number: 1041

Associated Factors and Direct Cost Analysis of Dose Reduction and Discontinuation of Biological Therapies in Rheumatoid Arthritis and Spondyloarthritis: Findings from a Colombian Cohort Within the Framework of an Integrated Management Model

Edwin Jauregui[1], Deisy Restrepo[2], Belcy Garzon[2], Alexis Atuesta[2], Nestor Correa[2], Jessica Barrera[2] and Andrea Rubio[2], [1]Riesgo de fractura S.A, Bogotá, Colombia, [2]Riesgo de fractura S.A, Bogotá, Colombia

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Dose reduction of biologic therapy (BT) in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA) has been increasingly implemented in recent years, in accordance with international and local clinical practice guidelines. This approach seeks to minimize the risk of adverse events and reduce direct healthcare costs. The objective of this study is to describe clinical characteristics and identify factors associated with dose reduction and discontinuation of BT in a cohort of RA and SpA patients managed within a comprehensive rheumatology care program at the healthcare institution Riesgo de Fractura SA – CAYRE IPS. Additionally, to evaluate direct pharmacologic treatment costs in this population.

Methods: This real-world evidence study describes a cohort of adult RA and SpA patients in sustained clinical remission—defined as DAS28 < 2.6 for RA and ASDAS < 1.3 for SpA—for at least 12 months. Patients were followed from April 2023 to October 2024. Clinical outcomes (DAS28 or ASDAS) were assessed at 6, 12, and 18 months after initiating biologic dose reduction. Per institutional policy, Rituximab and Adalimumab were used as first-line BT based on cost and biosimilar

Abbreviations: ACPAs= Anti-Citrullinated Protein Antibodies; BMI= Body Mass Index; csDMARD= Conventional Synthetic Disease-Modifying Antirheumatic Drug; HAQ= Health Assessment Questionnaire; RF= Rheumatoid Factor; NSAID= Non-Steroidal Anti-Inflammatory Drug; SD= Standard Deviation.

Table 2. Multivariable Logistic Regression Model for Biologic Therapy Optimization in Spondyloarthritis

	OR	CI 95%	Value *p*
Male sex	1.58	0.75 - 3.29	0.2261
HLA-B27 (+)	0.56	0.28 - 1.14	0.1118
Normal weight	1.17	0.59 - 2.34	0.6529
Disease duration (<5 years)	0.40	0.19 - 0.86	0.0192 *
Sacroiliitis (+)	1.71	0.78 - 3.79	0.1829

availability. Logistic regression was used to identify factors associated with successful dose reduction. Variables were selected based on clinical relevance and prior evidence; the most parsimonious model was applied. Limitations included small sample size and a lack of heterogeneity between groups. Drug costs were estimated using SISPRO platform by averaging unit prices, and all analyses were conducted using R software. Costs are reported in USD using an exchange rate of 1 USD = COP 4,293.00 (official Colombian rate (average), October 2024).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

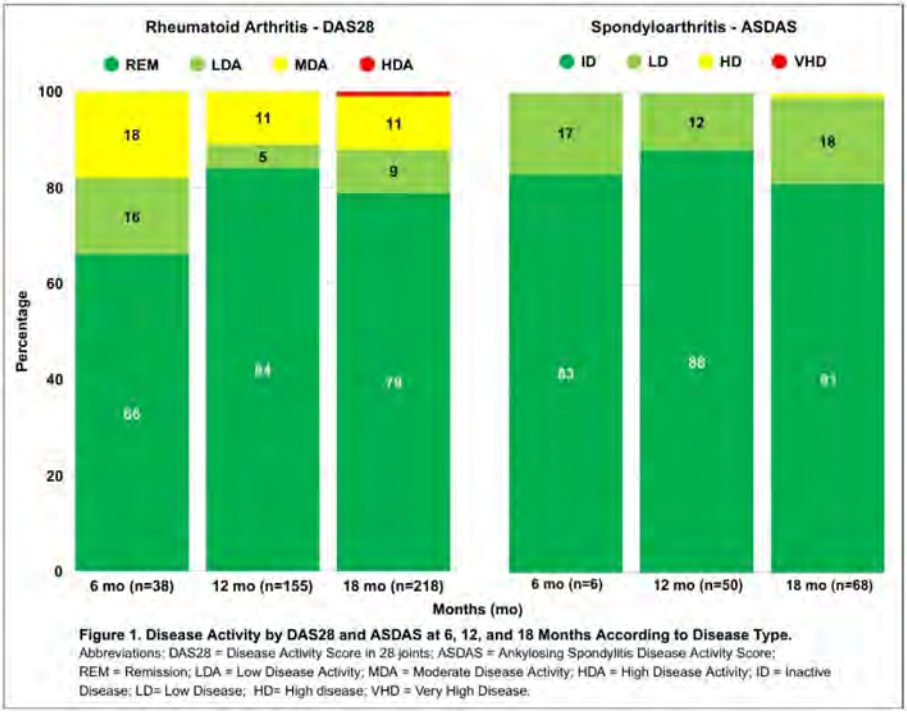

Figure 1. Disease Activity by DAS28 and ASDAS at 6, 12, and 18 Months According to Disease Type.
Abbreviations: DAS28 = Disease Activity Score in 28 joints; ASDAS = Ankylosing Spondylitis Disease Activity Score; REM = Remission; LDA = Low Disease Activity; MDA = Moderate Disease Activity; HDA = High Disease Activity; ID = Inactive Disease; LD= Low Disease; HD= High disease; VHD = Very High Disease.

Results: This cohort includes 1,456 patients with RA, of whom 402 are receiving BT, and 229 patients with SpA, of whom 146 are receiving BT. Over 18 months, BT doses were reduced in 65.9% (265) of RA patients and 50.6% (74) of SpA patients. BT was discontinued in 26 RA and 3 SpA patients. In RA, biologic dose reduction occurred in 58% of first-line and 24% of second-line therapies, with a failure rate of 17%. In SpA, reductions occurred in 65% of first-line and 24% of second-line therapies, with a 21% failure rate. Cost savings from dose reduction over 18 months were $854,874.8 for RA and $220,551.5 for SpA. Logistic regression was performed to identify variables associated with successful dose reduction. No statistically significant factors were found in RA. In SpA, shorter disease duration (< 5 years) was associated with lower odds of optimization (OR 0.40; 95% CI: 0.19–0.86; p=0.0192). HLA-B27 positivity was not significant but showed a trend toward lower odds of optimization (OR < 1, p = 0.1118).

Conclusion: This real-world study within a comprehensive care model showed that tapering or discontinuing biologic therapy in RA and SpA patients is feasible while maintaining disease control and achieving substantial cost savings, with a favorable economic impact on the healthcare system. Larger studies are needed to better identify factors associated with successful dose reduction or discontinuation of biologics.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: In 2023 patent exclusivity for adalimumab expired and nine biosimilars were introduced to the U.S. market with a tenth launched in May 2024. The arrival of these biosimilars was eagerly awaited given the potential to reduce costs and improve access however uptake in the first year of availability was very low. CVS Caremark removed adalimumab from its national formulary in favor of adalimumab-adaz in April 2024. Here we assess how this decision changed the uptake of -adaz and other biosimilar adalimumab molecules in community rheumatology practices.

Methods: Data derive from RISE, a national EHR database from over 1100 US rheumatologists. We included patients age $\geq$ 18 years, with Medicare, Medicaid or private insurance, prescribed adalimumab (reference or biosimilar) in 2023 or the first 9 months of 2024 (due to data availability). Covariates include age, sex, race-ethnicity, and area deprivation index. Psoriatic

Table 1. Demographic and clinical characteristics of patients prescribed adalimumab or its biosimilars in RISE 2023-2024.

*Data available through September 2024.

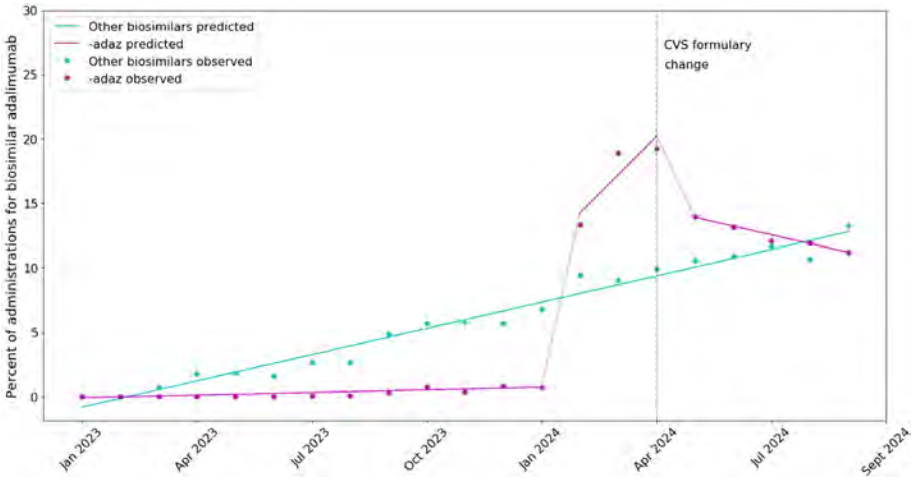

Figure 1. Interrupted time series analysis of the proportion of prescriptions dispensed that were adalimumab-adaz and linear regression of other adalimumab biosimilars by month. Each dot represents the actual proportion of prescriptions dispensed. Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

arthritis (PSA), ankylosing spondylitis (AS), or rheumatoid arthritis (RA) was defined by two ICD codes at least 30 days apart with patients assigned to one based on the clinically adjudicated hierarchy: PSA >AS >RA >other.

We tested for differences in ever use of a biosimilar between years as well as ever use in 2023/2024 combined across insurance coverage, demographics, and diagnosis using standardized mean differences. We used an interrupted time series (ITS) to model the effect of the CVS formulary change on the proportion of prescriptions (per month) for -adaz and all other biosimilars combined. Our final model is an ITS with interruptions at February 2024 and May 2024 to best characterize the observed pattern for -adaz, and a linear regression to characterize the other biosimilars (as ITS estimates suggested no discontinuity).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 22,079 patients received adalimumab or a biosimilar during our study period. In 2023 < 4% of patients received a biosimilar whereas in the first 9 months of 2024 this jumps to nearly 25% of patients (Table 1). 16.4% of patients with private insurance, 8.2% on Medicaid, and 6.5% with Medicare were ever on a biosimilar. There were only trivial differences by sex, race-ethnicity, ADI and diagnosis (Table 1). In 2024 most biosimilar prescriptions were -adaz (55.5%) followed by -bwwd (19%) (Table 2).

There were nearly no prescriptions for -adaz Jan 2023–Jan 2024 but a >13% jump in prescriptions in Feb 2024. Uptake continued to rise at the rate of nearly 3% per month through May 2024. There was a 9.3% drop from April to May with use continuing to decline thereafter at a rate of 0.7% per month (Figure 1). Prescriptions for the other biosimilars increased steadily at a rate of 0.7% per month over the study period.

Conclusion: The CVS formulary change had a dramatic effect on prescriptions. The increase started 2 months before the official date, which likely reflects proactive changes in ordering practices by clinicians and pharmacists. The large decrease immediately after the formulary change has not been reported elsewhere. This may reflect the nocebo effect, patient preference for certain reference product characteristics (e.g., citrate free formulation), or switching to a different product after the removal of manufacturer copay assistance programs.

Abstract Number: 1043

The Care Pathway and Treatment Patterns in Patients with Uncontrolled Gout: A Real-World Survey of Physicians In The United States

Gordon Lam[1], Menaka Bhor[2], James Hawthorne[2], Arinola Dada[3], Molly Edwards[4], Emily Goddard[4] and John Albert[5], [1]Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC, [2]Sobi Inc, Waltham, MA, [3]Overlake Arthritis and Osteoporosis Center, Bellevue, WA, [4]Adelphi Real World, Bollington, United Kingdom, [5]Rheumatic Disease Center, Glendale, WI

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Uncontrolled gout (UG) is a chronic, progressive, and systemic disease characterized by serum uric acid (sUA) >6 mg/dl and clinical manifestations such as tophi, flares and gouty arthropathy, despite the use of urate lowering therapy (ULT). Limited real-world evidence exists on the UG care pathway from diagnosis to long-term management. This study examined the care pathway and treatment patterns of patients with UG in the United States (US).

Methods: Data were extracted from the Adelphi Real World Gout Disease Specific Programme™, a cross-sectional survey, with retrospective data collection, of physicians (rheumatologists, nephrologists and primary care physicians [PCPs]) and their patients with gout in the US between August 2023 – March 2024. Physicians who participated in the study managed ≥8 patients with gout a month. UG was defined as sUA >6 mg/dl and at least one of the following: gouty arthropathy, ≥1 tophi, or ≥2 flares in the 12 months prior. Patients had to be receiving a ULT. Physicians reported patient demographics, treatment patterns, care pathway and clinical manifestations such as sUA levels, number of tophi and signs/symptoms at diagnosis, treatment initiation and data collection. All patients had a known treatment duration. Analyses were descriptive.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Overall, 88 physicians (45 rheumatologists, 22 nephrologists and 21 PCPs) reported data for 400 patients with UG. In patients who developed UG, there was a mean (standard deviation, SD) of 0.4 (1.3) years between a patients' first physician visit and gout diagnosis. At diagnosis mean (SD) patient age (n=310) was 53.0 (11.6) years, sUA level (n=330), number of tophi (n=173), and signs/symptoms (n=369) were 11.7 (4.7) mg/dL, 2.8 (2.9), and 2.7 (1.8), respectively.

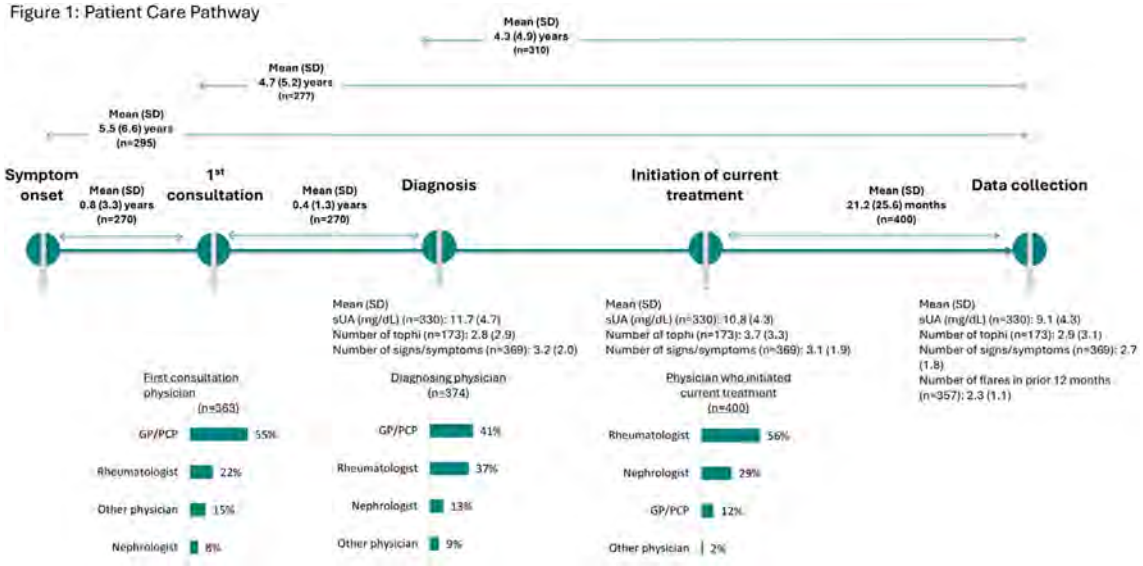
At initiation of current treatment (n=400), mean (SD) sUA level, number of tophi and signs/symptoms were 10.8 (4.3) mg/dL, 3.7 (3.3) and 3.1 (1.9), respectively. Rheumatologists prescribed the current treatment in 56% of patients, nephrologists 29% and PCPs 12%. The most common ULT was allopurinol (63%), followed by febuxostat (29%) and pegloticase (13%).

Table 1. Physician-Reported Patient Demographics At Gout Diagnosis

	Patients with uncontrolled gout (n=400)
Age at diagnosis	(n=310)
Mean (SD) years	53.0 (11.6)
Patient sex (male), n (%)	316 (79)
Race, n (%)	
White	244 (61)
Black or African American/African or Caribbean	113 (28)
South or Central American Native	11 (3)
East or Southeast Asian	10 (2)
American Indian, Indigenous American, or Alaska Native	9 (2)
South Asian (Indian subcontinent)	8 (2)
Middle Eastern or North African	7 (2)
Native Hawaiian or Pacific Islander	3 (1)
Other	3 (1)
Comorbidities present at diagnosis, n (%)	
Hypertension (≥140/90mmHg)	269 (67)
CKD	135 (34)
Obesity	129 (32)
Diabetes	119 (30)
Metabolic syndrome	118 (30)
CV disease	60 (15)
Hyperuricemia without gouty arthritis	40 (10)

CKD: chronic kidney disease. CV: cardiovascular disease. SD: standard deviation.

Figure 1: Patient Care Pathway



GP: general practitioner, PCP: Primary care physician, SD: standard deviation, sUA: serum urate acid. Other physicians include ER physician, Podiatrist, Nurse / nurse practitioner, Orthopaedic Surgeon, Other physician. Possible signs/symptoms: Cramp, Fatigue, Fever/flu like symptoms, Gouty arthropathy, defined clinically or radiographically as joint damage due to gout, High sUA (> 6mg/dL), Joint stiffness, Loss of movement/loss of mobility, Pain between flares (chronic pain), Sleep disturbance, Tender/swollen joint(s), Visible tophus(i), Warm joints, Other, None

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The most common reasons reported by physicians for choosing the current treatment were overall efficacy, long-term efficacy, and sUA reduction for 86%, 63%, and 54% of patients, respectively. However, these same characteristics were also reported by physicians as the most common areas where the treatments could perform better in 32%, 27%, 25% of patients respectively.

At data collection (n=400), after a mean (SD) of 21.2 (25.6) months on the current ULT, mean (SD) sUA level, number of tophi and signs/symptoms were 9.1 (4.3) mg/dL, 2.9 (3.1) and 2.7 (1.8), respectively. Mean (SD) number of flares (n=357) in the 12 months prior was 2.3 (1.1).

Conclusion: To our knowledge, this is the first real-world study examining the care pathway and treatment patterns of patients with UG. These data highlight that patients with UG experience extended periods of time with elevated sUA and UG clinical manifestations, despite receiving ULT for almost two years. Given that efficacy was noted as the most common reason for treatment choice and area of improvement, there is a need for optimal treatment utilization and alternative options for patients with UG.

Abstract Number: 1044

Analysis of Medicare and Medicaid Utilization and Expenditure of Newly Approved Biologics for Systemic Lupus Erythematosus Patients in the United States

Gunjan Rana[1], Mansi Mehta[1] and Joanne Cunha[2], [1]Saint Vincent Hospital, Worcester, MA, [2]BROWN MEDICINE, BROWN UNIVERSITY, Riverside, RI

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine is a cornerstone in the treatment of Systemic Lupus Erythematosus (SLE), while corticosteroids and immunosuppressive agents are employed for moderate to severe disease [1]. The introduction of targeted biologic agents such as Belimumab for active SLE and lupus nephritis (LN), Anifrolumab for moderate to severe active SLE and Voclosporin for active LN, has expanded the therapeutic armamentarium. These advances, however, are accompanied by a substantial economic burden and increased utilization of biologic disease-modifying antirheumatic drugs (bDMARDs) [2].

Methods: We analyzed publicly available Medicare Part D and Medicaid data from the Centers for Medicare & Medicaid Services. We examined total spending, claims, beneficiary counts, average spending per claim, and per beneficiary for belimumab, anifrolumab, and voclosporin. Belimumab was FDA-approved in 2011, while anifrolumab and voclosporin were approved in 2021. Cost data from 2012–2021 were adjusted for inflation to 2022 dollars. Percent changes were calculated for 2012 and 2021 versus 2022. IRB oversight was not required due to the public nature of the data.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Nationwide analysis shows sharp increases in spending and utilization of these targeted therapies (Table 1). From 2012 to 2022, Medicare spending on belimumab rose by 7,047%, and Medicaid by 1,765%. Between 2021 and 2022, increases were more modest (14.83% Medicare; 19.10% Medicaid). Anifrolumab spending jumped by 932.8% in Medicare and 3,762.03% in Medicaid from 2021 to 2022, with substantial increases in claims and beneficiaries. Voclosporin spending increased by 190.45% in Medicare and 198.8% in Medicaid, with a doubling in claims and beneficiaries. Average spending per beneficiary notably rose, especially in Medicare.

Conclusion: The rapid growth in spending reflects expanded utilization of biologics (Figure 1). Although average spending per claim showed only modest changes, the substantial rise in spending per beneficiary highlights increased reliance on these newly approved therapies (Figure 2). Patients with severe SLE exhibit elevated rates of inpatient admissions and emer-

gency department utilization, significantly contributing to increased healthcare expenditures [3]. These findings underscore an urgent need for policy interventions aimed at regulating biologic drug pricing and improving access to effective SLE therapies, particularly for individuals insured through public programs such as Medicare and Medicaid [4].

Bayesian Analysis of Factors Associated with Romosozumab Adherence Among Early Adopters in Medicare Beneficiaries

Hongke Wu[1], Ye Liu[1], Tarun Arora[2] and Jeffrey Curtis[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]FASTER, Birmingham, AL, [3]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL

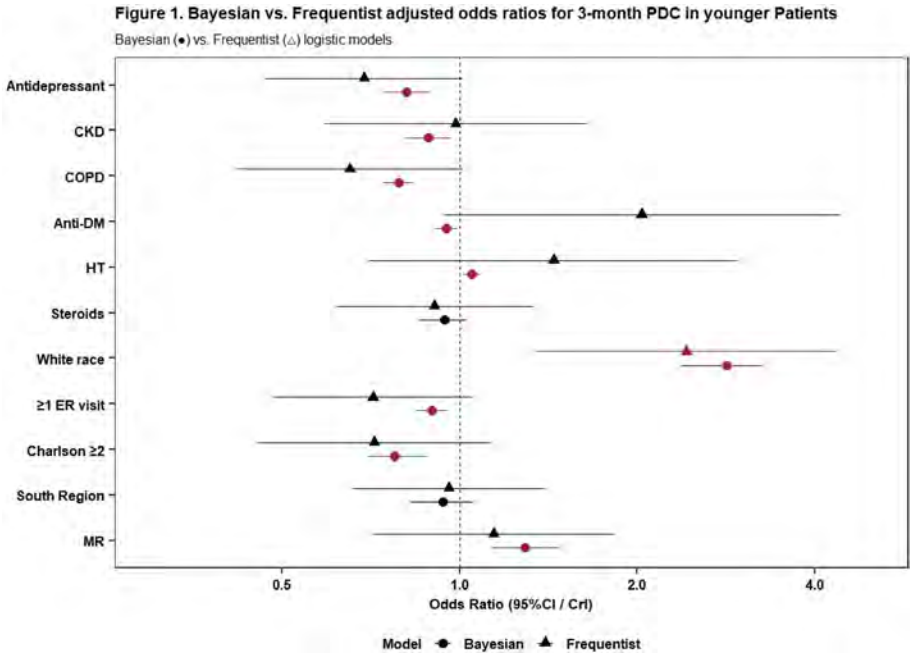
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: : Early adherence data for newly approved drugs guide clinical management, yet small cohorts hamper conventional analyses. Romosozumab (Romo), licensed April 2019 for high-risk postmenopausal osteoporosis, is an ideal example. This study is to identify determinants of Romo adherence using Bayesian logistic regression.

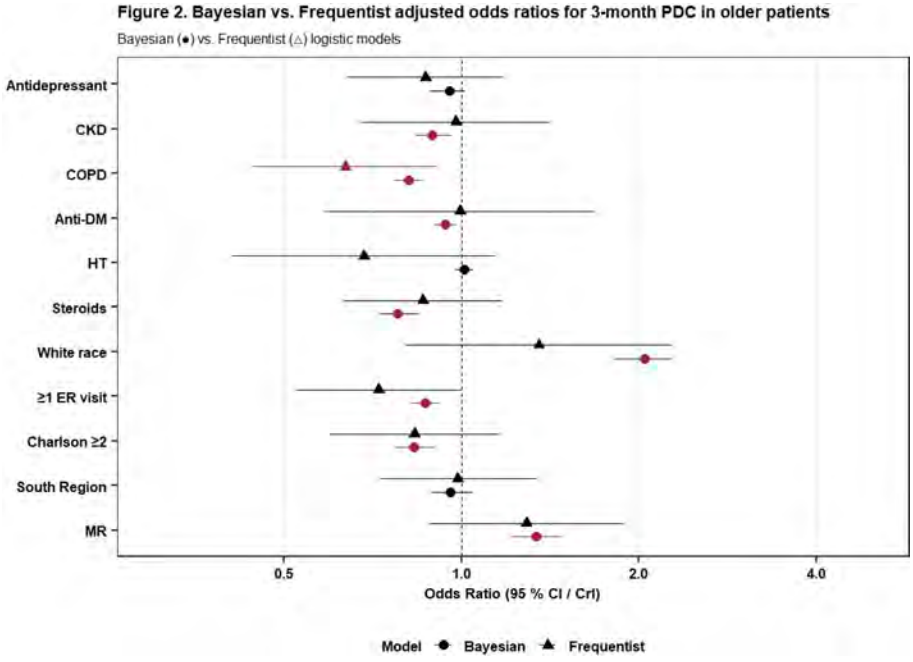
Methods: Medicare fee-for-service claims (2006–2022) were used to identify women ≥65 who began Romo in 2019 and maintained ≥4 years of continuous enrollment (≥3 baseline). Exclusion criteria include metastatic cancer, Paget's disease. A priori predictors – guided by literature and expert input – age groups (younger [≤75] vs older [>75]), race, regions, metropolitan residence (MR), Charlson Comorbidity Index (CCI), CKD, COPD, antidepressants (anti-DP), antidiabetics (anti-DM), hormone therapy (HT), steroids, and ER visits—were entered into frequentist and Bayesian logistic models. High adherence was proportional days covered (PDC) ≥80% in the first 3 months. Results are odds ratios (OR) with 95% confidence or credible intervals(CI/CrI).

Results: Among 1,777 initiators (younger: n = 752; older: n = 1,025), 77.8 % were indicated as high adherence. Frequentist analysis linked White race to higher adherence in younger women (OR 2.42, 95%CI [1.35–4.36]) and COPD to lower adherence in older women (0.64, [0.44–0.91]). Bayesian analysis revealed additional associations. In younger patients (Figure 1),

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Notes: PDC: proportion of days covered; CKD: chronic kidney disease; COPD: chronic obstructive pulmonary disease; DM: diabetes mellitus; HT: hormone therapy; ER: emergency room; MR: metropolitan region; CI: confidence interval; CrL: credit interval



Notes: PDC: proportion of days covered; CKD: chronic kidney disease; COPD: chronic obstructive pulmonary disease; DM: diabetes mellitus; HT: hormone therapy; ER: emergency room; MR: metropolitan region; CI: confidence interval; CrL: credit interval

anti-DP (OR=0.81, 95% CrI: [0.74–0.89]), CKD (0.88 [0.81–0.97]), COPD (0.79 [0.74–0.83]), anti-DM (0.95 [0.91–0.99]), ER visits (0.90 [0.84–0.96]), and higher CCI (0.78 [0.70–0.88]) were associated with decreased adherence, while White race (2.83 [2.37–3.26]) , MR (1.29 [1.13–1.47]) and HT (1.05 [1.01–1.09]) were associated with high adherence. In older patients (Figure 2), CKD (0.89 [0.84–0.96]), COPD (0.81 [0.77–0.86]), steroids (0.78 [0.73–0.85]), and higher CCI (0.83 [0.77–0.90]) were associated with decreased adherence, while White race (2.05 [1.82–2.28]) and MR (1.34 [1.22–1.48]) were associated with high adherence.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Bayesian analysis identified additional adherence factors among early Romo adopters compared with frequentist models, including anti-DP and HT. Future research should consider Bayesian modeling when studying medication adherence, particularly when sample size may be limited.

Cannabis Knowledge, Attitudes, and Practices Among Rheumatology Providers: Implications for Clinical Care and Education

Joanna Zeiger[1], Patti Katz[2], Mary-Ann Fitzcharles[3], Stuart Kassan[4], Teresa Simon[5] and Kaleb Michaud[6], [1]Canna Research Foundation, Boulder, CO, [2]UCSF, San Rafael, CA, [3]McGill University, Montreal-West, Canada, [4]National Jewish Health, Denver, CO, [5]Physicians Research Center, LLC, Toms River, NJ, [6]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: As medical cannabis becomes increasingly integrated into clinical care, healthcare providers—particularly those managing chronic rheumatologic conditions—must navigate wide-ranging levels of knowledge, attitudes, and prescribing comfort. This international study examined how rheumatology providers' cannabis-related knowledge and attitudes influence clinical practices, including theoretical prescribing behaviors, dosing decisions, and patient communication.

Methods: Between November 14, 2023, and February 3, 2025, 281 international rheumatologists and rheumatology-affiliated clinicians completed a cross-sectional survey. A six-item cannabis knowledge score (range 0–6) was standardized and trichotomized into low (n = 36, 15.9%), average (n = 156, 69.0%), and high (n = 72, 31.9%) knowledge-level groups. Two-step cluster analysis of 11 cannabis attitudinal items yielded three profiles:

Progressive (n = 90, 39.8%)—supportive of cannabis and policy reform;

Unsure (n = 91, 40.3%)—cautious, ambivalent, and often uncertain; and

Traditional (n = 84, 37.2%)—more skeptical, concerned about harms, and less supportive of legalization. Eight clinical practice outcomes and 10 theoretical dosing practices were analyzed using chi-square.

Results: Respondents were primarily female (61.2%) and white (78.9%), with most practicing in urban (87%) and academic (68.4%) settings in the United States (47%). Compared to lower cannabis knowledge, higher knowledge levels were significantly associated with greater comfort discussing cannabis (67.5% vs. 37.0%, $p < .001$), awareness of contraindications with other medications (39.5% vs. 26.0%, $p < .05$), believe it is opioid sparing (71.9% vs. 56.2%, $p< 0.001$) and recommending CBD (47.3% vs. 36.1%, $p < 0.05$) and THC (27.4% vs. 17.8%, $P< 0.05$). A preference for 'start low and build' dosing was more common among those with high knowledge (73.3%) compared to low knowledge (47.9%, $p < .01$). Among

*P<0.05; †P<0.01; ‡P<0.001

attitudinal clusters, Progressive providers were more likely to recommend CBD (58.6%) and THC (33.0%) compared to Traditional providers (34.1% and 14.5%, respectively, $p < .05$). Progressive providers also reported higher opioid-sparing beliefs (83.3% vs. 48.8%, $p < .001$). Uncertainty regarding dosing was common across all clusters and knowledge groups, particularly regarding THC and CBD starting and maximum doses.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Among rheumatology providers, both cannabis-related knowledge and attitudes significantly influence clinical perspectives and theoretical prescribing decisions. Educational efforts should address not only knowledge gaps but also attitudinal ambivalence to support informed, patient-centered cannabis care.

Primary Care Perspectives on Giant Cell Arteritis: Diagnostic Considerations, Referral Challenges, and Opportunities for Fast-Track Pathways in the U.S.

Ellen Ann Sockman[1], **Jon Golenbiewski**[1] and Rachel Wolfe[2], [1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]Wake Forest University School of Medicine, Winston-Salem

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant Cell Arteritis (GCA) is a medical emergency that can lead to irreversible vision loss without prompt recognition and treatment. Primary care providers (PCPs) often serve as the initial evaluators of suspected GCA. To date, no U.S. study has evaluated how PCPs approach GCA evaluation and management. This study aims to understand PCPs' perspectives, diagnostic and referral practices, and barriers they face in managing suspected GCA—highlighting opportunities to streamline subspecialty care and reduce risk for adverse outcomes.

Methods: A 35-question electronic survey was distributed to 350 PCPs as part of a large health system in central North Carolina. The survey explored awareness of GCA, diagnostic tools, treatment approaches, referral workflows, and perceptions of system-level challenges. Responses were analyzed descriptively.

Results: Forty-seven providers responded (13.4% response rate), including internal medicine and family medicine providers in academic (56.5%) and community (43.5%) settings. Most respondents (n=42, 89.2%) would sometimes or rarely consider GCA as a possible diagnosis. Confidence in diagnosing GCA was moderate with a mean of 6.2 (95% CI = 5.7 - 6.7) and slightly lower for management with a mean of 5.2 (95% CI = 4.6 - 5.8). Eighty percent of providers (n=38) initiate high dose glucocorticoids (≥1 mg/kg) when GCA is suspected with 58.3% (n=27) of respondents continuing until specialist evaluation. Most respondents referred to specialists for management of GCA; however, 2.1% (n=1) of PCPs manage patients independently. Over half (n=29, 63%) were unaware of biologic therapies as treatment options for GCA.

Referral pathways varied: 68.1% (n=32) referred to ophthalmology when vision loss was suspected, yet only 44.7% (n=21) involved the emergency department. Wait times to see rheumatology were frequently prolonged, with 51.1% (n=24) reporting delays greater than 4 weeks. Coordinating referrals was cited as difficult by 75.6% (n=35) of respondents, often requiring extra time and resources to have patients evaluated. Communication is rare among referring providers as only 19.1% (n=9) reported direct communication with an on-call provider. Respondents expressed strong interest (n=45, 95.7%) in a fast-track clinic or protocol to improve triage and access for suspected GCA cases.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: This is the first U.S.-based study to explore primary care experiences in managing suspected GCA. Our study highlights that GCA remains an infrequently considered diagnosis amongst PCPs, with variability in referral patterns and steroid management, underscoring the need for education on its recognition, diagnosis, and treatment. Limited awareness regarding the use of biologic therapies in GCA and their steroid-sparing potential highlights an important educational gap. Additionally, our findings suggest that system-level interventions—such as fast-track clinics or clearer referral protocols—may support PCPs in delivering timely, coordinated care and reducing the risk of vision loss and complications of prolonged steroid use. This study was limited by a small sample size, low response rate and geographically narrow focus that may limit generalizability.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is widely used for rheumatic diseases, but data on its cardiac safety, particularly QTc prolongation, remains limited. Concerns about HCQ inducing QTc prolongation, which can lead to Torsades de pointes and sudden death, arose during the COVID-19 pandemic, though extrapolating from sick patients with COVID to patients with stable RMD patients remains unclear.

Methods: We abstracted data from Veterans with RA, SLE, or Sjögren's syndrome (based on ICD-10 diagnostic codes) from 3 VA sites (Sept 2016–Mar 2022), aged 18–85 with ≥1 ECG.

Bazett-corrected QTc were abstracted. ECGs with Afib/flutter, pacing, or 300 > QTc > 600 ms were excluded. To define exposure to HCQ, windows were defined using days supplied on dispensed prescriptions (and then multiplied by 1.2 so as not to assume 100% adherence). Primary outcome was QTc > 500 ms. Secondary QTc outcomes included QTc > 400 ms and QTc mean. Multivariate models adjusted for age, gender, race/ethnicity, comorbidities, and concomitant QT-prolonging drugs.

Results: HCQ use was highest in Veterans with SLE (63%), followed by RA (41%) and Sjögren's (14%). Across the 3 VA sites, 4,774 Veterans had 24,549 ECGs. Of 3,157 Veterans never on HCQ, 5.4% of ECGs showed QTc >500 ms. 769 veterans were on HCQ at some time during the study period, but never on HCQ when ECG was obtained, and had the lowest proportion of QTc > 500 ms (3.7%). Veterans who were intermittently off and on HCQ at the time of ECG recordings had the highest proportion of QTc >500 (7.2% and 8.5%, respectively). While Veterans who were always on HCQ at time of ECG had similar proportion (5.7%) of QTc >500 to those Veterans never on HCQ. Differences between the proportion of QTc prolongation < 500 ms did not differ statistically across the HCQ exposure groups. Differences between the groups were statistically significant for the secondary outcomes of QTc > 400 ms and QTc mean (Refer to Table 2).

Among 35 patients with paired HCQ blood levels and ECGs, for each 100 ng/mL rise in HCQ level was linked to a 9.4 ms increase in QTc ($r = 0.50$, $p = 0.0005$). Eg. 70 kg patient taking 200 mg daily (2.9 mg/kg/day) might see a 6–12 ms QTc increase. This suggests a modest, dose-dependent QTc effect, consistent across cohorts. Of note, none of the 35 patients had a therapeutic HCQ level (suggestive of low adherence). Poor adherence was further noted in our overall cohort with a low median annual MPR of 72% yielding a median estimated dose of 2.3 mg/kg/day.

Conclusion: In this large, multi-site VA study involving patients with rheumatic diseases, HCQ use was associated with a small but statistically significant, dose-dependent QTc prolongation. Although the absolute QTc increase was small and unlikely to affect most patients, these results support targeted ECG monitoring, particularly in older or female patients, or in those receiving other QT prolonging medications or with CKD or cardiac comorbidities. These results also suggest the potential value of HCQ drug level monitoring where the detection of supratherapeutic HCQ levels should prompt ECG evaluation.

Background/Purpose: Guidelines recommend limiting glucocorticoid (GC) use in RA, but 30% of patients continue long-term GCs. Little is known about the influence of provider attitudes and characteristics on prescribing patterns. We conducted a provider survey nested within a RA registry to identify provider factors associated with GC use.

Methods: A survey was sent to providers contributing patients to the prospective, observational, CorEvitas Rheumatoid Arthritis registry, capturing demographics, provider concerns about the safety of different medications, and a range of healthcare-related and non-healthcare related beliefs. We then identified patients with RA initiating a new biologic or Janus kinase inhibitor (JAKi) who remained on the same therapy at a 6 month follow-up visit, using the first qualifying observation per patient. Patient factors associated with GC use 6 months after treatment initiation were assessed using a mixed effects logistic regression model clustered by provider. Similar models limited to patients of the survey responders assessed whether different provider characteristics and beliefs were associated with GC prescribing 6 months after treatment initiation, adjusting for patient factors. All models were weighted for number of patients per provider.

Results: Among 256 active providers contributing patients to the registry, 92 (36%) responded to the survey and 81 had patients meeting all inclusion criteria. These 81 responders had 3966 qualifying patients, while 164 non-responders had 3219 qualifying patients. Among all 7185 patients, higher baseline disease activity, less improvement at 6 months, age

Table 1: Association between patient characteristics and provider survey response (vs. non-response) with ongoing glucocorticoid use 6 months after biologic or JAKi initiation

Opioid use at baseline		
No	4992 (69.7%)	Reference
Yes	2170 (30.3%)	1.14 (0.98-1.34)

Adjusted odds ratio from a multivariable mixed effects logistic regression model clustering on provider, with weighting to account for the different number of patients per provider. Models also included body mass index and the Charlson comorbidity index (neither significant) and whether the treating provider responded to the survey (OR 0.68, CI 0.049-0.94). Odds ratios in bold were significant at the $p < 0.05$ level. TNF = tumor necrosis factor

* An improvement in CDAI of 1 point indicates a 1 point reduction in CDAI from baseline to 6 months

Not at all Important	0.85 [0.43, 1.68]	0.64

Analysis via individual random effects models with provider included as a random effect. All models adjusted for year, number of previous biologic/JAKi, patient sex and age, baseline clinical disease activity index (CDAI), change in CDAI, Charlson Comorbidity Index (CCI), BMI, Opioid use, Duration of disease, current DMARD, region.

[a]Burnout was based on 2 questions from the Maslach Burnout Inventory, range 0-12 with higher scores indicating higher burnout.

[b]Shared decision making was from the Alberta Shared decision-making Measurement Instrument (ASK-MI) tool, six questions with total score ranging 6 to 36 with lower scores indicating higher shared decision making. Beliefs about race were the Health Professionals

[c]Beliefs about Race (HPBR) scale - Biological domain, 7 questions with score 7 to 35 with lower scores indicating greater belief that race is a biologic factor that corresponds to genetic differences and can be useful in screening and treatment decisions.

≤45 or >75, more long-standing RA, more previous biologics/JAKi, and earlier calendar year were associated with greater GC use at 6 months (**Table 1**). Patients of survey responders were less likely to use GCs (OR 0.68, CI 0.049-0.94), and 13% of the variability in GC use was due to provider. In analyses limited to survey responders: provider demographics, burnout, and beliefs regarding shared decision making, complementary/alternative medications, race as a biologic factor in medicine, political leanings, and religiosity were not associated with GC prescribing (**Table 2**). As shown in **Figure 1**, concerns about long-term prednisone ≤5mg or >5mg or opioids were not associated with GC prescribing, but providers with less concern about biologics or JAKi were more likely to prescribe GCs at 6 months [adjusted OR 2.34 (1.15-4.76) for biologics, OR 2.52 (1.36-4.65) for JAKi for slightly/not at all vs. very much concerned].

Conclusion: While patient factors have a strong influence on GC use in RA, variability in practice patterns among providers also impacts GC use. Many provider characteristics and beliefs, and surprisingly even concerns about GCs, are not associated with GC prescribing. In contrast, providers with less concern about biologics and JAKi are more likely to prescribe GCs. These results suggest that broader attitudes towards prioritizing treatment benefits vs risks may drive GC prescribing, with important implications for provider education.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is a key therapy for lupus (or SLE). Yet, challenged to weigh benefits vs. harms, ~80% of patients self-discontinue HCQ. Shared decision-making (SDM) tools, like HCQ-SAFE© (Garg, 2023), can support patients and clinicians in complex treatment decisions. In a clinical trial, HCQ-SAFE SDM intervention (Fig. 1A) was used by 12 clinicians during 200 visits in 8 clinics of 2 health systems. Still adoption of SDM tools can be challenging in non-research settings, particularly busy clinics and low-resource settings.

Table 1. A. Key Visits Characteristics; B. Implementation Outcome Metrics Mapped to RE-AIM

A. Visit characteristics	N (%)
Center 1	120 (60)
Center 2	80 (40)
MDs	101 (50.5)
RNs	43 (21.5)

Table 2. Qualitative Analysis of Clinician Interviews Informed by Normalization Process Theory Domains to Deliver Strategies to Develop Practical Workflow for HCQ-SAFE Integration in Clinics

Domains	Themes	Recommended Strategies to Revise Workflow ›*(Illustrative Quotes)*
Coherence	1. Clear purpose of intervention (Why?) 2. Clear eligibility criteria (Who?) 3. Values aligned with clinic goals (Can we do this?)	**Strategy 1.** HCQ-SAFE e-tool and training should clearly states the reason to use it **Strategy 2.** Simplify eligibility criteria to all patients *"I think, all patients should see it at least once"*
Active Participation	1. Preparedness to use the intervention (How can I do it?) 2. Effectiveness of the intervention (What is the impact?) 3. Motivators or facilitators of participation (How?)	**Strategy 3.** Training should be tailored to clinician role *"The video and session [training] was good, but I think, it can be optional for MDs, but 1:1 session for staff with less experience could be helpful..."*
Collective Action	1. Compatibility with existing workflows (Easy to use?) 2. Division of labor, resources, responsibilities (Preferred user) 3. Facilitators/detractors to use 4. Strategies to circumvent challenges (What was done?)	**Strategy 4.** PharmDs or RNs should preferably complete HCQ-SAFE review in busy clinics *"RN: I liked the interaction part with patients... I would like to do more of these... It was meaningful"* *"Manager: I do not see why RNs can't do this in clinics... it only takes 5 mins..."* **Strategy 5.** Review HCQ-SAFE again during life changes (e.g., pregnancy, kidney disease), refill gaps, or resuming HCQ after self-discontinuation
Reflexive Monitoring	1. Early experiences and perception over time 2. Any adaptive improvements 3. Recommendations to ensure sustained use	**Strategy 6a.** Avoid recommending a post-HCQ-SAFE review follow up for everyone; limit follow-up to patients with concerns or refill gaps only **Strategy 6b.** Add training link to HCQ-SAFE e-tool for users to refresh training if needed **Strategy 6c.** Give patients a link to the tool in after visit summary or in patient message

We aimed to: 1) examine implementation outcome metrics mapped to the RE-AIM framework for using the HCQ-SAFE SDM intervention; 2) develop strategies based on clinician experiences using the Normalization Process Theory (NPT) to revise HCQ-SAFE implementation workflow for easier integration in clinics.

Methods: The HCQ-SAFE SDM intervention (Fig. 1A) was implemented in 200 unique visits by 6 MDs, 3 PharmDs, and 3 RNs (NCT05922722). Clinicians completed a questionnaire to report intervention details (version, topics, language), time, and rated feasibility & likelihood to use on a 1-9 Likert scale (9=best). Clinicians also participated in a cognitive interview to share experiences, barriers, & facilitators to HCQ-SAFE use.

Quantitative data from 200 questionnaires estimated RE-AIM implementation metrics. Reach: % eligible visits completing HCQ-SAFE. Effectiveness: change in decisional conflict scores (overall/by role). Adoption: % clinicians completing intervention. Implementation: Fidelity (% visits covering ≥1 benefit/harm, language) & Feasibility (median score ≥7, time ≤5 min). Maintenance: monthly completion rate & Net Promoter Score (NPS ≥80%, motivators - detractors).

Qualitative data from interviews were analyzed using a coding scheme informed by 4 NPT domains to identify strategies to refine workflows for easier integration of HCQ-SAFE in clinics.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

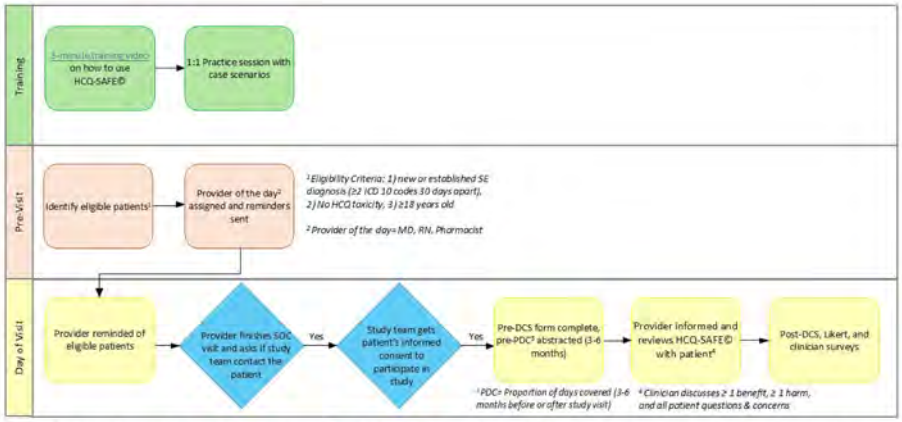

Figure 1B. An end-user-informed practical workflow for routine use of HCQ-SAFE shared decision-making intervention in clinics

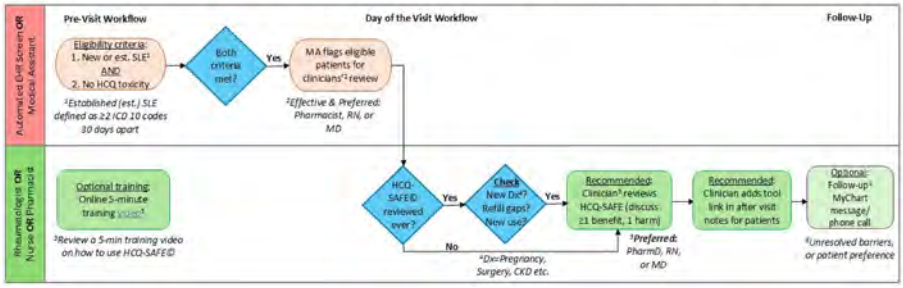

Figure 1A. Swim Lane diagram showing the study workflow used to implement the HCQ-SAFE shared decision-making intervention across 200 unique patient visits in 8 clinics of 2 health systems; Figure 1B. An end-user-informed practical workflow for routine use of HCQ-SAFE shared decision-making intervention in clinics

Results: In 200 visits, MDs (50%), PharmDs (28%), and RNs (22%) completed the HCQ-SAFE intervention (Table 1).

Data analysis showed excellent completion rates (100%) across MDs, PharmDs, RNs, with equally effective resolution of decisional conflicts regardless of clinician role (98% PharmD/RN vs. 99% MD; Table 1). Adoption was slightly lower among MDs (75%) vs. PharmDs/RNs (100%). HCQ-SAFE was rated highly feasible (median score 9, median time 5 mins) and received 100% NPS, indicating strong clinician willingness for continued use.

Content analysis of clinician experiences using NPT yielded 6 strategies for HCQ-SAFE implementation (Table 2; Fig. 1B). Key recommendations included: tailoring training by role, simplifying eligibility to include all SLE patients, using PharmDs/RNs to lead reviews. Clinicians preferred this equally effective staff-led model for easier integration and facilitate team-based care. The revised clinical workflow (Fig. 1B) gained unanimous endorsement from participating clinicians.

Conclusion: The impact of this study is 2-fold. First, it establishes HCQ-SAFE is a highly feasible and effective SDM intervention for clinical use. Second, it delivers an end-user-informed practical workflow to ensure sustainable integration in clinics to promote medication adherence via SDM.

Background/Purpose: Hydroxychloroquine (HCQ) prolongs disease-free and damage-free survival in lupus (SLE). Yet, ~80% of patients stop taking HCQ resulting in poor outcomes including early mortality. High nonadherence could be linked to complexity in treatment decisions and lack of support in decision-making. Unable to weigh benefits vs. rare harms of HCQ and align treatment goals with values, patients have greater risk aversion leading to nonadherence. Shared decision-making (SDM) tools can support patient-clinician communication, align treatment goals with values, and motivate patient

Table 1. A Multivariable Linear Regression Model Showing Change in HCQ Adherence (Proportion of Days Covered (PDC)) After HCQ-SAFE© Review

Variables at study visit	Adjusted Mean Change in PDC (95% CIs)	p-value

participation in decision-making. Thus, we aimed to test the efficacy of an SDM tool (HCQ-SAFE©) in a) improving HCQ adherence; b) resolving decisional conflicts around HCQ in SLE.

Methods: HCQ-SAFE© (hcqsafe.medicine.wisc.edu) is a 5-domain pictorial e- and paper-tool highlighting key benefits vs. rare harms of HCQ, developed by our group in English & Spanish using a collaborative iterative process involving 30 advisors (Garg et al. 2023).

To test the efficacy of HCQ-SAFE©, we recruited 200 adults with SLE on HCQ across 8 clinics in 2 diverse health systems (NCT05922722). The primary outcome was HCQ adherence measured using proportion of days covered (PDC) 3-6 months before and after HCQ-SAFE© review; nonadherence defined as PDC < 80%. The secondary outcome was decision conflict scale (DCS) scores measured pre- and post-intervention using the low literacy 10-item DCS questionnaire (DCS scores range: 0 (best) - 100 (worst); ≥25 indicate high decisional conflicts). We used paired t-test and adjusted linear regression analyses to examine change in 1) HCQ adherence; 2) DCS scores pre- vs. post-HCQ-SAFE© review.

Results: Among 200 participants, 90% were women, 10% preferred Spanish, 54% had high decisional conflicts at baseline. SDM during visits was completed by MDs (50%), RNs (21%), and pharmacists (29%). Mean±SD time spent to review HCQ-SAFE© was 6±2 mins. Intervention completion rate was 100%.

Next, a significant increase in HCQ adherence (post-PDC) by 47% was noted after HCQ-SAFE© review compared to baseline HCQ adherence (pre-PDC) after adjusting (Table. 1). Using pre-PDC adherence categories of 0%, < 40%, 40-79%, ≥80% (Hsu et al, 2018), an increase in post-PDC adherence by 29%, 56%, and 81% was noted in 0%, < 40%, 40-79% categories vs. ≥80% category (reference) after HCQ-SAFE© review (Table 2).

After reviewing HCQ-SAFE©, a 22-point and a 44-point reduction in DCS scores was seen in all patients ($p < 0.001$; Fig 1A), and those with high DCS (≥25) at baseline (Fig. 1B), respectively. After adjusting, a 35-point reduction in DCS was noted post-intervention in patients with high DCS at baseline (Fig 1C).

In analysis stratified by language, clinician, and education level, similar significant reductions were seen in DCS scores and PDC after HCQ-SAFE© review ($p < 0.0001$, data not shown).

Conclusion: HCQ-SAFE© provides clear, concise information, reducing decisional conflicts and significantly improving adherence across SLE populations. SDM tools like HCQ-SAFE© can mitigate nonadherence due to limited health literacy, linguistic clarity, lack of decision support, potentially improving SLE outcomes.

Abstract Number: 1052

"prednisone… a Necessary Evil…" Developing an Evidence-based Benefits vs. Harms Shared Decision-making Tool (PRED-SAFE) to Support Decisions Around Chronic Prednisone Use

Isabella Hartel[1], Jay Patel[1], Justin Levinson[1], Sancia Ferguson[2], Carmen Campbell[1], Amannda Weber[3], Shelby Gomez[4], David Gazeley[5], Ali Duarte-Garcia[6], Jennifer Barton[7] and **Shivani Garg**[8], [1]University of Wisconsin, School of Medicine and Public Health, Madison, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, Madison, WI, [3]University of Wisconsin (UW), UW Health, Madison, WI, [4]University of Wisconsin, School of Pharmacy, Madison, WI, [5]Medical College of Wisconsin, Milwaukee, WI, [6]Mayo Clinic, Rochester, MN, [7]VA Portland Health Care System/OHSU, Portland, OR, [8]University of Madison, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Guidelines recommend limiting chronic prednisone use (>5 mg/d for >3-6 mos.) given higher risks of fractures, infections, and damage. Yet, patients struggle to stop/reduce prednisone due to its perceived rapid benefits despite long-term harms. Shared decision-making (SDM) tools can help clinicians facilitate difficult conversations and support patients in such decisions. There are no feasible SDM tools for chronic prednisone use. Thus, we developed and piloted the PRED-SAFE SDM tool to resolve decisional conflict around chronic prednisone use.

Methods: PRED-SAFE was created using a collaborative process involving a multidisciplinary panel of patients, clinicians, implementation scientists, designers, and literacy experts across 4 institutions (n=23; Fig 1). Initial prototypes were informed by AHRQ low literacy and SDM tool development guidelines, key themes about prednisone in literature and based on interviews with patients, clinicians, experts (n=23). The multidisciplinary panel reviewed the first prototype and guided an iterative process to revise subsequent prototypes until a final version was endorsed by all 23 advisors. The final PRED-SAFE SDM tool was implemented in 4 clinics during 30 visits to examine usability and feasibility. Usability was measured by patient-reported understanding of cumulative harms vs. limited benefits with chronic prednisone use and resolution of decisional conflict using SURE scale (Score >3 shows no residual decisional conflicts) post PRED-SAFE. Using a 1-9 Likert scale (9 = best) to measure users' likelihood to recommend PRED-SAFE, we estimated Net Promoter Score (NPS = %promoters (extremely/very likely) - % detractors (extremely/very unlikely)). Feasibility of tool use in clinics was assessed using clinician-reported time to review and feasibility & likelihood to use on a 1-9 Likert scale (9=best).

Results: PRED-SAFE SDM laminated tool organized data in pictograms across 6 domains: a) bone fracture, b) infections, c) organ damage, d) cardiovascular disease (CVD), e) flares, f) taper (Fig 2A-D). During visits, a patient & clinician first reviewed increased chances of fracture with chronic prednisone vs. dose ≤5mg/d, followed by higher chance of infections, organ damage, and CVD with chronic prednisone. Limited benefits of chronic prednisone included slight decline in flares with >5mg/d. Finally, steps to taper prednisone were reviewed (Fig 2A-D).

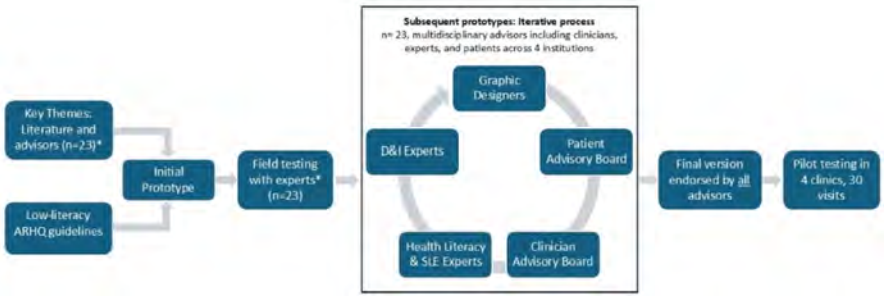

Figure 1. A Collaborative and Iterative Process to Develop PRED-SAFE, a Benefits vs. Harms Shared Decision-Making Tool Around Chronic Prednisone Use

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Abstract Number: 1053

Trends in Cost and Utilization of Biologic Medications for Rheumatologic Conditions: A Medicare Claims Study (2013–2022)

Taylor Koenig, Cleveland Clinic, Rocky River, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1038–1054) Health Services Research Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Biologic therapies have transformed rheumatologic disease management over the past two decades. As utilization of these high-cost medications increases and additional biologic and biosimilar therapies enter the market, understanding their financial and economic impact on the healthcare system is critical. Given rising Medicare part D drug spending, insights from longitudinal cost data can inform future policy and highlight areas for cost containment. This study leverages national Medicare Part D data from 2013 to 2022 to evaluate the cost of biologics prescribed for rheumatologic conditions with focus on the influence of market competition.

	Xeljanz		Olumiant		Rinvoq		Actemra		Kevzara		Orencia	
30-day Rx	#/year	Cost	#/year	Cost	#/year	Cost	#/year	Cost	#/year	Cost	#/year	Cost
2013	5,556	$2,640.00					2,513	$1,811.50			23,228	$2,898.84
2014	22,171	$2,872.00					7,009	$2,233.74			30,599	$3,241.78
2015	35,806	$3,277.00					11,340	$2,682.51			34,502	$3,748.96
2016	43,160	$3,992.00					14,375	$3,034.07			38,483	$4,173.32
2017	64,301	$4,435.00					17,206	$3,411.46	177	$3,552.54	39,422	$4,435.79
2018	92,577	$4,692.00	114	$2,400.00			23,863	$3,732.68	2,623	$3,624.94	41,664	$4,722.99
2019	111,371	$4,912.00	2,652	$2,456.00	199	$5,618.00	24,570	$3,662.45	6,847	$3,830.70	45,680	$4,859.90
2020	123,019	$5,037.00	3,588	$2,519.00	23,403	$5,486.00	28,020	$3,709.64	8,011	$3,951.23	49,932	$5,039.74
2021	119,471	$5,195.00	3,333	$2,635.00	48,768	$5,863.00	32,694	$3,720.86	8,188	$4,078.71	54,987	$5,202.69
2022	98,484	$5,200.00	3,240	$2,618.00	65,400	$5,935.00	39,394	$3,517.94	10,271	$4,061.33	65,669	$5,144.49

Figure 1. Annual number of and cost per 30-day prescription for selected biologics for rheumatologic indications 2013-2022. Cost is adjusted for inflation using Medical Care Consumer Price Index. As Olumiant, Rinvoq, and Kevzara entered the market during the study period, data reporting for each drug begins in the year it received FDA approval.

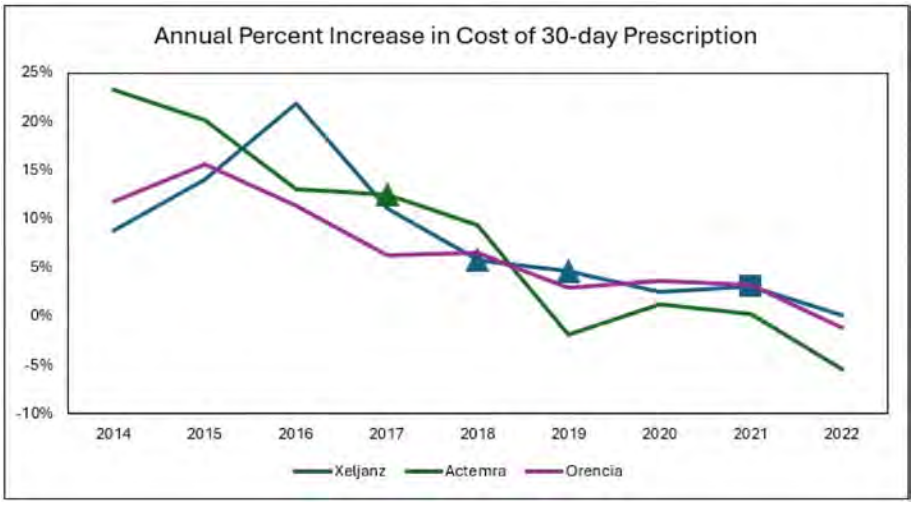

Figure 2. Comparison of the annual percent increase in cost of 30-day prescription for Xeljanz, Actemra, and Orencia 2014-2022. Triangles denote years in which a same-class drug came to market. The square denotes the year of the introduction of Xeljanz's black box warning.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

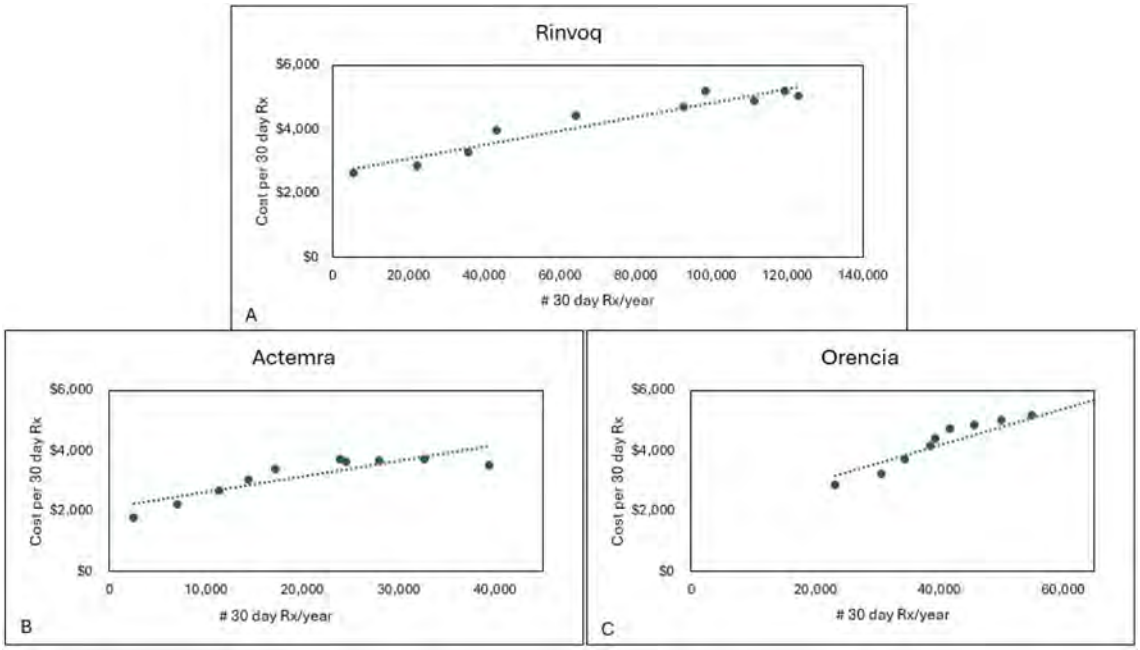

Figure 3. Correlation of annual number of 30-day prescriptions and cost per 30-day prescription for (A) Rinoq, (B) Actemra, and (C) Orencia.

Methods: This is a retrospective analysis of publicly available Medicare Part D Prescription Drug Event Data from 2013 to 2022 for Xeljanz, Olumiant, Rinvoq, Actemra, Kevzara, and Orencia. For each medication, the total number of prescribers, claims, and 30-day prescriptions as well as the total cost per year were captured. Claims attributed to non-rheumatologists were excluded. All cost values were inflation-adjusted to 2022 US dollars using the Medical Care Consumer Price Index. Trends were analyzed to evaluate changes in utilization and cost over time.

Results: The number of and cost per 30-day prescriptions increased annually, outpacing inflation, for all biologics from 2013-2022 (Figure 1). While 30-day prescription costs increased overtime, the annual percent increase declined during the study period for Xeljanz, Actemra, and Orencia (Figure 2). While additional JAK inhibitors and an IL-6 inhibitor received FDA approval and entered the market during this period, ANOVA showed no significant difference in this decline among these three drugs ($F(2, 24) = 0.094$, $p = 0.91$), including Orencia which lacks a direct market competitor. A strong correlation was also observed between drug cost (30-day prescription cost) and utilization (annual number of 30-day prescriptions) as seen in Figure 3 ($r = 0.96$ (Xeljanz), 0.76 (Olumiant), 0.82 (Rinvoq), 0.86 (Actemra), 0.96 (Kevzara), 0.91 (Orencia)).

Conclusion: This analysis demonstrates that the cost of biologics continues to increase, surpassing inflation. While the rate of increase is declining, these results suggest that market competition alone may not be a sufficient mechanism for controlling drug prices. Notably, the rate of decline in annual cost increases was similar across Xeljanz, Actemra, and Orencia—despite Orencia lacking a direct market competitor during the study period. This finding challenges the assumption that the entry of new therapies, including biosimilars, will lead to substantial price reductions. As biosimilar availability expands, their ability to generate meaningful cost savings may be more limited than anticipated. These results highlight the need for broader policy interventions and innovative reimbursement models to effectively address the growing burden of drug spending in rheumatology.

Abstract Number: 1054

Comedication Patterns of Romosozumab Early Adopters Among Medicare Enrollees: An Unsupervised Clustering Approach

Ye Liu[1], Hongke Wu[1], Tarun Arora[2] and Jeffrey Curtis[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]FASTER, Birmingham, AL, [3]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1038–1054) Health Services Research Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Polypharmacy is a major concern in osteoporosis (OP) management, especially in older adults. Romosozumab (romo), approved in April 2019, is a parenteral OP medicine for postmenopausal women at high fracture risk, given monthly for 12 months. We examined comedication patterns among early romo adopters and their association with treatment adherence. This study aimed to evaluate comedication patterns among early romo users.

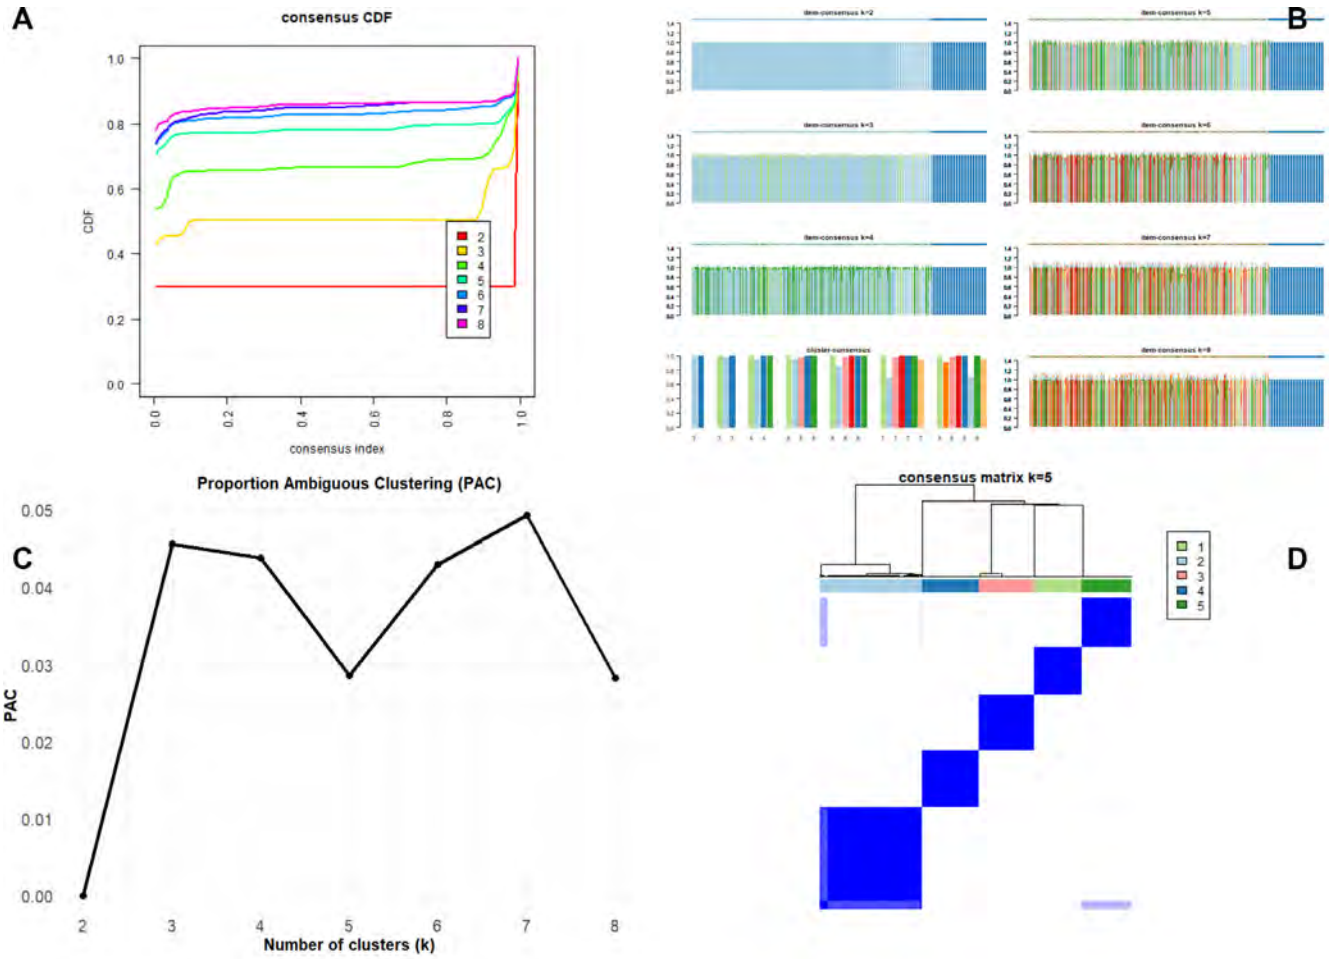

Figure 1. Diagnosis panel of consensus clustering analysis to determine optimal number of clusters (k)
A: Consensus cumulative distribution function (CDF) plot. B: item-consensus plot
C: Proportion ambiguous clustering (PAC) plot. D: Consensus matrix at optimal k = 5

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This retrospective cohort study used Medicare fee-for-service data (2006-2022) to identify female romo early adopters aged 65+ who initiated romo in 2019, with>=4 years of continuous enrollment, including 3 years pre-initiation. Those with metastatic cancer or Paget's disease were excluded.

We identified all prescription drugs covering the romo initiation day and selected 8 major medication categories for clustering: anti-hypertension (HTN), lipid-lowering, anti-diabetic, antidepressants, hypnotics, NSAIDs, opioids, and steroids. We used hierarchical agglomerative clustering to identify comedication patterns, with consensus clustering analysis to determine the optimal number of clusters.

We explored the association between comedication groups and romo discontinuation, defined as >= 60 days without injection, using a Cox proportional hazard model, adjusting for age, race, geographic region, Charlson comorbidity index (CCI), had emergency room visit, fracture history, romo billing in Part D, DXA scan, and prior OP treatment history. Patients were not considered discontinued after they completed 12 doses or 1 year of romo treatment.

Results: A total of 1,777 romo early users were included (mean age: 77.7 years; 90.9% White). Consensus clustering analysis identified 5 mutually exclusive comedication pattern groups (see Figure 1 for details):

1 (N=326). No patients used any pre-specified drugs of interest.

2 (N=275). All used anti-HTN only.

3 (N=281). All used lipid-lowering drugs, some (67%) also used anti-HTN.

4 (N=313). All used antidepressants, some also used anti-HTN (57%) and/or lipid-lowering (41%) drugs.

5 (N=582). Various drugs (>=1 of the 8 categories, not in other groups).

Patients in group 2 were the oldest (79.4 years, $p< 0.001$) and had the highest proportion from the South (47.3%, p=0.013). Group 5 had the highest CCI (4.8, $p< 0.001$) and the lowest percentage of White patients (88.5%, p=0.001). No significant differences in fracture or OP treatment history were observed. One-year overall romo discontinuation risk was 32.2% [29.1%, 35.7%]. Compared with group 1, all groups had higher discontinuation risk, with group 4 (HR=1.41 [1.14–1.76]) and group 5 (HR=1.39 [1.14–1.69]) significant after adjusting for covariables.

Conclusion: Distinct comedication patterns were identified among romo early adopters. Patients using antidepressants or multiple medication categories had a higher discontinuation risk and needed additional adherence support.

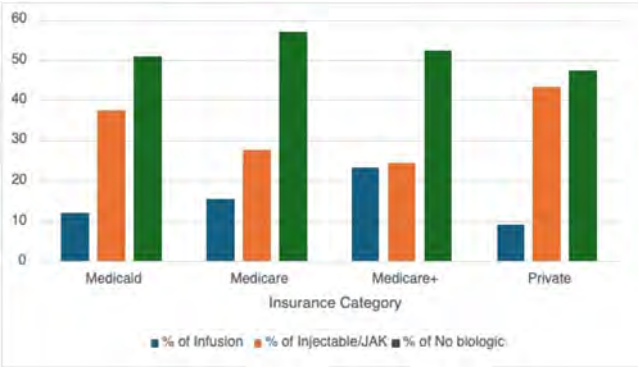
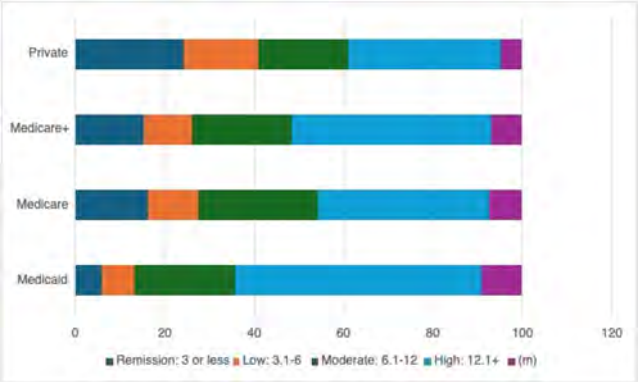
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: High-cost biologic therapies are integral to the management of rheumatoid arthritis (RA), yet access to these agents may be influenced by insurance type, particularly among publicly insured patients who may lack access to copay assistance. This study evaluated whether insurance category is associated with disparities in biologic prescribing patterns and remission outcomes among RA patients.



Graph 1: Comparing percentage of Infusion, Injectable/JAK & No Biologic use as a function of Insurance status



Graph 2: Patient reported outcome (RAPID3) scoring as a function of insurance status

Table 1: Comparing patient demographic as a function of insurance status

Table 1. Demographics as a Function of Insurance				
Insurance	**Medicaid**	**Medicare**	**Medicare+**	**Private**
Seropositivity	56.70%	65%	50.40%	59.50%
ECI	1.82 ± 6.89	3.073 ± 6.618	2.572 ± 6.243	0.196 ± 5.701
ADI	75.9 ± 18.5	62.85 ± 24.26	57.59 ± 25.13	58.57 ± 24.03
Total DMARDs	3.56 ± 2.08	3.92 ± 2.48	4.01 ± 2.75	3.6 ± 2.17

Methods: A retrospective chart review was conducted of 466 adult RA patients receiving care at a single academic medical center. Patients were stratified into four groups: private insurance, Medicaid, Medicare, and Medicare with supplemental coverage ("Medicare+"). Variables collected included current treatment regimen, route of biologic administration (infusion vs. injectable, including JAK inhibitors), radiographic erosions, seropositivity, demographics, Area Deprivation Index (ADI), Elixhauser Comorbidity Index (ECI), and patient-reported outcomes using the Routine Assessment of Patient Index Data 3 (RAPID3). Multivariable logistic regression analysis was used to assess associations between insurance type and biologic use/remission, adjusting for age, sex, race/ethnicity, and seropositivity.

Results: Biologic use was highest among privately insured patients (52.6%) compared to those with any form of government insurance (45.7%), with the lowest rates observed in Medicare patients (42.5%). Privately insured patients were also more likely to use injectable therapies compared to Medicare and Medicare+ groups (Graph 1). Remission, as assessed by RAPID3, was more common in the privately insured group, with notably lower rates among Medicaid patients (Graph 2). No significant differences were observed across insurance groups in seropositivity, prior treatment history, ECI, or ADI that could account for these disparities (Table 1).

Conclusion: Our project's findings highlight a 10% disparity in biologic prescribing and patient-reported remission between Medicare and privately insured patients with RA. Moreover, large differences were found in the RAPID3 based on insurance status. While limited by its retrospective, cross-sectional design and single-center sample, this study raises important questions about insurance-related barriers in rheumatologic care. Further research is warranted to explore systemic contributors to treatment inequities and to guide policy aimed at improving equitable access to high-cost therapies.

Abstract Number: 1056

High diagnostic rate of genetic testing in adult patients with autoinflammation: A Single Center Experience

Atif Towheed[1], Joshua Owens[2], Ann Parody[1] and Daniella Schwartz[3], [1]University of Pittsburgh Medical Centre, Pittsburgh, [2]UPMC Children's Hospital of Pittsburgh, Pittsburgh, [3]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Inborn errors of immunity (IEI), including autoinflammatory diseases and primary immune regulation disease (PIRD), are unfamiliar to many adult rheumatologists, leading to potential ascertainment bias and health disparities for adults with suspected IEI. While genetic testing is a cornerstone for diagnostic testing in pediatric autoinflammatory clinics, data from adult rheumatology clinics are limited. This study evaluates genetic diagnostic rates in an adult cohort with suspected IEI, including autoinflammatory diseases, at a single tertiary care center, comparing outcomes to pediatric benchmarks.

Methods: We retrospectively analyzed a cohort of 155 adult patients referred to our rheumatology immunogenetics clinic between 2022-2025 for suspected IEI, including autoinflammatory syndromes and PIRD. Patients underwent targeted array-based genetic testing (n = 68, 574 genes); somatic variant testing for *UBA1* and other genes associated with

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. myelodysplastic syndrome (MDS) (n = 6, 302 genes); or whole exome sequencing (n = 2) to identify potential disease-causal or disease-contributory variants. Clinical phenotypes, inflammatory markers (CRP, ESR, SAA, ferritin, 28-gene interferon score, S100A8/9, S100A12), family pedigrees, and demographic data were correlated with genetic findings. Variants were classified per American College of Medical Genetics and Genomics guidelines.

Results: Variants of interest (pathogenic, likely pathogenic, variant of uncertain significance/VUS) were identified in 30% (24/80) of the tested patients. Of these, 24 were ACMG P/LP and 70 were VUS. Functional testing revealed a potential causal role for 24 genes and contributory for 45 genes. IEI diagnoses included familial Mediterranean fever, HA20, NAIAD, DiGeorge syndrome, Trisomy 8, and others. An additional 45 patients were found to have variants that were not disease-causal but affected management (i.e. enhanced cancer screening) due to risk for other conditions. Of the six patients tested for VEXAS, four had pathogenic *UBA1* variants, and one had clinically significant MDS-associated variants in other genes. The genetic diagnostic rate was comparable to pediatric IEI cohorts (15–35%). Approximately 60% of patients did not obtain a genetic diagnosis; this could be to variants in novel IEI-causal genes or to non-genetic etiologies.

Conclusion: This single-center study demonstrates that rheumatology immunogenetics clinics achieve similar genetic diagnostic rates (33%) in adult and pediatric cohorts, underscoring the prevalence and significance of IEI in adults. The identification of VEXAS and MDS-causal variants further highlights the clinical relevance of targeted testing in this population. These findings advocate for increased availability of adult immunogenetics clinics to enable personalized management and genetic counseling. Multicenter studies are needed to validate novel variants and address undiagnosed cases.

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Social risk factors, such as housing instability, influence care access and outcomes in people with rheumatic conditions. In June 2022, 9 rheumatology clinics in a multihospital medical center began to screen patients for social risk factors. In September 2024, the Massachusetts Department of Public Health issued an alert of increased tuberculosis (TB) in Boston homeless shelters. Patients with systemic rheumatic conditions have higher TB infection risk and poorer outcomes; immunosuppressive medications heighten risk. We aimed to leverage the social risk screening infrastructure to rapidly respond to TB spread among homeless individuals with rheumatic conditions.

Methods: Using the Research Patient Data Registry and manual electronic health record (EHR) review, we identified patients with ≥1 ICD-9/10 code for a systemic rheumatic condition receiving ≥1 immunosuppressive or immunomodulatory medication who indicated that they did not have housing, lived in a shelter, or on the street on their most recent social risk screening. The rheumatology-based social risk screening team met with infectious disease (ID) specialists to develop protocols, and we alerted rheumatologists of patients at high risk for TB with a description of their patients' risk factors, and instructions to screen for active and latent TB. We reviewed the EHR to determine provider response (Figure 1). If no action was taken, we sent a reminder. The EHR was reviewed after 2 months. Rheumatologists were surveyed for feedback.

Results: Thirty-three patients with systemic rheumatic conditions experienced housing instability. Of these, 23 (70%) patients cared for by 17 rheumatologists were prescribed ≥1 immunosuppressive or immunomodulatory medication (Table 1). After the first alert, 3 (13%) patients had documentation of TB symptom screening, one provider responded that their patient was not homeless, and one ordered an interferon-gamma release assay ("T-SPOT"). Providers for two (9%) patients prescribed hydroxychloroquine were notified in case there was a therapy escalation plan, but a reminder was not sent due to lower risk. After the second alert, 7 (30%) T-SPOT tests were ordered. One patient self-reported a negative T-SPOT. Four (17%) patients had EHR documentation of symptom review at their subsequent rheumatology appointment, and 3 (13%) patients were messaged about their TB risk. Two (9%) patients had chest imaging ordered. There were no

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1.

referrals to ID and no action taken for 4 patients. Among the 41 rheumatologists who responded to the survey, 18 (45%) received an alert for ≥1 patient. Of those, 4 (22%) found it somewhat helpful, 5 (28%) found it very helpful and 16 (89%) indicated that the alert prompted action.

Conclusion: The social risk screening infrastructure in rheumatology facilitated a rapid response to a public health concern. Rheumatologists' responses varied, possibly due to increased clinical stressors with limited support. While there were challenges reaching patients with social risk factors, actions were taken for most. Efforts are now underway to prompt yearly TB screening for patients who indicate housing instability.

Prevalence of Depression Associated with Rheumatologic Medications with Labeled Warnings: Real World Evidence from a Tertiary Care Center

Cassandra Dolecki[1], Sama Hajizadeh[1], Yue Yin[2] and Adam Dore[1], [1]Allegheny Health Network, Pittsburgh, PA, [2]Allegheny Health Network, Pittsburgh

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: The prevalence of depression in patients who have rheumatic diseases is high and has been shown to be associated with poorer outcomes. Additionally, certain medications for rheumatologic conditions have been associated with an increased risk of depression, depressed mood, and suicidal ideation, namely apremilast and belimumab. Patient Health Questionnaire (PHQ9) screening is a well-established tool in screening for depression at medical appointments, including those with rheumatic diseases. A score of 10 or higher is a standard cut point to diagnose depression. This study assessed PHQ9 scores for patients with psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE) on apremilast and belimumab, respectively.

Methods: The study population included patients with PsA and SLE seen within Allegheny Health Network rheumatology clinics between November 2021 through November 2024 with at least one PHQ9 score documented. Demographic and clinical variables were collected. Descriptive statistics were used to describe the patient population. PHQ9 scores for persons with PsA were compared based on apremilast usage, and scores for patients with SLE were compared based on belimumab usage. The Kruskal-Wallis test was conducted to compare the PHQ9 score amongst the two patient populations. Fisher's exact test was performed to examine the association between PHQ9 category with medications.

Results: At least one PHQ9 score was documented for 1738 patients with PsA, and 892 patients with SLE (Table 1). Of the patients with PsA, 96 (5.52%) were treated with apremilast. There was no significant difference in median PHQ9 scores between patients that were on apremilast compared to those that were not (median 0 [IQR 0-0], median 0 [IQR 0-0]; p=0.2076). In addition, when stratified by apremilast usage, there was no significant difference found in patients with PsA who had PHQ9 scores of ≤9 compared to those with a score of ≥10 (p=0.2899; Table 2).

Of the patients with SLE, 36 (4.04%) were treated with belimumab. There was no significant difference in median PHQ9 scores between those treated with belimumab compared to those that were not (median 0 [IQR 0-1.5], median 0 [IQR

Table 2. PHQ9 Category Comparison Among Medication Groups and Diagnoses

Disease	Variable	PHQ-score category		P value
		≤9	>9	
PsA	Medication			.2899
	Apremilast	95(5.69%)	1(1.47%)	
	No med	1561(93.47%)	67(98.53%)	
	Other	14(0.84%)	0(0%)	
SLE	Medication			.1296
	Belimumab	31(3.69%)	5(9.62%)	
	No med	803(95.71%)	47(90.38%)	
	Other	5(0.60%)	0(0%)	

0-0]; p=0.0995). And when stratified by belimumab usage, there was no significant difference in the SLE patients with PHQ9 scores of ≤9 compared to those with a score of ≥10 (p=0.1296; Table 2).

Conclusion: In this single center observational cohort, we found that PHQ9 scores were no different between patients with PsA treated with apremilast compared to those not; and no difference between patients with SLE treated with belimumab compared to those who were not. The overall positive depression screening was low in all patients. This provides real world assurance of the safety of apremilast and belimumab, but should not underscore the importance of monitoring depression in rheumatologic diseases.

Abstract Number: 1059

Assessing the Relationship Between Multidimensional Area Level Indicators and Lupus Disease Activity in Children

Chelsea Reynolds[1], Natasha Ruth[2], Paul Nietert[1], Mileka Gilbert[1], Emily Vara[1] and Joyce Chang[3], [1]Medical University of South Carolina, Charleston, SC, [2]Medical University South Carolina, Charleston, SC, [3]Boston Children's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Recent research suggests that multidimensional area-level indicators, including the Social Vulnerability Index (SVI), Area Deprivation Index (ADI) and Childhood Opportunity Index (COI), associate with childhood-onset systemic lupus erythematosus (cSLE) outcomes in primarily urban populations. However, to date, there are no studies that have assessed the utility of multidimensional area level indicators in children with cSLE living in rural areas. The goal of this study is to estimate relationships between neighborhood conditions and disease activity in children with cSLE who live in a mixed rural and urban setting. We hypothesized that patients with cSLE living in areas with higher social vulnerability and area-level deprivation have increased lupus activity.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We retrospectively evaluated electronic health record data for pediatric patients with cSLE across three pediatric rheumatology clinics at a single center between January 1, 2020 and December 31, 2024. We included patients with a diagnosis of cSLE before 18 years of age, a residential address within South Carolina, and excluded PO box addresses. Chart reviews were conducted to collect demographic data and addresses were linked to census tract-level indicators, including ADI, SVI and COI, ranked at state and national levels. We assessed each patient's SLEDAI-2K score at their first clinic or hospital encounter associated with a SLE diagnosis.

Results: Baseline characteristics have been established for a cohort of 85 children with cSLE. The majority of patients identified as Black 65 (79%), followed by White 11 (13%), Latino/a 6 (6%), Asian 1 (1%), and Other 1 (1%). The cohort was predominantly female (87.1%), with a mean age at diagnosis of 13.0 years (range: 6–17). The mean SLEDAI-2K at the initial encounter was 14.4 (range: 0-38). Most participants (40%) lived in areas with low state-ranked SVI scores (mean 0.42), with no significant correlation with initial SLEDAI-2K (R= 0.014). National SVI levels were higher, with most patients classified in medium-to-high (51.2%) SVI category (mean 0.69), with no significant correlation with initial disease activity (R = 0.0223). Similarly, neither state nor national ADI rank correlated with initial SLEDAI-2K (R = 0.106 and 0.0905, respectively). Most patients lived in areas with very low (35.3%) state-ranked child opportunity and very low (38.8%) nationally ranked opportunity. Again, no significant correlation was found between COI and initial disease activity (R = 0.067 and 0.050, respectively).

Conclusion: In a mixed rural and urban population, we did not observe significant associations between area-level measures of social vulnerability, area deprivation or childhood opportunity (COI) and lupus disease activity, as measured by SLEDAI-2K score at initial presentation to rheumatology care. Despite the cohort's residence in predominantly deprived and low-opportunity areas, these indicators did not appear to predict lupus severity at first presentation to care. These findings highlight limitations in the use of available area-level indicators to explain pediatric lupus outcomes in mixed rural and urban areas.

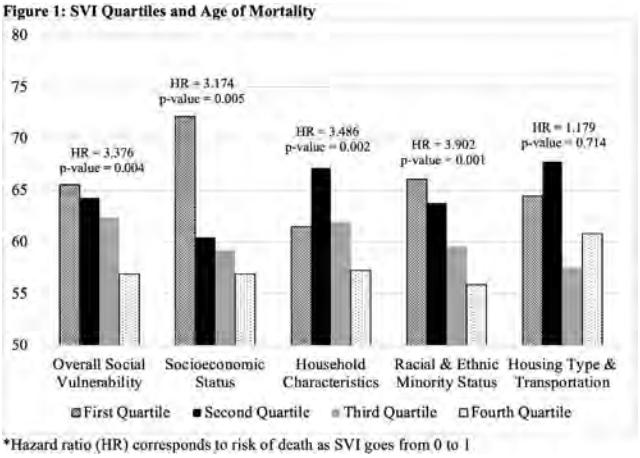
Figure 1: SVI Quartiles and Age of Mortality



*Hazard ratio (HR) corresponds to risk of death as SVI goes from 0 to 1

(SVI), developed by the Centers for Disease Control and Prevention (CDC), is a measure of demographic and socioeconomic factors that adversely affect health outcomes. We aim to determine the association between SVI and mortality in our lupus cohort.

Methods: This was a single-center retrospective study of all SLE patients hospitalized at the University of Rochester Strong Memorial Hospital between July 2016 and June 2023. We analyzed the age, race and ethnicity, mortality, and SVI among all those hospitalized. SVI is measured on a percentile ranking from 0 to 1, with higher percentiles indicating more social vulnerability. Additionally, SVI is divided into 4 subcategories (socioeconomic status, household characteristics, racial & ethnic minority status, and housing type & transportation) which are also assessed on a percentile scale from 0 to 1. The SVI and the scores of the 4 subcategories were determined based on publicly available CDC data and the patient's current addresses. The ANOVA and chi-squared tests were used to assess differences in demographic risk factors and mortality. The Cox regression was used to assess the hazard ratios for SVI and its subcategories.

Results: A total of 405 patients met criteria for a diagnosis of SLE. There were 75 deaths during the specified time period (Table 1). The mean age of death for the entire cohort was 61.51 years. The mean age of death for those patients identifying as White was 69.59 years, 55.72 years for Black patients, and 49 years for Hispanic patients (p-value = 0.0019) (Table 2). Although the age of mortality was not significantly different between females and males (61.46 vs 61.71 years, p-value = 0.9583), there was a significant difference in mortality rates (16.6% in females vs 34.9% in males, p-value = 0.0035). The average age of death of patients in the first quartile of SVI was 65.53 years of age compared to 56.81 years of age for patients in the last quartile of SVI. Patients of higher social vulnerability had a significantly higher risk of death with a hazard ratio of 3.38 (p-value = 0.004) (Table 2, Figure 1). Higher percentile scores were associated with significantly higher risk of death for all subcategories of SVI, except for housing type & transportation (Table 2, Figure 1).

Conclusion: There is a significant difference in age of mortality among hospitalized SLE patients based on race. Additionally, patients with a higher social vulnerability score are at a higher risk of death. Among the four subcategories of social vulnerability, socioeconomic status, household characteristics, racial & ethnic minority status contributed to significantly increased risk of death while housing type & transportation did not. Providing additional care and developing specific interventions to overcome barriers to care may help reduce mortality among lupus patients with high SVI scores.

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Hepatitis B virus (HBV) screening is insufficiently completed prior to initiation of immunosuppressive therapy nationwide. Various factors including alert fatigue, provider mistakes, non-compliance, and EMR faults / errors all play a role in leading to insufficient screening. HBV status is often difficult to ascertain given the indolent and asymptomatic nature of HBV progression. Immunosuppression can lead to HBV reactivation. Concerningly, the prevalence of HBV is higher in veterans than the general population at up to 1.0%, highlighting the increased importance of screening within this specific population (1). Additionally, prevalence is also higher within the Black American population as compared to others. While HBV screening rates within various Veterans Affairs Medical Centers (VAMC) facilities have been studied with regards

to prescribing Rituximab, which likely has the highest risk of reactivation, less research has been conducted to analyze screening rates before start of a wider array of anti-rheumatic medications, highlighting the need for further research.

Methods: A five-year retrospective study was performed reviewing HBV serologies – including HBV core Ab, surface Ag, and HBV DNA in patients who were started on immunosuppressive therapy within our rheumatology clinic at the VAMC in Memphis, TN. Using collected data from the pharmacy, patients were extracted who had previously been prescribed csDMARDs, bDMARD, and small molecules. The study period was set from 1/1/2017 to 12/31/2022. To more directly identify how well we were screening patients with a statistically higher risk of HBV infection, past or present, Black Americans within our clinic were specifically studied, with plans to study data from other races in the future as a comparison.

Results: Within our study period, 551 instances were found in which Black American patients had been prescribed medications from the list above. Out of these 551 patients, 75.9% had HBV screening labs prior to initiation of DMARD therapy. However, only 32.7% of patients had screening labs within six months of starting treatment. For those that did not have labs checked prior to start of treatment, 33.7% of these patients had labs checked within six months after starting treatment. Out of our population, 11.2% were HBV core Ab positive. Of these patients, 79% were sent to Hepatology and 50% were started on antiviral prophylaxis. No episodes of HBV reactivation leading to fulminant hepatitis or clinical deterioration / death were identified.

Conclusion: Our findings suggest a large number of patients are not being appropriately screened prior to initiation of DMARDs. While no episodes of HBV reactivation leading to fulminant hepatitis or clinical deterioration / death were identified, further correction of this lack of pre-screening is critical to ensure safety of our patients, particularly within this veteran group who inherently are at a higher risk. We plan to study data from other races to determine if there are any statistical differences between the two groups to further help us implement quality initiatives to improve outcomes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Sex-related differences in axial spondyloarthritis (axSpA) have been described regarding clinical features, disease burden, and particularly patient-reported outcomes. These differences influence patient management, including diagnostic strategies and referral patterns. However, it remains unclear whether these sex-specific differences represent a distinct feature of axSpA or if similar patterns also occur in the broader population of patients with chronic back pain (CBP) without axSpA. The objective of this study is to assess sex differences in demographic and clinical features, including patient-reported disease activity and functional impairment, among young adults with CBP referred by non-rheumatology specialists.

Methods: A prospective, cross-sectional observational study was conducted between July 2021 and October 2023 as part of the "Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis" (SHERPAS) Cohort. Adults aged 18–40 years with CBP (>3 months duration) referred for spinal magnetic resonance imaging (MRI) by non-rheumatology specialists completed detailed questionnaires capturing demographic characteristics, lifestyle factors and patient-reported outcomes (PROs), including disease activity and functional impairment measured by BASDAI and BASFI. MRI imaging of the spine and sacroiliac joints (SIJ) were performed within two weeks, as well as a consultation with the rheumatologist. Diagnoses were based on expert clinical judgment considering imaging, clinical, and laboratory data. Only patients in whom a diagnosis of axSpA had been ruled out were included. Statistical comparisons by sex were conducted using appropriate parametric or non-parametric tests.

Results: Among 260 patients, 149 (57.3%) were female, and mean age was 34.6±5.6 years. While most demographic and clinical characteristics did not differ significantly by sex (**Table 1**), marked differences were observed in PROs. Female reported significantly higher overall BASDAI (4.9±2.5 vs 3.6±2.4; p< 0.001) and higher overall BASFI (3.7±2.7 vs 2.8±2.5; p=0.004) versus males. Concerning individual BASDAI items (**Figure 1**), female reported higher scores in fatigue (5.6 ± 3.1 vs 4.1 ± 2.9; p< 0.001), spinal pain (6.5 ± 3.0 vs 5.1 ± 3.2; p=0.001), peripheral pain (3.4 ± 3.4 vs 1.9 ± 2.7; p < 0.001), and general discomfort/enthesitis (5.2 ± 3.5 vs 3.3 ± 3.1; p < 0.001) than males. Female also had higher functional impairment in BASFI items, particularly showing greater difficulty reaching an object on a shelf

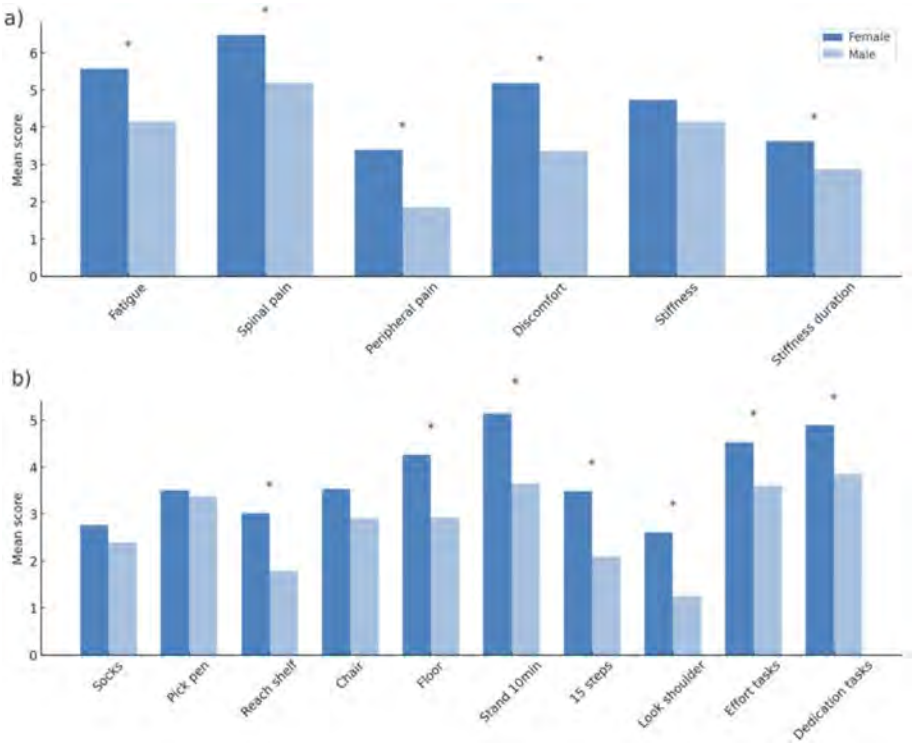

Figure 1. Items of BASDAI (a) and BASFI (b) stratified by sex

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(3.0 ± 3.4 vs 1.8 ± 2.8; p=0.002), rising from the floor (4.3 ± 3.7 vs 2.9 ± 3.3; p=0.002), standing for 10 minutes (5.1 ± 3.6 vs 3.7 ± 3.5; p=0.002), climbing 15 steps (3.5 ± 3.5 vs 2.1 ± 3.1; p=0.001) and turning the head over the shoulder (2.6 ± 3.3 vs 1.3 ± 2.4; p< 0.001).

Conclusion: Significant sex differences were observed in the clinical presentation of young adults with CBP, particularly in patient-reported disease activity and functional limitation scores. These findings suggest that sex-related disparities in disease burden are not specific to axSpA, highlighting the need for broader sex-sensitive strategies in the evaluation and management of all young patients with CBP.

Gender, Racial, and Geographic Trends in Mortality from Interstitial Lung Diseases Among Patients With Rheumatoid Arthritis in the U.S. Population, 1999–2020

Farheen Malik[1], Jawad Ahmed[2], Mandar Shah[1], Ritika Uttam[3] and Muhammad Fahimuddin[1], [1]Jacobi Medical Center, Bronx, NY, NY, [2]Northwest Health Porter, Valpraiso, IN, [3]Jacobi Medical Center, Bronx, NY

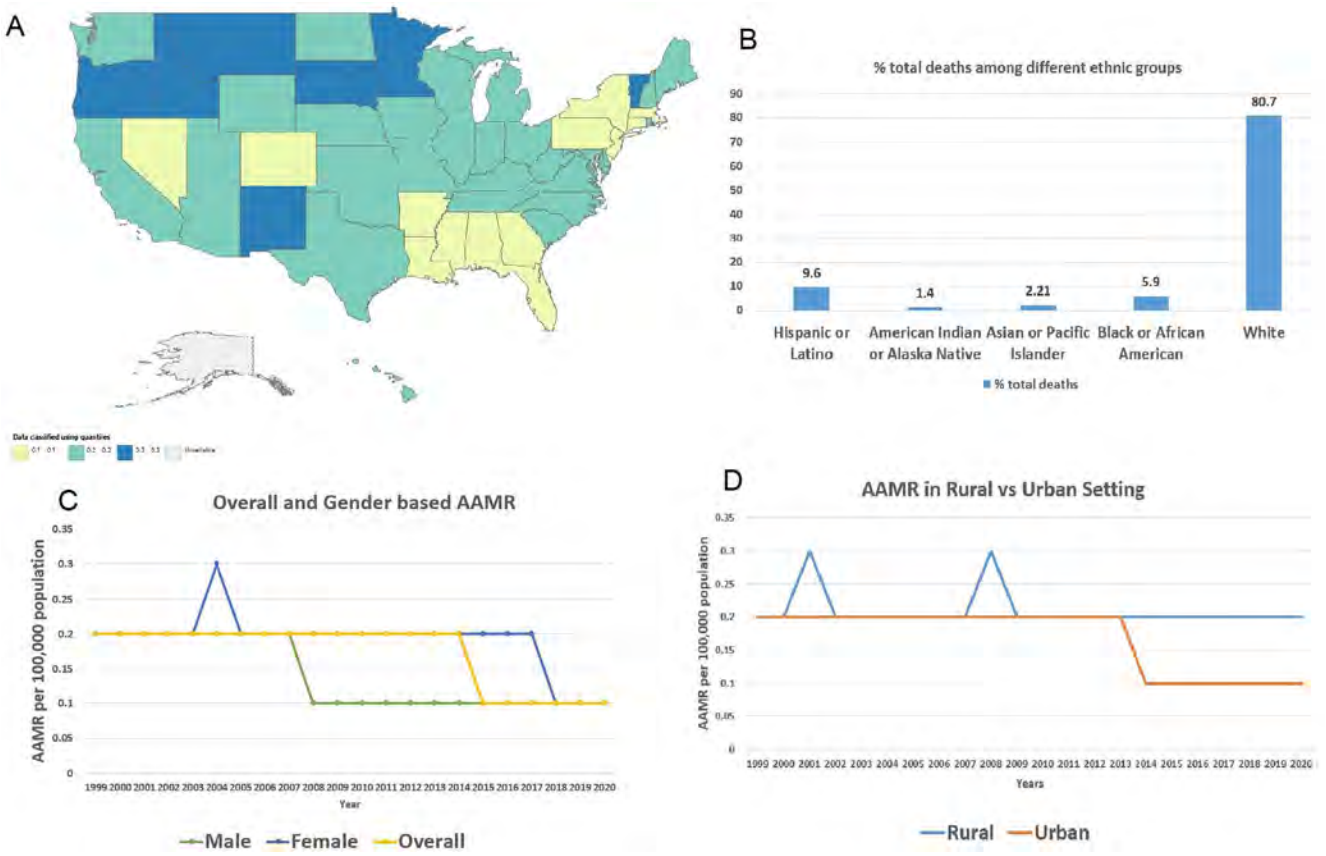
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a common autoimmune disease affecting up to 1.0% of the US population. RA is most commonly associated with synovial inflammation and articular symptoms but is also associated with extra-articular manifestations. Interstitial lung disease (ILD) is one of the most important and common pulmonary manifestations of RA and it is associated with significant morbidity and mortality. We aim to find variations in the mortality trend of ILD in RA patients.

Methods: Death certificates from the CDC Wonder Database were analyzed from 1999 to 2020 for ILD (J84.1) and RA (M05 and M06) patients. Age-adjusted mortality rates (AAMR) per 100,000 individuals, average annual percentage change (AAPC), and annual percent change (APC) with respective 95% CI were calculated and stratified for gender, racial, age, and geographic factors.

Results: A total of 10171 ILD and RA-associated deaths occurred between 1999 and 2020 with an overall AAMR of 0.2. AAMR declined from 0.2 in 1999 to 0.1 in 2020 with an AAPC of -3.08 (-4.79 to – 2.28; p< 0.01). From 1999 to 2014, a slight non-significant decrease was noted in mortality (APC -0.17), followed by a significant sharp decline from 2014 to 2017 (APC -24.09; p< 0.05)) and a gradual non-significant increase till 2020 (APC 6.70). Adults >55 years had higher AAMR

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Mortality Trends of Interstitial Lung Disease in Rheumatoid Arthritis Patients in the U.S. Population, 1999–2020. (A) By U.S. state; (B) By race/ethnicity; (C) By gender; (D) By rural vs. urban setting.

than the population < 55 years of age, and AAMR continued to increase as age increased. Females accounted for 63.5% (n=6463) of deaths and had higher AAMR of 0.2 compared to men (0.1) but had a sharp decline noted in AAMR from 2017 to 2020 (APC -24.97 [-43.01 to -2.83]). In the racial and ethnic groups, non-Hispanic (NH) Black or African American and Asian or Pacific Islanders had the lowest AAMR of 0.1 whereas the highest was observed in American Indian or Alaska Natives (0.5). White population accounted for most deaths reported (80.7%) and a significant downtrend was noted in the mortality trend from 2014 to 2020 (APC -11.99; p< 0.01). There was no difference in AAMR between Rural (0.2) and Urban (0.2) settings, but later had a falling mortality trend from 2013 to 2016 (APC -23.64 [-30.21 to -14.88], p< 0.01). The Northeast had the lowest AAMR of 0.1 whereas Midwest, South, and West had equally high AAMR of 0.2. Seven states (Idaho, Minnesota, Montana, New Mexico, Oregon, South Dakota, and Vermont) had the highest AAMR.

Conclusion: There has been a slight decrease in mortality rates from ILD in RA patients which could be due to advancements in treatment regimens. Females are more prone to developing autoimmune diseases, have higher AAMR, and therefore can contribute to a higher mortality burden. The older population was noted to have higher mortality rates. Noticeable differences were noted among different ethnic and racial groups as well as census regions and states in terms of mortality. Further research is warranted to identify the disparities noted.

Abstract Number: 1064

Characterization of Juvenile Idiopathic Arthritis in Indigenous North American Children enrolled in a North American registry

Hayley M Lynch[1], Jordan E. Roberts[1] and James N. Jarvis[2] For the CARRA Registry investigators, [1]Seattle Children's Hospital/UW, Seattle, WA, [2]University of Washington Center for Indigenous Health, Seattle, WA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Several studies detail a higher prevalence and severity of juvenile idiopathic arthritis (JIA) in Indigenous North American (INA) children compared to the general population. The reasons for this pattern are likely multifactorial, but efforts to investigate them are hindered by a paucity of data available for this population. The Childhood Rheumatology and Research Alliance (CARRA) registry offers a unique opportunity to investigate JIA in INA patients from across the U.S. and Canada using prospectively collected data confirmed by pediatric rheumatologists. We sought to characterize clinical presentation, serologic profiles and treatment course of JIA in the INA children captured in the CARRA registry.

Methods: Disease-related data was extracted from the CARRA registry for all participants of INA ancestry with a physician diagnosis of JIA. Data included sex-assigned at birth, self-identified ancestry, JIA subtype, serologies, age at diagnosis, presence of uveitis, and use of biologic medication. For the purposes of this study, participants with extended oligoarthritis were counted with those with polyarticular arthritis and sorted into sero-positive and sero-negative groups accordingly. Demographic data was also collected, including zip codes of participants.

Table 1: Characteristics of INA participants enrolled in the CARRA registry. The majority of participants were female, and polyarticular, RF-negative JIA was the most common subtype. Serology data for HLA-B27, RF, and CCP status was missing for 33-46% of participants; percentages were calculated using the total with a recorded result rather than the total number of participants in the study.

Category		INA (n,%)
Total		195
	Male	44 (23%)
	Female	151 (77%)
JIA Category		
	Oligoarticular	50 (26%)
	Polyarticular, RF neg (includes extended oligo)	75 (38%)
	Polyarticular, RF pos (includes extended oligo with RF+)	20 (10%)
	ERA	18 (9%)
	Psoriatic	14 (7%)
	Systemic JIA	11 (6%)
	Undifferentiated	7 (4%)
Serologic Status		
	ANA positive	95 (48%)
	HLA-B27 positive	23 (12%)
	RF Positive	21 (13%)
	Anti-CCP Positive	20 (19%)
Uveitis		25 (13%)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: Incomes for INA participants in US and Canada. Median income for U.S. participants fell between $50-74,999, while that for Canadian participants fell between $75-99,999.

Income Bracket	U.S. participants	Canadian participants
<$25,000	30	5
$25-49,999	38	3
$50-74,999	19	3
$75-99,999	18	4
$100-150,000	24	7
>$150,000	11	3
Not reported/unknown	20	10

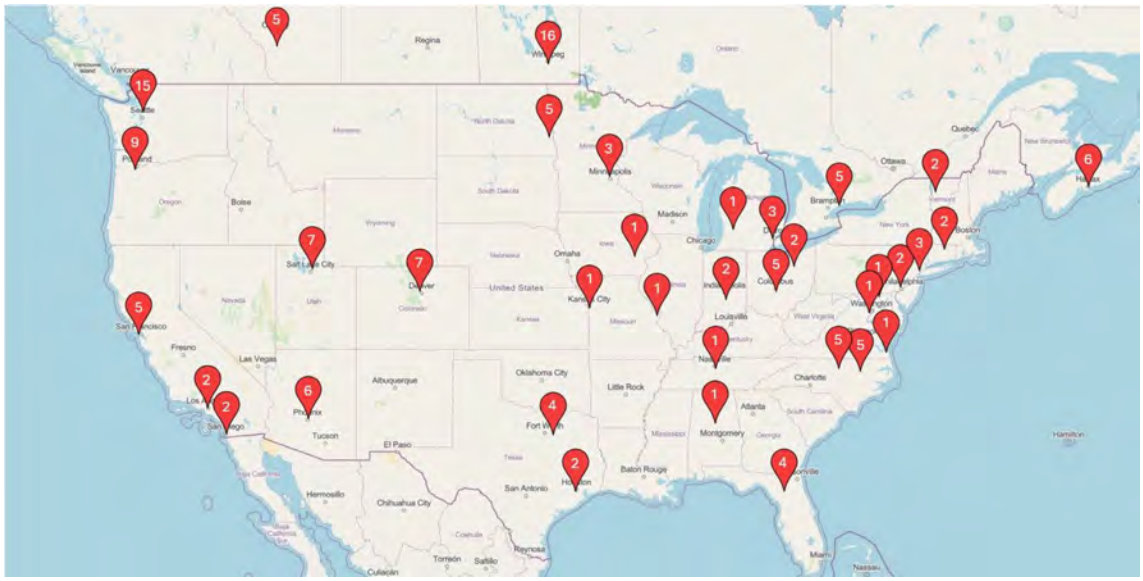

Figure 1: Map of CARRA enrollment sites with INA participants. Number of INA participants from each site indicated in the pin

Results: A total of 195 participants of INA ancestry are identified, making up approximately 1.7% of registry participants from the U.S. and Canada. Of these 195, 44 (23%) are male and 151 (77%) are female. Polyarticular, RF-negative arthritis was the most common subtype (38% of cases), followed by oligoarticular arthritis (26% of cases). 68% of INA participants received biologic therapies during their treatment. Figure 1 displays a map of enrollment centers with INA participants, and shows that only a small number of INA children were enrolled from the northern Great Plains, Canadian prairie provinces, and Alaska. The average distance traveled from home to enrollment site was 155 miles.

Conclusion: This is the first North America-wide survey of INA children with JIA using a national registry with prospectively collected data. We have characterized the disease presentation and treatment of these patients and analysis is underway to compare them with non-indigenous children in the registry. Further work is needed to evaluate the representativeness of INA children in the registry, and to identify opportunities to improve our understanding of JIA in this population.

Disclaimer: This study used data collected in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry. The views expressed are the authors' and do not necessarily represent the view of CARRA

Acknowledgements: This work could not have been accomplished without the aid of the following organizations: The NIH's National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS) & the Arthritis Foundation (AF). We would also like to thank all participants and hospital sites that recruited patients for the CARRA Registry.

Abstract Number: 1065

Age of Disease Onset and Risk of Serious Infection with Anti-tnf Use in Older Adults with Rheumatoid Arthritis

Jiha Lee[1], Sofia Pedro[2] and Kaleb Michaud[3], [1]University of Michigan, Ann Arbor, MI, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Older age is a recognized risk factor for serious infection (SI) associated with anti-TNF therapy in rheumatoid arthritis (RA). Among older adults with RA, one-third are diagnosed after age 60 (late-onset RA, LORA), while others are diagnosed earlier in life (young-onset RA, YORA). LORA is characterized by a more acute disease onset and higher inflammatory burden, potentially due to age-related immune dysregulation. However, it is unclear whether RA onset age independently influences infection risk associated with TNF initiation in older adults. This study examines SI risk in older adults with LORA versus YORA initiating anti-TNF therapy.

Methods: Using the FORWARD-The National Databank for Rheumatic Diseases data from 2001-2019, we studied RA patients aged ≥60 years who started anti-TNF therapy. Patients were categorized as LORA or YORA based on their age at RA diagnosis (≥60 or < 60 years) and propensity-matched on age at anti-TNF initiation, sex, race/ethnicity, Medicare coverage, comorbidities, and HAQ-disability scores. Those with other rheumatic diseases, cancer, or HIV before the first SI were excluded. Anti-TNF initiation was identified when patients not using anti-TNF at enrollment reported its use at subsequent biannual visits. SI was defined as infection requiring IV antibiotics, hospitalization, or resulting in death and was attributed to anti-TNF if it occurred during treatment or within three months of discontinuation. Patients were censored at the end of TNF treatment plus 3 months (to account for SI risk window), death, or the end of the study. Kernel propensity-matched survival analyses estimated the risk difference of SI between LORA and YORA.

Table 1: Baseline characteristics of propensity-score matched older adults with anti-TNF initiation by age of RA diagnosis

	LORA (N=1219)	YORA (N=6030)	P-value
Age at anti-TNF initiation	72.6 (5.6)	72.5 (6.3)	0.713
Female, %	74.8	74.9	0.976
Non-Hispanic White race/ethnicity, %	97.3	97.3	0.990
Medicare coverage	92.4	93.4	0.296
Educational level, years	13.1 (2.3)	13.1 (2.3)	0.621
Annual income, US$1,000	40.2 (29.2)	40.4 (28.5)	0.839
Urban community, %	26.9	26.7	0.926
RA disease duration, years	5.74 (4.5)	25.9 (13.0)	<0.001
Smoking habits			
Past	33.6	32.9	0.680
Current	10.3	7.7	0.022
RDCI (0-9)	1.8 (1.5)	1.8 (1.5)	0.438
HAQ (0-3)	1.1 (0.7)	1.2 (0.7)	0.144
Pain VAS (0-10)	4.0 (2.7)	4.1 (2.7)	0.673
Global severity VAS (0-10)	3.8 (2.5)	3.8 (2.4)	0.650
PAS (0-10)	3.89 (2.20)	3.94 (2.10)	0.785
Prior serious infections, %	4.6	7.6	0.002
Ever glucocorticoid use, %	80.7	79.4	0.404
Current glucocorticoid use, %	43.0	42.0	0.652
Long-term GC use, %	12.9	13.4	0.702
Concurrent methotrexate use, %	72.8	66.1	<0.001

Note: Each LORA patient was matched to YORA patients based on age at anti-TNF initiation, sex, race/ethnicity, Medicare coverage comorbidity burden, and HAQ disability.
*The values are presented as mean (SD) unless indicated otherwise.
Abbreviations: LORA=Late Onset Rheumatoid Arthritis, YORA=Young Onset Rheumatoid Arthritis, RDCI=Rheumatic Disease Comorbidity Index, HAQ=Health Assessment Questionnaire; VAS=Visual Analog Scale; PAS=Patient Activity Scale.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: Adjusted HR for risk of serious infection related to anti-TNF use in older adults with LORA vs YORA

Variable	Adjusted HR	95% (CI)	
LORA	0.82	0.63	1.08
Age Group			
60-70	Reference		
70-80	1.71	1.27	2.29
≥80	1.63	1.08	2.48
Prior infections	1.95	1.13	3.40
Long-term GC use (time-varying)*	2.17	1.68	2.81
MTX use	0.95	0.73	1.24
Current smoker	0.65	0.39	1.07

LORA=late-onset RA, YORA=young-onset RA
*long-term GC use (time-varying) defined as at least 5mg/day prednisone equivalent for 90 consecutive days prior to SI

Results: 1219 LORA patients were matched to 6030 weighted YORA patients. At baseline, LORA patients had shorter RA disease duration and fewer prior infections but were more likely to be current smokers and to use concomitant MTX compared to YORA patients. All other baseline variables were well-balanced (Table 1). During follow-up, the crude incidence of SI was 34.2 per 1000 patient-years in LORA patients and 27.9 per 1000 patient-years in YORA patients. After kernel propensity matching, the risk of SI did not significantly differ between LORA and YORA (HR 0.89, 95% CI 0.60-1.34). In Cox regression analyses with GC use treated as a time-varying variable, the risk of SI increased 1.6 to 1.7-fold with older age at TNF initiation, 1.9-fold with prior infection, and 2.2-fold with recent long-term GC use (Table 2).

Conclusion: The risk of SI did not differ between LORA and YORA, indicating that age at RA onset alone does not significantly impact infection risk associated with TNF initiation in older adults. Although older age at treatment initiation was associated with increased SI risk, it should not deter anti-TNF use, as appropriate treatment can substantially improve RA outcomes. Prior infection and recent long-term GC use were also independently associated with SI risk, emphasizing the importance of minimizing GC exposure and implementing infection prevention strategies to mitigate risk and optimize outcomes in older adults initiating TNF therapy.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) has a mission to deliver exceptional and equitable health care to children with rheumatic diseases with a current focus on patients with juvenile idiopathic arthritis (JIA). PR-COIN's registry tracks outcome, process, data quality, and balancing measures. PR-COIN assesses and addresses disparities across demographic variables by creating network SMARTIE (specific, measurable, actionable, realistic, time-bound, inclusive, equitable) aims. One aim is to increase the percent of patients with oligoarticular and polyarticular JIA who have inactive or low disease activity by the 10-joint clinical Juvenile Arthritis Disease Activity Score (cJADAS10) from 81.6% to 85% in addition to decreasing the gap between patients with commercial insurance and Medicaid from 8.8% to 5% by December 31, 2025. An additional aim is to increase the percent of patients with JIA in no pain or with mild pain intensity from 80.6% to 83% while decreasing the disparity gap between Black and White patients from 9% to 5% during this same timeframe.

Methods: A key driver diagram was created highlighting the SMARTIE aims and identifying key drivers and change ideas (Figure 1). Data from quality measures between January 2023-February 2025 were stratified by insurance type (comparing patients with commercial insurance and Medicaid) or race (comparing White and Black patients) for 2 outcome measures – inactive or low disease activity by cJADAS10 and no or mild pain – and 2 process measures – receipt of self-management support (SMS) and completion of setting a treatment target of disease activity. The differences in subgroup medians portrayed on run charts were translated to run charts of disparity gaps.

Results: Patients with JIA on commercial insurance consistently have a higher rate of inactive or low disease activity compared to patients on Medicaid (Figure 2A). The disparity gap between these populations decreased from 10% to 9% in November 2023 (Figure 2B). The percent of White and Black patients with no or mild pain have both increased slightly since January 2023

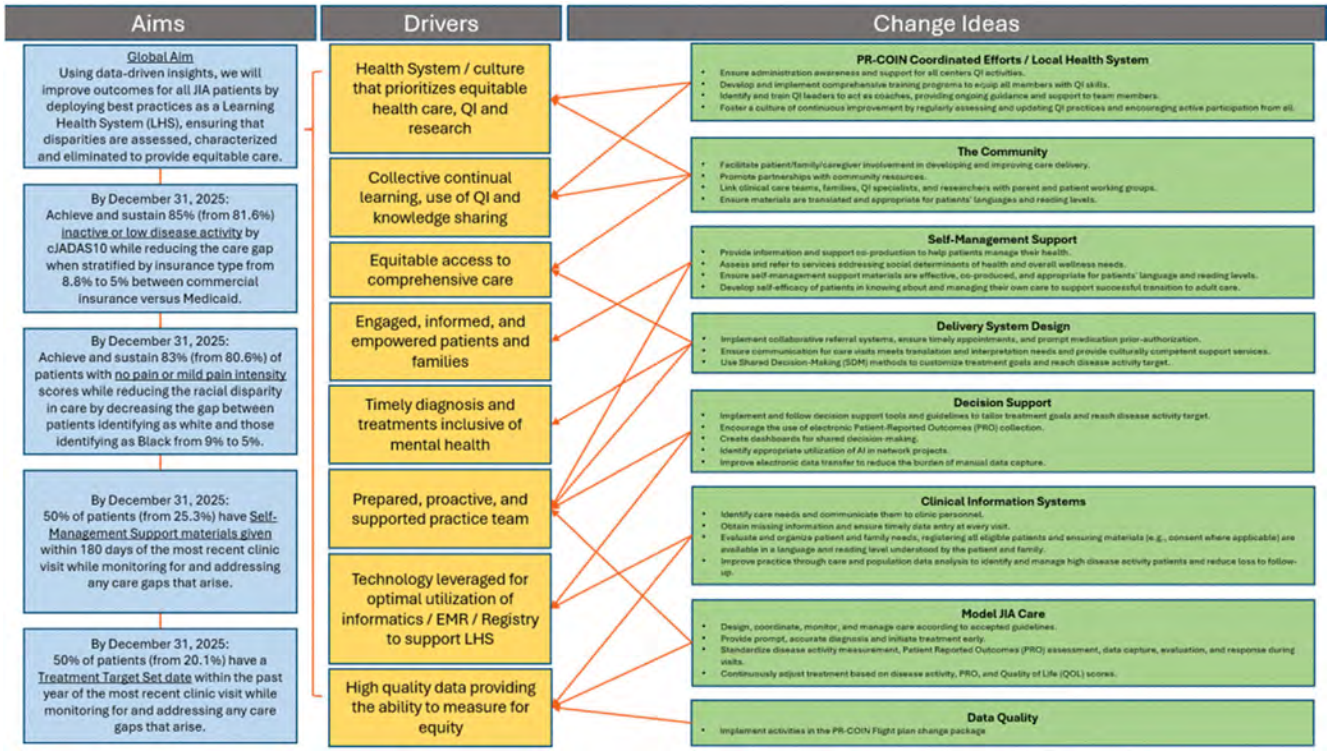

Figure 1. PR-COIN's key driver diagram.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

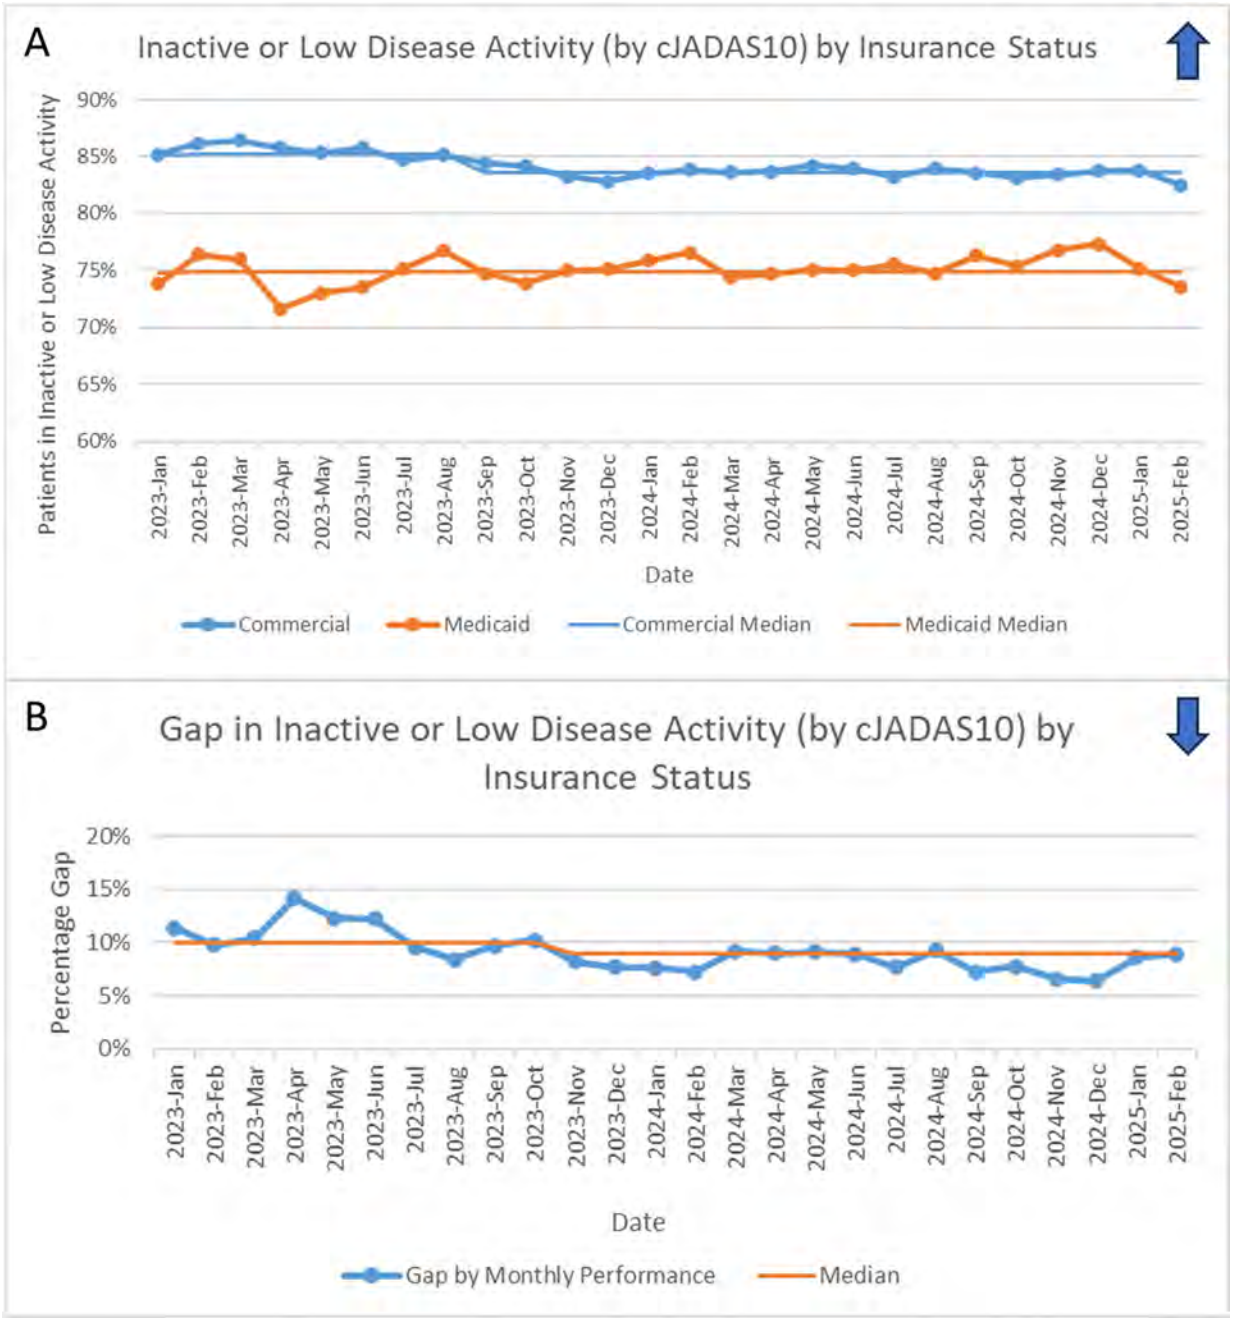

Figure 2. Run charts demonstrating inactive or low disease activity by insurance status (A) and the gap in performance by insurance status (B).

(currently 82.8% and 73.8%, respectively), although the disparity gap of 8.8% has been stable throughout this period (Figure 3). White patients are more likely to receive SMS compared to Black patients with a disparity gap of 7.7%. Patients on Medicaid were more likely to have a treatment target set than patients with commercial insurance (33.4% and 27.7%, respectively).

Conclusion: PR-COIN is striving to provide equitable health care to patients with JIA by making health equity a strategic priority, setting network aims with a health equity focus, and by assessing for differences in health outcomes related to social or demographic factors. We found a disparity by insurance type in our inactive or low disease activity measure. Disparities by race were present in pain intensity score and receipt of SMS. A focus on treatment target setting with patients on Medicaid may mitigate disparities in outcomes. PR-COIN will continue to monitor and address these disparity gaps over time to improve care for all patients with JIA. Further research into persistence of disparities is warranted.

Investigating Barriers to Care through Childhood Opportunity, Social Vulnerability, Area Deprivation, and Distance to Care in Pediatric Localized Scleroderma

Karen Lin[1], Yuhan Ma[1], Simrat Morris[2] and Kristina Ciaglia[3], [1]Scottish Rite for Children, Dallas, TX, [2]UT Southwestern Medical Center and Scottish Rite for Children, Dallas, TX, [3]UT Southwestern, Children's Medical Center, and Scottish Rite for Children, Dallas, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Delays in diagnosis and treatment of pediatric localized scleroderma (LS) are common due to the under-recognition at initial presentation. While previous studies on pediatric rheumatic diseases have highlighted the impact race, ethnicity, and socioeconomic disparities have on access to care, there is a lack of understanding for those with LS. We examined various Census tract-level datasets and distances to care in a single-center cohort of children with LS to identify factors preventing care.

Methods: A retrospective chart review was performed for patients diagnosed with LS at a single center from January 2021 to December 2024. Those with systemic scleroderma were excluded. Census tract-level datasets for the Childhood Opportunity Index (COI), Social Vulnerability Index (SVI), and Area Deprivation Index (ADI) were utilized. Patient demographics, distance to care, and Census tract data were analyzed using standard statistical analysis.

Results: A total of 52 patients were included. Most patients were Female (63.5%) and Non-Hispanic White (65.4%) with a mean age of 13 years (Table 1). The farthest driving distance to our center was 1,796 miles, and the mean was 128 miles (Figure 1). There was a statistically significant negative correlation between distance to our center and the SVI Racial and Ethnic Minority Status Percentile Statewide and Nationwide (p=0.0002 and p=0.0012 respectively). There was also a significant difference in the mean distance to our center across the COI Overall Index Nationwide and Statewide (p=0.0314 and p=0.0335 respectively) and COI Overall Education Statewide (p=0.0312) (Table 2). There were no significant findings between race/ethnicity, gender, insurance status, or language.

Conclusion: In conclusion, patients from our center come from diverse backgrounds and travel long distances to receive care. Statistically significant associations between distance to care and Census tract-level data are prevalent. Specifically, childhood opportunity was found to be significant overall nationwide and statewide as well as education statewide. Patients who live closest to our center have higher social vulnerability. These findings are enlightening and begin to examine the burdens of healthcare our patients face outside of the office visit. Future studies are needed to determine potential interventions to improve access to care.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Although studies have been published on the baseline characteristics of patients with autoimmune rheumatic diseases (AIRDs) with COVID-19 infection, little data exists on how social determinants of health (SDoH) influence outcomes. We investigated whether specific domains of SDoH are associated with COVID-19-related hospitalizations in adults with and without AIRDs.

Methods: We conducted a retrospective cohort study using electronic health record (EHR) data from the National Clinical Cohort Collaborative (N3C) COVID Enclave. We included adults ≥18 years who tested positive for SARS-CoV-2 (PCR or antigen test or diagnostic code) between April 2020 and March 2024. We identified patients with AIRD by the presence of ≥2 ICD-10 codes for an AIRD diagnosis, recorded ≥ 30 days apart before an incident COVID-19 infection. The AIRD diagnoses we included were polymyalgia rheumatica, polymyositis, dermatomyositis, rheumatoid arthritis, systemic sclerosis, ankylosing spondylitis, psoriatic arthritis, enteropathic arthritis, reactive arthritis, Behcet's disease, ANCA-vasculitis, giant cell arteritis, polyarteritis nodosa, SLE, and Sjogren's syndrome. Only individuals with available SDoH data in N3C were included in this study and SDoH were assessed at the time of incident COVID-19 infection. SDoH were assessed across three Healthy People 2030 domains: healthcare access, economic stability, and social cohesion. The primary outcome was COVID-19-related hospitalization defined as occurring within a window from 3 days before to 14 days after diagnosis. To examine the association between specific SDoH domains and COVID-19-related hospitalization among adults with and without AIRDs, we conducted hierarchically nested logistic regression models and adjusted for covariates including age, sex, comorbidities, and vaccination status, then stratified analyses by AIRD status.

Results: There were 362,359 people with incident COVID-19 infection and available SDoH domains in N3C at the end of data collection, of whom 16,261 (4.5%) had at least one AIRD diagnosis. In unadjusted analyses, COVID-19-related hospitalization was significantly higher among AIRD patients (19%) compared to non-AIRD patients (13%, $p < 0.001$; **Table 1**).

Across both AIRD and non-AIRD groups, having SDoH issues was associated with higher odds of COVID-19-related hospitalization (**Table 2**). In adjusted models including all SDoH domains, associations were consistently stronger among the AIRD group. Having access to healthcare issues was associated with higher hospitalization risk in both groups, with a larger effect in AIRD patients (aOR 1.73, 95% CI 1.41-2.11) than in non-AIRD patients (aOR 1.55, 95% CI 1.45-1.66). Similarly, social cohesion issues (aOR 1.44 vs 1.19) and economic instability (aOR 1.20 vs 1.16) had a more pronounced association with hospitalization in the AIRD group (**Table 2**).

Unknown/Missing	*98,281*	*4,900*	*93,381*
Covid-19 Related Hospitalization	49,384 (14%)	3,126 (19%)	46,258 (13%)

Autoimmune Rheumatic Diseases (AIRDs). AIRDs include polymyalgia rheumatica (PMR), polymyositis/dermatomyositis (PM/DM), rheumatoid arthritis (RA), systemic sclerosis (SSc), spondyloarthropathies (SpA) (including ankylosing spondylitis, psoriatic arthritis, enteropathic arthritis, and reactive arthritis), systemic vasculitidies (including Behcet's disease, ANCA-vasculitis, giant cell arteritis, and polyartertitis nodosa), and Sjogren's syndrome. Charlson Comorbidity Index (CCI) excludes rheumatic disease from CCI calculation.

Table 2. Odds of COVID-19-related hospitalization among Social Determinates of Health (SDoH) domains, stratified by presence of AIRD. Adjusted covariates included age, sex, comorbidities, and COVID-19 vaccination status prior to incident infection.

	AIRD Hospitalization		Non-AIRD Hospitalization	
SDoH	Unadjusted Odds Ratio (95% CI)	Adjusted* Odds Ratio (95% CI)	Unadjusted Odds Ratio (95% CI)	Adjusted* Odds Ratio (95% CI)
Economic Instability				
No Economic Instability Issue	Reference	Reference	Reference	Reference
Economic Instability Issue	1.15 (1.00, 1.32)	**1.20 (1.03, 1.40)**	**1.19 (1.14, 1.24)**	**1.16 (1.11, 1.21)**
Access to Healthcare

Social Cohesion				
No Social Cohesion Issue	Reference	Reference	Reference	Reference
Social Cohesion Issue	**1.62 (1.39, 1.90)**	**1.44 (1.23, 1.71)**	**1.28 (1.23, 1.34)**	**1.19 (1.14, 1.24)**

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Having SDoH issues was independently associated with higher odds of COVID-19-related hospitalization among adults, regardless of AIRD status. These associations were stronger in those with AIRDs, highlighting how underlying social disadvantage may exacerbate vulnerability to severe outcomes in this population.

Abstract Number: 1069

Strengthening Rheumatology Workforce Capacity and Impact on Patient Care in Louisiana: Expanding Fellowship Training Opportunities Through Strategic Partnerships

Luke Sharrock[1], Alexandra Anderson[2], Stephen Lindsey[3] and Milena Vukelic[4], [1]Louisiana State University Health Science Center New Orleans, New Orleans, LA, [2]Louisiana State University Health Science Center New Orleans, Phoenix, AZ, [3]LSU Health Sciences Center-New Orleans, Baton Rouge, LA, [4]Rheumatology Fellowship Program Director Louisiana State University, New Orleans, LA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Louisiana, along with other states, has long experienced significant challenges in accessing specialty care, particularly in the field of rheumatology. Limited availability of trained rheumatologists leads to delayed diagnoses, suboptimal disease management, and poor patient outcomes. In response, our institution has strategically expanded rheumatology fellowship training. In addition to two ACGME-accredited fellowship spots annually, we have implemented a model to add one extra fellow when funding is available. This additional fellow is supported through contracts with rural hospitals in the United States or internationally. These hospitals provide financial support for the additional fellow and, in return, the fellow commits to return and practice in the sponsoring institution for a defined period. The prospective fellow participates in the ACGME match process. Importantly, the additional fellow is fully integrated into the accredited training program and all aspects of training meet the ACGME requirements, ensuring parity in educational quality and clinical competence. This initiative aims to address the growing shortage of rheumatology specialists, improve patient access to timely care, and enhance patient outcomes across underserved areas.

Methods: A retrospective cohort study was conducted using Slicer Dicer, a data analytics tool embedded in the Epic Electronic Health Record system. The study spanned the period from 2017 to 2025. The impact of expanding rheumatology fellowship training on patient care was measured as patient access to care: number of referrals, wait time, number of new and follow-up visits. For statistical analysis, a t-test was used.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Yearly referrals to our clinic increased 3.7-fold since 2015 (1,139 in 2015 vs. 4,218 in 2024; $p < 0.05$). We had 5 fellows during 7/2017–7/2019 and 7/2023–7/2025, with 4 fellows in between. During the academic years 2023–2025, when we had 5 fellows, our clinic saw 8,052 total patients, compared to 4,568 patients in 2019–2021 and 6,125 patients in 2021–2023 during the years with 4 fellows. In 2023–2025, we doubled the number of new patient consults seen in our clinic (2,134 patients vs. 1,072 patients in 2019–2021; $p < 0.05$). We observed a trend toward an increased number of outpatient prescriptions, corticosteroid injections, and infusions. Before 2017, the average time to the next patient appointment was 118 ± 16 days, which was significantly shortened ($p < 0.001$) during the years with 5 fellows (47 ± 13 days in 2017–2019 and 53 ± 15 days in 2023–2025). Patient demographics were similar throughout the years.

Conclusion: Our strategic collaboration serves multiple purposes: expanding the workforce by increasing the number of graduating fellows and providing immediate access to care in underserved areas. This model led to an increase in the number of consultations and follow-up appointments, reducing wait times for patients by 40%. Additionally, this initiative enhances our program's visibility and attracts mission-driven candidates. This initiative exemplifies how academic-community partnerships can produce scalable solutions to subspecialty workforce shortages.

Cervical Cancer and HPV Screening in Women with Lupus vs Healthy Control Group: A Retrospective Study at a Tertiary Referral Center

Mahnoor Javed[1], Deepak Jagannath[2], Alma Aveytia Camacho[3], Alwyn Mathew[3], Konrad Harms[3], Soudabeh Daliri[3] and Myriam Guevara[4], [1]Houston Methodist, Richmond, TX, [2]Houston Methodist Hospital, Sugar Land, TX, [3]Houston Methodist, Houston, [4]Houston Methodist, Houston, TX

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Women with SLE are at an increased risk of developing cervical cancer, primarily by human papillomavirus (HPV) and immunosuppression. This elevated risk has been recognized by experts and updated guidelines recommend more frequent cervical cancer screening in women with SLE compared to the general population. This project aims to assess current cervical cancer screenings and HPV vaccination status in women with SLE compared to normal population at Houston Methodist Hospital (HMH).

Methods: We identified women aged 21-65 years who met the ACR/EULAR 2019 criteria for SLE diagnosis between 2015 and 2025 using electronic medical records, SlicerDicer software, and a retrospective chart review at HMH. Females with a history of hysterectomy or cervical cancer were excluded. A total of over 230 patients were initially identified, with 50 women confirmed through chart review. The SLE Disease Activity Index (SLEDAI) was obtained from their most recent visit. A healthy cohort of 50 women, matched by age and ethnicity, was also included. Individuals with diabetes, HIV, chronic immunosuppression, hysterectomy, cervical cancer, or tobacco use were excluded.

Results: Among the SLE group, 46% of the patients were Black, 32% were White, 16% were Hispanic, and 6% were Asian. The average age was 45, with a mean disease duration of 8 years. The mean SLEDAI score was 4, and most patients were

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

on a combination of medications including Prednisone, Hydroxychloroquine, Azathioprine, Methotrexate, Mycophenolate, and Belimumab (Table 1).

Our results indicated that 6% of the SLE group had received the HPV vaccine, compared to 20% in the healthy control (HC) group. Only 74% of SLE patients had undergone cervical screening and 64% had HPV testing within the past five years. However, the HC group had 100% cervical cancer screening and 72% had HPV testing within the same timeframe (Figure 1). Furthermore, only 30% of the SLE group had an annual PAP smear and 18% had annual HPV testing (Figure 2A). Among the SLE patients, 7 abnormal PAP smears were identified, including 2 low-grade squamous intraepithelial lesions (LSIL) and 5 cases of Atypical Squamous Cells of Undetermined Significance (ASCUS), compared to just one

Category	SLE Cohort	Healthy Control (HC)
Age	Mean: 45 (SD[1] ± 12.1)	Mean: 40.7 (SD ± 10.9)
Race	White: 46%	White: 66%
	Black: 32%	Black: 14%
	Hispanic: 16%	Asian: 12%
	Asian: 6%	Native American: 2%
		Declined: 6%
Disease Duration (years)	Mean: 8.1 (SD ± 8.9)	N/A
SLEDAI	Mean: 4.1 (SD ± 4.5) Mild (1-5): 62% Moderate (6-10): 28% Severe (>10): 6%	N/A
Immunosuppression	Hydroxychloroquine: 68%	
	Prednisone: 16%	
	Mycophenolate: 14%	N/A
	Azathioprine: 14%	
	Methotrexate: 6%	
	Belimumab: 6%	
LSIL[2]	4%	0%

[2]Low-Grade Squamous Intraepithelial Lesion

[3]Atypical Squamous Cells of Undetermined Significance

Table 1. SLE Cohort vs Healthy Control (HC) Characteristics

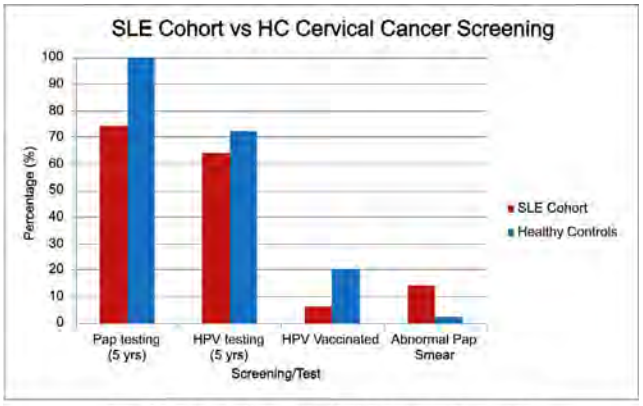

Figure 1. SLE Cohort vs Healthy Control (HC) Cervical Cancer Screening Data

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

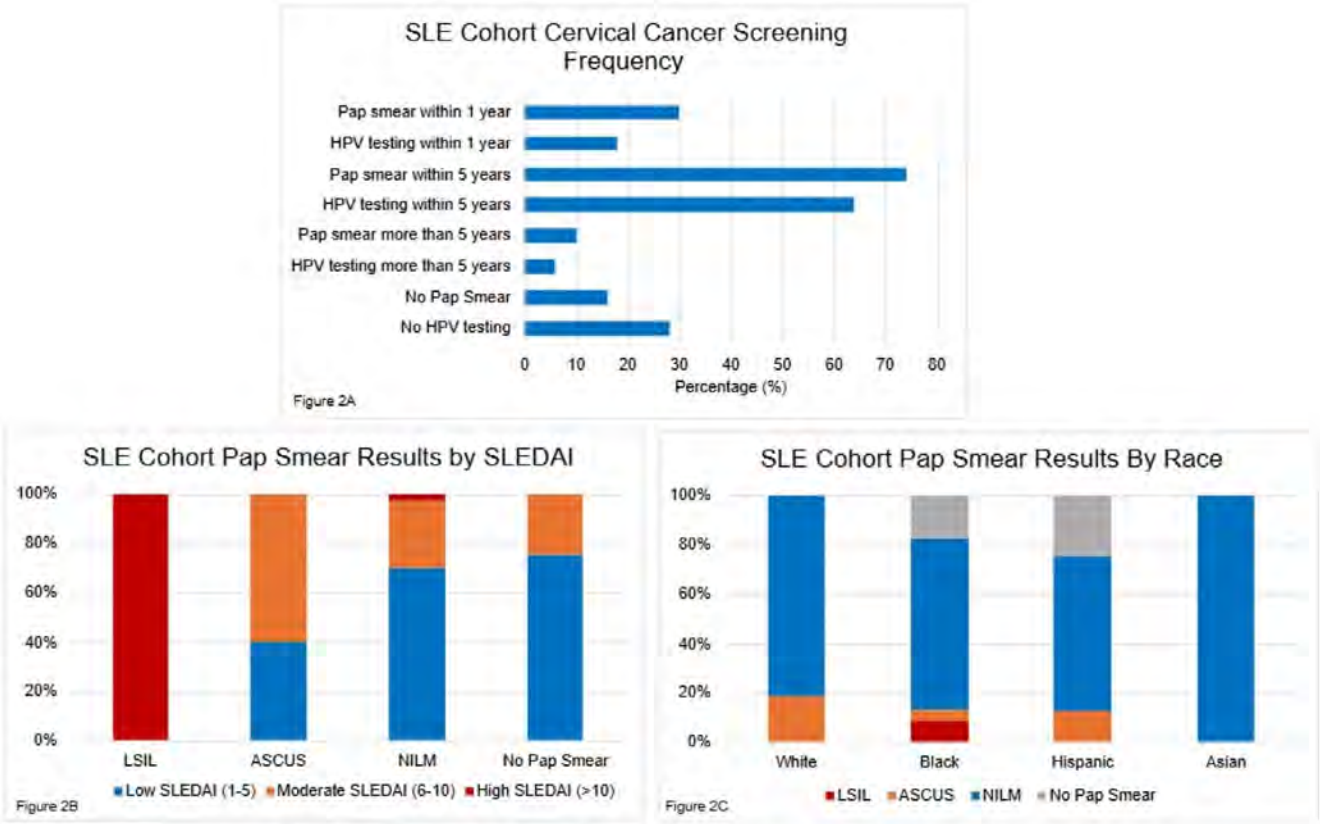

Figure 2. SLE Cohort Pap Smear Results by Frequency (2A), SLEDAI (2B) and Race (2C)

ASCUS in the HC group (Figure 2B). In the SLE group, 3% tested positive for HPV, including one patient with LSIL, while 8% of the HC group tested positive for HPV. The patients with LSIL were all Black and had notably higher SLEDAI scores (Figure 2C).

Conclusion: Our study confirms a significant gap in cervical cancer and HPV screening among women with SLE compared to healthy controls (HC). The findings underscore the importance of implementing annual screening for SLE patients. Additionally, the results suggest that a higher SLEDAI in Black patients may pose an increased risk for worse outcomes. The study also highlights the need for more HPV testing and greater education on vaccination to help prevent adverse outcomes in both groups. Collaborating with gynecologic experts could further raise awareness and improve screening practices. Larger studies are necessary to better understand the risks and long-term outcomes in this population.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune diseases are complex conditions that may predispose individuals to an increased mental health burden, including depression. The immune system leads to inflammation in affected organs and mediates behavioral abnormalities, including fatigue and depression-like symptoms. This study leverages data from the Behavioral Risk Factor Surveillance System (BRFSS) to evaluate the prevalence of depression and mental health service access among patients with autoimmune diseases compared to those without.

Methods: Using a simulated BRFSS dataset of 10,000 respondents, autoimmune status was defined as the presence of conditions such as rheumatoid arthritis, lupus, and psoriatic arthritis. Depression was measured using self-reported ever diagnosis (ADDEPEV2) and the number of days of poor mental health (MENTHLTH). Descriptive analyses quantified the prevalence of depression in autoimmune versus non-autoimmune groups. Bivariate analyses (chi-square tests and t-tests) were conducted to compare mental health indicators and access to services between groups. Multivariable logistic regression models, with depression as the outcome and predictors including autoimmune status, demographics (age, sex, race/ethnicity, education, income), and comorbidities, were implemented. Stratified analyses by income further evaluated disparities in mental health care.

Results: Preliminary analyses indicated that 36% of respondents with autoimmune diseases self-reported depression compared to 21% among non-autoimmune respondents (χ^2 $p < 0.001$). Additionally, individuals with autoimmune conditions reported an average of 11.2 poor mental health days, significantly greater than the 6.3 days reported by non-autoimmune individuals (t-test, $p < 0.001$). Logistic regression analyses revealed that, after adjusting for demographic and comorbidity factors, the odds of reporting depression were 1.85 times higher among autoimmune patients (OR = 1.85; 95% CI: 1.60–2.15). Stratified analyses further demonstrated that lower-income autoimmune patients experienced compounded disparities; those in the lower-income bracket had an OR of 2.05 (95% CI: 1.70–2.47) compared to an OR of 1.62 (95% CI: 1.35–1.95) for their higher-income counterparts.

Conclusion: These findings suggest that individuals with autoimmune diseases have a significantly higher burden of depression and poorer mental health outcomes than those without. Moreover, the observed disparities in mental health service

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: A growing number of older adults are living with autoimmune rheumatic diseases (AIRDs) as the global population is aging. And yet, they remain underrepresented in pharmacologic randomized clinical trials (RCTs). This has led to a gap in the evidence-base for the care of older adults with AIRDs. Understanding existing age-related inclusion practices in AIRD RCTs is essential to address this gap. This systematic review evaluates the inclusion of older adults in pharmacologic RCTs of AIRDs.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a systematic review (PROSPERO CRD42023457996) using PubMed, EMBASE, CINAHL Complete, Europe PMC, ClinicalTrials.gov, and the International Clinical Trials Registry Platform. We included completed phase II–IV pharmacologic RCTs with published results from 2010–2023. For rheumatoid arthritis (RA), the search began in 2017, as a prior review covered earlier studies.[1]

We included the following AIRDs: ANCA-associated vasculitis (AAV), axial spondyloarthritis (ax-SpA), giant cell arteritis (GCA), idiopathic inflammatory myopathies (IIM), polymyalgia rheumatica (PMR), psoriatic arthritis (PsA), reactive arthritis (ReA), RA, systemic lupus erythematosus (SLE), and systemic sclerosis (SSc). Ax-SpA, PsA, and ReA were grouped as spondyloarthritis (SpA), and GCA and PMR were analyzed together (GCA/PMR).

We included RCTs enrolling adults ≥18 years of age, except for AAV and SLE, in which a lower age threshold (≥15 years) was selected. Title/abstract screening, full-text review, and data extraction were performed independently by two reviewers. Conflicts were resolved a by a third reviewer. Mean age and standard deviation (SD) of participants by AIRD were calculated using methods developed by Palmowski et al[1] and compared to ages reported in historical observational cohorts for each AIRD.

Results: We identified 515 RCTs including 152,185 participants (Table 1). RA, SpA, and SLE accounted for 80% of RCTs and 94% of participants. Higher female representation was noted in RCTs for GCA/PMR, SLE, SSc, and IIM. Most trials were conducted in North America, Europe, and Australasia.

Age-related exclusion was common, with 56.4% of RCTs applying upper age limits, most frequently a cut-off at 70 years (Table 2). Only 33.3% of RCTs explicitly reported data on older adults. Across multiple AIRDs—including SLE, SSc, SpA, GCA/PMR, and RA—the mean participant age was lower than that observed in representative cohort studies.

Conclusion: Older adults are underrepresented in RCTs across all AIRDs. Upper age limit exclusion criteria are commonly used, restricting the inclusion of the older adult population. These findings highlight the limitations in the generalizability and applicability of RCT results to inform/guide the care of older adults. There is an urgent need to promote the inclusion

Table 1. Characteristics of included RCTs per AIRD

	AAV	GCA/PMR	IIM	RA	SLE	SpA	SSc
Number of trials included	27	10	18	172	101	141	46
Number of participants: n (median; range)	3,485 (105; 17-704)	718 (50.5; 20-250)	1,307 (49; 13-251)	72,360 (314; 5-4362)	27,179 (1,42; 9-4,003)	43387 (230; 18-1704)	3,749 (42; 12-576)

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Black and Latinx individuals with autoimmune and inflammatory rheumatic diseases (AIRD) face disproportionately higher risks of severe COVID-19 outcomes. Despite this elevated risk, vaccine uptake remains low in these populations. Interventions that leverage narrative communication and homophily may promote behavior change. We developed a culturally and linguistically tailored, storytelling intervention designed to support a future randomized controlled trial (RCT) of COVID-19 vaccine uptake in Black and Latinx patients with AIRD.

Methods: Intervention development was guided by a conceptual model (Figure 1) created by the study team, which included two community investigators and a representative from a patient advocacy organization. Patients with AIRD from two academic rheumatology clinics in Alabama and Massachusetts and from a patient advocacy organization were recruited as storytellers. Storytellers, selected based on congruence with anticipated background of future RCT participants, signed a media release form and were compensated for their time. Semi-structured in-person or virtual interviews elicited storytellers' experiences with COVID-19 vaccination, including barriers (e.g., access issues, safety concerns) and facilitators (e.g., trust in the healthcare system, vaccination health benefit) to vaccination. Filmed interviews were split into segments to identify key themes. Each segment was rated from 1 (lowest) to 5 (highest) for emotional authenticity, persuasiveness, content accuracy, and overall impression. The highest-rated segments discussing desired messages were compiled into a draft English-language video, which underwent structured review. A brief introduction featuring a rheumatologist was recorded to provide context for the audience. A professional videographer combined the introduction with the highest-rated storytelling segments, added titles, subtitles, and music to produce the final video. The Spanish-language footage was reviewed and edited to select storytelling segments with the same messages as those in the English-language video (Figure 2).

Results: Black (N=4) and Latinx (N=4) individuals with AIRD participated in structured ~30 minutes interviews in English or Spanish. Eight study team members reviewed and rated 165 minutes of footage in English and six Spanish-fluent study team members reviewed and rated 131 minutes of Spanish-language footage. The ~10 minutes draft English-language video was edited to ~4 minutes after the second round of review. Table 1 shows key broad themes, subthemes, and second round of review rating scores for each clip selected for the final videos. Both English and Spanish-language videos were edited to ~4 minutes (Figure 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Key overarching themes, subthemes, and rating scores for each clip represented in final storytelling video.

Broad Theme	Subthemes	Video Clips Rating Categories*				Representative Quotes
		Emotional Authenticity	Persuasiveness	Content	Overall Impression	
Infection Risk in AIRD	Ongoing concerns due to personal history of infections	4.3	4.3	4.7	4.7	"I have a lot of concerns about getting infections more easily."
	Need to stay proactive in protecting oneself	4.0	3.7	4.0	4.0	"It's like trying to fight the flu or a cold. You've got to protect yourself."
	Concern that COVID-19 could trigger RA flare	3.0	4.0	4.0	4.0	"I have my arthritis problem under control. I really would not want it to get out of whack and give me more problems."
Personal Experiences with the Updated COVID-19 Vaccine	Preventing serious health consequences	4.7	4.3	4.7	4.7	"The problems I have are already major. I decided to take all the vaccines that I needed."
	Vaccine improves safety and health outcomes	4.7	4.3	4.3	4.7	"The benefit for vaccination for people with autoimmune disease is that it keeps us safe, especially with COVID-19. I knew my risk and I knew I had a better outcome in having that vaccine."
	Vaccination is a personal health priority	4.0	3.0	2.7	3.0	"It's to protect me and keep me healthy."
	Willing to accept some risk for the potential benefit	4.7	4.7	4.7	4.7	"If there was anything that could help, I was willing to take that chance."
	Make vaccination a personal decision	4.0	4.0	3.3	3.7	"You have to think hard about what may benefit you, and then, make a decision."
Reasons to Get the Updated COVID-19 Vaccine	Stay informed—talk to providers and peers, not misinformation	4.7	4.7	4.7	4.7	"Do not rely on misinformation, social media, there's a lot of that out there. Please talk to your provider and people like me"
	New variants require updated vaccines	3.7	4.0	4.7	4.3	"I assume that as the virus mutates or changes, the newer vaccine would be adjusted, somehow, to the new virus that is prevalent in the community."
	Benefits outweigh concerns like fear or anxiety	4.0	3.0	2.7	3.0	"You may be skeptical, you be nervous. You may be scared. But in the end, you will see the benefit"
	Keep up with updated vaccines to protect yourself and loved ones	4.7	4.7	4.7	4.7	"It's very important that we continue to work on COVID. This means we have to continually get the vaccinations. As they are updated, we need to get updated with the work they are doing. Knowing that you're keeping your family safe and loved ones safe at the same time. What more can you ask for?"

Conclusion: Guided by the storytelling narrative communication theory and a structured iterative editing process, we produced two culturally tailored storytelling videos in English and Spanish that can be tested, together with patient navigation, as an approach to improve COVID-19 vaccination rates in Black and Latinx individuals with AIRD. Our robust approach to intervention development is scalable and adaptable to other preventative care interventions.

Abstract Number: 1074

Racial Disparities in Cardiovascular, Ocular, and Treatment Outcomes in US Patients with Behçet's Disease: A Propensity-Matched Real-World Analysis

Michael Hamilton[1], Justin Riley Lam[2], Emmanuel Otabor[3], Laith Alomari[3], Maxim Barnett[3], Shahrzad Abdollahi[2] and Irene Tan[4], [1]Jefferson Einstein Hospital, Philadelphia, Philadelphia, PA, [2]Jefferson Einstein Hospital, Philadelphia, PA, [3]Jefferson Einstein Hospital Philadelphia, Philadelphia, PA, [4]Einstein Healthcare Network Philadelphia - Jefferson Health, Bala Cynwyd, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Racial/ethnic disparities in Behçet's disease (BD) outcomes are largely undocumented in the United States. Given known differences in disease expression across populations globally, we used a large real-world database to evaluate potential disparities in cardiovascular, ocular, and treatment outcomes between White and Black/Hispanic (B-His) patients with BD.

Methods: Using TriNetX Global Collaborative Network, we conducted a retrospective cohort study. Adults (≥18 years) with ICD-10 BD (M35.2) were assigned to a White or B-His cohort based on electronic health records (EHR) and matched 1:1 on age, sex and ten cardiometabolic comorbidities, yielding 1400 patients per group. Outcomes captured 1 day–10 years after the index BD diagnosis were- stroke, heart failure (HF), myocardial infarction (MI), venous/arterial thrombosis, uveitis, all-cause death and exposures to systemic corticosteroids, tumour-necrosis-factor (TNF) inhibitors and non-biologic immunosuppressants. Between-group differences were assessed using risk ratios (RRs) with 95% confidence intervals (CIs) and Kaplan–Meier survival analysis with log-rank tests.

Results: Groups were well balanced after matching (standardised differences < 0.03). Over the follow-up period, B-His patients experienced nearly twice the stroke incidence of White patients (3.9 % vs 1.7 %; RR 0.43, 0.26–0.69; $p = 0.001$) and a similar pattern for HF (4.6 % vs 2.5 %; RR 0.54, 0.36–0.82; $p = 0.007$). Although MI, thrombosis, seizures and death did not differ significantly, the directionality of the outcomes numerically favoured the White group. Uveitis occurred in 9.6 % of B-His and 6.4 % of White patients (RR 0.66, 0.51–0.86; $p = 0.002$). Therapeutic patterns also diverged: B-His patients were more likely to receive systemic corticosteroids (51 % vs 44 %; RR 0.86, 0.77–0.96; $p = 0.009$) and TNF inhibitors (13 % vs 10 %; RR 0.77, 0.63–0.95; $p = 0.014$), while non-biologic immunosuppressant use was similar between cohorts. Kaplan–Meier curves confirmed lower cumulative hazards for stroke, HF and uveitis in White patients (log-rank $p \leq 0.01$); survival did not differ significantly.

Conclusion: In this nationwide, propensity-matched analysis, White adults with Behçet's disease experienced significantly fewer strokes, HF events, ocular flares and immunosuppressive courses than Black/Hispanic adults, despite equivalent baseline characteristics. The data highlights racial disparities in both disease burden and treatment intensity. Further investigation into genetic susceptibility, care delivery inequities, and social determinants of health is essential to inform equitable, evidence-based management strategies for diverse BD populations.

Abstract Number: 1075

Racial Differences in Management and Clinical Outcomes of Giant-Cell Arteritis: A Real-World Propensity-Matched Study

Michael Hamilton[1], Justin Riley Lam[2], Emmanuel Otabor[3], Laith Alomari[3], Maxim Barnett[3], Fabian Rodriguez Quinonez[4] and Irene Tan[5], [1]Jefferson Einstein Hospital, Philadelphia, Philadelphia, PA, [2]Jefferson Einstein Hospital, Philadelphia, PA, [3]Jefferson Einstein Hospital Philadelphia, Philadelphia, PA, [4]Einstein Medical Center Philadelphia, Philadelphia, PA, [5]Einstein Healthcare Network Philadelphia - Jefferson Health, Bala Cynwyd, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Giant-cell arteritis (GCA) is usually described in people of Northern-European ancestry, and little is known about outcomes in Black and Hispanic (B-His) patients. Using a large U.S. multi-center electronic-health-record network, we compared clinical management and 1-year outcomes between White and B-His adults with GCA.

Methods: We conducted a retrospective cohort study using the TriNet-X Global Collaborative Network. Adults (≥18 years) with an ICD-10 diagnosis of GCA were assigned to a White cohort or a B-His cohort based on electronic health records; individuals with mixed race/ethnicity were excluded. One-to-one propensity-score matching on age, sex, and 12 cardiovascular or metabolic comorbidities produced two balanced groups of 8323 patients each. Outcomes recorded 1–365 days after the index date were vision loss, stroke, myocardial infarction (MI), temporal-artery biopsy, CT angiography, prednisone use, tocilizumab use, death, C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). Risk ratios (RRs) with 95 % confidence intervals (CIs) and Kaplan–Meier log-rank tests were used for comparisons.

Results: After matching, baseline characteristics were well balanced (standardized differences < 0.05). Inflammatory activity was greater in B-His patients, whose mean CRP (24.5 mg/L vs 21.0 mg/L; p = 0.005) and ESR (40.1 mm/h vs 27.0 mm/h; p < 0.001) exceeded those of White patients. Temporal-artery biopsy was performed more often in B-His patients (22.6 % vs 17.8 %; RR 0.79, 0.74–0.84; p < 0.001), but vision-loss and CT-angiography frequencies were low (< 0.7 % and < 0.3 %, respectively) and did not differ. Prednisone exposure was equivalent in both groups (≈58 %), yet tocilizumab was prescribed nearly twice as often to White patients (5.1 % vs 2.8 %; RR 1.82, 1.56–2.13; p < 0.001). During follow-up period, stroke occurred in 3.5 % of B-His patients and 2.6 % of White patients (RR 0.74, 95 % CI 0.62–0.89; p = 0.002), while MI rates were similar (2.0 % vs 1.9 %). All-cause mortality, however, was higher in Whites (5.0 % vs 3.2 %; RR 1.53, 1.32–1.78; p < 0.001). Survival analysis confirmed lower stroke-free survival for B-His patients and lower overall survival for Whites.

Conclusion: In this large, propensity-matched real-world cohort, Black and Hispanic adults with GCA displayed higher inflammatory markers and greater stroke risk yet were less likely to receive tocilizumab than their White counterparts. Conversely, White patients had higher 1-year mortality despite comparable comorbidity burdens. These bidirectional disparities underscore the need for earlier recognition of vascular events in B-His patients and investigation into factors driving excess mortality among White patients. Tailored diagnostic vigilance and equitable access to advanced therapies are essential to optimize outcomes across racial and ethnic groups.

Abstract Number: 1076

Racial Differences in Real-World Use of Urate-Lowering and Adjunctive Therapies for Gout: A 10-Year Propensity-Matched Cohort Study

Michael Hamilton[1], Justin Riley Lam[2], Emmanuel Otabor[3], Laith Alomari[3], Maxim Barnett[3], Arthur Lau[4] and Irene Tan[5], [1]Jefferson Einstein Hospital, Philadelphia, Philadelphia, PA, [2]Jefferson Einstein Hospital, Philadelphia, PA, [3]Jefferson Einstein Hospital Philadelphia, Philadelphia, PA, [4]Jefferson Einstein Hospital, Maple Glen, PA, [5]Einstein Healthcare Network Philadelphia - Jefferson Health, Bala Cynwyd, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Although achieving target serum urate (SU) and reducing cardiovascular events are cornerstones of gout management, little is known about contemporary treatment patterns across racial and ethnic groups. We compared long-term exposure to urate-lowering therapy (ULT), acute-attack medications, procedures, SU, and major adverse cardiovascular events (MACE) between non-Hispanic White (NHW) and racial/ethnic minority (MIN) adults in routine U.S. practice.

Methods: We conducted a retrospective cohort study using TriNetX Collaborative Network. Adults ≥ 18 years with an incident gout diagnosis (ICD-10 M10) were classified as NHW or MIN (Black, Hispanic, Asian)- based on electronic health records. One-to-one propensity matching balanced age, sex, nine comorbidities, cardiometabolic drugs and BMI, yielding 359 020 patients per cohort. Outcomes captured 1–10 y post-index were initiation of allopurinol, febuxostat, pegloticase, colchicine, oral corticosteroids, NSAIDs, IL-1 inhibitors, arthrocentesis, most-recent SU, and composite MACE (myocardial infarction, heart failure, stroke). Risk ratios (RR, 95 % CI) and Kaplan–Meier log-rank tests ($\alpha = 0.05$) compared groups.

Results: Baseline characteristics were well balanced. During the follow-up period, NHW patients were modestly more likely to start allopurinol than MIN patients (29.8 % vs 28.1 %; RR 1.06, 1.05–1.07), Conversely, febuxostat initiation was nearly twice as common among MIN patients (3.8 % vs 2.1 %; RR 0.56 [0.55–0.58]; $p < 0.001$). Pegloticase use remained rare at 0.05 % in both cohorts (RR 1.13 [0.92–1.38]; $p = 0.25$).

Acute-therapy patterns differed: colchicine was prescribed to 20.1 % of MIN versus 14.3 % of NHW patients (RR 1.40 [1.38–1.42]; $p < 0.001$); NSAIDs to 32.4 % versus 30.5 % (RR 1.07 [1.06–1.08]; $p < 0.001$); and systemic corticosteroids

Table 1: Propensitiy score matching-Demographics and baseline characteristics

Propensity score matching- Medications

Table 3- Outcomes

Outcomes After Propensity-Score Matching in Gout Cohort (NHW vs Minority)

Outcome	NHW % / Mean	MIN % / Mean	RR or Δ (95% CI)	p-value
Allopurinol initiation	29.8 %	28.1 %	1.06 (1.05–1.07)	<0.001
Febuxostat initiation	2.1 %	3.8 %	0.56 (0.55–0.58)	<0.001
Pegloticase initiation	0.05 %	0.05 %	1.00 (0.80–1.25)	0.94
Colchicine use	14.3 %	20.1 %	1.40 (1.38–1.42)	<0.001
NSAID use	30.5 %	32.4 %	1.07 (1.06–1.08)	<0.001
Systemic corticosteroid use	45.5 %	46.0 %	1.01 (1.00–1.02)	0.02
IL-1 inhibitor use	0.08 %	0.14 %	1.69 (1.43–2.03)	<0.001
Arthrocentesis	8.6 %	7.3 %	0.85 (0.83–0.87)	<0.001
Mean serum urate, mg/dL	6.39 ± 2.08	6.71 ± 2.32	+0.32	<0.001
Major adverse CV events	15.5 %	16.8 %	1.08 (1.06–1.10)	<0.001

to 46.0 % versus 45.5 % (RR 1.01 [1.00–1.02]; p = 0.001). IL-1 inhibitors, although infrequent, were used in 0.14 % of MIN versus 0.08 % of NHW patients (RR 1.69 [1.43–2.03]; p < 0.001). Arthrocentesis or joint injection occurred in 7.3 % of MIN versus 8.6 % of NHW patients (RR 0.85 [0.83–0.87]; p < 0.001).

Biochemically, mean serum urate remained higher in MIN than NHW patients (6.71 ± 2.32 vs 6.39 ± 2.08 mg/dL; p < 0.001). Clinically, major adverse cardiovascular events occurred in 16.8 % of MIN versus 15.5 % of NHW patients (RR 1.08 [1.06–1.10]; p < 0.001), and Kaplan–Meier curves showed earlier event accrual in MIN patients (log-rank p < 0.001).

Conclusion: Despite similar comorbidity profiles, minority adults with gout were less likely to initiate guideline-preferred allopurinol yet more likely to receive febuxostat and multiple acute agents, had higher residual SU, and experienced greater cardiovascular morbidity than non-Hispanic-White adults. These findings highlight treatment and outcome inequities and call for targeted dose-titration protocols, SU monitoring, and cardiovascular-risk mitigation strategies to improve gout care in underserved populations.

Abstract Number: 1077

Health literacy and work status in people with inflammatory arthritis: a cluster analysis in a national cohort

Mrinalini Dey[1], Sam Norton[2], Andrew Cope[2], MAYA BUCH[3], Richard Osborne[4], James Galloway[2] and Elena Nikiphorou[2], [1]Centre for Rheumatic Diseases, King's College London, London, United Kingdom, [2]King's College London, London, United Kingdom, [3]UNIVERSITY OF MANCHESTER, MANCHESTER, United Kingdom, [4]La Trobe University, Melbourne, Victoria, Australia

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Work status and employment can be impacted in people with inflammatory arthritis (IA). We aimed to assess the association between health literacy and work status in people with IA.

Methods: Adults with IA, recruited to the National Early Inflammatory Arthritis Audit (NEIAA) in the UK, were invited to complete an online survey (March to May 2024), comprising the Health Literacy Questionnaire (HLQ), Work Productivity and Activity Impairment questionnaire, and questions on demographics, employment and education.

The HLQ comprises 44 questions and nine scales which each measure an aspect of health literacy, and assess experiences of understanding, accessing and using health information.

Occupation was classified as per the International Standard Classification of Occupations (ISCO) and UK Standard Occupational Classification (SOC), which classifies by skill levels (1-4).

Responses were matched with original records within NEIAA. Agglomerative hierarchical clustering, using Ward's method, was applied. Differences in health literacy, socio-demographics and work status were compared between clusters.

Table 1: Outcomes presented by health literacy cluster. Absenteeism is defined as the percentage of time absent from work. Here, absenteeism was analysed as a binary variable, as absent ≤5% or >5% of time. Presenteeism is measured by the degree health problems affected work productivity of the last 7 days, expressed as a percentage score representing impairment due to health reasons while working; higher numbers denote greater impairment and less productivity. SD= standard deviation.

Cluster by health literacy	Highest n=90	High n=190	Moderate n=296	Low n=270	Lowest n=149
Age (Mean, SD)	63.4 (11.4)	57.1 (14.7)	57.9 (13.4)	56.9 (12.6)	53.9 (11.8)
Gender (% female)	62.2	65.8	65.6	66.0	69.8
Smoking status (%)					
Current smoker	8.9	5.3	3.7	11.5	10.7
Ex-smoker	22.2	23.7	30.4	30.0	26.2
Never smoker	53.3	45.3	44.3	39.3	42.3
Unknown	15.6	25.8	21.6	19.3	20.8
Education (%)					
No formal qualifications	6.8	8.1	7.7	12.5	9.8
GCSE, O Level, or equivalent	27.3	28.0	28.6	30.9	36.4
A Level, or equivalent	21.6	16.1	18.8	21.5	19.6
Undergraduate degree, or equivalent	26.1	25.3	26.1	20.4	19.6
Postgraduate degree, or equivalent	18.2	22.6	18.8	14.7	14.7
Work hours per week (Mean, SD)	45.7 (46)	34.4 (14.9)	34.1 (15.5)	38.8 (27.2)	36.7 (23.3)
Absent >5% of time (%)	4.7	9.0	23.4	20.0	33.8
Presenteeism (Mean, SD)	18.3 (18.9)	23.4 (23.3)	30.9 (25.3)	38.1 (26)	52.2 (27.2)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

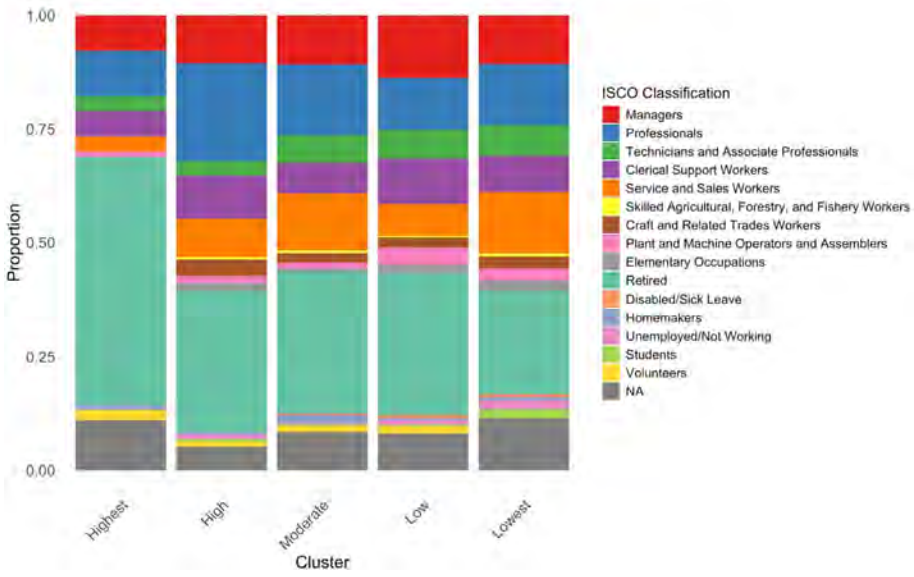

Figure 1: International Standard Classification of Occupations (ISCO) distribution by health literacy cluster

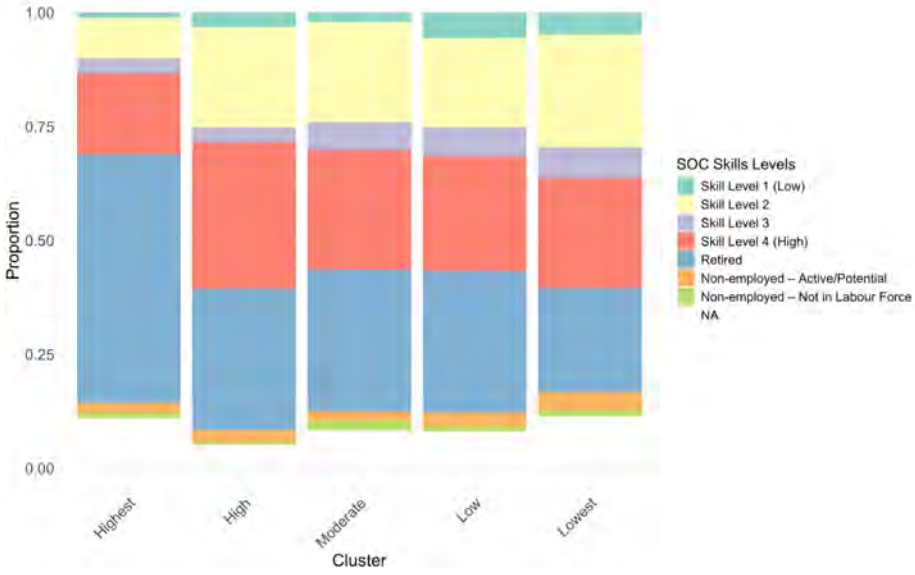

Figure 2: Standard Occupational Classification (SOC) skill levels by health literacy cluster

Results: In total, 995 patients with IA were included, with median age 59 years (IQR 50-67) and 66% female. Cluster analysis yielded five clusters according to HLQ scores (Table 1).

The "highest" health literacy cluster contained the greatest proportion of retired individuals compared to all other clusters, with the "lowest" health literacy cluster having the smallest proportion of retired individuals and greatest proportion of unemployment (Figures 2 and 3). The "highest" health literacy cluster also had lowest mean presenteeism (18.3; SD 18.9), compared to 52.2 (SD 27.2) in the cluster with lowest health literacy. The "lowest" health literacy cluster had seven-fold greater absenteeism compared to the "highest" health literacy cluster and greatest impairment in the HLQ domains: "Feeling understood and supported by healthcare providers", "Engagement with healthcare providers" and "Navigating the healthcare system".

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The greatest combined proportion of managers and professionals, and SOC Skill Level 4, was in the "high" health literacy cluster, while the greatest proportion of SOC Skill Level 1 was in the "low" health literacy cluster.

Education did not significantly vary between clusters. The lowest two health literacy clusters had the greatest proportion of people with highest educational level at GCSE or equivalent and the lowest proportion of people with a postgraduate degree or equivalent.

Conclusion: The "highest" health literacy cluster comprised largely retired individuals, compared to all other clusters. Clusters with higher HLQ scores had a greater proportion of people in high-skilled work, and lower absenteeism and presenteeism. Lower health literacy was associated with low-skilled work, and higher absenteeism and presenteeism.

Our results suggest being in work leads to increased communication, support and wellbeing of individuals with IA, important for engagement with healthcare providers. Retired individuals have very high HLQ scores, suggesting health literacy may increase with experience and engagement with health services over time.

Trends in Hospitalization rate with Lupus in the State of Florida: A retrospective data review from Florida Health Charts from 1992-2023

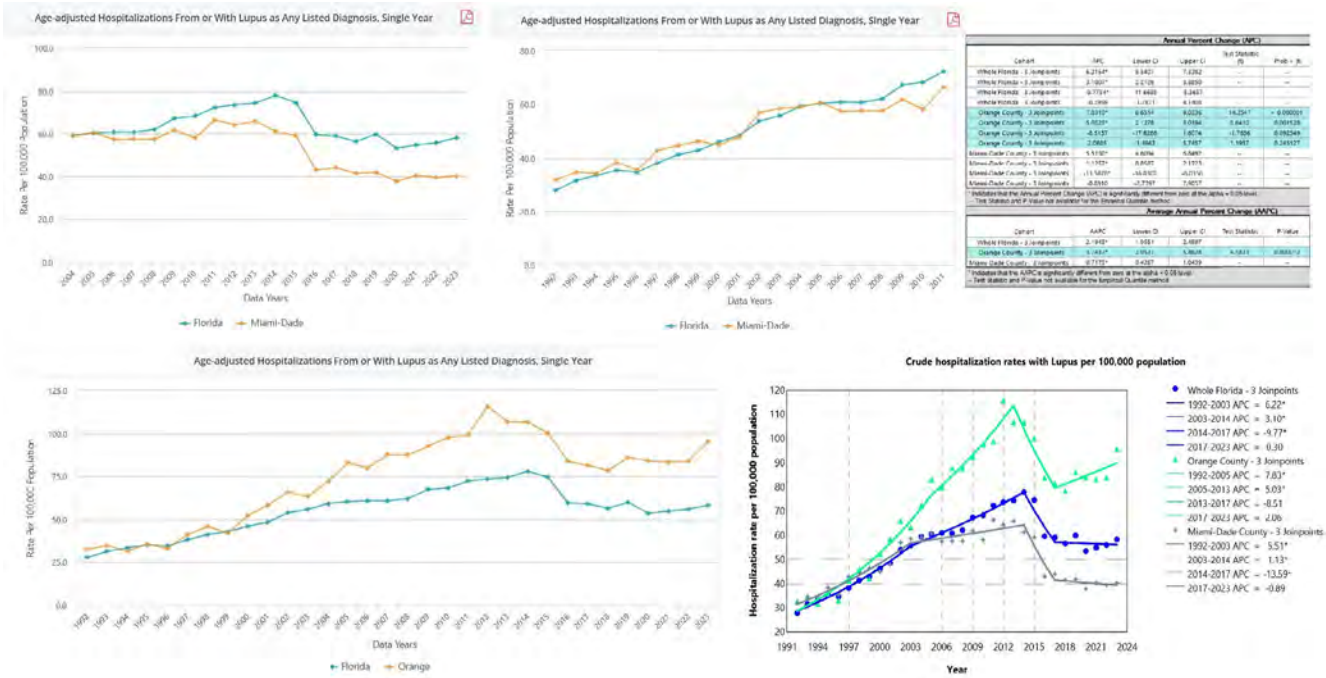
Muhammad Sohaib Asghar[1], Mohammed Akram[2], Veerkaran Banga[1], rajkaran Banga[1], Woo Joo Lee[1], Afsana Ansari Shaik[3], Syed Muhammad Muneeb Akhtar[4] and Thomas Shimshak[1], [1]AdventHealth Sebring, Sebring, FL, [2]HCA Aventura, Aventura, FL, [3]Mayo Clinic, Rochester, MN, [4]Dow University of Health Sciences, Karachi, Pakistan

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

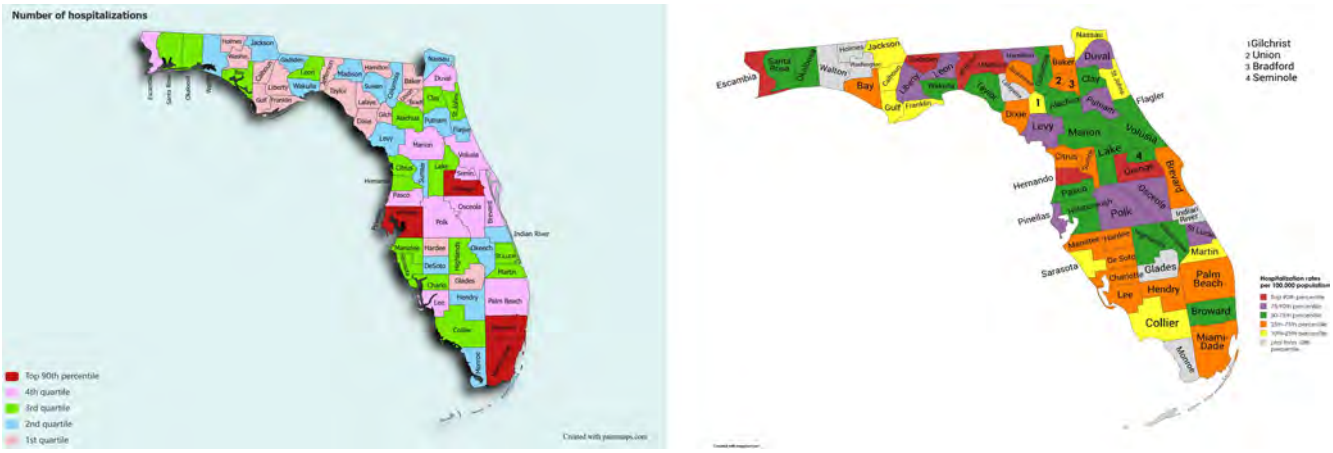
Background/Purpose: Lupus is a systemic autoimmune disease that occurs when the body's immune system attacks its own tissues and organs. This study was conducted to analyze the trends of hospitalization in patients where lupus was any listed diagnosis among the residents in the State of Florida with data from Inpatient hospitalizations, discharged from civilian, non-federal hospitals located within Florida.

Methods: Data on hospitalization rates was sourced from the Florida Department of Health's Florida CHARTS database. We included data from 1992 to 2023, utilizing hospitalization counts and rates per 100,000 population. The dataset was stratified by race (Black, White, and other categories), and ethnicity (Hispanic vs. non-Hispanic). For county-level analysis, age-adjusted hospitalization rates for lupus were compiled across the entire study period. Trends were assessed using Joinpoint regression analysis, which identified significant changes in the direction and magnitude of these trends over time. The results are expressed either as annual percent change (APC) and average annual percent change (AAPC), and their respective 95% confidence intervals (CI).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Age-adjusted hospitalization rates with lupus in Florida, including Orange County (fourth quartile) and Miami-Dade county (second quartile).



County-wise distributions of age-adjusted hospitalization count and rates in the State of Florida from 1992-2023.

Results: During 1992-2023, a total of 353,984 lupus-related hospitalizations were reported in Florida. In 2023, the age-adjusted rate per 100,000 of hospitalizations from or with lupus as any listed diagnosis in Orange County was 95.6 compared to Florida at 58.3, while the same for Miami-Dade county was 40.2 (Figure 1). Overall, from 1999-2023, the total number of hospitalizations in Orange county were 27,525 which ranked third in the State in terms of frequency, but in the highest quartile for age-adjusted hospitalization rate (Figure 2), followed by 2nd-ranked Broward county (n=33,159; third quartile) and most hospitalizations in Miami-Dade county (n=40,733; 2nd quartile). About 65% of the hospitalized patients were White, followed by 39% Black and 11% others. AAPC was found +1.86 [1.14-2.58] vs Black & others combined +1.84 [1.50-2.16], with significant p-value < 0.001 for Whites, 0.08 for Black (non-significant) and 0.01 for others (Figure 3). Data for Hispanics vs non-Hispanics were only available from 2004-2023 and showed non-significant declining trends (P=0.76).

Conclusion: Lupus can result in discomfort, lower quality of life, premature death, loss of productivity, and high medical costs from hospitalization. The State of Florida showed diverse trends in the hospitalization rates with lupus over the last three decades. By monitoring counts and rates of hospitalizations, public health professionals can take effective and timely action to prevent increases in disease and death.

Sociodemographic, Clinical, and Community-Level Deprivation Factors are Associated with Health-Related Quality of Life in Systemic Sclerosis

Sarah Smith[1], **Paula Ramos**[2], Dulaney Wilson[3], Diane Kamen[4] and Richard Silver[1], [1]Medical University of South Carolina, Charleston, SC, [2]Emory University School of Medicine, Atlanta, GA, [3]Medical University of South Carolina, Charleston, [4]Medical University of South Carolina, Johns Island, SC

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease with heterogeneous manifestations and significant impairment in health-related quality of life (HRQoL). SSc outcomes are shaped by biological, clinical, socio-demographic, and psychosocial factors, with well-documented disparities by race, sex, and socioeconomic status. While clinical contributors to HRQoL are established, the role of community-level deprivation remains understudied in SSc.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: We analyzed data from 314 adult patients with SSc who met 2013 ACR/EULAR classification criteria and were enrolled in a longitudinal observational cohort at the Medical University of South Carolina. HRQoL was measured using the SF-36 Physical (PCS) and Mental (MCS) Component Summary scores. We examined associations between HRQoL scores and sociodemographic factors, clinical characteristics, and community deprivation indices - Area Deprivation Index (ADI) and Environmental Justice Index Social-Environmental Rank (EJI-SER). ADI, evaluated at the census block level, was assessed using national percentiles and state deciles to reflect neighborhood-level disadvantage. EJI-SER, evaluated at the census tract level, captured cumulative environmental and social vulnerability. Bivariate comparisons and multivariable linear regression were used to estimate associations with PCS and MCS scores.

Results: Among 314 SSc patients (44.6% limited cutaneous, 48.1% diffuse cutaneous, 7.3% sine), significant differences by SSc subtype were observed for race, gender, modified Rodnan skin score (mRSS), forced vital capacity (FVC), esophageal stricture, and history of renal crisis (Table 1). Average PCS and MCS scores varied significantly across demographic,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

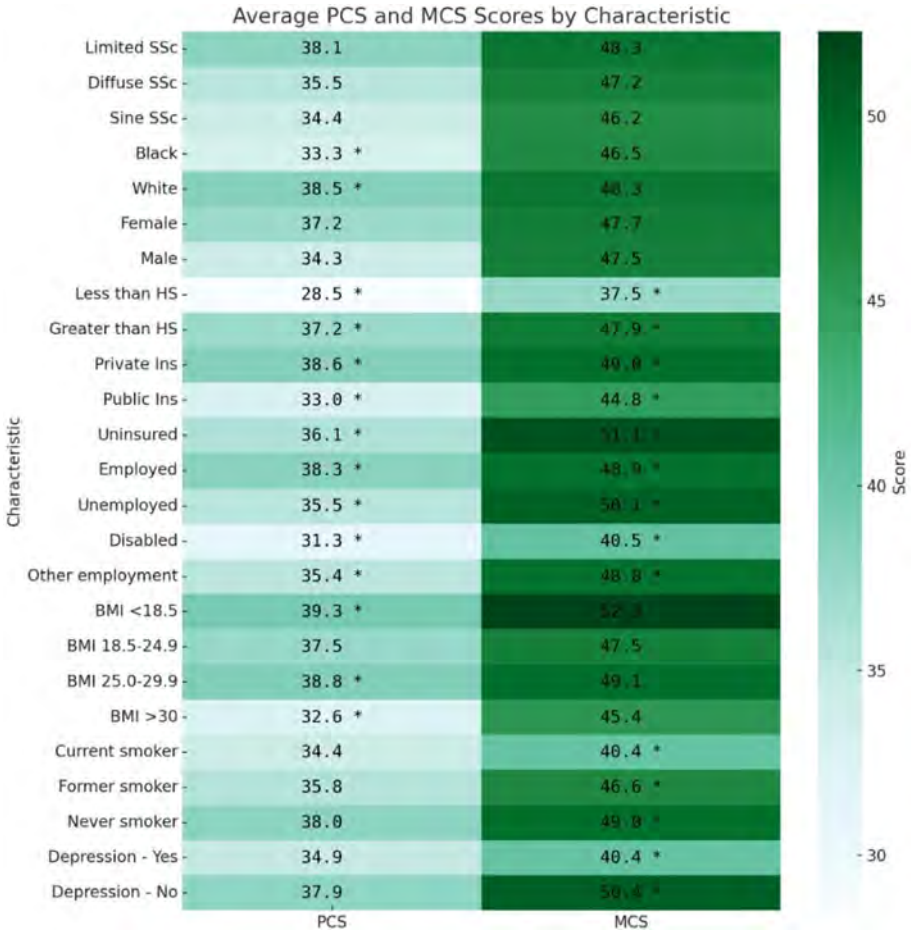

Figure 1. Heatmap of Average PCS and MCS Scores by Patient Characteristics and Social Factors. This heatmap displays mean Physical Component Summary (PCS) and Mental Component Summary (MCS) scores across demographic and socioeconomic subgroups among patients with systemic sclerosis. Darker shading indicates higher (better) average quality of life scores. An asterisk (*) indicates that the subgroup belongs to a characteristic category with a statistically significant association ($p < 0.05$) with PCS or MCS. Abbreviations: PCS = Physical Component Summary; MCS = Mental Component Summary; SSc = Systemic sclerosis; HS = High School; Ins = Insurance; BMI = Body Mass Index.

clinical, and socioeconomic factors (Figure 1). In multivariable linear regression analysis (Figure 2), lower PCS was associated with Black race (β=–4.08, p=0.002), public insurance (β=–5.65, p< 0.001), disability (β=–5.69, p=0.01), and depression (β=–5.17, p=0.001), while higher education was protective (β=8.40, p=0.02). Higher (worse) deprivation scores for ADI (state β=–1.09, p< 0.0001; and national rank β=–0.10, p=0.0002), and EJI-SER (β=–0.73, p=0.005) were associated with worse PCS. For MCS, depression (β=–0.83, p< 0.0001), current smoking (β=–6.32, p=0.01), and ADI national rank (β=–0.06, p=0.03) were significantly associated. A range of additional clinical variables, including measures of pulmonary, gastrointestinal, and renal involvement, also demonstrated associations with HRQoL scores (Figure 2).

Conclusion: Both individual- and community-level social determinants contribute meaningfully to disparities in HRQoL among patients with SSc. Consistent with prior literature, factors associated with more severe disease—such as organ involvement, Black race, lower educational attainment, public insurance, smoking, and depression—were linked to lower HRQoL. Notably, this is the first study to demonstrate that higher ADI and EJI-SER scores, reflecting neighborhood-level deprivation, are associated with worse HRQoL in SSc. These indices may offer novel tools for identifying at-risk populations and guiding equity-focused care strategies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Respiratory Syncytial Virus (RSV) is a leading cause of hospitalization and mortality in older adults and young children, particularly those with chronic illnesses or immunocompromising conditions (IC). Patients with rheumatic diseases (RD) are at increased risk for severe RSV infection.

Three RSV vaccines (RSVPreF3, RSVPreF1, and mResvia) were approved by the FDA in May 2023 for individuals aged ≥60 with the Advisory Committee on Immunization Practices (ACIP) recommending vaccination for ≥75 and for individuals ≥60 with chronic IC, including RD and those on immunosuppressive medications. In July 2024, RSVPreF1 was approved for ages 18–59 and RSVPreF3 for ages 50–59 at high risk, with ACIP extending recommendations to these groups in April 2025.

Despite these guidelines, surveys indicate that only 16% of eligible individuals receive the RSV vaccine. Uptake is typically lowest in younger adults, minority populations, and those with lower income and educational attainment. Vaccine hesitancy in these groups is frequently cited, yet provider recommendation and patient education are well-documented factors influencing vaccine acceptance.

Table 1

Provider Questionnaire Results – Pre vs. Post Intervention

Category	Response	Pre (n=9)	Pre %	Post (n=9)	Post %
Knowledge of Guidelines	Knew FDA/CDC guidelines	2	22.2%	9	100%
Vaccination Frequency	Rarely vaccinated	7	77.7%	5	55.6%
	Often vaccinated	1	11.1%	1	11.1%
	Almost always vaccinated	1	11.1%	3	33.3%
Comfort Addressing Vaccine Hesitancy	Completely comfortable	2	22.2%	6	66.6%
	Somewhat comfortable	7	77.7%	3	33.3%
	Not at all comfortable	0	0%	0	0%
Barriers to Vaccination	Time restraints	4	44.4%	4	44.4%
	Limited understanding of who to vaccinate	1	11.1%	1	11.1%
	Limited resources (not in clinic)	4	44.4%	4	44.4%
	Patient refusal	3	33.3%	3	33.3%
	Other reasons	6	66.6%	6	66.6%

Figure 1

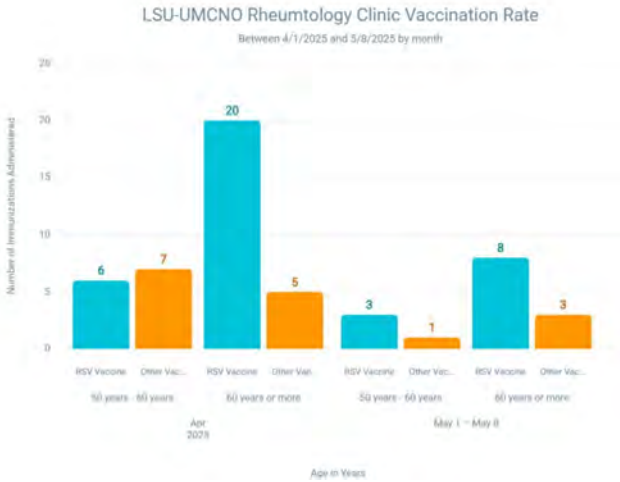

Figure 2

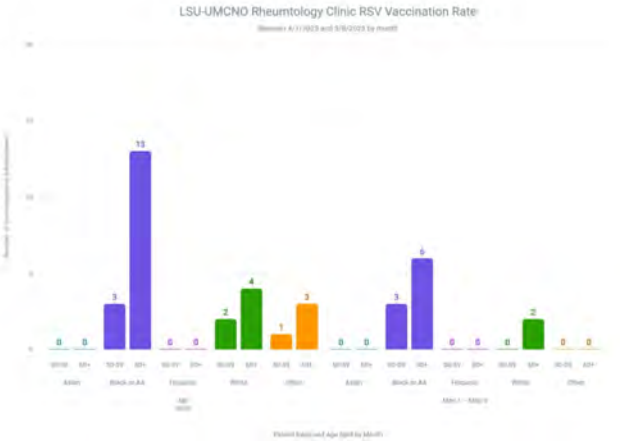

This study assessed RSV vaccination rates among RD patients at our clinic before and after implementing provider-focused education designed to promote in-visit patient education and vaccine administration.

Methods: We queried Epic for patients aged ≥50 with RD or immunosuppressive medication use who received an RSV vaccine at the University Medical Center New Orleans (UMCNO) LSU Safety net Rheumatology Clinic between May 1, 2023, and September 2025. In late March 2025, rheumatology faculty and fellows received an educational presentation on RSV vaccines, including pre- and post-session knowledge assessments. Beginning April 1, 2025, providers were encouraged to spend 1–2 minutes during visits educating eligible patients and recommending same-day vaccination. Key talking points included hospitalization risk, mortality, and risk to grandchildren. If patients required a steroid injection, vaccination was scheduled for a follow-up visit.

Results: Between May 1, 2023, and March 31, 2025, 381 patients aged ≥50 received vaccines at our clinic. Only one patient was vaccinated for RSV in September 2024. Post-education surveys revealed substantial knowledge improvement among providers (Table 1). UMCNO is a safety net system that cares for a majority of minority and disadvantaged people.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

From April 1 to May 8, 2025, 37 patients were vaccinated for RSV—9 aged 50–59 and 28 aged ≥60 and were of a minority population (Figure 2).

Conclusion: Approximately 70% of patients at the LSU-UMCNO Rheumatology Clinic identify as a minority groups. Following provider education and proactive in-clinic promotion, RSV vaccination rates increased markedly in a short timeframe. These results suggest that vaccine hesitancy in minority populations may be driven more by "Provider Hesitancy"—such as limited time, competing priorities, or lack of awareness—than by patient reluctance. Focused provider engagement and in-clinic vaccine availability appear to be effective strategies to improve uptake in high-risk, diverse populations.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Recognizing health care disparities in Rheumatoid Arthritis is crucial to improving outcomes. This study analyzes factors contributing to RA care inequities.

Methods: We examined RA disease activity, treatment, and vaccine rates over 12 yearly periods, 2012-2023. Eligibility criteria included RA patients ≥18 years. Low Clinical Disease Activity Index (CDAI≤10), steroid use ≥3 months, DMARD use ≥6 months, and vaccine (pneumococcal, shingles, flu) rates were compared based on insurance types and gender. Generalized estimating equations regression models were used to analyze binomial/multinomial outcomes.

Results: Population included 24,469 patients, median age 63, white 96%, women 74%, RF+ 74%, anti-cyclic citrullinated peptide (CCP+) 28%, Medicare 49%, Medicaid 5%, and Commercial insurance 22%. Insurance type didn't affect DMARD use: Commercial versus (vs) Medicare and Medicaid (Odds Ratio (OR) 0.98, 0.97, p=0.7936, p=0.8242), Medicaid vs Medicare (OR 1.01, p=0.9426) (Figure 1). More women used DMARDs than men (OR 1.22, p=0.0074) (Figure 2). Steroid use was higher with Medicaid than Medicare and Commercial patients (OR 1.25, 1.41, p=0.0128, p=0.0003) respectively (Figure 1),

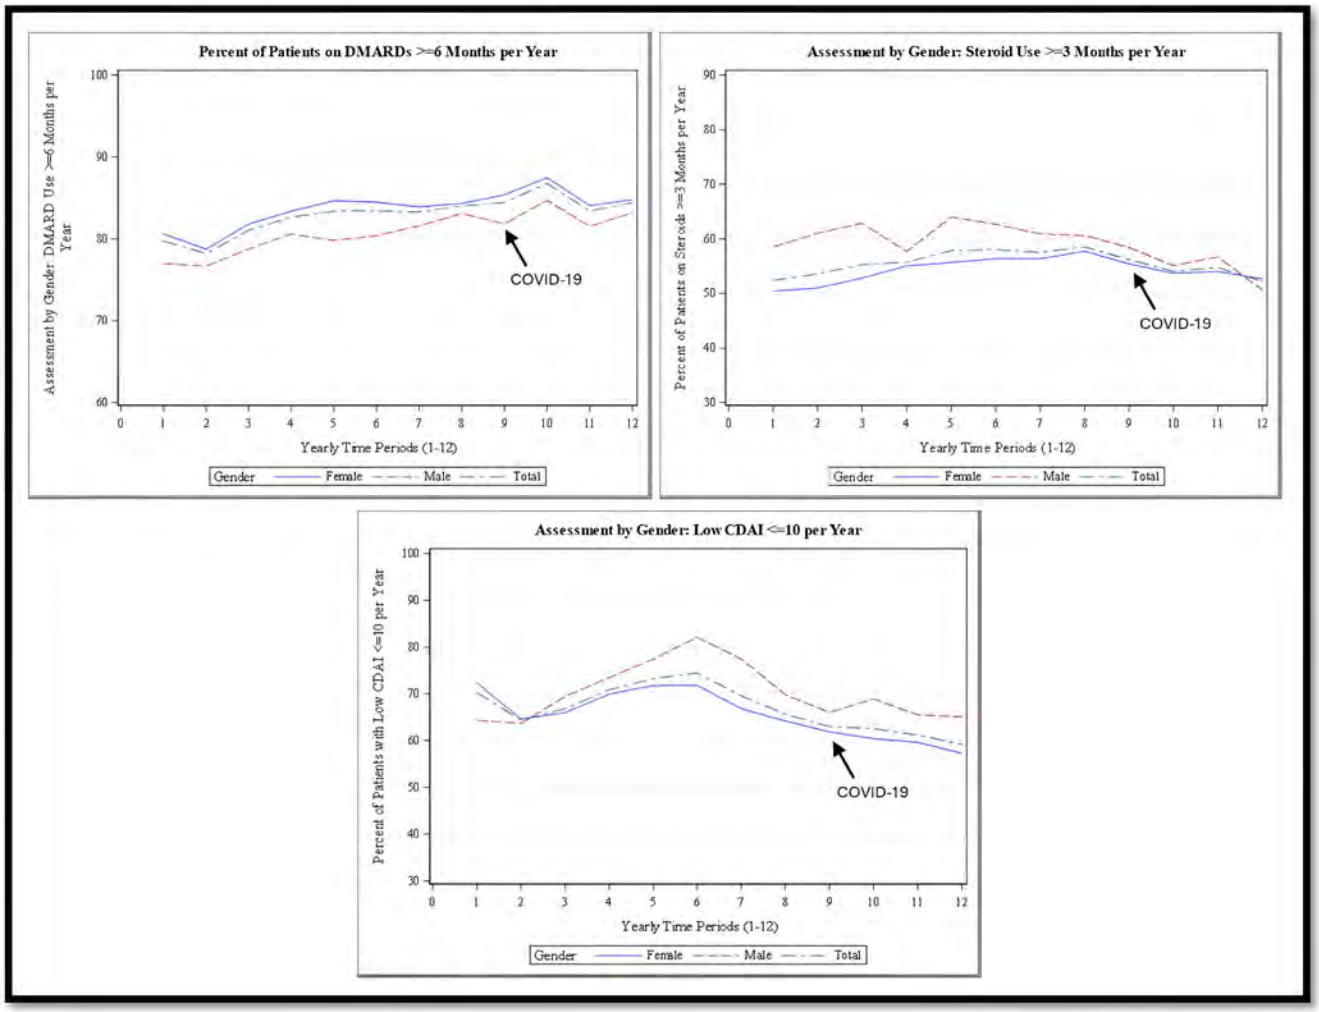

Figure 2. The Treatment Rates (DMARD ≥6 months, Prednisone ≥3 months) and Low Disease Activity (CDAI ≤10) Assessment by Gender

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

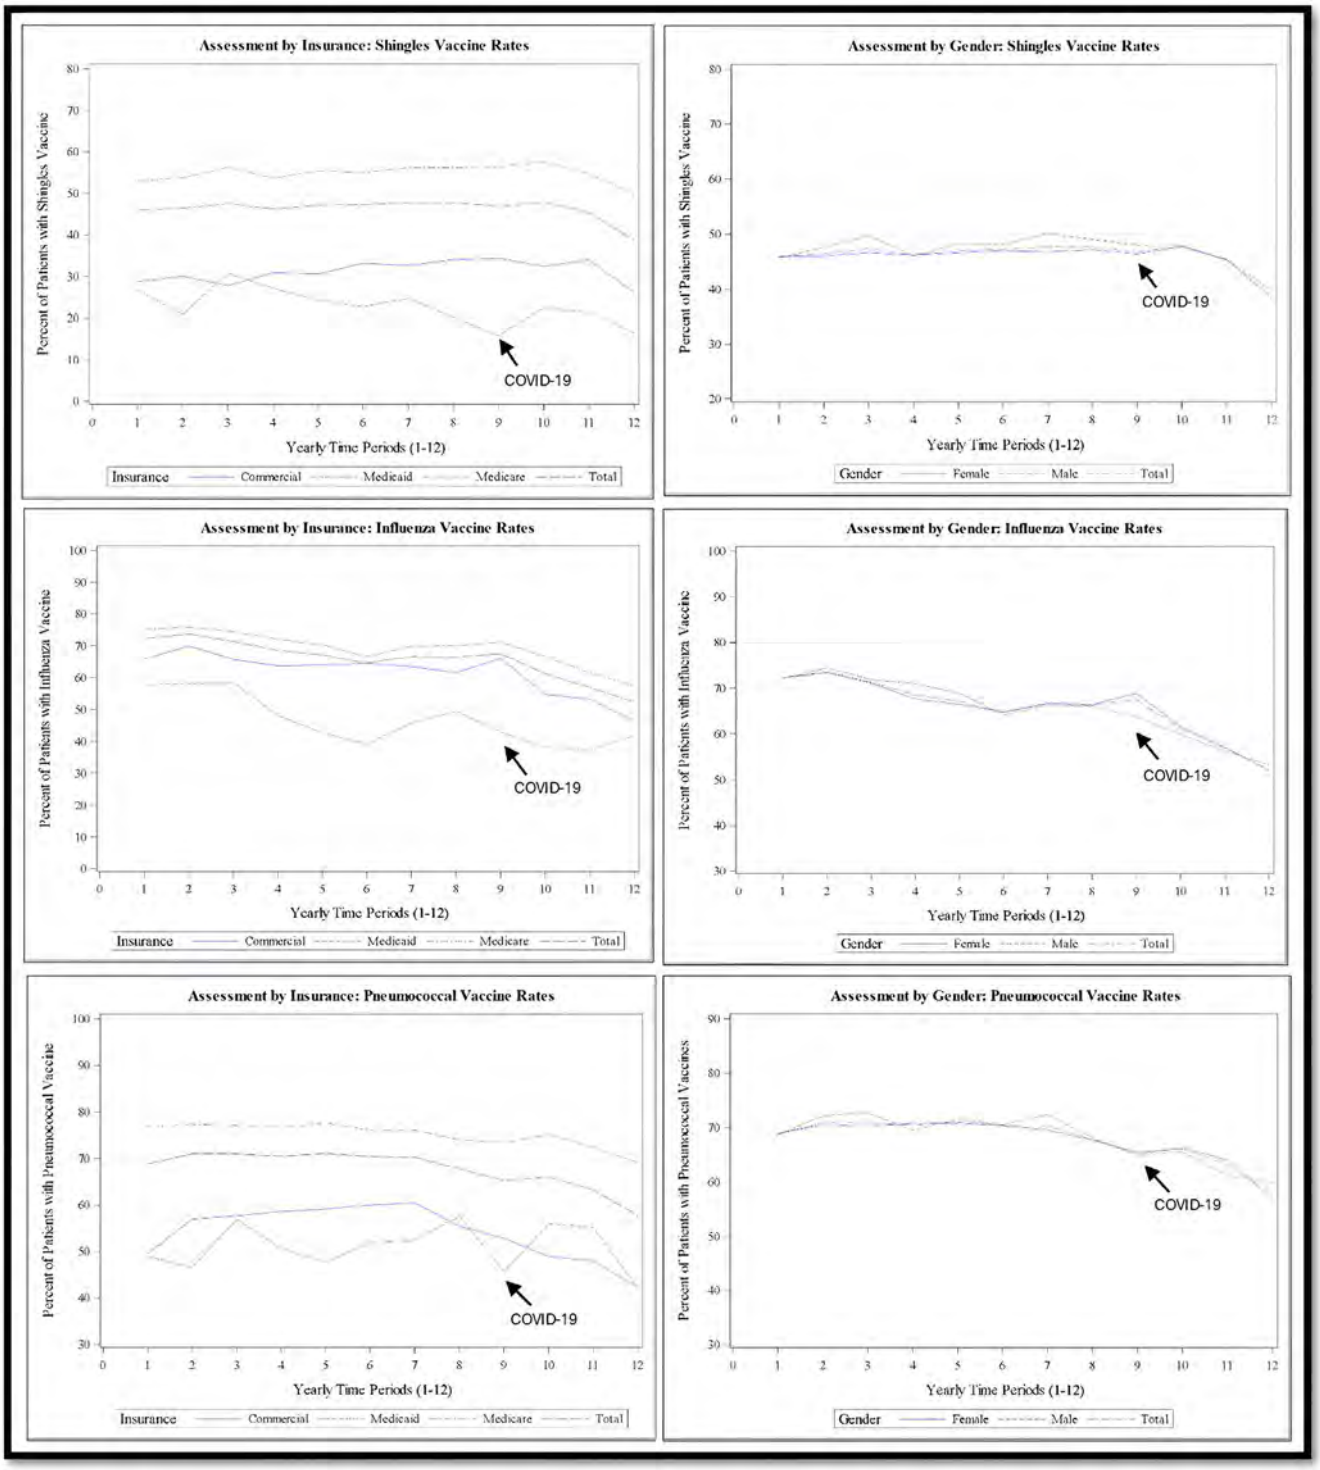

Figure 3. The Vaccine Rates (Shingles, Flu, and Pneumococcal) Assessment by Insurance types and Gender

and higher in men than women until period 9 (p=0.0002) (Figure 2). Disease control was better with Medicare and Commercial than Medicaid patients (OR 2.39, 2.22, p=0.001 respectively) but worse over time for all insurances (70.34% to 59.14%, p< 0.0001) (Figure 1). Men started with lower rates of CDAI ≤10 than women in period 1 (62% vs 71%) but achieved greater low disease activity than women in periods 2-12 (68% vs 59% p=0.046) (Figure 2). Disease activity worsened post COVID-19 pandemic for both insurance and gender in period 9 (2020) to 12 (2023) (Figures 1,2). Vaccine rates were higher with Medicare than Commercial or Medicaid (Singles OR 2.51, 3.28 p< 0.0001), (Pneumococcal OR 2.31, 2.33 p=0.0001),

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(Flu OR 1.41, 2.59 p=0.0001) (Figure 3). Pneumococcal and flu vaccine rates declined over time for all insurances (69% to 58%, 72% to 52%, p=0.0185, p=0.0001 respectively) (Figure 3). Gender didn't influence vaccine rates, but they all declined with time (p< 0.05) (Figure 3). The decline in vaccination trend was particularly worsened post COVID-19 (period 9-12) independent of insurance or gender (Figure 3). Comparing to national data, our vaccine rates were similar for flu (53-72% vs 61%) (Coca, Arth. Rheumatol.2018;70(9)) but superior for shingles (39-46% vs 19%) (Calabrese, Arth. Care Res.2020;72 (3)), and pneumococcal (58-69% vs 43%) (Alvarez, Vaccine.2024;42(3)).

Conclusion: Insurance type, gender, and COVID-19 played a substantial role in RA care delivery. Higher vaccine rates were achieved with Medicare, however, an overall declining trend, worse post COVID-19, left a considerable gap in our RA patients. Men (period 1-9) and Medicaid patients used more steroids. Men used less DMARDs, while percent at low disease activity worsened for all patients over time. This may be due to a higher capture of elevated CDAI measures (requires an in person visit) during COVID-19 (when the sickest patients were seen in person). Recognizing the drivers of RA inequities provides us with the opportunity to use a targeted approach to improving care.

Lupus Patient Navigator Program for Improving Care Adherence for Minority Patients

Rashi Vora[1], Samiha Karim[2], Dulaney Wilson[3], Jasvinder Singh[4], Gary Gilkeson[1], Jim Oates[1] and Diane Kamen[5], [1]Medical University of South Carolina, Charleston, SC, [2]Emory University, Atlanta, GA, [3]Medical University of South Carolina, Charleston, [4]Baylor College of Medicine, Houston, TX, [5]Medical University of South Carolina, Johns Island, SC

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Minority patients with systemic lupus erythematosus (SLE) experience a higher disease burden and encounter more barriers to care than White patients, resulting in worse outcomes and increased healthcare utilization. A Lupus Patient Navigator Program (LPNP) has been associated with improved SLE disease activity and quality-of-life scores in minority populations. This study aims to evaluate the impact of an LPNP on adherence to medication and scheduled visits.

Methods: Self-identified minority patients with SLE aged >18 years were recruited from an academic center. Inclusion criteria included being prescribed ≥1 immunosuppressant and meeting at least one of the following: 1) ≥1 missed clinic or laboratory visit in the past 6 months, 2) nonadherence to medical therapy, or 3) newly diagnosed SLE. The LPNP was modeled after the CDC STEPS to CARE toolkit. Patients engaged with the patient navigator every 3 months over a 12-month period via phone or in-person, with real-time resource support. Patient-reported outcomes included a medication diary, with adherence defined as the ratio of pills taken to pills prescribed over the week prior to each navigator encounter. Rheumatology visit adherence (in-person or telehealth) was tracked through chart review.

Results: Twenty-five patients (96% female; 92% Black; 8% Hispanic or Latino; mean age 32 years) completed the 12-month program. Among these, 92% were high school graduates, 88% had health insurance, and 48% were unemployed or disabled (**Table 1**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Baseline LPNP Participant Characteristics

Characteristics	LPNP Participants (N=25)
Age at enrollment (mean years ± SD)	32.2 ± 10.0
SLE age of diagnosis (mean years ± SD)	22.8 ± 10.4
Female (%)	24 (96%)
Black (%)	23 (92%)
Hispanic (%)	3 (8%)
High School Graduate (%)	23 (96%)
Commercial Insurance (%)	22 (88%)
Unemployed or Disabled (%)	12 (48%)
Taking HCQ (%)	24 (96%)
Taking glucocorticoids (%)	13 (52%)
Number of Immunosuppressants (mean ± SD)	1.7 ± 0.6

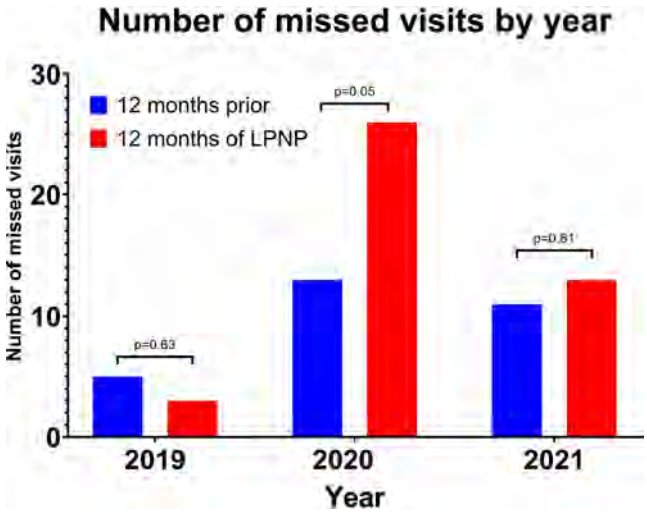

Figure 1. Number of Missed Rheumatology Visits by Year

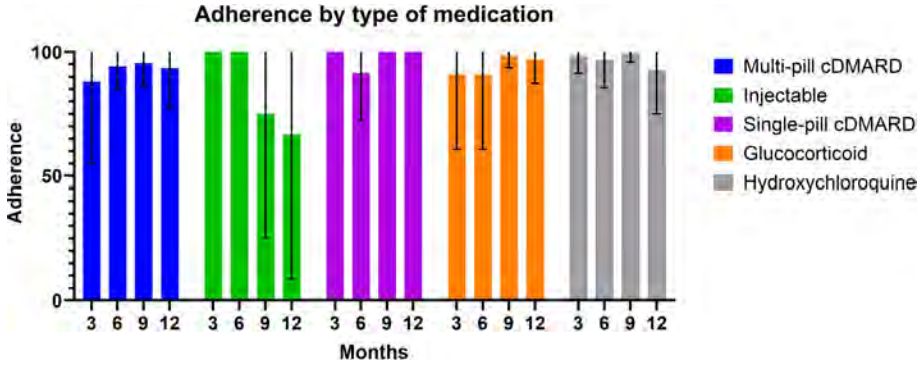

Figure 2. Adherence by Type of Medication Over 12 Months of LPNP Participation. cDMARD = conventional DMARD

There was no statistically significant difference in visit adherence when comparing the year prior to LPNP enrollment to the LPNP period (**Figure 1**), with the exception of 2020 when missed visits increased (2019 p=0.63; 2020 p=0.05; 2021 p=0.81).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

During the study period, 52% of participants reported glucocorticoid use and 96% reported hydroxychloroquine (HCQ) use, with an average of 1.7 immunosuppressive medications per patient (**Table 1**).

Medication adherence over the 12-month period (**Figure 2**) appeared to vary by medication type: adherence to injectable therapies declined, while adherence to oral agents—including DMARDs, hydroxychloroquine, and glucocorticoids—remained relatively stable.

Conclusion: The COVID-19 pandemic led to a peak in missed rheumatology visits among the high-risk patients with SLE participating in the LPNP. There appears to be mitigation of barriers with the LPNP in 2019, however missed visits increased in 2020 and 2021 despite the LPNP intervention. This may reflect a higher number of scheduled visits overall due to more frequent healthcare touchpoints introduced by the program. Tailoring navigator interventions to address the specific barriers associated with different treatment modalities—particularly injectable therapies—may enhance effectiveness. Further research is warranted to optimize navigator-based strategies and assess long-term outcomes in the context of evolving healthcare delivery challenges.

Abstract Number: 1083

How Do Social Determinants of Health Differ Across Age and Disability Groups Among Adult Medicare Advantage Enrollees with Systemic Lupus Erythematosus?

Alexjandro Daviano[1], Vijay R. Nadipelli[2], Yihua Xu[1], Karen Worley[2], Shireen Haq[1], Josephine Ohioma[3], Jeffrey J. Ellis[2], Brandon T. Suehs[1] and **S. Sam Lim**[4], [1]Humana Healthcare Research, Inc., Louisville, KY, [2]GSK, Global Real-World Evidence & Health Outcomes Research, Collegeville, PA, [3]GSK, US Medical Affairs, Philadelphia, PA, [4]Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Management of patients with SLE should consider social determinants of health (SDoH) and their impact on access, treatment, and patient outcomes; however, such a holistic approach is not routinely studied or adopted in clinical practice.[1] To close this knowledge gap, we assessed patient characteristics including SDoH, disease burden and clinical outcomes, and healthcare resource use (HCRU) among adult Medicare Advantage (MA) plan enrollees with SLE.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This retrospective analysis (GSK Study 222168) used administrative claims data supplemented with patient- and community-level measures of SDoH. Humana MA enrollees 18–89 years of age (YOA) with SLE (with or without LN) and enrolled during the 2023 calendar year were included. Diagnosis of SLE was required on ≥1 medical claim during 2023 and ≥1 diagnosis prior to 2023. Measures of disease burden, medication use, and HCRU were based on claims data. Measures of social risk (e.g. low-income subsidy [LIS], dual eligibility [DE], disability) were based on enrollment file data. Community-level measures of social risk (e.g. public assistance, educational attainment) were based on publicly available data sources. Analyses were descriptive.

Results: Among 20,188 patients with SLE identified (90.3% female, 30.7% of Black race), 76.2% had a Health Equity Index and 46.3% had a DE/LIS status. Approximately half of MA enrollees were < 65 YOA (45.5%). Compared with enrollees ≥65

Table 1. Patient SDoH characteristics stratified by age and qualification for MA on the basis of disability. *Enrollees ≥65 YOA who originally qualified for MA based on disability; †a higher ADI score is indicative of high levels of area deprivation and lower score is indicative of area affluence; ‡approximately 91% of patients were matched to the AHRQ SDoH database at census tract level, and the rest were matched at zip code level. There were 72 observations with missing value on median household income, 91 on percentage of families with children that are single-parent families. The rest of the AHRQ measures had 0–5 missing values; §percentage below national median; ||percentage above national median. ADI, area deprivation index; AHRQ, Agency for Healthcare Research and Quality; CMS, Centers for Medicare and Medicaid Services; HEI, Health Equity Index; SD, standard deviation.

Patients with a nephrologist visit	659 (7.2)	551 (5.0)	255 (5.5)
Patients with a PCP† visit	4631 (50.4)	5586 (50.7)	2294 (49.4)

YOA, < 65-year-olds had elevated social risk factors, with nearly all (99.7%) having disability and DE/LIS status (**Table 1**). MA enrollees < 65 YOA also tended to reside in communities with greater social risk (lower income and educational attainment, higher unemployment, greater use of public assistance; **Table 1**). Moderate/severe SLE was more common among enrollees < 65 YOA (82.8% vs 78.4%), who also had higher treatment rates with SLE medications compared with enrollees ≥65 YOA (**Table 2**).

Disability as the original reason for MA qualification was common overall (67.7%), including 98.3% of < 65 YOA and 42.2% of ≥65 YOA enrollees (**Table 1**). Among enrollees ≥65 YOA who originally qualified for MA based on disability, social risk factors, disease severity, SLE medication use, and HCRU were generally greater than for the enrollees ≥65 YOA overall (**Table 1** and **2**).

Enrollees < 65 YOA were more likely to visit a rheumatologist (36.5% vs 30.3% of those ≥65 YOA) or a nephrologist (7.2% vs 5.0% of those ≥65 YOA) for an SLE-related visit (**Table 2**). Among the enrollees < 65 YOA who visited a rheumatologist or nephrologist, 46.1%, 70.7%, and 14.2% received immunosuppressant, antimalarial, and biologic treatment, respectively.

Conclusion: We observed substantial social risk factors among MA enrollees with SLE, with disability being the dominant reason for MA qualification. SLE severity, treatment patterns, and HCRU varied between ≥65 and < 65-year-olds. Interventions to address the unmet needs should consider the burden of SDoH and diversity of the MA SLE population. Further research is needed to identify and evaluate specific health-related unmet needs of this population, potential interventions, and impact on patient outcomes.

Background/Purpose: Patients with polymyalgia rheumatica (PMR) are commonly diagnosed and cared for by non-rheumatology providers (i.e., primary care). Lack of access to specialty care can impact diagnosis and treatment. The aim of this study was to describe the clinical and sociodemographic factors associated with receiving specialty care in patients with a new diagnosis of PMR.

Methods: An inception cohort of patients with a new diagnosis of PMR was created using Medicare fee-for-service claims data from 2016-2022. Patients with PMR were included if they were age ≥50 years and had: 1) ≥1 inpatient or ≥2 outpatient claims with ICD-10-CM M35.3 ≥30 days and < 365 apart, 2) a prescription for glucocorticoids (GC) 7.5–30 mg/day filled within 30 days from 1st inpatient diagnosis, or filled between 1st outpatient diagnosis to 30 days after 2nd diagnosis, with a cumulative GC use of ≥200 mg over ≥120 days of first prescription period, 3) continuous enrollment ≥1 year prior to index

Table 2. Factors associated with access to any rheumatology care during first-year of follow-up

Table 3. Access to rheumatology in patients with PMR at 2-year follow-up (n = 16,098)*	
Rheumatology visits	N (%)
No rheumatology visits during first year	6,608 (41.0)
≥1 rheumatology visit during 2nd year follow-up	469 (7.1)
≥ 1 rheumatology visit during 1st year follow-up	9,490 (59.0)
≥1 rheumatology visit during 2nd year follow-up	6,924 (66%)
Continuous rheumatology care**	4,792 (50.5%)
* All patients with continuous enrollment in Medicare Part A, B, and D during two-year follow-up after diagnosis.	
** Continuous care defined as ≥2 rheumatology visits per year	

date (first GC prescription) with no evidence for PMR or giant cell arteritis (GCA), 4) ≥1 year of continuous enrollment after index date. Exclusion criteria applied at baseline using all available prior data included GCA or any other rheumatologic conditions, except for seronegative rheumatoid arthritis.

Sociodemographic and comorbidity data was collected at baseline. Other covariates of interest included: social vulnerability index, rural-urban commuting area, rheumatologist density per county, initial GC dose, and frailty, calculated using a validated claims-based frailty index.

The outcome of interest was care from a rheumatology provider (≥1 visit) during the first year after PMR diagnosis. Univariate Poisson regression was performed to assess factors associated with access to rheumatology. In patients with two-year follow-up, we assessed continued rheumatology visits, including ongoing rheumatology care, defined as ≥2 rheumatology visits per year during each of the 2 years after PMR diagnosis.

Results: A total of 20,536 patients with new-onset PMR were included (Table 1). During the first year of follow-up, 11,965 (58.3%) patients received care from a rheumatology provider. Of these, 3,907 (32.7%) were seen by a rheumatologist after initiation of GC treatment (i.e., inclusion in cohort), with median (IQR) time to first rheumatology visit of 57 (25, 135) days.

In univariate analysis, older age, non-northeast US region, non-urban areas, lower rheumatologist density, frailty, and higher comorbidity burden were associated with a lower likelihood of seeing rheumatology during the first year (Table 2). Patients started on GC doses either lower or higher than recommended by current guidelines were also less likely to see rheumatology during the first year. Of 16,098 patients with continuous two-year follow-up, only half who saw rheumatology during the first year remained under continuous rheumatology care (Table 3).

Conclusion: In the U.S., over half of patients newly diagnosed with PMR see a rheumatologist within the first year. However, patients at higher risk for GC toxicity (older, frail, high multimorbidity) are less likely to receive rheumatology care, highlighting the need to improve PMR referral practices.

Abstract Number: 1085

Bridging the Gap: The Use of Patient Joint Self-Assessment in RA Treatment Response Evaluation

Sri Lakshmi Sathiyaseelan[1], Sandeep Kansurkar[2], Kavita Krishna[3] and Varsha Bhatt[4], [1]Bharati Vidyapeeth medical college and hospital, chennai, Tamil Nadu, India, [2]Bharti vidyapeeth (DTU) Medical College, Pune, Pune, Maharashtra, India, [3]Bharati Vidyapeeth University Medical College and Hospital, Pune, Maharashtra, India, [4]Department of Clinical Immunology and Rheumatology, Bharati Vidyapeeth (Deemed To Be) University Medical College,Pune, Pune, Maharashtra, India

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Rheumatoid arthritis presents with multiple joint pains and it is traditionally, examined by the clinicians. The utility of patient self-joint counts has become an increasingly important area to explore, with remote disease monitoring and telehealth taking on a larger role across rheumatology practices post the global pandemic and increasing scarcity of Rheumatologist in comparison to the increasing case load. This study was inspired from the video released by Centre for Epidemiology and Arthritis on self-assessment of joints in patients with RA to replace clinical examination.

Methods: Sixty-two consecutive patients of RA over the age of 18 who attended our out-patient department between October 2022 and December 2022 were included in this study. We prepared an instructional manual with pictorial representation in English and local language to explain the joint examination to patients. If the patient had difficulty in reading, the attendant was allowed to explain to the patient. A pilot testing was done on ten patients for clarity of understanding, and it was well accepted. Same manual was applied to study participants to maintain uniformity. They marked the tender and swollen joints and the clinical was blinded to their findings. They also scored the pain, difficulty of the questionnaire and patient global assessment score. The patient was then evaluated by an experienced Rheumatologist well versed in RA joint examination.

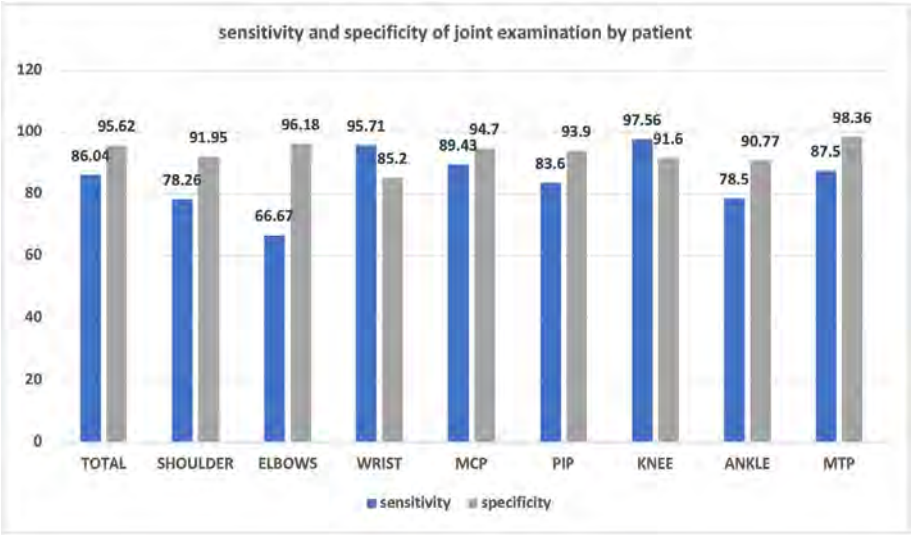

Figure 1

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

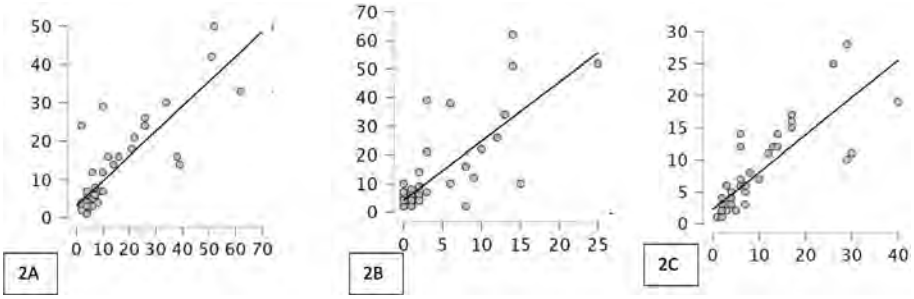

Fig 2A: correlation between total number of joints examined by patient vs clinician ; 2B: Correlation between swollen joints examined by patient vs clinician; 2C: Correlation between tender joints examined by patient vs clinician

Results: The total number of joints assessed by patients and clinicians was 3968. The number of joints with either tender or swollen as examined by clinician and patient was 559 and 499, respectively. The sensitivity of patient-reported joint counts was 86.02% (82.6–88.9%), while the specificity was 95.62% (94.8–96.3%). For swollen joints, the sensitivity was 89.2% and the specificity was 96.2%. For tender joints, the sensitivity was 85.04%, and the specificity was 93.8% (Figure 1)

Among joint categories, patient self-assessment was more accurate for proximal joints such as the shoulder (specificity 91.95%) and elbows (sp 96.18%). In contrast, distal joints like the wrist, metacarpophalangeal joints, knee, and ankle were assessed more accurately by clinicians. The CDAI was calculated as per clinician and patient tender, swollen joints were calculated individually. There was a strong correlation between CDAI (phy) and CDAI (pt) (rho-0.99).Cronbach's alpha for CDAI (patient) was 0.701.

There was a strong correlation between the total joint counts reported by physicians and patients with higher propensity for swollen joints than tender joints (rho= 0.887 and 0.827, respectively ($p < 0.001$)) Intraclass correlation coefficients (ICC) for total joints, swollen joints, and tender joints were 0.810, 0.880, and 0.770, respectively, indicating good to excellent reliability.(Figure 2A,2B,2C)

Conclusion: This study shows that with proper training, patient self-assessment of joints is a reliable alternative for online consultations, especially in remote areas. It is particularly accurate for detecting swollen joints, making it useful for remote monitoring and treatment decisions. The findings support integrating self-assessment into telemedicine to improve access and care quality.

Background/Purpose: Pain management in autoimmune rheumatic diseases (ARDs) increasingly includes NSAIDs, physical therapy, and self-management. However, the role of cannabis in ARD symptom relief remains unclear. We used natural language processing (NLP) on electronic health records (EHRs) to systematically characterize cannabis use patterns, motivations, and disparities in ARD patient

Sociodemographic and Disease-Related Distribution of Reasons for Cannabis Use Among Patients with Autoimmune Rheumatic Diseases Among Cannabis Users, 2015-2024 *These proportions add up to more than >100% because individuals can mention any or all the uses in the clinic notes

Methods: A retrospective analysis (2004–2024) included 5,051 patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc), Sjögren's syndrome (SjS), or ankylosing spondylitis (AS) from an academic health system. NLP models (ClinicalBERT) extracted cannabis documentation from 2,626,542 clinical notes, classifying cannabis use as current, past, or none and categorizing reasons as pain, sleep, anxiety, nausea, or appetite. Sociodemographic factors, comorbidities, medications, and healthcare utilization were compared between cannabis users and non-users.

Results: Clinical notes documenting current cannabis use rose from 0.1% (2017) to >1% (2024), a 900% relative increase. NLP classifiers performed well for cannabis documentation, current vs. past use (F1=0.85), and reasons for use (F1=0.86). Overall, 1,237 patients (24.5%) had current cannabis use documented. Higher usage was observed among Hispanic/Latino (30.1%) and Black (36.2%)

patients. Pain was the primary reason overall (37.9%), notably higher among Black (54.5%) and Hispanic/Latino (43.2%) patients compared with White (38.5%) and Asian patients (21.6%). Women more frequently reported using cannabis for pain (39.4%) and sleep (16.4%) compared to men (33.0%, 11.6%, respectively). Older adults (≥66 years) most likely to report

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Annual Percentage of Notes Mentioning Current Cannabis Usage by Gender, Race, Ethnicity, Mean Age, and Disease Status, 2004-2024

pain-related cannabis use (46.4%), whereas middle-aged adults (17.8%) and early middle-aged adults (16.1%) were more likely to use cannabis for sleep. Disease-specific differences showed pain-related use was highest among patients with RA (40.7%), SjS (38.3%), and SLE (37.0%), while sleep-related cannabis use was most frequently documented in patients with SLE (27.4%) and SjS (26.4%). Cannabis users had greater comorbidity burdens, more emergency visits, hospitalizations, and opioid prescriptions.

Conclusion: This study represents one of the largest and most comprehensive efforts to characterize cannabis use in ARDs using NLP and machine learning. This study demonstrates the feasibility of systematically identifying cannabis use patterns and motivations in ARD patients, highlighting opportunities for clinicians to initiate informed discussions with patients regarding cannabis as a symptom management strategy. Future research should investigate factors driving cannabis use, including specific ARD subphenotypes, disease activity and severity, treatment interactions, and the impact on overall disease management. Efforts to address disparities in medical cannabis access and rigorous studies evaluating safety and effectiveness will be essential for informing potential clinical guidance.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1055–1087) Healthcare Disparities in Rheumatology Posters
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with considerable clinical and molecular heterogeneity. Significant disparities exist in SLE, with minority populations experiencing higher prevalence, increased disease severity, and earlier mortality. Recent studies suggest that adverse social determinants of health may contribute to these disparities. This study evaluated the association between neighborhood-level social vulnerability, measured by the Social Vulnerability Index (SVI), and disease severity, clinical manifestations, and early mortality among female SLE patients in the Lupus Family Registry and Repository (LFRR).

Methods: The LFRR is a large, cross-sectional cohort of SLE patients and their unaffected family members. Patients met ACR 1997 classification criteria for SLE, were female, and had available residential addresses for geocoding (n=3,033). Of those patients, 1,091 were deceased prior to 2024 and included in the early mortality analysis. Disease severity was assessed using the Montgomery Lupus Severity Index (LSI; high severity defined as LSI >7). SVI percentiles (range 0-1) were categorized as high (percentile >0.50) or low (≤ 0.50) vulnerability. Early mortality was defined as death before the average age of death in the US population from 1999-2020, stratified by sex and race. Descriptive statistics and separate logistic regression models were used to evaluate associations with SVI factors, LSI, ACR criteria, and lupus nephritis (LN).

Results: Consistent with previous studies, we observed significant racial differences in disease severity, and clinical manifestations along with higher percentages of early mortality (Table 1 and Figure 1). In univariate analyses, high SVI was associated with increased odds of certain ACR criteria and LSI (Figure 1A). However, these associations were no longer statistically significant after adjusting for race (Figure 1B). Racial differences in disease severity and organ involvement persisted even after accounting for SVI (Figure 1). Patients who died early had significantly higher SVI scores for low economic and household instability factors, indicating greater social vulnerability (Figure 2). Notably, these factors remained significantly associated with early mortality following adjustment for race, sex and high LSI (Figure 2).

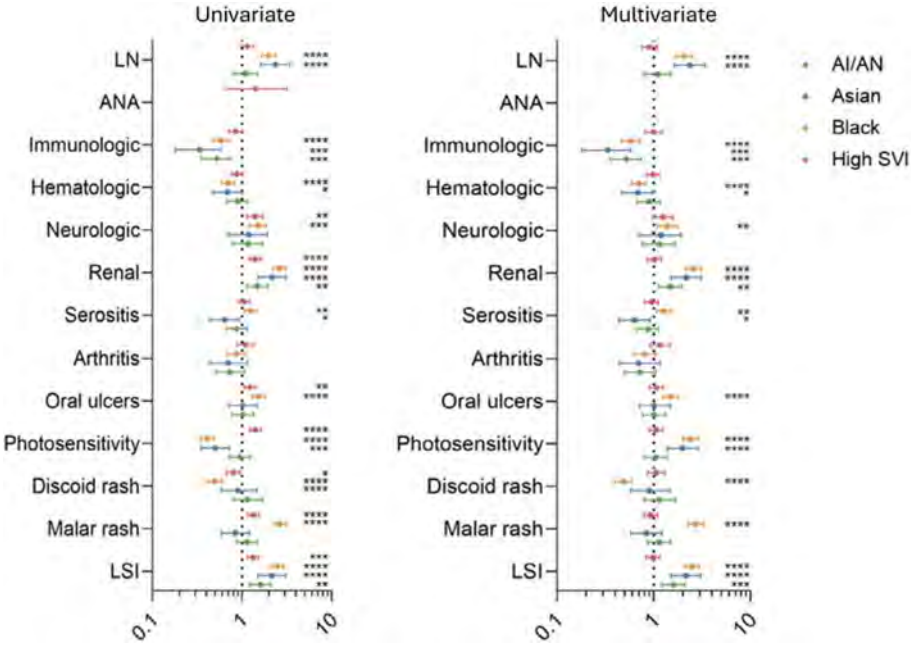

Figure 1: Associations of social vulnerability index and self-reported race with SLE disease severity and clinical manifestations. (A) Univariate and (B) multivariate logistic regression models for associations with different clinical characteristics. The multivariate model incorporates self-reported race categories and low vs high SVI.

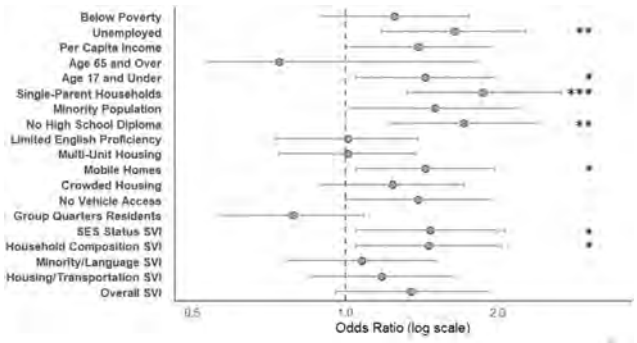

Figure 2: Associations of social vulnerability index with early mortality in SLE; multivariate logistic regression models for associations with different SVI factors. The multivariate model incorporates self-reported race categories, sex, high LSI, and low vs high SVI.

Conclusion: In the LFRR, neighborhood-level social vulnerability was not associated with SLE severity or organ involvement after accounting for race. Persistent racial disparities in SLE severity and manifestations suggest that factors beyond area-level vulnerability, including genetic, epigenetic, and individual-level environmental exposures, may play a more substantial role. Social vulnerability, particularly low economic and household instability factors, was significantly associated with early mortality.

Abstract Number: 1088

Unsupervised characterization of immune checkpoint inhibitor induced inflammatory arthritis using cluster and latent class analysis: result from a multicenter prospective registry

Alice Tison[1], Deanna Jannat-Khah[2], Laura Cappelli[3], Anne R. Bass[2], and the RADIOS registry consortium, [1]LBAI, UMR1227, University of Brest, CHU Brest, Brest, France, Brest, France, [2]Hospital For Special Surgery, New York, NY, [3]Johns Hopkins School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The broad use of immune checkpoint inhibitors (ICIs) in oncology has led to the emergence of ICI-induced inflammatory arthritis (ICI-IA). The aim of this study was to define ICI-IA phenotypic patterns using unsupervised clustering and latent class analysis (LCA) and determine their association with the need for an immunosuppressive DMARD.

Methods: Data was extracted on 11/6/2024 from the Rheumatology Adverse Events Due to Immunotherapy Observational Study (RADIOS) registry regarding patients with ICI-IA or ICI-polymyalgia rheumatica (PMR) who had been prospectively recruited at nine sites around the United States. Clinical data at the date of registry enrollment was used to group patients. Clinical features involving < 10% of patients were excluded to avoid outliers. We analyzed only immunosuppressive DMARDs (methotrexate, leflunomide, biologic/targeted synthetic DMARDs). Multiple correspondence analysis (MCA) was used to group binary variables followed by a hierarchical classification on the generated coordinates using the Ward method, with Euclidean distances. An LCA was then performed to group patients. The optimal number of classes was determined according to goodness of fit. Classes were compared using descriptive statistics. Stepwise backwards multivariable logistic

Figure 1 : Results from multiple correspondence and latent class analysis in the RADIOS registry

b/tsDMARD: biologic/targeted synthetic Disease Modifying Antirheumatic Drug, ICI-IA: immune checkpoint inhibitor mediated inflammatory arthritis, ICI-PMR: immune checkpoint inhibitor mediated polymyalgia rheumatica, LCA: Latent Class Analysis, MTX: methotrexate, RF: rheumatoid factor.

regression (retaining variables with $p \leq 0.1$) was used to compare DMARD utilization between classes adjusted for maximum ICI-IA/PMR grade, cancer type, the use of combination ICI, recruitment institution and age. The LCA model was then validated in the HSS Registry, an independent single center prospective ICI-IA/PMR registry, and the same statistical methods were applied to compare DMARD utilization between classes.

Results: 443 patients with ICI-IA/PMR in the RADIOS registry were included in the cluster analysis. The variables included in the MCA were: swollen hand/wrist/knee/ankle/foot, tenosynovitis and enthesitis. The hierarchical classification identified 3 main groups (figure 1A) and isolated a group of variables, swollen ankle/foot, enthesitis and tenosynovitis, from the others. The LCA identified 3 classes of patients (figure 1B). Class 1 was dominated by rare swollen joints, while swollen hand, wrist and/or knee predominated in Class 2. Swollen ankle and foot reached a probability >80% in class 3, along with a high

probability of having other swollen joints. The median CDAI was higher in class 3, as was the 28 swollen joint count (Table 1). The stepwise logistic regression model showed an OR for DMARD use of 3.64 ([95%CI 1.5-9.1] p=0.006) for class 3 compared to class 1. The estimates of the LCA were applied to the validation cohort (n=117) and demonstrated greater use of DMARDs in HSS class 3 compared to class 1 and 2 (Table 2), but this was not statistically significant (OR 3.7 [95%CI 0.5-27], p=0.2), likely due to the small number of patients in class 3 (n=6).

Conclusion: In this large multicenter prospective cohort we identified 3 phenotypic patterns of ICI-IA. One group, characterized by ankle and foot joint swelling and more swollen joints in general, was more likely to require an immunosuppressive DMARD. This information could help stratify patients prognostically at their first rheumatology visit.

ICI-IA: immune checkpoint inhibitor mediated inflammatory arthritis, ICI-PMR: immune checkpoint inhibitor mediated polymyalgia rheumatica, RF : Rheumatoid factor

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Background/Purpose: Inflammatory arthritis (IA)- and polymyalgia rheumatica (PMR)-like syndromes occur in about 6% of patients receiving an immune checkpoint inhibitor (ICI) and can worsen quality of life. Finding the balance between immunosuppression use without affecting the tumor response is critical. Currently, ICI-IA/PMR management is not standardized and is based on expert opinion. It is unknown whether ICI-IA and ICI-PMR can be treated with the same immunosuppressive regimens. We aimed to compare the utilization of steroids and other DMARDs between these two entities.

Methods: Data were extracted from the Rheumatology Adverse Events Due to Immunotherapy Observational Study (RADIOS) registry regarding patients with ICI-IA or ICI-PMR and no preexisting IA who had been prospectively recruited into RADIOS since 2015 at nine sites around the United States. Data was downloaded on 11/6/2024. Steroids were defined as methylprednisolone and prednisone. We excluded hydrocortisone, used for adrenal replacement, and dexamethasone, used for cancer-related symptoms. Cumulative steroid utilization from the time of onset of IA was available for a subset of patients. We analyzed only immunosuppressive DMARDs, such as methotrexate, leflunomide and biologic/targeted synthetic DMARDs, because of potential impact to tumor responses from ICIs. Categorical and continuous data were compared using descriptive statistics. Kaplan Meier curves were used for survival analyses and groups were compared using a log rank test. We measured the time to a prednisone equivalent dosage i. 10 mg/day or ii. 5 mg/day starting from the first steroid dose received at or after the date of the patient's baseline visit in RADIOS. Multivariable logistic regression was used to compare DMARD utilization in ICI-IA versus ICI-PMR, adjusted for maximum grade (severity), cancer type, the use of combination ICI (anti-CTLA4 plus anti-PD1), recruitment institution and age.

Results: 443 patients were included, n=379 with ICI-IA and n=64 with ICI PMR. 49% were female, with a median age of 66 years (IQR 55,73). Anti PD-1/PDL-1 was used in 265 patients (72%) and combination ICI in 92 (25%). At baseline, 11 ICI-PMR patients (20%) had a peripheral synovitis primarily involving the hand, knee and wrist (Table 1). The median maximum steroid dose prescribed after baseline did not differ between groups (p=0.92) (Table 2). Time to reach a steroid dose of 10 or 5 mg/day from first steroid prescription after baseline was also comparable (p=0.74 and p=0.50 respectively) (Figure 1 A, B). There was no difference

Table 2: Immunosuppressive use and ICI management in ICI-IA compared to ICI-PMR

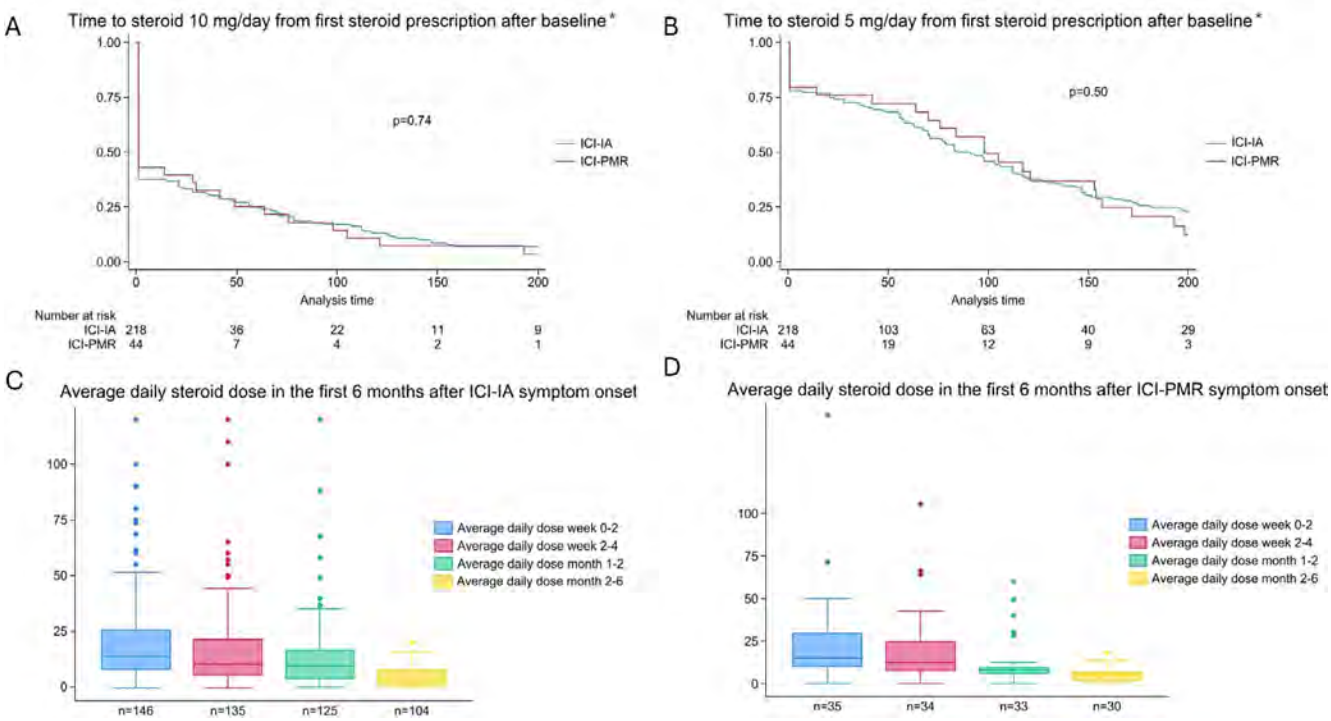
Figure 1 : Steroid utilization in ICI-IA and ICI-PMR



* Baseline = Baseline RADIOS registry visit

in average daily steroid dose between the two groups in the first 6 months after symptoms onset (Table 2, Figure 1 C, D). DMARDs were more prescribed to patients with ICI-IA (43%) than ICI-PMR (23%) (p=0.004). This difference remained after adjusting for confounders in a multivariable logistic regression model (OR= 3.03 [95%CI 1.10, 8.34], p=0.032).

Conclusion: Patients with ICI-IA were more likely to be treated with immunosuppressive DMARDs than patients with ICI-PMR. Treatment with steroids was comparable between the two groups. Identifying more severe phenotypes at diagnosis might help to avoid longer steroid exposure before DMARD initiation.

Quantitative Immunoglobulin Screening Prior to Rituximab Initiation: A Retrospective Cohort Study

Amelia Khoo and Anokhi Saklecha, Yale University, New Haven, CT

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Background/Purpose: Rituximab, a monoclonal antibody which binds to the CD20 antigen of B cells, is used in the treatment of many rheumatologic conditions. Due to its mechanism of action, which depletes B cells and reduces production of immunoglobulins, patients who receive rituximab are at significantly increased risk of developing hypogammaglobulinemia. Studies suggest that as many as 38% of patients who receive rituximab develop hypogammaglobulinemia, which in turn places them at increased risk of recurrent infection (Casulo et al., 2014). A reduced baseline level of immunoglobulins is associated with severe infections after receiving rituximab. Current literature suggests that patients should therefore be pre-screened with quantitative measurement of immunoglobulins prior to initiation of rituximab (Buch et al., 2011). In this study, we aimed to assess the prevalence of this pre-screening in a large academic health center.

Methods: We conducted a retrospective cohort study based on electronic health records in a large academic health system. Adults (≥18 years) who received their first rituximab dose between 1/1/2023 and 12/1/2024 were included. Baseline screening was defined as any recorded quantitative immunoglobulin panel drawn in the six months prior to initiation of rituximab. IVIG administration ≤ 6 months after initiation (follow-up through 1 May 2025) served as a proxy for clinically significant antibody failure. Screened and unscreened groups were compared with Fisher's exact test.

Results: Among **238** patients who started rituximab, only 115 (48.3 %) underwent guideline-recommended baseline Ig screening, leaving 123 (51.7 %) unscreened. All screened patients had normal IgA and IgM levels. Quantitative IgG levels were not available. IVIG rescue occurred in 17 patients (7.1 %) overall—11/115 (9.6 %) in the screened group and 6/123 (4.9 %) in the unscreened group (p=0.21).

Conclusion: Despite guideline recommendations, over half of patients did not receive baseline Ig screening in the 6 months before rituximab initiation. No screened patient with abnormal IgA/IgM proceeded to treatment, indicating that screening—when performed—effectively excludes overt hypogammaglobulinemia. Interestingly, however, early IVIG rescue did not differ significantly between screened and unscreened patients, calling into question the short-term protective value of current screening practice. Limitations include the absence of quantitative IgG data and single-center design. Future work includes assessing screening rates and clinical outcomes across multiple sites and launching a quality-improvement initiative using an electronic Best Practice Advisory to improve adherence.

Background/Purpose: Immune-related adverse events (irAEs) are a significant concern for patients receiving immune checkpoint inhibitors (ICIs), particularly those with pre-existing rheumatoid arthritis (RA). Managing ICIs in RA patients is complex due to potential immune activation leading to disease flares or new autoimmune manifestations. Although RA patients were often excluded from ICI trials, their increasing representation among cancer patients highlights the need for a better understanding of the safety and toxicity of ICIs in this population.

Methods: We conducted a propensity score-matched cohort study using the TriNetX Analytics Network database, comprising anonymized data from over 140 collaborating healthcare institutions worldwide. We compared the incidence and risk of irAEs in cancer patients with and without RA. Adult patients (age ≥18) receiving ICIs were included. The primary outcome was composite irAEs within one year of ICI initiation, while secondary outcomes were individual irAEs and all-cause mortality. Matching criteria included demographics (age, sex), metastatic disease, chemotherapy and radiation history, underlying comorbidities, ECOG performance status, and cardiovascular medication use. Risk of irAEs was assessed using Cox proportional hazards models, with hazard ratios (HR) and 95% confidence intervals (CI). P-values < 0.05 were considered significant.

*Excluding inflammatory arthritis								

Results: We included 969 RA patients and 969 non-RA patients after matching. The mean age was similar between groups (66.2 ± 10.9 years for RA vs. 66.7 ± 12.0 years for non-RA). The proportion of male patients was also comparable (43.6% in RA vs. 44.6% in non-RA). The incidence of irAEs in the RA group was not significantly different from the non-RA group (HR 1.13, 95% CI 0.99–1.29, p=0.072). Notably, the RA group exhibited a significantly lower all-cause mortality (HR 0.84, 95% CI 0.71–1.00, p=0.049). Specific irAEs with increased risk in the RA group included adrenal insufficiency (HR 1.60, p=0.033) and other rheumatic irAEs (HR 3.44, p=0.001). No significant differences were observed in the incidence of colitis, hepatitis, pancreatitis, pneumonitis, myocarditis/pericarditis, or other irAEs.

Conclusion: In this analysis, RA patients receiving ICIs demonstrated no significant difference in the incidence of composite irAEs and a lower risk of all-cause mortality compared to non-RA patients. The findings underscore the importance of close monitoring and multidisciplinary care for RA patients undergoing ICI therapy to mitigate immune toxicity while optimizing cancer outcomes.

Background/Purpose: Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy by enhancing the immune system's ability to fight cancer. However, their use is associated with immune-related adverse events (irAEs), including rheumatologic complications such as inflammatory arthritis. This study aims to evaluate the incidence and predictors of new-onset inflammatory arthritis and other irAEs in cancer patients treated with ICIs, with a focus on the impact of PD-1 versus PD-L1 blockade and the influence of pre-existing arthritis.

Methods: This study retrospectively analyzed electronic medical records of 3,341 patients treated with ICIs at Upstate University Hospital from 2011 to 2024. It screened for rheumatic immune-related inflammatory arthritis and systemic irAEs. Statistical analysis used chi-square or Fisher's exact test with GraphPad V10 software, considering a two-tailed p-value < 0.05 as significant.

Results: Table 1 outlines characteristics of 3,341 ICI-treated patients. Pembrolizumab (51% of patients) and nivolumab were most common (17.5%). The vast majority of patients were on monotherapy (92.2%). 5.4% of patients had a pre-existing history of inflammatory arthritis.Table 2 outlines the prevalence of arthritis in ICI-treated patients. PD-1 inhibitors

were associated with a higher incidence of inflammatory arthritis as compared to PD-L1 inhibitors ($p < 0.001$). Pembrolizumab was associated with a higher incidence of arthritis, affecting 19.05% of patients, compared to nivolumab, which affected 1.37% of patients ($p < 0.001$). Lung cancer patients had highest incidence of inflammatory arthritis (2.62%) compared to patients with other types of cancer (1.32%, $p = 0.0081$).Furthermore, the data shows a highly significant

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

association between a pre-existing history of arthritis and the development of inflammatory arthritis during treatment ($p < 0.0001$), with 17.8% of patients with prior arthritis developing inflammatory arthritis compared to 0.8% of those without such a history. Table 3 outlines the association between pre-existing arthritis and the development of total irAEs is highly significant ($p < 0.0001$), with 49.4 % of patients with prior arthritis developing irAEs compared to 14.2% of those without such prior history. Regarding subtypes of irAEs, conditions such as Colitis, Pneumonitis, Hepatitis, and Nephritis show highly significant associations ($p < 0.00016$), whereas other subtypes like vasculitis, sarcoidosis, sicca syndrome, encephalitis, SLE, Dermatitis, and Myositis were not statistical significance in patients with a pre-existing history of arthritis compared to those without ($p > 0.05$).

Conclusion: PD-1 inhibitors are markedly more prone to induce inflammatory arthritis than PD-L1 inhibitors. Amongst PD-1 inhibitors, pembrolizumab is associated with a higher incidence of inflammatory arthritis as compared to nivolumab. Lung cancer patients have a higher incidence of inflammatory arthritis compared to patients with other types of cancer. Moreover, prior history of arthritis overall predisposes to all types of irAEs. Prospective studies are warranted to validate these findings.

Rituximab Associated Risk for Progressive Multifocal Leukoencephalopathy Among Patients with Systemic Lupus Erythematosus: A Retrospective Cohort Study

Blake Baay[1], Lorien Nassi[2] and Zachary Most[3], [1]Scottish Rite for Children, Dallas, TX, [2]UT Southwestern, Children's Medical Center, and Scottish Rite for Children, Dallas, TX, [3]UT Southwestern, Dallas, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Rituximab is one of the many immunosuppressive medications used to treat SLE that can increase a patient's risk for developing progressive multifocal leukoencephalopathy (PML), a rare but largely fatal neurologic disease. However, despite being one of the few issued with a label warning regarding its association with PML, no study has determined the specific risk rituximab poses among these other medications. We attempted to quantify this risk by retrospectively comparing the prevalence of PML in two matched cohorts of SLE patients with and without previous exposure to rituximab.

Methods: We queried the TriNetX Research Network, a large database of anonymized electronic health records, to identify patients diagnosed with SLE after January 1, 1998. Patients exposed to rituximab or diagnosed with PML prior to this date were excluded. International Classification of Disease (ICD) codes were used to identify diagnoses of SLE and PML, and RxNorm and Healthcare Common Procedure Coding System (HCPCS) codes were used to determine rituximab exposure. Patients with any previous exposure were separated from those without to create the two cohorts. After nearest neighbor propensity score matching, we used Kaplan-Meier curves and the unadjusted hazard ratio (HR) to assess the risk of PML.

Results: The network included 316,307 patients diagnosed with SLE on or after January 1, 1998, without prior orders for rituximab or diagnosis of PML. The prevalence of PML in this initial general population was 0.015%. After propensity score matching, the two cohorts each consisted of 6,452 patients, with fewer than 10 diagnosed with PML in each group. PML

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Kaplan-Meier curves and calculated hazard ratio of the two cohorts. The section where the curves diverge has been enlarged and overlayed onto the unaltered graph.

occurrence was higher in the rituximab exposed cohort (Figure 1), although the difference was not statistically significant by log-rank test (P = 0.16) or in the proportional hazards model (HR = 2.97, 95% CI 0.60-14.73).

Conclusion: We were unable to demonstrate a statistically significant risk of developing PML from rituximab in patients with SLE when accounting for other comorbidities and immunosuppressive medications. Even assuming the high end of the confidence interval, the number needed to harm patients given rituximab to lead to one case of PML would be high at 513 patients.

Background/Purpose: Janus kinase inhibitors (JAKi) are effective in rheumatoid arthritis (RA); however, concerns regarding safety, particularly the risk of infections and malignancies, have been raised. This study aimed to assess the impact of JAKi on immune cell subsets in RA patients.

Methods: This prospective study included RA patients initiating JAKi therapy (tofacitinib, baricitinib, upadacitinib, and filgotinib), diagnosed according to ACR/EULAR 2010 criteria. Control groups consisted of healthy donors and RA patients starting biological disease-modifying antirheumatic drugs (RA-bDMARDs). Peripheral blood mononuclear cells were analyzed using multiparametric flow cytometry to characterize the immunophenotype of various immune cell subsets.

Results: We analyzed 78 RA patients treated with JAKi (Baricitinib: 46.2%, Filgotinib: 24.4%, Tofacitinib: 17.9%, Upadacitinib: 11.5%), 20 RA patients treated with bDMARDs (tocilizumab: n=11, abatacept: n=9), and 20 healthy controls (Table).

RA-JAKi patients showed a significant decrease in cytotoxic NK Dim cells (vs RA-bDMARD) and NK cells expressing Nkp30 (vs RA-bDMARD and healthy controls). The proportion of effector memory (EM) $CD4^+$ T cells was higher in RA-JAKi (20.47 [14.77–30.69]) vs RA-bDMARD (12.12 [7.62–17.05]) and healthy controls (10.79 [7.16–16.25]), while central memory (CM) T cells were reduced (38.40 [29.26–45.66] vs RA-bDMARD: 48.32 [43.82–58.8] and healthy controls: 48.87 [42.07–56.52]).

Total $CD4^+$ T-helper cells were significantly increased in RA-JAKi (1.50 [0.66–3.13]) vs healthy (0.38 [0.14–1.55]) and RA-bDMARD (0.33 [0.14–1.18]) (p=0.005 and p=0.003). Th17 and $Th1^+17$ cells were reduced in RA-JAKi vs both controls (Figure 1).

The proportion of double-negative B cells differed significantly between JAKi patients and controls, with switched memory B cells elevated in RA-JAKi (20.25 [11.18–29.08] vs healthy: 12.24 [8.31–18.82], p=0.018). $CD21^-$ low B cells were higher in RA-JAKi (4.44 [3.05–7.97] vs RA-bDMARD: 3.16 [1.42–4.75], p=0.045) (Figure 2).

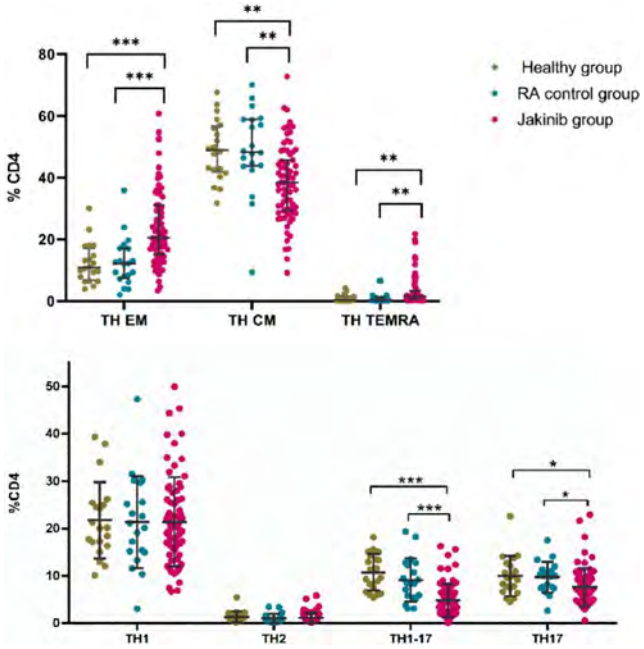

Figure 1. Differentiation status and percentage of T-Helper subsets in the three groups studied. A) Dot-plots depicting the percentage of T-helper according to their differentiation status categorized as Effector Memory T helper (TH EM, CD3+ CD4+ CD62L- CD45RA-), Central Memory T helper (TH CM, CD3+ CD4+ CD62L+ CD45RA-) and Effector memory re-expressing RA T helper cells (TH TEMRA, CD3+ CD4+ CD62L- CD45RA+) among healthy (green), rheumatoid arthritis control group (blue) and jakinib group (pink). B) Dot-plots depicting the percentage of T-helper subsets categorized as T helper 1 (TH1, CD3+ CD4+ CD45RA- CXCR3+ CCR6-), T helper 17 (TH17, CD3+ CD4+ CD45RA- CXCR3- CCR6+), T helper 1-17 (TH1-17, CD3+ CD4+ CD45RA- CXCR3+ CCR6+) and T helper 2 (TH2, CD3+ CD4+ CD45RA- CXCR3- CCR6- CD294+) among healthy (green), rheumatoid arthritis control group (blue) and jakinib group (pink).*p<0.05, **p<0.01 and ***p<0.001.

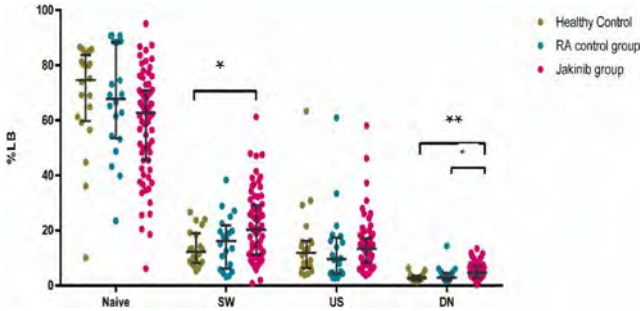

Figure 2. Differentiation status of B cells. Dot-plots depicting the percentage of B cells according to their differentiation status, categorized as Naïve (CD19+ IgD+ CD27-) Switched memory B cells (CD19+ IgD- CD27+), Unswitched memory B cells (CD19+ IgD+ CD27+) and Double negative B cells (CD19+ CD27-IgD-) among healthy (green), rheumatoid arthritis control group (blue) and jakinib group (pink).*p<0.05, **p<0.01 and ***p<0.001.

Conclusion: JAKi differentially impact innate immune cells compared to biological DMARDs. The observed reduction in cytotoxic activated NK cells and intermediate monocytes may contribute to increased susceptibility to viral infections and potential malignancies. Alterations in T and B cell subsets suggest an exhausted immune phenotype, emphasizing the need for further functional studies to fully elucidate the long-term immunomodulatory effects of JAKi.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The use of TNFα antagonist is not recommended if the patient have a suspicion or demyelinating diseases (DD) confirmed **[1]**. There are a few cases reported that non-TNFi targeted are used in this situation **[2-3]**.

To establish the evolution of DD (stability, aggravation) in patients with a rheumatic disease receiving biological non TNFαi or synthetic therapies, in a retrospective French cohort study.

Methods: A retrospective French multicenter descriptive, national study. Reported cases followed notifications via the CRI (Club Rhumatisme Inflammatoire) newsletter.

Inclusion criteria: Patients > 18 years of age, with IRD (rheumatoid arthritis [RA], spondyloarthritis [SpPA], psoriatic arthritis [psoriatic arthritis]), treated with a non TNFi targeted therapy for more than 3 months, and presenting with demyelinating disease (MS and/or neurological manifestations suggestive of demyelinating disease), whether or not they occurred while on TNFi therapy.

Results: 51 patients received at least one non-TNF targeted therapy (33 SpA, 13 RA, 5 R Pso), with clinical, biological and therapeutic characteristics at Baseline. The mean age of diagnosis of demyelinating pathology was 37.8 years (12-76) in the SpA group, 42.7 (24-58) in the RA group and 45.8 (32-56) in the R Pso group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

51% (n=26) had at least one prior exposure to an anti-TNF before the onset of demyelinating pathology (21 SPA, 1 Rpso, 4 PR). Exposure to non-TNF treatments in the different therapeutic lines is: 40 patients to anti-IL17 with a mean duration of 25 months (2-103), 5 patients to Anti-IL6R with a mean duration of 42.2 months (21-133), 9 patients to CTLA-4Ig (Abatacept) with a mean duration of 18.6 months (3 -64), 7 patients to Jaki with a mean duration of 19.3 months (2-38), 2 patients to anti-IL23 with a mean duration of 8.5 (7-10), 12 patients to anti-CD20 with a mean duration of 18.1 months (4-118), 1 patient to apremilast (phosphodiesterase 4 (PDE4) inhibitor) with a mean duration of 29 months and 3 patients to anti-IL-12 and IL-23 with a mean duration of 31.5(14-64).

100% of patients (n=51) had stability or improvement of demyelinating pathology.

The combination in 6 patients treated with secukinumab, 1 patient with tocizulumab, and 1 patient with rituximab with a background MS treatment (interferon beta, teriflunomide, ocrelizumab, glatiramer acetate) was well tolerated.

Conclusion: The use of non-anti-TNF targeted therapies (anti-IL17, anti-IL6R, CTLA-4Ig, Jaki, anti-IL23, anti-CD20, PDE4 inhibitor, and anti-IL-12 and IL-23) in patients with RIC does not appear to worsen demyelinating disease.

Background/Purpose: Interleukin-6 (IL-6) is a proinflammatory cytokine involved in B cell differentiation and antibody production through the JAK/STAT pathway. In clinical practice, hypogammaglobulinemia (HGG) has been observed in patients with inflammatory rheumatic diseases (IRDs) treated with IL-6 receptor inhibitors (IL6Ri) (Vílchez-Oya et al., 2020), but this potential adverse effect remains insufficiently studied. We aimed to evaluate the impact of IL6Ri and Janus kinase inhibitors (JAKi) on humoral immunity through an ambispective approach.

Methods: We first conducted a retrospective chart review of adult patients with rheumatoid arthritis (RA), giant cell arteritis (GCA), or spondyloarthritis (SpA) treated with IL6Ri or JAKi. The primary endpoint was HGG (IgG < 750 mg/dL), also collecting cases of severe HGG (IgG < 450 mg/dL) and severe infections. Subsequently, we initiated a prospective observational study including patients with IRDs initiating IL6Ri or JAKi. Serum immunoglobulin levels and lymphocyte populations were assessed at baseline, 3 and 6 months. Statistical analyses included Student's t-test or Wilcoxon test for paired comparisons, and Fisher's exact test for categorical data.

Results: In the retrospective cohort (n=56) (Table 1), HGG was observed in 20 patients: 35.7% (95% CI 24–49%); 41.9% with IL6Ri (95% CI 26-59%) and 28% with JAKi (95% CI 14-48%). Among these patients, 7 had baseline HGG, three of them had prior rituximab treatment. Severe HGG occurred in 5 patients (25%), with one requiring immunoglobulin replacement. Eight cases had low IgA levels, and six had low IgM. Lymphocyte counts remained within normal limits in all cases. Five patients with HGG developed severe infections, with no associated mortality.

Table 1. Demographic and Clinical Characteristics of the Study Population.

A. Retrospective Phase (n=56).	
Age (years), mean±SD	64.8±12
Sex, n (%)	
Female	44 (78.6)
Male	12 (21.4)
Underlying disease, n (%)	
Rheumatoid arthritis	40 (71.4)
Giant cell arteritis	13 (23.2)
Spondyloarthritis	3 (5.4)
Treatment, n (%)	
Tocilizumab	25 (44.6)
Sarilumab	6 (10.7)
JAKi	25 (44.6)
Concomitant corticosteroid, n (%)	
Yes	33 (58.9)
No	23 (41.1)
Daily prednisone dose, mg/day, mean±SD	16±14
B. Prospective Phase (n=17).	
Age (years), mean±SD	58.65±12.9
Sex, n (%)	
Female	14 (82.35)
Male	3 (17.65)
Underlying disease, n (%)	
Rheumatoid arthritis	7 (41.2)
Giant cell arteritis	6 (35.3)
Spondyloarthritis	2 (11.7)
Polymyalgia rheumatica	1 (5.9)
Calcium pyrophosphate deposition disease	1 (5.9)
Treatment, n (%)	
Tocilizumab	12 (70.6)
Sarilumab	1 (5.9)
JAKi	4 (23.5)
Concomitant corticosteroid, n (%)	
Yes	11 (64.7)
No	6 (35.3)
Daily prednisone dose mg/day, mean±SD	17±9

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Distribution of Immunoglobulins at baseline, 3 and 6 months.

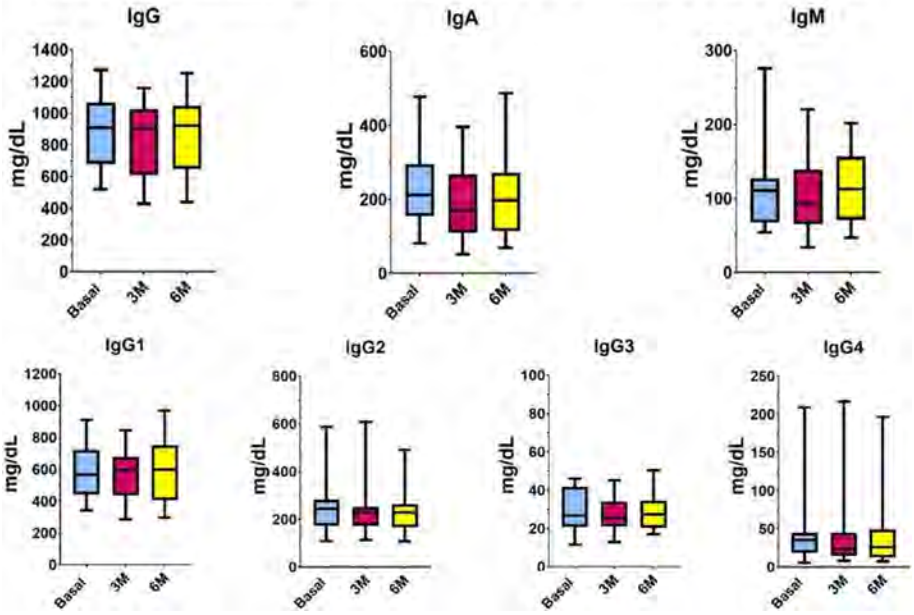

Figure 2. Distribution of B Lymphocytes at baseline, 3 and 6 months.

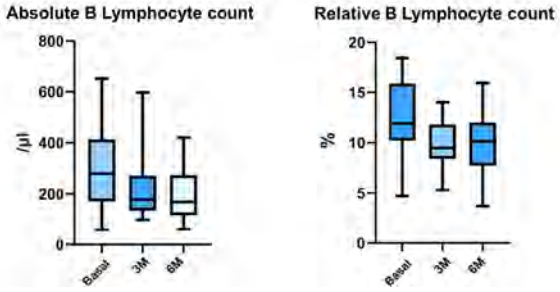

In the prospective cohort (n=17) (Table 1), IgG levels decreased significantly at 3 months (mean difference –50.7 mg/dL, p=0.018), primarily driven by a reduction in IgG4. However, no significant differences in IgG levels were observed at 6 months. Significant decreases in IgA and IgM levels were observed at 3 months, but only IgA persisted at 6 months (Figure 1). Four patients had baseline HGG, none had prior rituximab exposure. At 3 months, 6 patients (35.3%) had HGG (one severe), that was persistent in all cases at 6 months. Both the relative proportion and the absolute count of CD19+ B lymphocytes were reduced; however, the reduction was statistically significant only for the relative proportion at both 3 months (p=0.01) and 6 months (p=0.014) (Figure 2). No significant changes were observed in T lymphocytes.

Conclusion: Our findings suggest that HGG in patients with IRDs treated with IL6Ri or JAKi is frequent. However, the determination of immunoglobulins in these patients is not integrated into clinical practice. These therapies may impact in immunoglobulin production and B cell function. Further studies are warranted to better assess this potentially harmful association.

Abstract Number: 1097

Polymyalgia rheumatica and giant cell arteritis induced by immune checkpoint inhibitors: a systematic review and meta-analysis highlighting differences with the idiopathic forms

Elvis Hysa[1], Andrea Casabella[2], Emanuele Gotelli[3], Rosanna Campitiello[4], Carlo Genova[4], Enrica Teresa Tanda[4], Carmen Pizzorni[5], Alberto Sulli[5], Vanessa Smith[6], Marco Amedeo Cimmino[7], Sabrina Paolino[5] and Maurizio Cutolo[4], [1]University of Genoa, Genoa, Italy, [2]IRCCS Ospedale Policlinico San Martino, Genova, Italy, [3]University of Genoa, Genoa, Liguria, Italy, [4]University of Genova, Genova, Italy, [5]University of Genoa, Genova, Italy, [6]Ghent University Hospital, Gent, Belgium, [7]Rheumatology Outpatient Clinic, Villa Ravenna, Chiavari, Italy, Genova, Italy

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: An altered immune tolerance disturbed by immune checkpoint inhibitors (ICIs) may contribute to new-onset polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) in treated cancer patients. This systematic literature review (SLR) and meta-analysis synthesizes data on the characteristics of ICI-induced PMR and GCA, including pooled prevalence, demographic patterns, clinical features, and treatment-related outcomes. The aim is to present a large-scale meta-analysis offering insights into these syndromes and their potential differences from idiopathic forms.

Methods: The SLR analyzed Medline and EMBASE databases up to July 2024, comparing ICI-induced PMR and GCA to their primary forms. For studies without direct comparisons, SLRs or large observational studies provided the data on primary PMR and GCA. A meta-analysis pooled prevalence, demographics, clinical features, and treatment outcomes when sufficient data were available.

Results: From 1,237 abstracts, 46 were included, yielding 358 patients (314 with ICI-PMR and 44 with ICI-GCA).

ICI-PMR had a pooled prevalence of 0.3% [95% CI: 0.1%–1.2%] among ICI recipients. Patients were predominantly males (64% [95% CI: 54%–73%]), with a mean age of 71 years [95% CI: 68–74]. PD1/PDL1 blockers were used in 85% [95% CI: 80%–89%] of cases. Inflammatory pain in the girdles was universal (100%), however pelvic girdle involvement was explicitly reported in only 3 studies. Peripheral arthritis in ICI-PMR was present in 26% [95% CI: 9%–54%], and normal inflammatory markers were detected in 26% [95% CI: 15%–40%]. Glucocorticoids (GCs) completely improved symptoms in 83% of patients [95% CI: 66%–92%], with 13% [95% CI: 12%–34%] requiring DMARDs and 18% [95% CI: 9%–33%] experiencing relapses (Figure 1).

Two comparative studies explored differences between ICI vs primary PMR. Vermeulen et al suggested milder symptoms and better outcomes in ICI-PMR (Figure 1) while Fremont et al more frequent peripheral arthritis and higher DMARD use in the ICI group. However, the latter was a brief report with methodological limitations, warranting cautious interpretation.

ICI-GCA prevalence was 0.06% among ICI recipients. Male patients comprised 51% [95% CI: 36%–66%], with a mean age of 71 years [95% CI: 68–74]. About 50% [95% CI: 23%–77%] received anti-CTLA4 blockers (alone or with PD1 blockers), while the rest received PD1/PDL1 blockers. Clinical features included cephalic symptoms (85% [95% CI: 70%–93%]), permanent visual loss (23% [95% CI: 12%–39%]), and large-vessel involvement (62% [95% CI: 40%–80%]). High-dose GCs permitted remission in 95% [95% CI: 73%–99%], though 19% [95% CI: 7%–41%] experienced relapses and 10% [2% - 31%] required DMARDs (**Figure 1**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

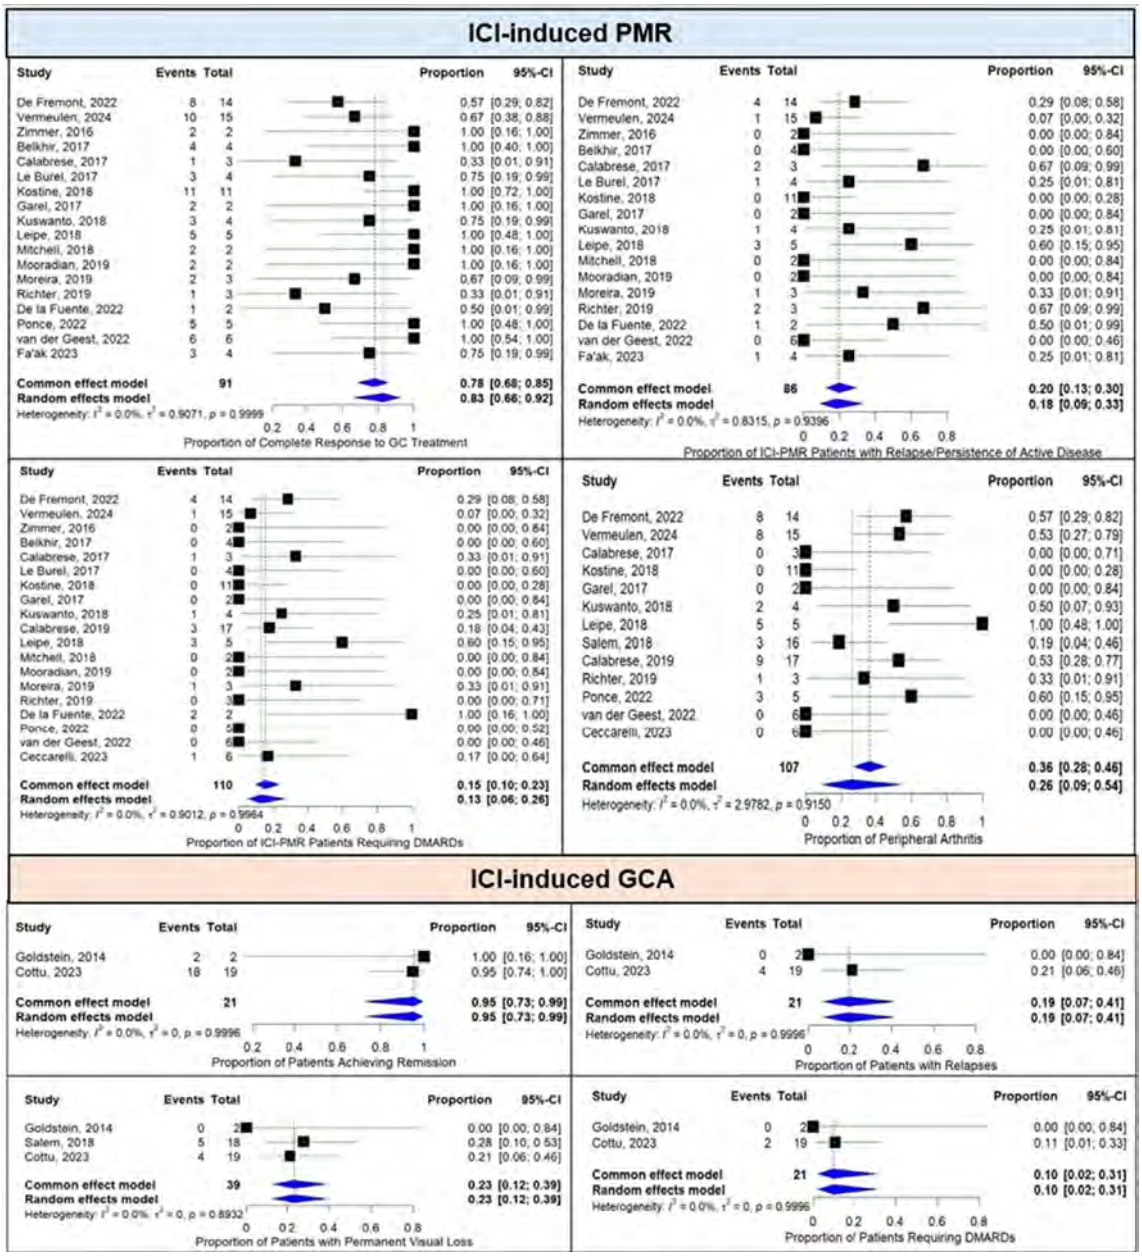

Figure 1. Forest plots related to the main outcomes and clinical features in ICI-PMR (upper panel) and ICI-GCA (lower panel)

Conclusion: ICI-induced PMR and GCA may have distinct clinical profiles than idiopathic forms, potentially with milder symptoms and better treatment responses.

Large observational data and meta-analyses on primary forms suggest higher relapse rates and prolonged GC use [1,2], yet further robust comparative studies are needed to validate whether ICI-induced syndromes truly represent a distinct and less severe clinical entity.

Tolerability of Apremilast: Gastrointestinal Side Effects Dominate While Cardiac Safety Remains Reassuring

Francisco Arias[1], Omar Hamdan[2], Asim Khanfar[3], Kristel Barturen[4] and Roa'a Alshajrawi[5], [1]University of Texas Rio Grande Valley, McAllen, TX, [2]University of Jordan, Az-Zarqa, Jordan, [3]Rochester General Hospital, Rochester, NY, [4]Universidad San Martin de Porres, McAllen, TX, [5]University of Jordan, Amman, 'Amman, Jordan

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Apremilast, a PDE-4 inhibitor, is commonly indicated for patients with psoriasis as well as Behçet's disease. Although this medication is generally well tolerated, numerous adverse events have been reported, and these are among the leading causes of treatment discontinuation. This study aims to identify and describe the most common adverse effects of apremilast and to explore their relationship with underlying comorbidities, particularly cardiovascular and gastrointestinal conditions, to support more personalized and appropriate treatment selection.

Methods: The United States Food and Drug Administration Adverse Event Report System (FAERS) was searched for adverse reactions related to apremilast use. Detailed analysis of cardiac arrhythmias (Tachycardia, bradycardia, atrial fibrillation, QRS complex abnormalities, QT interval abnormalities, bundle branch block (BBB), atrioventricular blocks (AV blocks) and supraventricular tachycardia (SVT)) and gastrointestinal disorders associated with the use of apremilast were reported. Data were reported as frequencies, percentages, and as reporting odds ratios (ROR) with a 95% confidence interval (95% CI).

Results: We analyzed 30,179,725 adverse event reports from the FAERS database, of which 133,748 were associated with the use of apremilast. Among these, 62.91% of the cases involved females, while 4.08% had an unspecified sex. The most reported reaction group among apremilast users was gastrointestinal disorders, documented in 48,652 reports.

When gastrointestinal side effects were analyzed in more detail, diarrhea was the most frequently reported, occurring in 23,163 patients. Patients using apremilast had significantly higher reporting odds of diarrhea compared to users of other drugs (ROR 10.12; 95% CI: 9.98–10.27). Nausea was the second most reported gastrointestinal side effect (20,700 reports) (Figure 1), followed by abdominal discomfort (7,058 reports), with RORs of 6.91 and 11.29, respectively (Figure 2).

In contrast, when evaluating apremilast for its association with cardiac arrhythmias, none were found to have significantly increased reporting odds compared to other drug users. However, among all arrhythmias reported, the most common were tachycardia (51.6%) and atrial fibrillation (43.0%) (Table 1).

Conclusion: This FAERS analysis reveals key findings on apremilast side effects. Cardiovascular issues like tachycardia and atrial fibrillation were reported but showed no significant outcomes, reassuring for cardiac comorbidities, though careful monitoring is advised. Gastrointestinal side effects, particularly diarrhea and nausea, were the most common. Pre-existing gastrointestinal and cardiovascular comorbidities should be considered, highlighting the need for early recognition and

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) has been recommended [1-3] as a steroid-sparing agent for immune checkpoint inhibitor-inflammatory arthritis (ICI-IA), preferred due to its low immunosuppressive effect. However, there is little published data on its efficacy for ICI-IA; to date, the largest study is a case series of 11 patients [4]. This study's aim was to further assess the safety and effectiveness of HCQ for treatment of rheumatic immune-related adverse events (irAEs), including ICI-IA.

Table 1: Patient characteristics

Patient Characteristics (n=40)	Number of Patients (%), Mean (SD)
Male	20 (50)
White	39 (97.5)
Age at HCQ initiation	68.6 (10.0)
Cancer Type	
Melanoma	21 (52.5)
Non-small cell lung cancer	5 (12.5)
Other*	14 (35)
Immune checkpoint inhibitor regimen	
PD-1/PD-L1 monotherapy	25 (62.5)
Dual PD-1/PD-L1 and CTLA-4 therapy	9 (22.5)
CTLA-4 monotherapy	3 (7.5)
LAG-3 (+/- other ICI)	3 (7.5)
Serology	
+RF/CCP	9 (22.5)
RF/CCP not assessed	2 (5)
+ANA	17 (42.5)
ANA not assessed	8 (20)
+SS-A/SS-B	2 (5)
SS-A/SS-B not assessed	21 (52.5)
Outcomes	
Remission or improvement to grade 1 arthritis**	17 (42.5)
Improvement, but remained ≥ grade 2 arthritis	5 (12.5)
No improvement	7 (17.5)
Unclear response or treatment course <3 months	11 (27.5)
Presentation Type	
ICI-inflammatory arthritis	34 (85)
Polymyalgia rheumatica-like	3 (7.5)
Activated crystalline arthritis	3 (7.5)
Activated osteoarthritis	1 (2.5)
Activated (pre-existing) rheumatoid arthritis	2 (5)

*Renal cell carcinoma (2), urothelial cell carcinoma (2), head and neck squamous cell carcinoma (2), Breast cancer (1), other (7)

**Includes patients requiring escalation of DMARD therapy (1) and patients who were started on HCQ as an augmenting agent (2)

Table 2: Hydroxychloroquine utilization

	Mean (SD)	Median
Duration on HCQ (months)	15.5 (20.6)	7.5
Time between onset of ICI and HCQ initiation (months)	19.7 (18.7)	15
Time between discontinuation of ICI and HCQ discontinuation	14.8 (18.2)	10
DMARD Regimen	**Number of patients (%)**	
HCQ monotherapy without subsequent augmentation	25 (62.5)	
HCQ used as augmenting agent	5 (12.5)	
DMARD added onto HCQ as augmentation	9 (22.5)	
DMARD added after HCQ discontinuation	6 (15)	
HCQ Intolerance*	**Number of patients (%)**	
Patient did not tolerate HCQ	13 (32.5)	
Specific intolerance		
Gastrointestinal upset	6 (15)	
Vision change, excluding retinal toxicity	2 (5)	
Fatigue	2 (5)	
Dizziness	2 (5)	
Headache	2 (5)	
Dermatologic	1 (2.5)	
Laboratory abnormality	2 (5)	
Other	3 (7.5)	

*4 patients reported >1 AE from HCQ

Table 3: Subgroup analyses by ICI, serostatus, HCQ regimen, and arthritis type

Subgroup*	At least partial response** (%)	Remission or improvement to grade 1 arthritis (%)
ICI Type		
PD-1/PD-L1 monotherapy	15/16 (93.8)	10/16 (62.5)
Dual PD-1/PD-L1 and CTLA-4 therapy	4/7 (57.1)	4/7 (57.1)
CTLA-4 monotherapy	2/3 (66.7)	2/3 (66.7)
LAG-3 + other ICI	1/3 (33.3)	1/3 (33.3)
Serology		
RF/CCP positive	4/7 (57.1)	1/7 (14.3)
RF/CCP negative	16/20 (80.0)	14/20 (70)
ANA positive	8/12 (66.7)	7/12 (58.3)
ANA negative	10/12 (83.3)	6/12 (50)
HCQ regimen		
Monotherapy without augmentation	16/18 (88.9)	14/18 (77.8)
Arthritis Type		
ICI-IA	18/22 (81.8)	14/22 (63.6)
PMR-like	2/2 (100)	2/2 (100)
Crystalline	3/3 (100)	3/3 (100)
Activated OA	0/1 (0)	0/1 (0)

*Subjects without treatment response data were excluded from subgroup analyses

**Partial response was defined by improvement but remaining in ≥ grade 2 arthritis.

Methods: This retrospective observational study included patients at a large academic medical center who were treated with HCQ for rheumatic irAEs by rheumatologists from 2017 to 2025. Outcomes were ascertained by manual chart review. The primary outcome was arthritis control defined as grade 1 arthritis with HCQ monotherapy with grade 1 arthritis defined as at most mild pain not impacting activities of daily living [3]. HCQ and prednisone dose were recorded at the time of HCQ discontinuation or, if HCQ therapy was ongoing, at the time of data collection. Subgroup analyses were also performed.

Results: The study included 40 patients with mean age at HCQ initiation of 69 years (SD 10 years) **(Table 1)**. 25 (62.5%) patients were on anti-PD-1/PD-L1 monotherapy and 9 (22.5%) were on dual therapy with both anti-PD-1/PD-L1 and anti-CTLA-4 ICIs. Mean follow-up time was 29 months (SD 24 months) with 32 patients living at the time of chart review, 8 (25%) of whom remained on HCQ therapy. Among the 27 patients who discontinued HCQ (excluding those 5 patients who were on HCQ at time of death), 13 (48.1%) discontinued due to medication intolerance or an adverse event, 5 (18.5%) discontinued due to resolution of arthritis, and 5 (18.5%) discontinued due to inefficacy. 25 (62.5%) patients were treated with HCQ monotherapy only while 15 (37.5%) were treated with additional disease-modifying antirheumatic drug(s)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(DMARD) **(Table 2)**. 17 (42.5%) patients achieved grade 1 arthritis, noting that this includes 4 who required ongoing prednisone therapy with mean dose of 5.5 mg/day (SD 3.3 mg/day). 13 (32.5%) patients achieved grade 1 arthritis on HCQ monotherapy without concomitant prednisone dosing > 5 mg daily or subsequent escalation of DMARD therapy. Among these 13 patients, only 5 remained on ICI therapy following addition of HCQ. Seronegative patients (RF/CCP-, ANA-) had slightly higher rates of response than seropositive patients **(Table 3)**.

Conclusion: In this largest cohort to date observing patients treated with HCQ for rheumatic irAEs, we found a high rate of HCQ intolerance, in line with prior studies in SLE and RA [5, 6], noting that symptoms were often nonspecific and attributable to other treatments. While there was moderate response to HCQ therapy, many patients required escalation of DMARD therapy to achieve disease control. Most patients who achieved grade 1 arthritis after HCQ initiation had not resumed ICI therapy. These findings suggest that HCQ may be effective for a subset of patients, particularly those with mild arthritis or in cases where continuation of ICI therapy is not planned.

Unspecified, n (%)	20 (32.3%)	480 (37.1%)

Abbreviations: CAR, chimeric antigen receptor; n, number; SD, standard deviation; CD, cluster of differentiation; BCMA, B cell maturation antigen.

[a] Percentages (%) of autoimmune disease type by organ system were calculated among patients with pre-existing autoimmune disease.

Background/Purpose: Chimeric antigen receptor (CAR) T cell therapy is being investigated to treat individuals with autoimmune diseases. Data regarding the safety of CAR T cell therapy in this population is limited. We aimed to assess whether pre-existing autoimmune disease was associated with an increase in major toxicity or hospital length of stay (LOS) among patients receiving CAR T cell therapy for treatment of hematologic cancer.

Methods: This retrospective cohort study utilized nationwide United States data from the National Inpatient Sample (2021–2022) to investigate in-hospital outcomes in adult patients receiving CAR T cell therapy. The primary outcome for the study was a composite of major toxicity, defined as the occurrence of at least one of the following: cytokine release syndrome

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Hospital length of stay, toxicity, and in-hospital mortality among patients receiving chimeric antigen receptor (CAR) T cell therapy for cancer by pre-existing autoimmune disease status

	Pre-existing autoimmune disease (n=62)	Without pre-existing autoimmune disease (n=1259)
Length of stay (days), median (IQR)	14 (9–17)	14 (10–19)
Major toxicity[a], n (%)	42 (67.7%)	989 (78.6%)
CRS, all grades	34 (54.8%)	773 (61.4%)
Grade 1	20 (32.3%)	429 (34.1%)
Grade 2	11 (17.7%)	275 (21.8%)
Grade 3 or higher	<11	56 (4.4%)
ICANS, all grades	13 (21.0%)	313 (24.9%)
Grade 1	<11	62 (4.9%)
Grade 2	<11	46 (3.7%)
Grade 3 or higher	<11	84 (6.7%)
HLH	<11	17 (1.4%)
Neutropenia	23 (37.1%)	471 (37.4%)
Pneumonia	<11	40 (3.2%)
Sepsis	<11	64 (5.1%)
Intubation	<11	45 (3.6%)
Acute kidney injury	<11	185 (14.7%)
Other toxicity		
Cytopenia (includes neutropenia)	29 (46.8%)	586 (46.5%)
Lymphopenia	<11	<11
Thrombocytopenia	<11	60 (4.8%)
Anemia	<11	170 (13.5%)
Tocilizumab use, n (%)	<11	109 (8.7%)
In-hospital mortality, n (%)	<11	37 (2.9%)

Abbreviations: CAR, chimeric antigen receptor; n, number; IQR, interquartile range; CRS, cytokine release syndrome; ICANS, immune effector cell-associated neurotoxicity syndrome; HLH, hemophagocytic lymphohistiocytosis.

[a] Major toxicity is a composite that includes CRS, ICANS, neutropenia, HLH, pneumonia, acute kidney injury, sepsis, or intubation.

(CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), hemophagocytic lymphohistiocytosis (HLH), sepsis, pneumonia, intubation, acute kidney injury, or neutropenia. Secondary outcomes included each individual component of the primary outcome, in-hospital mortality, hospital length of stay (LOS), and tocilizumab use. Comparisons were drawn between patients with and without pre-existing autoimmune disease, identified using International Classification of Diseases, Tenth Revision (ICD-10) codes for common rheumatic, gastrointestinal, endocrine, dermatologic, and neurologic autoimmune diseases. A multivariable regression model with adjustment for age, sex, race, cancer type, and comorbidities assessed associations with hospital LOS, major toxicity, and inpatient mortality.

Results: Among 1,321 patients receiving CAR T cell therapy, 62 (4.7%) had a pre-existing autoimmune disease (**Table 1**), most commonly rheumatologic (50.0%) or gastrointestinal (19.4%). The median hospital LOS among all patients was 14 days (IQR 10-19). Patients with pre-existing autoimmune disease had a significantly shorter hospital LOS compared to patients without autoimmune disease (mean reduction of 2.1 days, 95% confidence interval [CI] 0.5, 3.6; **Tables 2 and 3**). Major toxicity was observed in 78.0% of all patients and occurred less frequently in patients with pre-existing autoimmune disease than in patients without (67.7% vs 78.6%; adjusted odds ratio 0.55, 95% CI 0.31, 0.99). Rates of CRS and ICANS were numerically lower in patients with pre-existing autoimmunity than in patients without (54.8% vs 61.4% and 21.0% vs

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

24.9%, respectively), while rates of HLH and neutropenia were similar between groups (1.6% vs 1.4% and 37.1% vs 37.4%, respectively). Tocilizumab use (11.3% among those with preexisting autoimmune disease and 8.7% among those without) and inpatient mortality (3.2% and 2.9%, respectively) were not statistically different between groups.

Conclusion: Patients with pre-existing autoimmune disease had shorter hospital stays and lower risk of major toxicity following CAR T cell therapy for cancer treatment. This nationwide study offers reassurance as to its safety in this population while providing additional data for research studies of CAR T cell therapy to treat autoimmune diseases.

Distinct Clinical Phenotypes of Immune Checkpoint Inhibitor–Associated Arthritis: Comparative Analysis of Inflammatory Arthritis, Polymyalgia Rheumatica-like, Activated Crystalline, and Activated Osteoarthritis

Heba Altarawneh[1], Gregory Challener[2], Mazen Nasrallah[3], Janeth Yinh[4], Hyon K. Choi[5] and Minna Kohler[6], [1]Mass General Hospital, Boston, MA, [2]MGH, Boston, MA, [3]MGB-Salem Hospital, Lynn, MA, [4]Massachusetts General Hospital, Boston, MA, [5]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA, [6]Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Immune checkpoint inhibitor (ICI)–associated arthritis has been classified into distinct phenotypes, including inflammatory arthritis (IA), polymyalgia rheumatica (PMR)-like syndrome, activated crystalline arthritis, and activated osteoarthritis (aOA). However, the boundaries between these phenotypes are often challenging to discern, and differences in their presentation, natural history and outcomes remain poorly defined[1].

Methods: We retrospectively analyzed 85 patients with ICI-associated arthritis, classified as IA (n=58), crystalline (n=9), PMR-like (n=7), and aOA (n=23), referred to rheumatology at a tertiary center (Jan 2014–Feb 2020). We compared clinical features, joint involvement, serologies, synovial fluid, treatment, symptom duration, and DMARD use. Chi-square tests were used for proportions and Kruskal-Wallis for medians.

Results: IA typically presented as polyarthritis (43%) with frequent knee (79%), PIP (43%), and MCP (41%) involvement. PMR-like cases had predominant shoulder (71%) and MCP (71%) involvement. Crystalline arthritis favored elbows (33%) and hips (33%). aOA was more often monoarthritis (26%) with a degenerative pattern (wrists 30%, PIPs 35%, DIPs 4%) (p=0.7). Inflammatory synovial fluid was most frequent in IA (31%), and rare in PMR-like (0%) and aOA (4%) (p=0.1). Peripheral involvement in both IA and PMR-like suggests classification may hinge on shoulder involvement, despite overlap with IA features.

*P-value calculated using chi-square test.

Table 3: Symptom Duration and DMARD Exposure by ICI-Arthritis Phenotype

	Total (N=85)	IA (N=58)	Crystalline (N=9)	PMR-like (N=7)	AOA (N=23)	P- value*
Duration of symptoms, median months(IQR)	23 (5-44)	14 (6-14)	35 (26-72)	65 (63-70)	31 (21-47)	0.2
Total duration on DMARD, , median months(IQR)	24 (7-55)	33 (9-63)	13 (6-51)	12 (12-34)	20 (6-39)	0.6

*P-value calculated using Kruskal-Wallis test.

PMR-like patients had the longest symptom duration (65 months, IQR 63–70) but the shortest DMARD exposure (12 months, IQR 12–34). Crystalline (35 months, IQR 26–72) and aOA (31 months, IQR 21–47) had shorter durations but comparable DMARD use (13 months, IQR 6–51; 20 months, IQR 6–39) (p=0.2). IA had the shortest duration (14 months, IQR 6–14) but longest DMARD use (33 months, IQR 9–63) (p=0.3), reflecting higher inflammatory activity. DMARDs—methotrexate (16%), sulfasalazine (43%), hydroxychloroquine (40%), and TNFi (7%)—were used almost exclusively in IA (p=0.9). Among aOA patients, 48% had concurrent inflammatory arthritis, affecting interpretation of DMARD use. Limited DMARD use in PMR-like cases may reflect historical steroid-based treatment; however, small sample size (n=7) limits interpretation.

Conclusion: ICI-associated arthritis includes phenotypes with differing inflammatory burden, duration, and treatment. IA is more active and treated more aggressively; others persist longer but receive less therapy. Whether these differences reflect biology or treatment variation is unclear. This historical cohort had low biologic use, possibly contributing to symptom duration. Findings support phenotype-based approaches that balance arthritis and cancer therapy, but small subgroup sizes warrant further study.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: New onset inflammatory arthritis (IA) is reported in 6% of patients who receive immune checkpoint inhibitors (ICI). We previously developed an administrative claims-based algorithm to identify patients with ICI-IA.[1] In this study, we compare ICI-IA cases at a single center identified in administrative claims and those identified via manual medical record review.

ICI = immune checkpoint inhibitor; IA = inflammatory arthritis; HSS = Hospital for Special Surgery

Table 2: Characteristics of patients with ICI-IA identified by applying claims-based algorithm to Komodo HealthMap Database

	ICI-IA, ($n = 142$) n (%)
Age, mean (SD)	64 (11)
Female	71 (50)
Medicare insurance	68 (48)
Doctor Type seen at HSS	
Rheumatologist / Internal Medicine MD	42 (30)
Orthopedist MD	43 (30)
Other MD	57 (40)
Pembrolizumab*	74 (52)
Nivolumab*	64 (45)

* Instances of treatment with Pembrolizumab or Nivolumab medication as part of regimen (either as monotherapy or part of combination regimen with some patients receiving more than one ICI therapy)

Methods: Using an Alteryx electronic health record (EHR) screening tool, we identified patients seen at Hospital for Special Surgery (HSS) who received ICI therapy between 2016-2025. Chart adjudication was performed independently by a team of three physicians to determine whether patients had ICI-IA. We defined ICI-IA as a condition developing within 1 year of receiving ICI, in patients without a prior diagnosis of inflammatory arthritis or PMR. The diagnosis was verified by 1. MD documentation in the EHR; or 2. treatment with steroids or DMARDs for joint symptoms; or 3. imaging or joint histopathology demonstrating joint inflammation. Patients with ICI-IA treated at HSS were also identified by applying our administrative claims algorithm to the de-identified Komodo Healthmap dataset which includes patients on commercial insurance, managed and fee for service Medicare.

Results: ICI-treated patients seen at HSS (n=500) were identified and a random sample of 119 of these patients' charts were reviewed and extracted. Of these, adjudicators recognized 53/119 (45%) as having ICI-IA (44 ICI-arthritis, 2 ICI-arthralgia, 7 ICI-PMR) and 66/119 (55%) as not having ICI-IA. Patients with ICI-IA had a mean (SD) age 62 (19) years, 52 (98%) were seen by a rheumatologist, 51(96%) were enrolled in an HSS irAE registry, and 46 (87%) received oral steroids for management of joint symptoms (Table 1). Of the patients who were seen at HSS for joint-related symptoms but did not have ICI-IA, 34 (51%) of patients had OA or other non-inflammatory joint pain (such as bursitis or tendonitis) leading to presentation and others had pre-existing inflammatory arthritis. The characteristics of patients identified as having ICI-IA who were treated at HSS in the unidentified Komodo dataset is shown in Table 2. In this cohort of 142 ICI-IA patients, average

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

age (SD) was 64 (11), 71 (50%) were female, 68 (48%) were insured with Medicare, and 42 (30%) were seen by a rheumatologist or internal medicine provider.

Conclusion: Demographic characteristics and insurance of patients with ICI-IA identified through chart review and through query of the deidentified Komodo dataset were similar but fewer in Komodo were seen by a rheumatologist. In a future study using tokenization and linkage of the Komodo claims to cases identified at HSS, we will determine the positive predictive value of the ICI-IA algorithm.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The use of immune checkpoint inhibitors (ICI) continues to increase with an expanding number of indications across varying cancer types and stages. ICIs can induce an inflammatory arthritis (ICI-IA) which can have significant impacts on patient function and quality of life. The Health Assessment Questionnaire Disability Index (HAQ-DI) is a health-related patient-reported outcome measure widely used to assess functional limitations in patients with rheumatoid arthritis. To date, use of the HAQ-DI has not been studied in patients with ICI-IA. Our objective was to evaluate the measurement properties (reliability, construct validity and responsiveness) of the HAQ-DI in patients with ICI-IA.

Methods: All patients enrolled in a multicenter prospective cohort, with a diagnosis of ICI-IA, who completed a baseline HAQ-DI at first study visit were included. Demographic, clinical and laboratory data including the HAQ-DI were extracted from the study database. Internal consistency reliability was assessed using Cronbach's alpha coefficient with values ≥ 0.7 considered acceptable. Construct validity was assessed by correlating HAQ-DI scores with other measures of disease activity including c-reactive protein (CRP), tender joint count (TJC), swollen joint count (SJC), patient global assessment of disease activity (PtGA) as well as physician global assessment of disease activity (PGA). Responsiveness was assessed

by calculating the standardized response mean (SRM) and effect size (ES) in those with ≥ 3-point improvement on the PGA (defined a priori) at 3-6 month follow up.

Results: Ninety-six patients from 9 centers were included in this study. The median age of study participants was 67 years (range 39-84), 50% were female and the most common malignancies were melanoma and non-small cell lung cancer (Table 1). The most common presentation of ICI-IA was polyarticular involvement (64%) with a median TJC of 6 (range 0-36) at baseline and SJC of 2 (range 0-30). The median HAQ-DI at baseline was 0.5 (range 0, 3). The median HAQ-DI at 6 months (n=66) was 0.125 (range 0, 2.375). HAQ-DI floor and ceiling effects for the whole group were 24% and 1%, respectively. Cronbach's alpha for the 8 HAQ-DI categories ranged from 0.72-0.91 and for the 20 HAQ DI Items was 0.94 suggesting high internal consistency reliability (Table 2). The HAQ-DI had a significant positive correlation with CRP, TJC, SJC, ptGA and PGA (Table 3). Responsiveness of the HAQ-DI was moderate with an SRM =1.4 and ES = 0.3 when calculated in the 23 participants with ≥ 3-point improvement on the PGA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: HAQ-DI Score component and overall internal consistency reliability (Cronbach's alpha) component analysis at baseline (n=96)

HAQ Components	Cronbach's alpha
Dressing	0.75
Rising	0.91
Eating	0.85
Walking	0.86
Hygiene	0.75
Reach	0.72
Grip	0.80
Activity	0.88
Overall mean HAQ-DI Score	0.94

Table 3: HAQ correlations with clinical and demographic variables Legend: CRP = c-reactive protein, TJC = tender joint count, SJC = swollen joint count, PtGA = patient global assessment of disease activity, PGA = physician global assessment of disease activity

Demographic Variables	R*	p-value
Sex	-0.19	0.06
Age	-0.0024	0.98
Clinical Variables		
Stage	-0.03	0.75
Metastatic disease	-0.05	0.62
CRP	0.19	0.05
TJC	0.20	0.06
SJC	0.22	0.03
PtGA	0.40	<0.0001
PGA	0.25	0.02

*Spearman correlation coefficient used

Conclusion: In this prospective cohort study, the HAQ-DI was reliable, valid and sensitive to change in patients with ICI-IA. Future research will further explore content validity, establish the minimal clinically important difference of the HAQ-DI in ICI-IA and explore correlation of the HAQ-DI with the physical functioning components of other patient-reported outcome measures currently validated in cancer patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients (pts) with rheumatoid arthritis (RA) face a higher lifetime burden of cardiovascular disease (CVD) vs the general population with approximately 1.5-2-fold increase in heart failure, myocardial infarction and CVD mortality. Recent data suggest that immune checkpoint inhibitors (ICIs), a major anti-cancer therapy class, may also contribute to CVD risk. We conducted a comparative evaluation of CVD outcomes in pts with cancer receiving ICI-based therapy, focusing on differences between those with vs without pre-existing RA. We hypothesized that pts with pre-existing RA receiving ICI-based therapy would have a higher risk of adverse CVD events vs those without RA.

Methods: We conducted a population-based cohort study using electronic health records of pts with cancer receiving ICIs between 2011 and 2025 from 101 U.S. healthcare organizations. We identified pts with pre-existing RA using at least two diagnostic codes who were treated with anti-programmed death-1/programmed death ligand-1 (PD-1/PD-L1) and/or cytotoxic T-lymphocyte associated protein 4 (CTLA4) agents. We calculated propensity scores using covariates including demographics (age, sex, race/ethnicity), comorbidities, cancer type, metastatic status, previous and concurrent anti-cancer treatments, history of exposure to statins and systemic steroids. Pts with RA on ICI were propensity-score matched 1:1 with pts treated with ICI without RA. We used Cox proportional hazards models to assess the risk of individual outcomes of all-cause mortality, stroke, ischemic heart disease, including myocardial infarction and heart failure.

Results: We analyzed 2,270 pts with pre-existing RA treated with ICI and 2,270 propensity score-matched comparators (Table 1). Mean age was 69 years, 60% were female, 78% were White. After initiation of ICI-based therapy, over a mean follow-up of 47.6 months, pts with RA did not have a significantly higher risk of all-cause mortality (HR 1.03, 95% CI 0.94–1.12) or stroke (HR 0.99, 95% CI 0.86–1.14) vs pts without RA. However, the risk for ischemic heart disease (HR 1.35, 95% CI 1.13–1.62), specifically myocardial infarction (HR 1.49, 95% CI 1.16–1.91) and heart failure (HR 1.25, 95% CI 1.02–1.54) were higher for pts with RA vs pts without RA (**Figure 1**).

Conclusion: Among pts on ICI-based therapy, those with pre-existing RA did not have significant higher all-cause mortality or risk for stroke, but higher risk of ischemic heart disease and heart failure vs pts without RA. Our hypothesis-generating findings are consistent with the known CVD burden in pts with RA and cancer that may be possibly exacerbated by ICI. Further studies are needed to validate our data and, also, investigate prophylaxis, early diagnosis and proper management of CVD in pts with RA receiving ICI-based therapy for cancer.

CI: confidence interval; HR: hazard ratio; irAE: immune-related adverse event

Background/Purpose: Immune checkpoint inhibitors (ICIs), widely used to treat a variety of cancers, are associated with immune-related adverse events (irAEs) that are increasingly encountered in rheumatology clinics. However, it remains unclear how outcomes differ between patients with and without pre-existing rheumatoid arthritis (RA) receiving ICIs for cancer treatment. We aimed to compare irAE risk following ICI initiation between those with and without RA.

Methods: We conducted a population-based cohort study including patients receiving ICIs from 101 U.S. health care organizations between 2011 and 2025 in the U.S. We identified patients with pre-existing RA based on the presence of ≥2 ICD-10 codes before treatment with ICIs, including anti–programmed death-1/programmed death ligand-1 (PD-1/PD-L1) and cytotoxic T-lymphocyte–associated protein 4 (CTLA-4) agents. Propensity scores were calculated using demographics (age, sex, race/ethnicity), comorbidities, cancer type, metastatic status, prior cancer therapies, and previous RA treatments. Patients with RA receiving ICIs were matched 1:1 to ICI-treated patients without RA using propensity score matching. We then used Cox proportional hazards models to evaluate the risk of cutaneous, pulmonary, hepatic, and gastrointestinal irAEs among these two groups, overall and stratified by sex.

Results: We included 1,976 patients with RA and 1,976 propensity score-matched comparators (**Table 1**), with mean age 69 years, 55% female and 76% White. Lung cancer was the most common malignancy (57.1%) and 36.1% of patients with RA underwent radiation oncology treatment. After propensity score matching, those with RA had an 18% higher risk of cutaneous irAEs (aHR 1.18, 95% CI 1.01-1.39) and 17% higher risk of pneumonitis (aHR 1.17, 95% CI 1.01-1.36) versus those without RA (**Table 2**). When stratified by sex, females with RA had a higher risk than females without RA for cutaneous irAEs (aHR 1.26, 95% CI 1.02-1.57), colitis (aHR 1.32, 95% CI 1.03-1.70) and pneumonitis (aHR 1.36, 95% CI 1.10-1.68). There was no difference in the risks of these outcomes when comparing males with and without RA.

Conclusion: In this large nationwide study, those with pre-existing RA had a higher risk of cutaneous irAEs and pneumonitis. When stratifying by sex, females with RA had a higher risk of cutaneous irAEs, colitis and pneumonitis compared to females without RA while there was no difference by RA status among males. If future studies confirm these findings, these data can be used to counsel patients with RA contemplating starting an ICI as part of their cancer treatment.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) retinopathy is a progressive, vision-threatening retinal disease. While HCQ is typically discontinued after toxicity is detected, some patients undergo tapering due to disease control needs. This study investigates whether ellipsoid zone (EZ) loss progresses more rapidly in patients who taper HCQ compared to those who discontinue it, using longitudinal optical coherence tomography (OCT) data from a Taiwanese cohort.

Methods: In the NTUH-HCQ cohort, we retrospectively included patients who were diagnosed with HCQ retinopathy by a retinologist following the onset of visual symptoms, seen at National Taiwan University Hospital between March 2017 and August 2024. The inclusion criteria required that each eye had at least 6 months of serial OCT follow-up after HCQ tapering or complete discontinuation, while patients with concurrent retinal diseases or other ocular conditions affecting the macula were excluded. Tapering was defined as the continuation of HCQ at less than 75% of the patient's long-term maintenance dose. EZ width was defined as the average distance between nasal–temporal and superior–inferior ellipsoid zone termini on OCT scans. The primary outcome was the individual rate of EZ loss (μm per year). We compared the average EZ loss rates between individuals and assessed differences across treatment and pattern subgroups.

Results: A total of 51 eyes from 26 patients were included in the analysis. Among them, 88% (23/26) were female. The median age was 55.06 years (interquartile range [IQR], 38.65–66.49), and the median duration of HCQ exposure was 11.74 years (IQR, 10.41–14.09). The median follow-up duration after HCQ retinopathy diagnosis was 2.35 years (IQR, 1.34–4.29). Pericentral-type HCQ retinopathy was observed in 15 patients (57.7%), while 12 patients (42.3%) had the parafoveal type. Following diagnosis, 15 patients (57.7%) continued HCQ on a tapered regimen, and 11 patients (42.3%) discontinued the drug entirely. Full patient characteristics are summarized in Table 1.

Figure 1 shows that the most rapid EZ loss occurred in patients with pericentral-type HCQ retinopathy who remained on a tapered regimen, averaging -600 ± 407 μm per year. In contrast, those who discontinued HCQ in the same subgroup declined significantly more slowly, at -149 ± 139 μm per year ($p < 0.001$). In the parafoveal subgroup, the corresponding rates were -162 ± 116 μm per year with taper and -124 ± 81 μm per year after discontinuation, with no significant difference between groups ($p = 0.394$).

HCQ regimen after diagnosis			
Tapered, n (%)	15 (58%)	10 (67%)	5 (45%)
Discontinued, n (%)	11 (42%)	5 (33%)	6 (55%)
Follow-up duration, years (median (IQR))	2.35 (1.34–4.29)	2.19 (0.94–4.29)	3.27 (1.71–4.94)

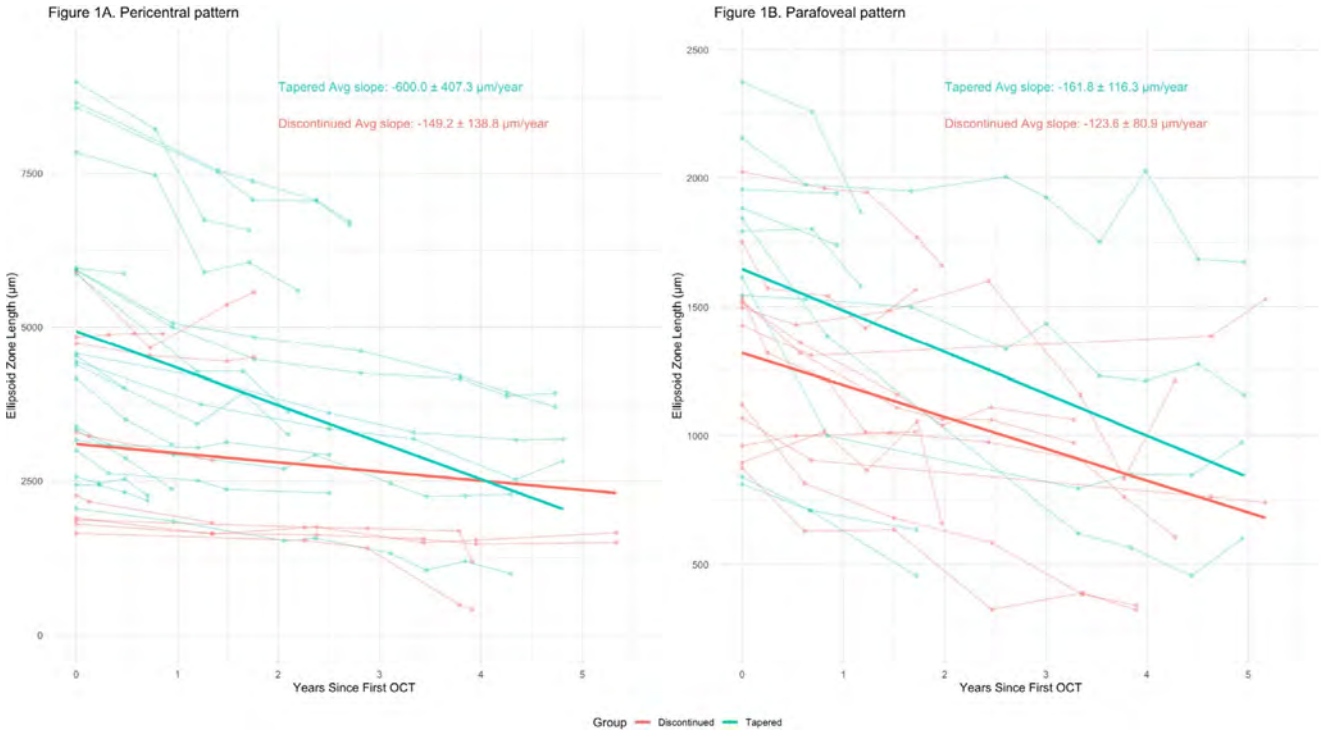

Figure 1

Conclusion: Our findings show that EZ loss progresses more rapidly in pericentral-type HCQ retinopathy patients who continued HCQ at a reduced dose than in those who discontinue it entirely, indicating heightened susceptibility of the perifoveal region to continued low-dose toxicity. These results underscore the limitations of tapering alone and support complete drug cessation once retinopathy is detected. EZ width may serve as a sensitive marker to guide management and monitor progression in clinical practice.

Background/Purpose: Large, multi-center efforts are needed to optimally study rheumatic immune-related adverse events (rh-irAEs) from immune checkpoint inhibitor (ICI) use. We aimed to characterize the baseline clinical features of patients enrolled in the Rheumatology Adverse Events Due to Immunotherapy Observational Studies (RADIOS) consortium and examine the severity of rh-irAE at presentation.

Methods: RADIOS is a prospective multi-institutional, national effort enrolling patients with rh-irAEs from 12 academic centers in the US. The consortium began enrolling in 2015 at the initial site and 2022 at additional sites. Patients were included if they were diagnosed by their rheumatologist as having developed a rh-irAE. Descriptive statistics were used to summarize the cohort's demographics (including age, sex, race, ethnicity), cancer characteristics, and ICI use at enrollment. We evaluated the type of rh-irAE the patient had as well as the Common Terminology Criteria for Adverse Events (CTCAE) grade of the adverse event. Among patients with ICI-induced inflammatory arthritis (ICI-IA), clinical disease activity index (CDAI) was obtained and mean (standard deviation) was calculated.

Results: As of April 1, 2025, the consortium had enrolled 671 patients with a rh-irAE with a mean age of 63.6 years (SD 12.7), of whom 336 were female (50.1%); 580 (86.4%) patients identified as White and 6% as Hispanic. ICI-IA was the most common rh-irAE (n=435, 65%) followed by arthralgia (n=146, 21.8%), PMR (n=69, 10.3%), and myalgia (n=25, 3.7%) (**Table 1**). Among the cancer types, most patients had melanoma (n=204, 30.5%), followed by non-small cell lung cancer (n=100, 14.9%); 439 patients had received PD-1 inhibitors alone as treatment; 188 patients had anti-CTLA-4/

Table 2. Cancer type, stage, and ICI exposure at baseline rheumatology visit

Characteristic	Rheum irAE Cohort (n=669), N (%)
Cancer Type	
- Melanoma	204 (30.5%)
- NSCLC	100 (14.9%)
- Renal Cell Carcinoma	86 (12.9%)
- Breast	59 (8.8%)
- Bladder	33 (4.9%)
- Endometrial	23 (3.4%)
- Other*	164 (24.5%)
Cancer Stage at Baseline	
- Stage 1	10 (1.7%)
- Stage 2	46 (7.7%)
- Stage 3	168 (28.1%)
- Stage 4	373 (62.5%)
ICI Exposure	
- Anti-PD-1	439 (65.6%)
- Anti-CTLA-4/PD-1 combination	188 (28.1%)
- Anti-PD-L1	57 (8.5%)
- Other	59 (8.8%)
- Anti-PD-1/LAG-3 combination	13 (1.9%)
- Anti-CTLA-4	3 (0.4%)
ICI Duration at Baseline (months; mean, SD)	
- Atezolizumab	10.6 (18.6)
- Avelumab	17.7 (25.9)
- Cemiplimab	10.3 (8.5)
- Durvalumab	5.0 (5.0)
- Ipilimumab alone	38.7 (63.5)
- Ipilimumab/Nivolumab	4.5 (11.0)
- Nivolumab	20.2 (15.3)
- Pembrolizumab	9.3 (9.3)
- Relatlimab/Nivolumab	4.6 (6.0)

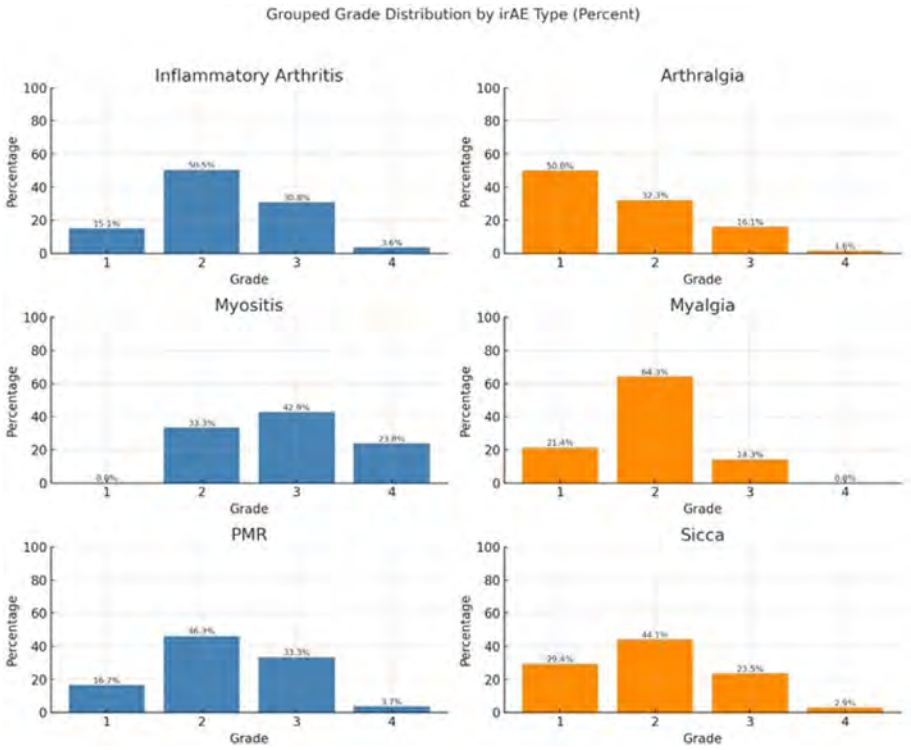

Figure 1: Common Terminology Criteria for Adverse Events (CTCAE) grade for rh-irAEs at time of enrollment to RADIOS. Grade 1 events are mild and/or self-limited, grade 2 events limit instrumental activities of daily living, grade 3 events are severe and limit self-care activities of daily living, and grade 4 events are severe, potentially life threatening, and/or require hospitalization.

PD-1 combination therapy (**Table 2**). Average duration of ICI treatment tended to be shorter in those who received combination therapies (ipilimumab/nivolumab and nivolumab/relatilmab) than in those who received anti-PD-1/PD-L1 monotherapy. Among patients with ICI-IA and baseline CDAI available (n=315), the mean score was 16.1 (SD 10.8), indicating most had moderate disease activity. Maximum CTCAE grade of rh-irAE at enrollment for each irAE type is shown in **Figure 1**. Patients with ICI-IA, PMR, and sicca syndrome most commonly had grade 2 severity while in myositis grade 3 severity was most common.

Conclusion: ICI-IA was the most common rh-irAE in RADIOS, the largest US-based prospective cohort. Melanoma and NSCLC were the most frequent tumor types, with PD-1 inhibitors being the most used class of ICI. Disease activity for ICI-IA measured by CDAI was moderate on average, and the majority of rh-irAEs were grade 2 (limiting instrumental activities of daily living), except for myositis which tended to have a more severe presentation.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are effective therapies commonly used to treat malignancies but can cause flares or unrelated immune-related adverse events (irAEs) in patients with pre-existing rheumatic disease prior to ICI initiation (pre-ICI RD). As patients with pre-ICI RD were excluded from initial ICI studies, there is still a paucity of information about risks of ICI treatment and how to manage pre-ICI RD while patients are on ICIs.

Methods: Rheumatic Adverse Events Due to Cancer Immunotherapy Observational Studies (RADIOS) is a United States-based academic consortium of 12 sites prospectively collecting data to evaluate outcomes of patients with pre-ICI RD who receive cancer immunotherapy. Patients were included if they had pre-ICI RD and had a baseline visit with rheumatology. Descriptive statistics were calculated for the cohort's demographics (including age, sex, race, ethnicity), cancer characteristics, ICI use at enrollment, and prior treatment for autoimmune disease; clinical disease activity index (CDAI) was calculated for those with inflammatory arthritis. Data on irAE development and autoimmune disease treatment were queried for follow up visits.

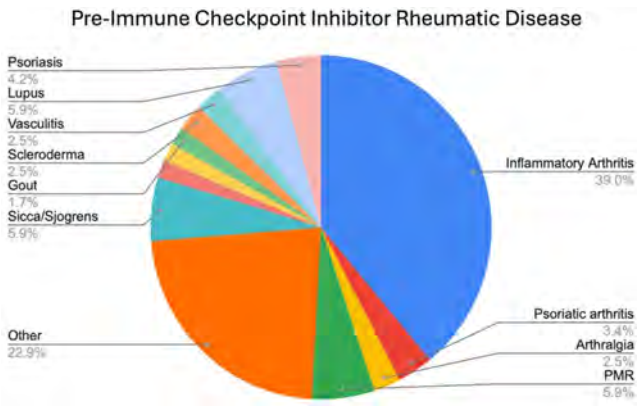

Figure 1: Frequency of Pre-Immune Checkpoint Inhibitor Rheumatic Diseases in the RADIOS Study

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Ever use of disease modifying anti-rheumatic drugs (DMARDs) prior to immune checkpoint inhibitor (ICI) start

Table 1: Demographics and baseline characteristics for patients with pre-ICI Rheumatic Disease

	N (%) or Mean (SD)
Age	67.4 (10.2)
Female sex	42 (53.9%)
Cancer type	
Melanoma	23 (29.1%)
NSCLC	17 (21.5%)
Renal Cell carcinoma	5 (6.3%)
Breast	4 (5.1%)
Other	30 (38%)
Cancer stage at baseline	
1	2 (3.1%)
2	5 (10.8%)
3	21 (32.3%)
4	37 (56.9%)
ICI exposure at baseline	
CTLA-4i	0 (0%)
PD-1i	43 (54.4%)
PD-L1i	3 (3.8%)
CTLA-4i/PD-1i	10 (12.7%)
PD-1i/LAG-3i	1 (1.3%)
Other	3 (3.8%)
Not on ICI	19 (24.1%)

ICI: Immune checkpoint inhibitor; NSCLC: Non-small cell lung cancer; CTLA-4: Cytotoxic T lymphocyte associated protein inhibitor; PD-1i: Programmed cell death protein 1 inhibitor; PD-L1i: Programmed cell death protein 1 ligand inhibitor; LAG-3i: Lymphocyte activation gene 3 inhibitor

Results: As of 4/1/2025, 78 patients with pre-ICI RD were enrolled into the cohort; mean age was 67 years and 54% were female. Inflammatory arthritis was the most common diagnosis (39%) followed by systemic lupus (5.9%) and Sjogren's disease (5.9%) (Figure 1). Melanoma was the most common cancer type followed by non-small cell lung cancer. The majority of patients had stage 4 cancer, and anti-PD-1 was the most common category of ICI used (Table 1). Patients had been previously treated for their RD with a wide variety of DMARDs, most commonly TNF-inhibitors, methotrexate, and hydroxychloroquine (Figure 2). At RADIOS enrollment, 23 (29.5%) were currently on corticosteroids. For those with inflammatory arthritis and CDAI available (n=36), mean CDAI was 11.4 (SD 11.4) and most had low disease activity or remission (n=20, 55.6%).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The most common non-rheumatic irAEs developed were rash and pneumonitis (n=5 for both). At follow up visits, TNF-inhibitors were the most administered biologics (n=9) followed by IL-6R inhibitors (n=7); methotrexate (n=15) and hydroxychloroquine (n=13) were the most common conventional synthetic DMARDs administered. No patients received JAK-inhibitors in follow-up.

Conclusion: By characterizing treatment patterns and outcomes in diverse rheumatic diseases, this multi-institutional, prospective research collaboration will improve knowledge regarding ICI safety for patients with rheumatic diseases who require ICI therapy for cancer.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with systemic autoimmune rheumatic diseases (SARD) treated with B-cell-depleting therapies such as rituximab (RTX) have impaired humoral immune responses, increasing their susceptibility to SARS-CoV-2, including severe infections. Despite vaccination, COVID-19 remains a concern in this population. This study aimed to describe the occurrence of SARS-CoV-2 infections in RTX-treated SARD patients and to explore potential predictors of infection.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Severe SARS-CoV-2 infections

Patient	Sex	Age	Diagnosis	Disease duration	Treatment	Number of vaccine before infection	Time since last vaccine	Time since last RTX	Evusheld prophylaxis	Anti-Spike ER[1]
1	F	60	RA	47 years	Methotrexate NSAID	4	77 days	31 days	Yes	Negative
	Day[2] 31: URTI symptoms, headache, and weakness with positive COVID test, treated with Paxlovid Day 53: Persistent symptoms with positive COVID test Day 99: Persistent URTI and fatigue with third positive COVID test Day 115: ED visit for fever, CXR with suspicion of pneumonia and SARS-CoV-2 infection sequelae, fourth positive COVID test Day 139: Clinical improvement at medical follow-up Anti-N antibodies[3] measured through the study were all negative									
2	M	62	RA	16 years	Methotrexate Sulfasalazine	5	181 days	118 days	Yes	Negative
	Day 118: URTI symptoms and positive COVID test Day 121: ED visit for cough and dyspnea, pneumonia on CT-scan, treated with inhalation therapy, antibiotics and Paxlovid Days 122-124: ED visit for increasing cough and respiratory distress, antibiotics continued and treated with Paxlovid Day 127: Negative COVID test Day 132: ED visit for bronchospasm, diagnosed with viral bronchitis Anti-N antibodies measured through the study were all negative									
3	M	72	ANCA	11 years	None	5	53 days	28 days	Yes	Negative
	Day -11: Mild SARS-CoV-2 infection with positive COVID test Day 28: Relapsing symptoms of cough and fatigue with fever and positive COVID test Days 34-36: ED visit for COVID-19 pneumonia, treated with antibiotics Day 42: Persistent fever and hospitalization for one week, treated with antibiotics and Remdesivir Anti-N antibodies measured through the study were all negative									
4	M	49	ANCA	7 years	None	5	23 days	178 days	No	Negative
	Day 178 : Respiratory symptoms, ED visit with positive COVID test, treated with Paxlovid et prednisone Anti-N antibodies measured through the study were all negative									
5	M	64	RA	13 years	Leflunomide Prednisone Sulfasalazine	5	15 days	197 days	No	Positive
	Days 197-213: Hospitalization for pulmonary embolism, COVID-19 and pseudogout Anti-N antibodies became positive after the infection									

[1]Anti-Spike ER (Evusheld-resistant) antibodies are antibodies directed against variants of the SARS-CoV-2 spike protein that are resistant to neutralization by Evusheld
[2]Days are calculated from the last RTX dose
[3]Anti-N antibodies are antibodies directed against the nucleocapsid (N) protein of SARS-CoV-2, produced in response to natural infection but not after vaccination
ANCA: ANCA-associated vasculitis
CT-scan: computed tomography scan
CXR: chest X-ray
ED: emergency department
URTI: upper respiratory tract infection
RA: rheumatoid arthritis

Methods: COVBIRD is an open-label, non-randomized, comparative trial evaluating humoral responses following at least three COVID-19 vaccinations in SARD patients treated with RTX. We conducted a subanalysis of participants who developed SARS-CoV-2 infection during the study period. Patients were grouped based on their infection status. Descriptive statistics and univariable logistic regressions were used to compare demographic and clinical characteristics between groups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among the 125 RTX-treated patients, 29 (23.2%) experienced at least one SARS-CoV-2 infection, including five classified as severe. Table 1 reports on the patient demographic and diseases characteristics comparing those who developed COVID infection vs those with no infection. No significant differences were observed between groups in terms of diagnosis and treatment-related variables (see Table 1). Age was the only significantly different factor: infected individuals were younger on average (55.2 years; 95% CI, 49.7–60.8) compared to those without SARS-CoV-2 infection (61.8 years; 95% CI, 59.0–64.6); p = 0.034. We also observed a female predominance for infection, but this was not statistically significant. Table 2 summarizes the clinical presentations of the five severe cases.

Conclusion: In this cohort of immunocompromised patients treated with RTX, nearly one in four developed SARS-CoV-2 infection despite having received three to five doses of vaccines, with a subset experiencing severe disease. Baseline clinical characteristics were generally similar between infected and non-infected individuals, highlighting a broad susceptibility likely driven by both immunosuppressive therapy and underlying disease. The younger age of infected patients may reflect behavioral factors such as reduced adherence to preventive measures. These findings emphasize the elevated risk of COVID-19 in RTX-treated individuals and support the implementation of individualized, reinforced preventive strategies regardless of clinical profile.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of an increasing number of malignancies. Because patients with pre-existing autoimmune disease have been excluded from clinical trials of ICIs, there is a paucity of data regarding outcomes in patients with pre-existing rheumatoid arthritis (RA). The aim of our study was to describe rheumatologic and oncologic outcomes of patients with a pre-existing diagnosis of RA who received ICIs for treatment of their malignancy.

Methods: We conducted a cohort study of previously collected data at a single center. We used TriNetX to broadly identify patients receiving an immune checkpoint inhibitor and a disease-modifying antirheumatic drug (DMARD) from January 1st, 2010 to September 19th, 2023. Electronic medical records were abstracted to identify patients with pre-existing RA, patient demographics, laboratory investigations, type of malignancy, type of ICI administered, and flares of RA. Response

Stable disease, n (%)	5 (22.7%)
Progressive disease, n (%)	13 (59.1%)

Evaluation Criteria in Solid Tumors (RECIST) at 6 months was performed by a radiologist to assess for malignancy progression.

Results: We identified 22 patients who had pre-existing RA and received both an ICI and a DMARD. The mean patient age was 70.4 years old and on average patients had been diagnosed with RA for 6 years. There was a history of tobacco use in 77.3% (17/22) of patients. The most common malignancy was non-small cell lung cancer in 31.8% (7/22). Pembrolizumab was the most common ICI with 77.3% (17/22) of patients receiving it. Methotrexate had been used by 81.8% (18/22) of patients, hydroxychloroquine by 86.4% (19/22), and sulfasalazine by 18.2% (4/22). Rheumatoid factor was positive in 40.1% (9/19) and anti-CCP was positive in 50% (8/16). 45% (10) of patients experienced a flare of their RA. Of the 10 patients who had an RA flare, 9 flared by 6 months following ICI initiation, and 8 after one cycle of ICI. RECIST at 6 months after ICI initiation revealed progressive disease in 59.1% (13/22), stable disease in 22.7% (5/22), partial response in 9.1% (2/22), and complete response in 9.1% (2/22).

Conclusion: Approximately half of patients with pre-existing RA treated with ICIs had flares of RA, typically after one dose of ICI administration. Eight of the ten patients who had RA flares flared within six months of ICI initiation. The average number of cycles of ICI administrations prior to flare was 2.7. The majority of patients had been treated with methotrexate and hydroxychloroquine. The rate of progressive disease at 6 months was high, though reflective of the diversity of malignancies included. It is important to be aware of a high flare rate in patients with RA who are undergoing ICI therapy. It would be prudent to increase the frequency of rheumatologic follow up in this patient population in order to quickly diagnose and treat RA flares secondary to oncologic therapy. As most patients who experience an RA flare following ICI initiation do so following the

Background/Purpose: Immune checkpoint inhibitor (ICI) induced myositis is the ICI rheumatic toxicity with the greatest case mortality rate, especially when associated with myocarditis and/or myasthenia gravis (MG). Presentation, progression and treatment for ICI-myositis/myocarditis/myasthenia gravis overlap syndrome (IMOS) is poorly understood. We aim to better understand IMOS clinical presentation, evaluation and disease progression.

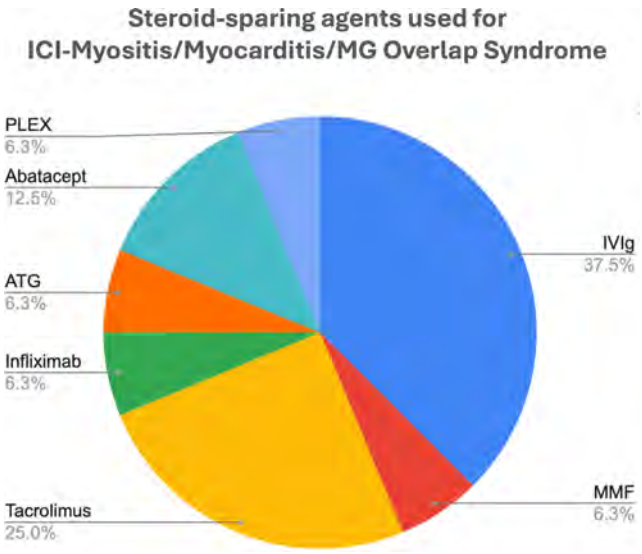

Figure 1: Most patients required therapy beyond systemic steroids. The steroid-sparing therapies ranged for the immune checkpoint inhibitor (ICI) associated Myositis/Myocarditis/Myasthenia Gravis (MG) Overlap Syndrome (IMOS) as depicted here.

Table 1: Baseline characteristics

	n (%) or Median (IQR)
Age	71.5 (67.3, 80.3)
Sex (F, %)	3 (30%)
Race, Ethnicity	
White	7 (70%)

ICI: Immune checkpoint inhibitor; CK: Creatine Kinase, AchR-Ab: Acetylcholine Receptor Binding Antibody, Triple M: Myositis, Myocarditis and Myasthenia Gravis; MG: Myasthenia Gravis; Sx: symptom, Dx: diagnosis
*Data reported excluding one patient with outside troponin using a different, non-high-sensitivity troponin assay

Methods: This is a retrospective, single center, observational study investigating patients with IMOS defined as patients with history of ICI treatment for cancer and development of some combination of ICI-myositis, myocarditis and/or MG overlap. We included adult patients with ICI therapy for cancer between 1/1/2011 and 4/1/2025. IMOS diagnosis was determined by the multidisciplinary treating team of clinicians. We examined demographics, presenting syndrome, clinical evaluation, treatment and outcomes as available in clinical annotations. Data were analyzed using descriptive statistics.

Results: Of 35 patients with either ICI-induced myositis, myocarditis or MG, 10 patients had overlap and fit definition of IMOS: four patients with ICI-myositis, myocarditis and MG (Triple M); three with myocarditis/myositis, three with myocarditis/MG (Table 1). Only three patients (30%) were diagnosed with overlap syndrome at initial diagnosis, with the other seven (70%) being diagnosed sequentially (Table 2). Initial creatine kinase (CK) was elevated in all patients (median 2507, IQR 894, 5543), even in patients without myositis. Median time to steroids after symptom onset was 4 days (IQR 3-6) and time from symptoms to steroid sparing agent was 13 days (IQR 7-15). IVIg was the most frequently used steroid-sparing agent

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(37.5%). Overall, eight patients (80%) died during the follow up period, with six deaths (60%) attributed to IMOS. The myocarditis/MG had the highest mortality at follow-up (100%) followed by Triple M (75%) and then myocarditis/myositis (67%).

Conclusion: Our findings reflect high mortality with IMOS, especially with myocarditis/MG overlap. High CK was prevalent even without myositis and 70% of patients had sequential rather than simultaneous diagnosis of the overlap syndrome. Delay in steroid sparing agent initiation may be a result of time necessary for multidisciplinary conversations and ambivalence in optimal second line therapy. Future research will require higher-powered multi-institutional study to identify the most effective and safe therapies for IMOS.

Breaking Bones, Breaking Hearts: A FAERS Perspective on Osteoporosis Medications

Manush Sondhi[1], Namrata Singh[2], Julie Carkin[1] and Grant Hughes[3], [1]University of Washington, Seattle, WA, [2]University of Washington, Bellevue, WA, [3]University of Washington, Lynnwood, WA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The cardiovascular risks associated with osteoporosis medications remain incompletely understood. Previous studies suggest that romosozumab (ROM) is most strongly associated with major adverse cardiovascular events (MACE), while denosumab (DMB) and teriparatide (TPT) have shown associations with select cardiovascular events in some reports [1–3]. Evidence for alendronate (ALN) and zoledronic acid (ZOL) is mixed, with some studies linking ZOL to atrial fibrillation (A-fib) [4–5]. Limited data exist for risedronate (RIS) and abaloparatide (ABA), with no consistent evidence of increased cardiovascular risk [1,4]. This study aims to evaluate the association between osteoporosis treatments and MACE.

Methods: We conducted a retrospective pharmacovigilance analysis using the FDA Adverse Event Reporting System (FAERS) from 2019 to 2024. All included drugs were FDA-approved by 2019. We examined reports of MACE—including myocardial infarction (MI), stroke, A-fib, and cardiac failure (CF)—associated with ALN, RIS, ZOL, DMB, TPT, ABA, and ROM. Reports involving individuals under 18 years of age were excluded. Disproportionality signal analysis using Reporting Odds Ratios (RORs) was conducted to evaluate MACE events associated with osteoporosis medications, comparing event reporting for each drug to the overall FAERS database. When the lower limit of the 95% Confidence Interval was >1, the ROR was deemed significant.

Results: We analyzed the characteristics of MACE reported in association with each osteoporosis medication. Stroke and CF were most frequent in the 65–85 age group across most drugs, while MI and A-fib were more common in those aged 18–64. Women were more frequently affected overall, except for A-fib, where men predominated.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

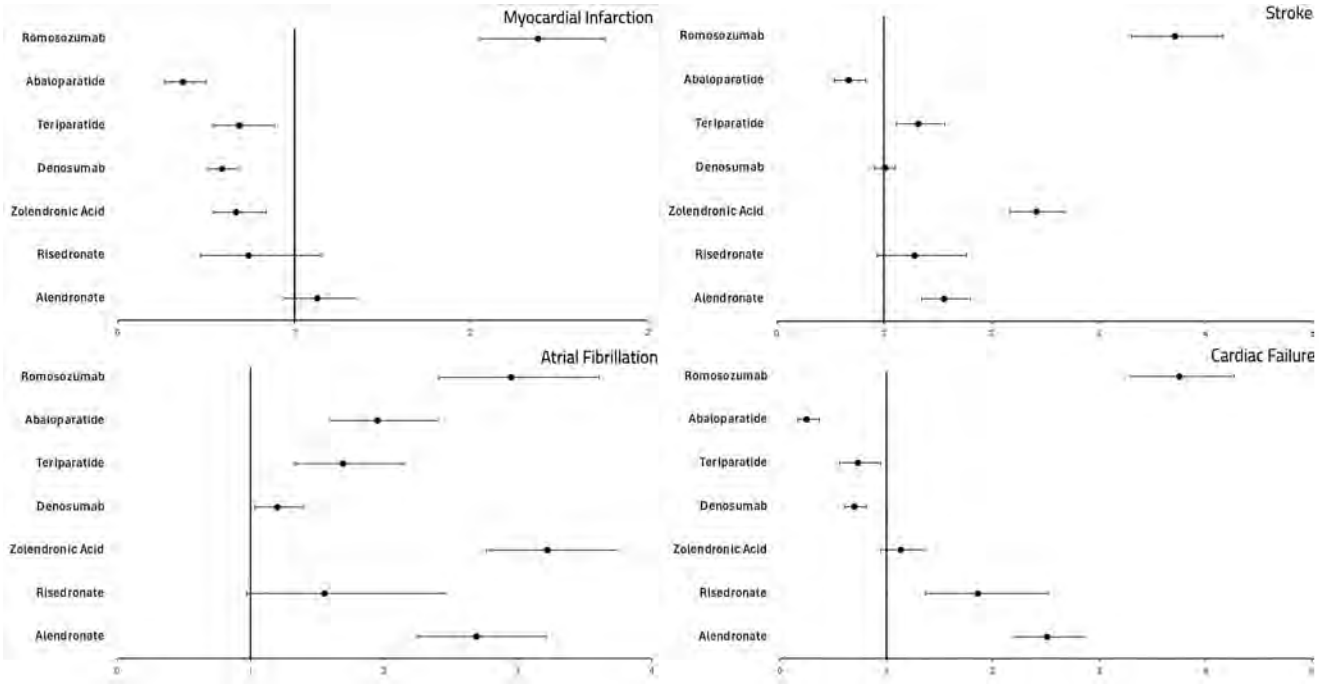
For MI, ROM had the highest ROR (2.38; 95% CI: 2.05–2.70; P < 0.0001), while DMB and ABA were linked to the lowest RORs. For stroke, ROM again showed the highest ROR (3.72), followed by ZOL (2.42). Only ABA demonstrated a negative association. For A-fib, ZOL had the highest ROR (3.22), followed by ROM and ALN; DMB showed a modest association (ROR: 1.20) relative to the other drugs. For CF, ROM had the highest ROR (3.76), followed by ALN (2.52) and RIS (1.86). ABA, TPT, and DMB were associated with the lowest RORs in this category.

Conclusion: We found that among the drugs considered, only ROM was associated with increased ROR for all MACE outcomes. In contrast, DMB and ABA demonstrated relatively low cardiovascular risk signals across most outcomes. ZOL showed notable positive associations with both stroke and A-fib, while ALN was linked to increased reporting of A-fib and CF.

Our findings suggest that a patient's individual risk for MACE should be considered when choosing osteoporosis drugs. Despite MACE risks, treating osteoporosis remains crucial, as fracture prevention significantly reduces morbidity and mortality. Limitations of our analysis include potential reporting bias, residual confounding, and its observational design, which precludes causal inference. Further prospective cohort studies and randomized clinical trials are needed to validate these associations and clarify the mechanisms of risk.

Table depicting the calculated RORs of MACE associated with the medications used for the treatment of osteoporosis.

Drugs	Myocardial Infarction	Stroke	Atrial Fibrillation	Cardiac Failure
Alendronate	1.13 (0.94-1.35)	1.56 (1.35-1.81)	2.69 (2.25-3.21)	2.51 (2.20-2.87)
Risedronate	0.74 (0.47-1.15)	1.29 (0.94-1.77)	1.55 (0.97-2.46)	1.86 (1.37-2.52)
Zoledronate	0.67 (0.54-0.84)	2.42 (2.17-2.69)	3.22 (2.76-3.74)	1.14 (0.95-1.36)
Denosumab	0.59 (0.51-0.68)	1.01 (0.91-1.11)	1.20 (1.03-1.39)	0.70 (0.61-0.81)
Teriparatide	0.69 (0.54-0.89)	1.32 (1.12-1.57)	1.69 (1.33-2.15)	0.73 (0.56-0.95)
Abaloparatide	0.37 (0.27-0.50)	0.67 (0.54-0.83)	1.95 (1.59-2.40)	0.25 (0.17-0.37)
Romosozumab	2.38 (2.05-2.76)	3.71 (3.31-4.16)	2.95 (2.41-3.61)	3.75 (3.29-4.27)



Forest plot depicting the association of MACE with the medications used for the treatment of osteoporosis.

Abstract Number: 1113

Immune checkpoint inhibitor–associated myocarditis: Incidence, risk factors, and clinical outcomes in a global real-world cohort

Qi Wang[1], Zhiting Tang[2] and Lei Deng[3], [1]Metrohealth System/Case Western Reserve University, Cleveland, OH, [2]Unity Hospital, Rochester, NY, [3]Fred Hutchinson Cancer Center, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Immune checkpoint inhibitor (ICI)-associated myocarditis is a rare but life-threatening immune-related adverse event (irAE), with a mortality rate of 30–50%. Most available evidence comes from case series and adverse event reporting databases, leaving its risk factors and clinical outcomes largely undefined.

Methods: We performed a retrospective investigation using the TriNetX Global Research Network. Patients were included if they had been diagnosed with solid tumors after 2016 for which ICIs are approved. We calculated myocarditis incidence among ICI users and compared myocarditis risk between ICI and non-ICI cohorts using propensity score matching (accounting for demographics, comorbidities, cancer types, and treatments). Univariate and multivariate models were applied to assess risk factors. Risks of hospitalization, ICU admission, and major adverse cardiovascular events (MACE) were compared in ICI-treated patients with and without myocarditis using propensity score matching.

Results: Among 130,234 ICI-treated patients, 643 (0.49%) developed myocarditis. Most cases (82.0%) occurred within the first year of ICI initiation. The risk of myocarditis was 27 times higher in the ICI group compared to the non-ICI group (Relative Risk [RR]=27.78, 95% CI: [17.36-44.45]).

Univariate analysis identified older age, male sex, White race, hypertension, hyperlipidemia, ischemic heart disease, diabetes, chronic kidney disease, heart failure, cardiomyopathy, urothelial cancer, melanoma, ipilimumab, nivolumab, pembrolizumab, radiation therapy, inflammatory arthritis, lupus, and systemic connective tissue disease as potential risk factors. In multivariate analysis, only age over 65 (Hazard Ratio [HR] = 1.34, 95% CI: [1.11–1.63], $p < 0.01$), hypertension (HR=1.31, 95% CI: [1.06-1.62], p=0.01), hyperlipidemia (HR=1.34, 95% CI: [1.09-1.65], $p< 0.01$), melanoma (HR=1.52, 95% CI: [1.25-1.86], $p< 0.01$), and ipilimumab (HR= 2.44, 95% CI: [1.87-3.19], $p< 0.01$) were significantly associated with myocarditis.

Patients who developed ICI-associated myocarditis had higher risks of hospitalization (RR=1.39, 95% CI: [1.28-1.52]), ICU admission (RR=2.35, 95% CI: [1.86-2.98]), myocardial infarction (RR=5.58, 95% CI: [3.73-8.34]), heart failure (RR=1.59, 95% CI: [1.38-1.85]), stroke (RR=2.94, 95% CI: [1.75-4.97]), MACE (RR=3.92, 95% CI: [2.91-5.27]), and all-cause mortality (RR=1.32, 95% CI: [1.13-1.55]) within one year compared to those who received ICIs but did not develop myocarditis.

Conclusion: ICI-associated myocarditis is a rare irAE but carries an increased risk of cardiovascular complications and death. Advanced age, hypertension, hyperlipidemia, melanoma, and ipilimumab use appear to be risk factors. Clinical vigilance is warranted to facilitate early detection and management of this potentially fatal complication.

Abstract Number: 1114

Multi-omics Integration Analysis of the Cross-scale Mechanism of MTX-induced T2DM Risk and the Precise Intervention Strategy of Leonurine

Mei-Feng Shi[1], Fang-Shu Zou[1], Xiao-Na Ma[1], Wei Feng[1], Yi-Fang Zhang[2], Chang-Song Lin[1], Min-Ying Liu[2] and **Qiang Xu**[1], [1]Guangzhou University of Traditional Chinese Medicine, Guangzhou, China (People's Republic), [2]The First Clinical Medical College of Guangzhou University of Chinese Medicine, Guangzhou, Guangdong, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Methotrexate (MTX) is a first-line treatment for autoimmune diseases, including rheumatoid arthritis (RA). Its potential risk of inducing type 2 diabetes mellitus (T2DM) remains controversial, and the underlying mechanism is not well understood.

Methods: This study utilized a multi-omics integration approach to systematically assess the association mechanism between MTX and T2DM. Initially, a binary logistic regression model was constructed based on clinical cohort data from 1,253 RA patients, to analyze the correlation between MTX exposure and glycemic metabolism indicators. Additionally, genetic instrumental variables associated with MTX metabolism were selected using public Genome-Wide Association Study (GWAS) databases. The causal relationship was evaluated employing a two-sample Mendelian randomization (MR) framework, combined with inverse variance weighted (IVW), weighted median (WM1), MR-PRESSO, and MR-Egger regression methods, and Bayesian colocalization analysis was used to pinpoint shared genetic variations across the genome. At the molecular mechanism level, a network toxicology approach was utilized to construct an MTX-T2DM interaction network. Molecular docking validation was then performed on selected core targets to confirm their affinity. For potential intervention strategies, the network pharmacology approach was employed to predict the multi-target action network of leonurine, and molecular docking techniques were applied to evaluate the binding stability with key targets.

Results: Clinical data indicates a significant positive correlation between MTX exposure and the risk of T2DM (aOR=19.28, 95%CI:11.86-31.34). MR analysis reveals a significant positive correlation between MTX exposure and the risk of T2DM (OR: 4.50, 95% CI: 3.62-5.61, p=4.03E-31). Bayesian colocalization analysis demonstrates significant genomic colocalization between genetic variants associated with MTX drug response and T2DM risk loci, suggesting that both conditions share causal genetic drivers. Network toxicology and molecular docking elucidate that MTX disrupts fat differentiation and aggravates insulin resistance by inhibiting the PPARG ligand binding domain (docking energy -6.69 kcal/mol) and affecting lipid storage and metabolism. Notably, network pharmacology predictions, combined with molecular dynamics simulations, have confirmed that leonurine can target and activate PPARG and interfere with the Toll-like receptor signaling pathway, thereby reversing the metabolic-immune imbalance induced by MTX.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Graphical abstract

Conclusion: This study has, for the first time, constructed a four-dimensional interaction model of "drug-gene-metabolism-immunity" based on clinical data, proposed a multi-target cascading mechanism of MTX-induced T2DM, and provided interdisciplinary evidence chains for the use of leonurine as a precise intervention agent. This lays a theoretical foundation for optimizing clinical medication with MTX and strategies for the prevention and treatment of T2DM.

Background/Purpose: Approvals for immune checkpoint inhibitors (ICIs) have expanded, and triple therapy combining anti-PD-1, anti-CTLA-4, and anti-LAG3 have been evaluated with encouraging results. But they lead to increasing toxicities, called immune-related adverse events (irAEs). IrAEs have been considered one organ at a time but in reality, comprise a range of systemic inflammatory syndromes targeting multiple organs. A global toxicity score called Organ, Severity, and total Toxicity (OST) has been developed. Patients experiencing irAEs have been shown to have longer survival compared with patients without irAE. But most studies did not correctly account for the immortal time bias. The objective of this study was to quantify the OST in patients with rheumatologic irAE and determine the impact of OST on oncologic outcomes, taking into account the immortal time bias.

Methods: The inclusion criteria were ICI treatment for any cancer leading to a rheumatologic irAE. We calculated the OST score to assess the cumulative toxicity burden at 6 and 9 months after ICI initiation. The OST score was composed of 3 parameters: number of organs (O), number of ≥ CTCAE G3 irAEs (S), and the sum of all CTCAE grades (T). Patients were

Cumulated Steroids dosage (mg) at 6 months of ICI initiation (mean, SD)	1164(1749)	1288(2042)	915(907)

Patients characteristics according to their cOST group.

divided into low and high-toxicity groups for each O, S, and T categories: high - O≥3, S≥1, T≥4 attributing 1 point each to calculate a composite OST score (cOST). To account for immortal time bias, landmark analysis methods were used at 2 time points: 6 and 9 months. Patients were included if they had experienced rheumatologic iRAE and were alive before the time points. Kaplan Meier (univariate) analysis was performed to compare patients according to the cOST score with 2 thresholds at the landmark timepoint.

Results: Out of 109 patients 74 patients were included in the landmark analysis. They mostly presented with polymyalgia rheumatica (53%), then peripheral polyarthritis (26%). Of these patients, 49 (66%) had a cOST=0 at 6 months after the ICI initiation, whereas 25 patients (34%) had a cOST >0. In the landmark analysis starting at 6 months, there was no significant difference in progression-free survival (PFS) according to cOST (p = 0.7) Fig 1A. The median of progression-free survival was 20 months in the cOST=0 group, and 30 months in the cOST >0 group. Likewise, there was no significative difference in overall survival (OS) between patients with cOST > 0 vs cOST=0 at 6 months of ICI initiation (p = 0.4) Fig 1B. The median of overall survival was 68 months in the cOST=0 group and was not reached in the cOST > 0 group. The same analysis performed with landmark at 9 months of ICI initiation returned similar results. When using a different threshold comparing a cOST score of 0-1 with cOST score of 2-3, there was also no significant difference in PFS or OS. There was no major misbalance between cOST groups regarding factors that might influence PFS or OS (table 1). Adjusted analysis will be presented during the meeting.

Conclusion: Patients with articular irAE tend to have a mostly low global inflammatory burden when assessed with this global score that is cOST. There were no significant differences in survival (PFS and OS) in patients with high or low global burden of checkpoint inhibitors toxicity, in this cohort of patients with rheumatic irAEs.

Abstract Number: 1116

Second-line Therapy for Immune-checkpoint Inhibitor-induced Pneumonitis

Sarah Sun[1], Cathryn Lee[2] and Pankti Reid[3], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Chicago, [3]University of Chicago Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) used for cancer therapy can have varied toxicities among which pneumonitis (ICI-pneumonitis) is a rare (< 5%) but often fatal complication. There is scant data to guide second-line therapy for ICI-pneumonitis if systemic steroids are insufficient. We sought to evaluate and compare the effectiveness of key second-line immunosuppressive agents in achieving ICI-pneumonitis resolution.

Methods: For this retrospective observational study, we identified patients with ICI-pneumonitis whose symptoms were refractory or recurrent after systemic steroid treatment and who received a second line agent. We collected data regarding cancer type, ICI type, pneumonitis phenotype and grade, pulmonary comorbidities, steroid details, secondary immunosuppression and outcomes including time to pneumonitis resolution, overall survival, and progression free survival. Count data, t-tests, and chi-square tests were used when appropriate. Cox proportional hazards regression was used for survival data.

Results: Of 1156 patients with ICI-pneumonitis, 13 ICI-pneumonitis patients with second-line treatment (mean age 60.5 (SD 16.5), 8 (61.5%) males) were included in the study. 6 (46.1%) were previous or current smokers, and 9 (69.2%) had pulmonary involvement of their malignancy. 8 (61.5%) patients received chest radiation. All patients had received anti-PD1 monotherapy. Second line immunosuppressive agents included tocilizumab (6 patients), infliximab (4 patients), mycophenolate mofetil (MMF) (4 patients), and Intravenous immunoglobulin (IVIg) (2 patients). Among these, 2 were treated with tocilizumab after failing infliximab or IVIG; one received MMF after failing infliximab. Cancer progression occurred in 2 (50%) MMF, 1 (25%) infliximab, 1 (16.7%) tocilizumab, and 0% patients receiving IVIg. Pneumonitis resolution or sustained improvement occurred most frequently with tocilizumab (4 (66.7%)) compared to MMF (1 (25%), IVIg (0%), or infliximab (0%). The hazard

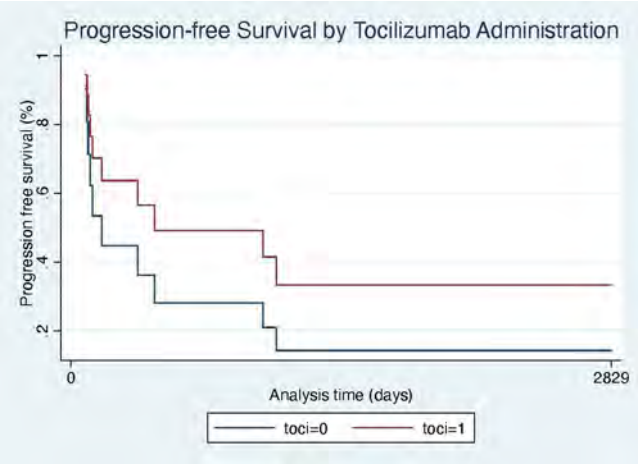

Figure 1. Progression-free survival in refractory or recurrent ICI-pneumonitis patients who received tocilizumab (toci=1, red line) compared to patients who did not receive tocilizumab (toci=0, blue line).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. of the combined outcome of progression or death was lower in patients receiving tocilizumab compared to those without; however did not reach statistical significance (Figure 1; HR 0.56, 95% CI 0.16-2.01).

Conclusion: This study, while underpowered, demonstrates that tocilizumab is not associated with worse outcomes and may be associated with improved survival in patients with ICI-pneumonitis. Future studies should prospectively investigate this finding in larger cohorts.

Inflammatory Arthritis after Hematopoietic Stem Cell Transplant: A Case Series and Literature Review

Scott Yeudall[1], Mark Levis[2], Jonathan Webster[2] and Laura Cappelli[3], [1]The Johns Hopkins Hospital, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Hematopoietic stem cell transplant (HSCT) is a commonly employed treatment for hematologic malignancies including acute leukemias and lymphomas but can be complicated by graft-versus-host disease (GVHD), an inflammatory syndrome affecting multiple organs. While there have been case reports of post-transplant rheumatic syndromes (e.g. myositis and psoriasis), the incidence of post-HSCT inflammatory arthritis is less clear. We aimed to characterize the clinical phenotypes of patients evaluated for inflammatory arthritis after HSCT and to perform a literature review of reported cases of post-HSCT inflammatory arthritis.

Methods: We analyzed the clinical and demographic data of six patients evaluated in the Division of Rheumatology at Johns Hopkins for inflammatory arthritis with initial symptoms after HSCT for hematologic malignancy. Chart review included evaluation of the patient's hematologic malignancy treatment history, clinical arthritis phenotype, arthritis symptom severity and disease activity, serum inflammatory markers, autoantibodies, and arthritis treatment outcomes. For the literature review, the PUBMED database was queried with 24 targeted search terms including those related to inflammatory arthritis, rheumatic disease, and joint involvement combined with hematopoietic stem cell transplant and GVHD, and primary reports were reviewed to assess for common presenting clinical features, immunologic history, and response to treatment.

Results: Of the six patients evaluated in our center for concern of inflammatory arthritis presenting after HSCT, five had HSCT for treatment of acute myeloid leukemia, and three had received at least some treatment for GVHD (Table 1). Symptoms of inflammatory arthritis arose 4-72 months after HSCT (Table 1). Clinical phenotype varied in severity from mild to severe as measured by the Clinical Disease Activity Score (CDAI), and did not clearly correlate with timing of onset post-transplant, prior GVHD, or prior history of autoimmune disease (Table 2). The most frequently involved joints were PIPs, MCPs, MTPs, wrists, and ankles. A majority (5/6) of cases did not have positive serologic markers of rheumatoid arthritis (RF, anti-CCP) or other tested autoantibodies (Table 2). A variety of immunosuppressive medications were employed for treatment of arthritis symptoms, and some patients required corticosteroids for management of symptoms. Literature search identified 16 primary case reports and literature reviews of inflammatory arthritis post-HSCT. The two largest case

series each reported three cases. Psoriatic arthritis, seropositive rheumatoid arthritis, pseudogout, and spondylarthritis were described in case reports.

Conclusion: De novo seronegative inflammatory arthritis occurs after HSCT, characterized by variable severity of presentation and association with other symptoms of GVHD. A literature review identified a limited number of reports of inflammatory arthritis after HSCT, suggesting that continued research is needed to identify predisposing factors in the post-transplant period and advance understanding of rheumatologic complications arising from immunotherapy treatment of hematologic malignancies.

Abstract Number: 1118

Increased Risk of Azathioprine-Induced Leukopenia in Patients with Systemic Lupus Erythematosus: A 10-Year Retrospective Cohort Study at a Quaternary Care Hospital in Thailand

Settawut Buadee[1], Kittikorn Wilasrusmee[1], Tanakrit Kamonsumlitpon[1], Sirirat Charuvanij[2], Ekapun Karoopongse[3] and Praveena Chiowchanwisawakit[4], [1]Medical Student, Faculty of Medicine, Siriraj Hospital, Mahdol University, Bangkok, Thailand, [2]Division of Rheumatology, Department of Pediatrics, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand, [3]Division of Hematology, Department of Internal Medicine, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand, [4]Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: To estimate the incidence and identify associated factors of azathioprine (AZA)-induced leukopenia.

Methods: A retrospective cohort study was conducted on 1,062 adult patients with non-malignant diseases who received azathioprine for the first time between 2014 and 2023 at Siriraj Hospital, Thailand. Inclusion criteria required patients to have a baseline complete blood count (CBC) within eight weeks before starting AZA and a follow-up CBC performed two weeks after treatment. Patients were excluded if they had an abnormal CBC, defined as a white blood cell (WBC) count < 3,000 cell/μl, a neutrophil count < 1,500 cell/μl (neutropenia), or a lymphocyte count < 1,500 cell/μl. Patients with active infections or a history of splenectomy were also excluded. Clinical and laboratory parameters were collected from a medical database during the first year of azathioprine treatment. Follow-up CBC were analyzed to identify cases of AZA-induced leukopenia, defined as a WBC count < 3,000 cell/μl and/or neutropenia. Hazard ratios for factors associated with AZA-induced hematologic abnormalities was analyzed using Cox regression.

Results: Among the cohort, SLE was the most common underlying condition, affecting 274 patients (25.80%). The overall incidence of AZA-induced leukopenia was 6.21%, with an incidence rate of 5.28 per 1,000 person-months (95% CI: 4.15–6.73).

Table 1: Incidence and incidence rates of azathioprine-induced hematologic abnormalities in the overall cohort and the SLE subgroup.

Categories of Abnormal Complete blood count	Incidence (person, percent)		Incidence rate (1000 person-month, 95% confidential interval)	
	Overall (n=1062)	SLE (n=274)	Overall (n=1062)	SLE (n=274)
AZA-induced leukopenia (WBC count < 3000 cell/μl and/or Neutrophil count < 1500 cell/μl)	66 (6.21%)	33 (12.04%)*	5.28 (4.15-6.73)	10.60 (7.54-14.91)
Leukopenia (White blood cell [WBC] count < 3000 cell/μl)	52 (4.90%)	28 (10.22%)*	4.12 (3.14-5.41)	8.88 (6.13-12.86)
Neutropenia (Neutrophil count < 1500 cell/μl)	47 (4.43%)	22 (8.03%)*	3.74 (2.81-4.97)	6.96 (4.58-10.56)
Agranulocytosis (Neutrophil count < 500 cell/μl)	9 (0.85%)	3 (1.09%)	0.71 (0.37-1.37)	0.95 (0.31-2.94)
Lymphopenia (lymphocyte count < 1500 cell/μl)	535 (50.38%)	176 (64.23%)*	64.66 (59.41-70.38)	96.89 (83.58-112.32)
Severe lymphopenia (lymphocyte count < 500 cell/μl)	14 (1.32%)	5 (1.82%)	1.69 (1.00-286)	2.75 (1.15-6.61)

*The incidence in the SLE group significantly differed from the non-SLE populations (P < 0.05) using the Chi-square test.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2: Hazard ratios with 95% confidence intervals for factors associated with azathioprine-induced hematologic abnormalities, analyzed using Cox regression. Statistically significant associations are highlighted by color intensity based on P values. AZA-induced leukopenia was defined as a white blood cell (WBC) count <3,000 cells/μL and/or neutrophil count <1,500 cells/μL. Individual abnormalities were classified as follows: leukopenia (WBC <3,000 cells/μL), neutropenia (neutrophil count <1,500 cells/μL), and lymphopenia (lymphocyte count <1,500 cells/μL).

Factors	Hazard ratio (95% CI)			
	AZA-induced leukopenia	Leukopenia	Neutropenia	Lymphopenia
Age	0.985 (0.970-1.001)	0.981 (0.964-0.999)	0.995 (0.977-1.013)	1.003 (0.997-1.008)
Female gender	1.378 (0.737-2.567)	1.133 (0.583-2.205)	1.132 (0.563-2.276)	1.152 (0.936-1.417)
SLE patients	3.001 (1.852-4.862)	3.495 (2.026-6.029)	2.608 (1.471-4.625)	1.607 (1.342-1.925)
Other connective tissue diseases	1.332 (0.608-2.915)	1.459 (0.623-3.417)	1.338 (0.530-3.383)	1.309 (0.981-1.747)
Dose of AZA > 100 mg/day	7.033 (4.187-11.811)	9.609 (5.493-16.811)	6.719 (3.595-12.557)	1.810 (1.469-2.231)
Concurrent use of Allopurinol	13.736 (3.357-56.121)	17.007 (4.134-69.969)	6.626 (0.914-48.066)	1.080 (0.270-4.332)
Concurrent use of Cotrimoxazole	0.904 (0.363-2.250)	0.914 (0.330-2.534)	0.747 (0.232-2.405)	1.389 (1.050-1.836)
Baseline White blood cell count	0.858 (0.787-0.935)	0.808 (0.727-0.899)	0.877 (0.795-0.967)	0.954 (0.931-0.978)
Baseline Neutrophil count	0.860 (0.781-0.948)	0.826 (0.735-0.929)	0.870 (0.778-0.974)	0.994 (0.969-1.020)
Baseline lymphocyte count	0.765 (0.565-1.036)	0.559 (0.366-0.855)	0.845 (0.608-1.175)	0.485 (0.423-0.555)
Baseline eGFR less than 60mL/min/1.73m²	0.435 (0.136-1.387)	0.565 (0.176-1.819)	0.189 (0.026-1.371)	1.342 (1.022-1.762)

P <0.05 P <0.01 P <0.001 * Each color corresponds to a specific significance level.

Notably, SLE patients had a significantly higher incidence of 12.04% and an incidence rate of 10.60 per 1,000 person-months (95% CI: 7.54–14.91), $P < 0.05$ compared to non-SLE populations. Incidence and incidence rates of each lineage of WBC abnormalities with different cut point were shown in Table 1. SLE was a significant risk factor for AZA-induced leukopenia (HR = 3.001, $P < 0.001$), as well as for leukopenia, neutropenia, and lymphopenia. Other predictors included AZA dose >100 mg/day, associated with higher risk of leukopenia (HR = 9.609, $P < 0.001$) and neutropenia (HR = 6.719, $P < 0.001$). Concurrent allopurinol use conferred the highest risk for leukopenia (HR = 17.007, $P < 0.001$). Lower baseline WBC and neutrophil counts were linked to higher risk of AZA-induced leukopenia and neutropenia, as shown in Table 2. SLE remained an independent risk factor after adjusting for baseline leukocyte counts and AZA dose. Additionally, AZA-induced leukopenia incidence did not significantly differ between patients with normal pharmacogenetic profiles for Thiopurine S-methyltransferase (TPMT), Inosine triphosphate pyrophosphatase 94C >A (ITPA 94C >A), and Nudix hydrolase 15C415T (NUDT15 C415T) and those without testing.

Conclusion: Given the notably high incidence of AZA-induced leukopenia in SLE patients, regular CBC monitoring and AZA dose adjustment are essential to prevent its occurrence, even in those with normal baseline CBC at the start of treatment. Additionally, patients receiving allopurinol concurrently, an AZA dose over 100 mg/day, or those with low baseline WBC and neutrophil counts should be monitored closely. Relying solely on pharmacogenetic testing (including TPMT, ITPA, and NUDT15) may not be sufficient to prevent AZA-induced leukopenia.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have transformed cancer therapy, but their use is often limited by immune-related adverse events (irAEs), particularly in barrier tissues such as the skin. The mechanisms underlying cutaneous irAEs remain incompletely understood. We aimed to identify cellular and antigenic drivers of skin irAEs in ICI-treated patients

Methods: We performed single-cell RNA sequencing (scRNA-seq) and T cell receptor (TCR) sequencing on paired lesional skin biopsies and peripheral blood mononuclear cells (PBMCs) from ICI-treated cancer patients who developed cutaneous irAEs. In parallel, we conducted ex vivo stimulation of patient PBMCs with microbial antigens, followed by flow cytometry to assess T cell activation and cytokine production

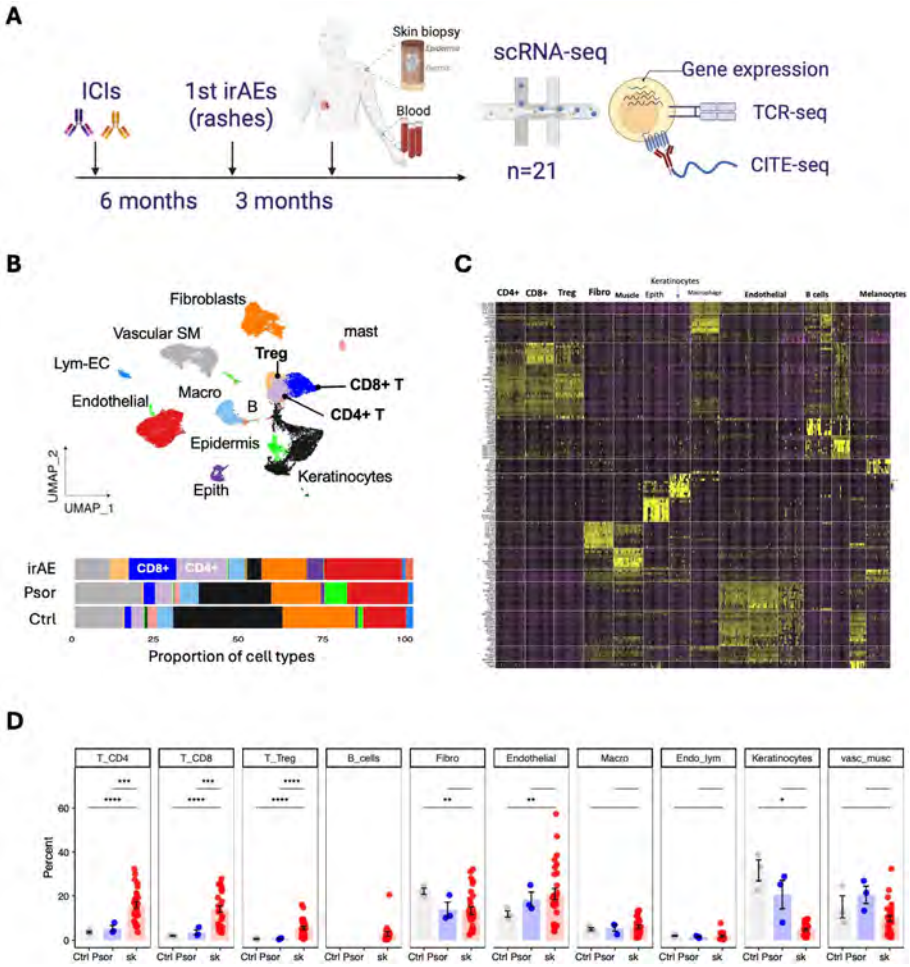

Figure 1. Single-cell analysis of skin and blood samples from patients with cutaneous irAEs following ICI therapy. (A) Schematic overview of the study design. Patients treated with immune checkpoint inhibitors (ICIs) developed immune-related adverse events (irAEs) manifesting as skin rashes. Skin biopsies and blood were collected approximately 3 months after rash onset (average 6 months post-ICI initiation) for single-cell RNA sequencing (scRNA-seq), TCR-seq, and CITE-seq. (B) UMAP embedding of skin immune and stromal cells from 28 samples, color-coded by annotated cell types. Bar plot (bottom) shows the proportion of each cell type across conditions: irAE (red), psoriasis (blue), and healthy control (gray), highlighting increased $CD4^+$ and $CD8^+$ T cell infiltration in irAE skin. (C) Heatmap of scaled gene expression across all clusters, showing top differentially expressed genes that distinguish immune, stromal, and epithelial populations. (D) Quantification of major immune and non-immune cell types across control (Ctrl), psoriasis (Psor), and irAE (sk) samples. Each dot represents an individual patient sample; statistical comparisons were performed using two-tailed t-tests. $P < 0.05$ (*), $P< 0.01$ (**), $P< 0.001$ (***), $P< 0.0001$ (****).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

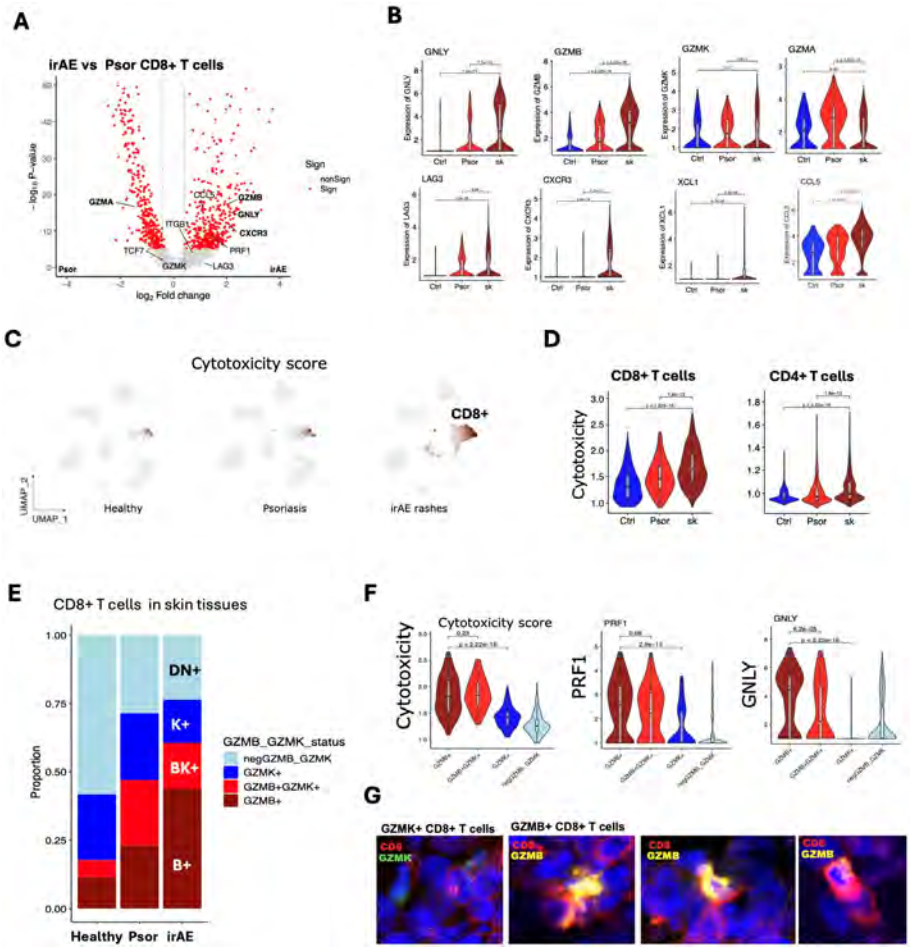

Figure 2. Cytotoxic CD8$^+$ T cells are expanded and activated in irAE skin lesions. (A) Volcano plot showing differentially expressed genes in CD8$^+$ T cells from irAE versus psoriasis skin lesions. Cytotoxic effector genes (GNLY, GZMB, PRF1) and chemokine receptors (CXCR3, XCL1, CCL5) are significantly upregulated in irAE CD8$^+$ T cells. (B) Violin plots showing expression of cytotoxic and chemotactic genes across CD8$^+$ T cells from control (Ctrl), psoriasis (Psor), and irAE (sk) samples. (C) UMAP plots depicting CD8$^+$ T cell distribution and cytotoxicity scores across healthy, psoriasis, and irAE skin tissues.

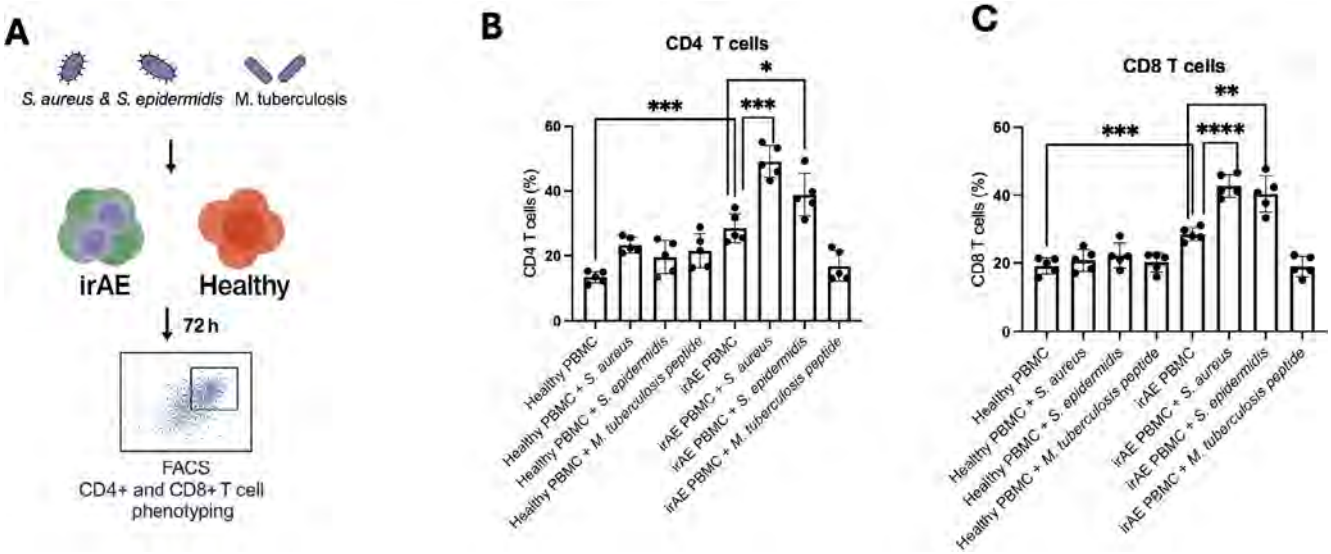

Figure 3. Bacterial stimulation induces activation of cytotoxic CD8$^+$ T cell in PBMCs from irAE patients. (A) Schematic of experimental workflow: PBMCs from irAE patients and healthy controls were stimulated ex vivo for 72 hours with S. aureus, S. epidermidis, or M. tuberculosis antigens. CD4$^+$ and CD8$^+$ T cell phenotypes were analyzed by flow cytometry (FACS). (B–C) Frequencies of CD4$^+$ T cells (B) and CD8$^+$ T cells (C) as a percentage of total lymphocytes across conditions.

Results: Inflamed skin lesions harbored a dominant population of clonally expanded $CD8^+$ T cells expressing cytotoxic effectors including GZMB, PRF1, and IFNG, indicative of tissue-damaging potential. Notably, $CD8^+$ T cells from irAE lesions exhibited substantial expansion of the $GZMB^+$ subset accompanied by a reduction in the less cytotoxic $GZMK^+$ subset, highlighting a skew towards a more pathogenic cytotoxic phenotype. TCR clonotype tracking revealed overlap between skin-infiltrating clones and circulating $CD8^+$ T cells, suggesting antigen-driven recruitment. Computational analysis using GILPH identified shared sequence motifs between patient TCRs and known anti-pathogen TCRs. Additionally, stimulation of patient PBMCs with Staphylococcus aureus and S. epidermidis antigens led to robust activation of $GZMB^+$ $CD8^+$ T cells and enhanced IFN-γ production

Conclusion: Our study identifies microbial antigens as candidate drivers of cytotoxic and inflammatory T cell responses in cutaneous irAEs. These findings highlight the contribution of microbial-reactive $CD8^+$ T cells to irAE pathogenesis and suggest that targeting $GZMB^+$ $CD8^+$ effector functions may offer a therapeutic strategy to alleviate irAEs without compromising anti-tumor immunity

Synergistic Effects of IL-17F and IL-17A on Neutrophil Chemotaxis: Increased Risk of Candidiasis with Dual Blockade of IL-17A and IL17-F

Siba Raychaudhuri[1], Disha Chakraborty[2], Christine Abria[2] and Smriti K Raychaudhuri[3], [1]UC Davis, School of Medicine/VA Medical Center, Sacramento, Davis, CA, [2]Sacramento VA Medical Center, Mather, CA, [3]Sacramento VA Medical Center, Davis, CA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: IL-17 is primarily secreted by Th17 cells. The IL-17 family has 6 related cytokines (IL-17A to IL17F); IL-17A and IL-17F, being key proinflammatory mediators. IL-17A is known for its critical role in neutrophil-mediated immune defense. Notably, dual blockade of IL-17A/F has been associated with a higher risk of candidal infections compared to IL-17A inhibition alone. The objective of this study is to investigate the reason for increased risk of candidiasis linked to dual IL-17A/F blockade. Both IL-17A and IL-17F signal through IL-17RA/IL-17RC. This shared pathway suggests a synergistic role in neutrophil-mediated innate immunity; thus, inhibiting both may increase susceptibility to infections. Here we determined synergistic effects of IL-17A/IL-17F on (i) neutrophil chemotaxis and (ii) candidal killing.

Methods: Blood was collected from psoriatic arthritis (PsA) and osteoarthritis (OA) patients (n=12/each). Neutrophils were isolated using density gradient centrifugation; 1×10*6 cells were seeded into 5 μm pore Transwell inserts (upper chamber) in a 24-well plate. In the lower chambers rIL-17A, rIL-17F, with or without anti-IL-17A/F mab antibodies were added (100 ng/ml each, ThermoScientific). After 12 hours, the inserts were removed, and neutrophil migration was quantified by measuring the number of neutrophils in the lower chamber by MTT assay (optical density (OD) at 450nm, Millipore Sigma).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

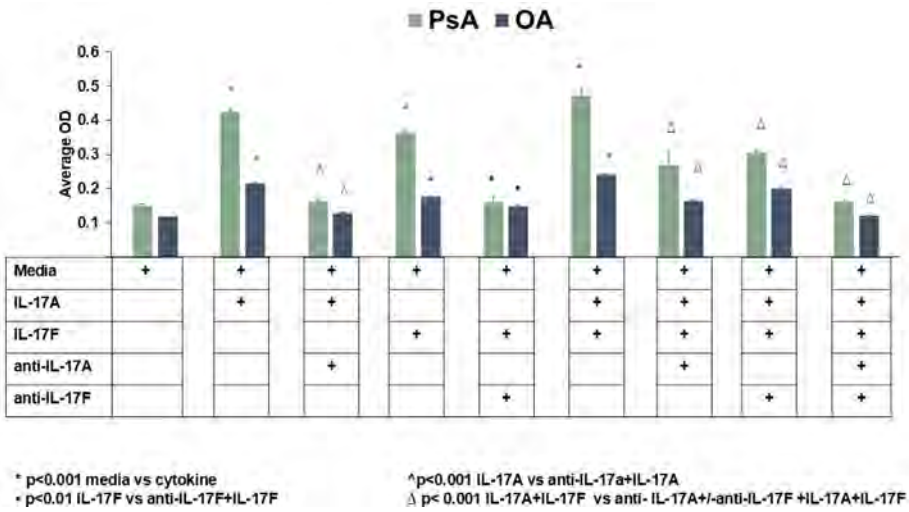

Figure 1: Comparison of neutrophil chemotaxis induced by rIL17A, rIL17F and anti rIL17A + rIL-17F. Both rIL17-A and rIL-17F induced chemotaxis of neutrophils; however combined rIL-17A + rIL-17F showed significantly higher neutrophil chemotaxis. Another intriguing observation was increased chemotaxis with rIL-17A/rIL17F on the neutrophils of psoriatic arthritis (PsA) compared to osteoarthritis (OA).

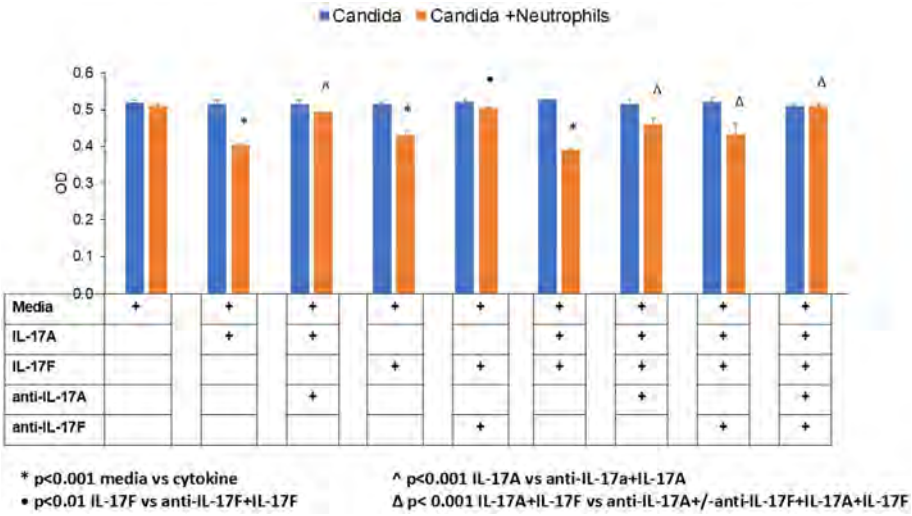

Figure 2: Reduction of candida population as a result of significant neutrophil chemotaxis induced by rIL-17A + rIL-17F. The IL-17A/ILF mabs significantly reduced neutrophil chemotaxis (Fig-1A) resulting in higher candida survival.

To assess neutrophil phagocytic killing of candida, 0.25×10*6 *Candida* with the same cytokine/antibody conditions as above were added in the lower chamber and 1×10*6 neutrophils in the upper chamber. After 12 hours, migrated neutrophils in the lower chamber were lysed with pH11 H_2O; rest of the living cells (*Candida*)were measured by MTT assay. Results are expressed in OD (Mean±SEM) of lower chamber cells.

Results: Neutrophils treated with rIL-17A (OD: 0.149±0.006), rIL-17F (OD: 0.362±0.007), and rIL-17A+rIL-17F (OD: 0.474 ±0.018) showed significantly higher chemotaxis (p< 0.001) compared to media only in PsA patients. Chemotaxis was also significantly higher with rIL-17A vs. rIL-17A+anti-IL17A mab (OD: 0.161±0.008, p< 0.001) and rIL-17F vs. rIL-17F+anti-IL-17F mab (OD: 0.160±0.019, p< 0.01). Notably, rIL-17A+rIL-17F induced greater chemotaxis compared to rIL-17A or rIL-17F (p< 0.001) and which could be effectively blocked by anti-IL17A/F (Fig-1).

rIL-17A+rIL-17F driven neutrophil chemotaxis effectively killed and significantly reduced candida population (OD: 0.363 ±0.014) compared to rIL-17A (OD: 0.410±0.005) or rIL-17F (OD: 0.435±0.25)[p< 0.004; Fig-2].

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This study reports a unique innate immune function of IL-17A and IL-17F, a synergistic enhancement of neutrophil chemotaxis, which could be effectively blocked by anti-IL17A and anti-IL17F mabs (Fig-1). Furthermore, IL-17A+IL-17F significantly reduced Candida survival by inducing neutrophil chemotaxis, which was neutralized by IL-17A/IL-17F mAbs, leading to increased survival of candida (Fig-2). These findings suggest that dual IL-17A/IL-17F blockade may increase the risk of candidal infections, highlighting the need for close monitoring for mucosal and systemic candidiasis in patients with these therapies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Use of immune checkpoint inhibitors (ICIs) can lead to a broad spectrum of immune-related adverse events (irAEs) affecting multiple organ systems. No clear pattern for organs and systems most likely to be affected by simultaneous toxicity has emerged in the published reports of multisystem irAEs. Understanding co-occurrence patterns and prognostic outcomes of irAEs is critical for immunotherapy management. Herein, we focused our analysis on patients from a multi-ethnic Southeast Asian cohort with the intention of identifying distinct phenotypes of irAEs associated with survival after ICIs.

Methods: In total, 870 cancer patients treated with ICIs were recruited into this prospective, multi-institution cohort study of which 341 patients had irAE(s). We used an unbiased approach to identify patients with different patterns of irAEs and to see if these clusters predict outcome. The irAE manifestations were considered as binary (yes/no) variables and used in a latent class analysis (LCA) to identify different phenotypes of multisystem irAEs. Multivariable Cox regression was performed to

Table 2. Clinical characteristics of patients with and without irAEs.

Variables		No irAE (n=526)	Cluster 1 (n=118)	Cluster 2 (n=40)	Cluster 3 (n=183)	p-value

Figure 3. Kaplan–Meier curves for OS according to the different phenotypic clusters.

determine which phenotypic cluster was associated with shorter progression-free and overall survival (OS). An odds ratio (OR) cutoff of ≥ 15.0 was used to define irAEs that drove the clustering. irAEs do not have to occur within the same timeframe to be considered as being multisystem.

Results: Three clusters were identified using LCA (Table 1). All patients in Cluster 1 (C1) (n = 118) had dermatologic (100%) irAEs. With respect to Cluster C1, Cluster 2 (C2) (n = 40) had predominant hepatic (32.5%, OR = 116.3) and pulmonary (77.5%, OR = 785.8) irAEs while Cluster 3 (C3) (n = 183) was characterized by multisystem irAEs such as cardiac (7.7%, OR = 20.3), neurologic (7.7%, OR = 20.3), cytokine release syndrome (12.0%, OR = 33.0), rheumatic (16.9%, OR = 49.0) and hepatic (17.5%, OR = 50.8) toxicities. Comparing patients without irAEs (n = 526), C1, C2 and C3, they were significantly different in terms of concomitant use of proton pump inhibitors, week 6 neutrophil count, week 6 neutrophil-to-lymphocyte ratio, number of cycles of ICI, cumulative dose of ICI and cancer treatment responses. Multivariable COX regression analysis revealed that C2 had the best OS. Compared to C2, no irAE [adjusted hazard ratio (HR) = 6.3, 95% confidence interval (CI) 2.1-18.5, $p < 0.001$], C1 (adjusted HR = 3.5, 95% CI 1.1-11.1, $p = 0.036$) and C3 (adjusted HR = 4.2, 95% CI 1.4-12.4, $p = 0.010$) were associated with shorter OS after adjusting for body mass index, performance status, primary diagnosis and number of cycles of ICI (Figure 1).

Conclusion: Our study reveals differences in patterns of clustering of irAEs. In particular, C3 tends to have toxicities in multiple organ systems and is associated with shorter OS. In addition, we found significant survival benefits for C1 and C2. This may suggest differences in terms of the interactions between the degree of immune activation, immunosuppression and treatment responses that will require further studies to elucidate.

A Retrospective Study of Adverse Cardiovascular Events in Patients Started on JAK Inhibitors at Two Major Health Systems in Northeast Ohio: Analysis of the 2019 JAK Inhibitors FDA Boxed Warning for Increased Risk of Serious Heart-related Problems

William Koch[1], Donald Anthony[2], Janeen Leon[2] and Nora G. Singer[2], [1]University Hospitals Parma Medical Center, Parma, OH, [2]The MetroHealth System at Case Western Reserve University School of Medicine, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1088–1122) Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Janus kinase (JAK) inhibitors are immunosuppressive medications that target the JAK-STAT signaling pathway. Tofacitinib (Xeljanz) was the first JAK inhibitor approved for the treatment of rheumatoid arthritis (RA) in November 2012. Additional JAK inhibitors such as baricitinib (Olumiant) and upadacitinib (Rinvoq) were later approved for the treatment of RA in May 2018 and August 2019, respectively. Shortly after the FDA approved tofacitinib, randomized clinical safety trials found a higher incidence of venous thromboembolic events within the first year of treatment. In 2019 the FDA released a Boxed Warning stating the increased risk of serious heart-related problems and cancers in those treated with tofacitinib. Here we compare the number of adverse cardiovascular events in those patients started on a JAK inhibitor (tofacitinib, baricitinib, upadacitinib) within two major health systems in Northeast Ohio.

Methods: SlicerDicer in EPIC at University Hospitals (Cleveland, OH) and MetroHealth (Cleveland, OH) were used to identify patients who were prescribed a JAK inhibitor (tofacitinib, baricitinib, upadacitinib) who were 18 years or older from November 2012 (first approval of tofacitinib) through May 2025. Subsequently, adverse cardiovascular event (venous thromboembolic event, stroke, ischemic heart disease, heart failure, cardiac arrest, and tachyarrhythmia) were identified using problem list and emergency department diagnosis as narrowing filters. Adverse cardiovascular events were measured from 1 week to 52 weeks after JAK inhibitor initiation.

Results: We identified 2788 patients (University Hospitals, n = 1917; MetroHealth, n = 871) treated with JAK inhibitors (tofacitinib, baricitinib, upadacitinib) of which 294 patients (University Hospitals, n = 226; MetroHealth, n = 68) were diagnosed with an adverse cardiovascular event within 1 year of treatment initiation. The majority of patients were 65 years or older (< 65 years old, n = 131; > 65 years old, n = 163), with 28% males and 72% females. The incidence of adverse cardiovascular events of those on a JAK inhibitor at University Hospitals and MetroHealth collectively was 11%. Yearly trends from November 2012 to May 2025 favored an increase in the number of adverse cardiovascular events following the 2019 FDA Boxed Warning.

Conclusion: JAK inhibitors (tofacitinib, upadacitinib and baricitinib) have been shown to be associated with increased reporting of VTE, stroke, ischemic heart disease, heart failure, cardiac arrest and tachyarrhythmia within the first year of treatment initiation. Our data from two major health systems in Northeast Ohio suggests an incidence of 11%, which is higher than commonly reported. Next steps will include adjudicating patient charts in EPIC SlicerDicer in order to validate and broaden our dataset in EPIC Cosmos. As the FDA approval for JAK inhibitors has expanded beyond inflammatory

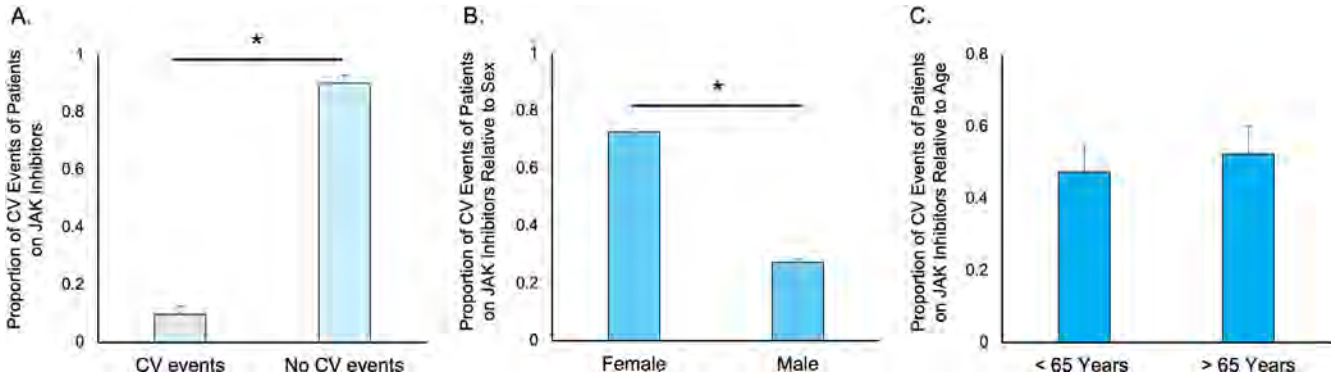

Figure 1. Proportion of adverse cardiovascular (CV) events. A) Proportion of adverse CV events of patients on JAK inhibitors, T-test, *p<0.05. B) Proportion of adverse CV events of patients on JAK inhibitors relative to sex (female vs male), T-test, *p<0.05. C) Proportion of adverse CV events of patients on JAK inhibitors relative to age (< 65 years old vs > 65 years old), no significance between age groups.

Nanoencapsulated Sirolimus plus Pegadricase (NASP) Demonstrates Long Term Efficacy and Safety in Patients with Uncontrolled Gout: Results from the 24-week Double-blind Extension of the Phase 3 DISSOLVE I Study

Alan Kivitz[1], Atul Singhal[2], Anand Patel[3], Rehan Azeem[4], Ben Peace[5], Bhavisha Desai[6] and Herbert Baraf[7], [1]Altoona Center for Clinical Research, Duncansville, PA, [2]SouthWest Arthritis Research Group, Mesquite, TX, [3]Conquest Research, Winter Park, FL, USA, Winter Park, FL, [4]Global MACD, Sobi Inc., Waltham, MA, [5]Statistical Science, Sobi, Stockholm, Sweden, [6]Sobi, Glastonbury, CT, [7]The Center for Rheumatology and Bone Research, Rheumatology, Wheaton, Maryland, USA; Division of Rheumatology, The George Washington University, Washington, DC

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Uncontrolled gout (UG) occurs when serum uric acid (sUA) levels remain persistently elevated despite use of oral urate-lowering therapies and can result in progressively painful gout flares (Dalbeth *et al. Nat Rev Dis Primers* 2019). Nanoencapsulated sirolimus plus pegadricase (NASP, formerly SEL-212) is a novel investigational therapy delivered every 4 weeks as a sequential, two-component infusion consisting of targeted nanoencapsulated sirolimus and pegadricase, a pegylated uricase (**Figure 1A**). Here, we report outcomes through 48 weeks in a subset of patients (pts) in the DISSOLVE I study who received 6 doses of NASP or placebo (PBO) during the 24-week main study period.

Methods: This is a *post-hoc* analysis of the DISSOLVE I (NCT04513366) trial that randomized pts 1:1:1 to one of two doses of NASP (high-dose [HD] or low-dose [LD]) or PBO. After each study drug administration, 4 weeks of observation followed for a total of 6 treatment periods during the main study. Pts could enter a 24-week double-blind extension after the main study period (**Figure 1B**). Evaluated endpoints included reductions in sUA, gout flares, and pts meeting stopping rule criteria (Kivitz *et al. EULAR 2024*, POS0244). Safety was monitored throughout.

Results: Of the 38 pts receiving HD NASP, 37 LD NASP and 37 PBO in DISSOLVE I, 19, 16 and 25, respectively, received all 6 doses of study drug during main study period, and all (100%) entered the extension phase. At baseline, mean (standard deviation [SD]) sUA was 8.4 (1.45) mg/dL in HD NASP, 8.7 (1.08) mg/dL for LD NASP, and 8.3 (1.43) mg/dL for PBO. Immediately after the first dose, mean (SD) sUA dropped to 0.2 (0.00) mg/dL with HD and LD NASP, while remaining stable for PBO at 8.2 (1.36) mg/dL. sUA was maintained low at the end of the first treatment period (Week 4) with NASP (mean (SD) sUA: HD, 1.0 (2.5) mg/dL; LD, 0.2 (0.13) mg/dL) while remaining stable with PBO at 8.4 (1.28) mg/dL. Low sUA were maintained throughout treatment with NASP (Weeks 24: HD, 1.8 (3.29) mg/dL; LD, 1.7 (2.41) mg/dL; Week 48: HD, n=16, 2.4 (3.67) mg/dL; LD, n=12, 1.3 (2.80) mg/dL). In PBO-treated pts, sUA remained consistent at 8.6 (1.43) mg/dL and 8.1 (1.94) mg/dL at Weeks 24 and 48 (n=22), respectively. The proportion of pts with gout flares decreased with NASP treatment over the study period. During Weeks 1–4, flares occurred in 3/19 (15.8%) pts on HD NASP, 7/16 (43.8%) on LD

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Schematic representation of nanoencapsulated sirolimus plus pegadricase (NASP) composition (A) and DISSOLVE I (NCT04513366) study design (B). #Treatment was discontinued if the stopping rule was met: sUA <2.0 mg/dL 1 hour after infusion of the second component of the study drug during week 1 AND either sUA >1.0 mg/dL at the end of week 3 OR sUA >6.0 mg/dL at the end of any subsequent week (i.e. week 7, 11, 15, 19, 23, 27, 31, 35, 39, or 43). Arrows at each interval indicate the timing of drug administration. *sUA measured 1 hour after completing infusion of second study drug. †Evaluation of primary endpoint, defined as the percentage of patients who achieved and maintained sUA <6 mg/dL for ≥80% of the time during Weeks 21–24. Evaluation of sUA during Weeks 21–24 for the primary endpoint was done before study drug infusion, 1 hour after completion of study drug infusion, and at the end of each week during Weeks 21–24. HD, high-dose; IV, intravenous; LD, low-dose; NAS, nanoencapsulated sirolimus; NASP, nanoencapsulated sirolimus plus pegadricase; PEG, polyethylene glycol; PLA, polylactic acid; R, randomization; sUA, serum uric acid.

NASP, and 7/25 (28.0%) on PBO. During Weeks 21–24, flares occurred in 1/19 (5.3%) pts on HD NASP, 2/16 (12.5%) on LD NASP, and remained at 7/25 (28.0%) on PBO and during Weeks 45–48, 0/16 (0%) pts on HD NASP and 1/13 (7.7%) on LD NASP experienced flares vs 5/22 (22.7%) on PBO. In the extension phase, no new safety signals were reported, and no patients experienced an infusion reaction within 1 hour. Only 1 pt (3.7%) in each NASP dose group discontinued treatment due to meeting the stopping rule criteria.

Conclusion: These data support the long-term durability of NASP as shown by sustained sUA reductions and decreased gout flares over time, with 100% on HD NASP and 92.3% on LD NASP being flare-free at the end of the extension phase. NASP was generally well tolerated with low discontinuation rates during the extension phase. Overall, NASP led to improvements in key clinical manifestations of UG.

Abstract Number: 1124

ABCG2 Variants as Genetic Risk Factors for Hyperuricemia and Gout: Focus on Pediatric and Familial Manifestations

Blanka Stiburkova[1], katerina pavelcova[2], Jana masinova[3], Pavel Jesina[4], Yu Toyoda[5] and Tappei Takada[5], [1]Institute of Rheumatology, Praha 10, Czech Republic, [2]Institute of Rheumatology, Praha 2, Czech Republic, [3]Institute of Rheumatology, Prague, Czech Republic, [4]Revmatologický ústav, Praha 2, Czech Republic, [5]The University of Tokyo Hospital, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Gout, a condition arising from hyperuricemia, is considered as both a metabolic disorder and an autoinflammatory disease. Genetic factors are estimated to contribute approximately 40% to serum uric acid levels. Among urate transporters, ABCG2 (ATP-binding cassette sub-family G member 2) plays a crucial role in uric acid homeostasis as an efflux machinery, being expressed in the proximal renal tubules and the intestine.

This study aimed to identify novel and functionally uncharacterized variants of the *ABCG2* gene and to determine the frequency of known pathogenic variants in patients with primary hyperuricemia and gout.

Methods: A total of **549 patients** were recruited from the RU Biobank, of whom **327 with primary gout** and **222 with primary hyperuricemia**. Individuals with secondary gout were excluded. Specific primers were designed to amplify all coding regions (15 exons; transcript ID: ENST00000650821), exon-intron boundaries, and two deep intronic variants (rs13120400 and rs7672194) of *ABCG2*. PCR amplification and Sanger sequencing were optimized and used to analyze the patient DNA (1). Identified ABCG2 variants were biochemically characterized using a mammalian cell-based expression system, followed by **urate transport assays** to assess transporter function.

Results: We detected a nonsynonymous variant p.Q141K with an allelic frequency of 0.22 (which is significantly higher than its minor allele frequency - MAF - in the European population: 0.094). This variant increases the risk of gout, while the common p.V12M variant appears to reduce the risk (MAF in patients: 0.026, MAF in European population: 0.061). We also identified one frameshift variant p.I63YfsTer54, two short deletions (p.K360del and p.F373del) and 14 rare or novel missense variants: p.M71V, p.G74D, p.M131I, p.R147W, p.T153M, p.I242T, p.R236X, p.F373C, p.T421A, p.T434M, p.S476P, p.A528T, p.S572R, and p.D620N (2,3). According to functional studies, nine of these variants lead to reduced or null transport function of ABCG2: p.M131I, p.R147W, p.T153M, p.I63YfsTer54, p.R236X, p.F373C, p.T434M, p.S476P, and p.S572R – all these variants were identified in pediatric patients with hyperuricemia and/or in patients with positive family history of hyperuricemia and gout.

Conclusion: Our findings confirm that the common **p.Q141K** variant and the majority of the identified rare ABCG2 variants negatively impact urate transport and significantly contribute to the risk of **primary hyperuricemia and gout**. Genetic screening for ***ABCG2* variants** may be valuable in clinical practice, particularly in cases of **early-onset** or **familial gout**. Early identification and treatment of hyperuricemia in genetically predisposed individuals - including pediatric or adolescent patients with asymptomatic hyperuricemia - could **delay the onset of gout** and reduce the risk of **related comorbidities**.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Despite evidence-based recommendations, allopurinol dose escalation to goal serum urate (SU) is frequently suboptimal. The EasyAllo tool was developed to facilitate pre-planned allopurinol dose escalation by predicting the allopurinol dose needed to achieve SU < 6 mg/dL >80% of the time and promote easier dose titration (Wright et al. Br J Clin Pharmacol 2024). The purpose of this study was to externally validate EasyAllo among trial participants who achieved goal SU using protocolized dose escalation.

Methods: We included participants in the STOP Gout trial who were randomized to the allopurinol arm, and limited our analyses to those without tophi at baseline who achieved goal SU < 6 mg/dL and completed week 48 of the study to ensure adequate dose escalation and SU capture. All participants fulfilled the 2015 ACR-EULAR gout classification criteria. The trial used protocolized allopurinol dose escalation if SU was ≥6 mg/dL through week 30 to a maximum of 800 mg daily. Two versions of EasyAllo exist: EasyAllo2 based on weight and creatinine clearance and EasyAllo1 which also incorporates baseline SU. We used EasyAllo2 in the primary analysis to allow for inclusion of participants taking allopurinol at enrollment whose baseline SU reflected active treatment, and secondarily explored EasyAllo1 among those not already taking allopurinol. In primary analysis, we determined the frequency with which the study dose required to achieve SU goal < 6 mg/dL between weeks 36 and 48 was at the EasyAllo2 predicted dose or lower. As a secondary aim, we assessed univariate associations between baseline characteristics and being at the EasyAllo predicted dose or lower. We also evaluated whether participants who study dose was the EasyAllo2 predicted dose at the time of first achieving SU < 6 mg/dL demonstrated superior long-term maintenance of SU < 6 mg/dL compared to participants whose study dose was less than the predicted dose.

Results: A total of 291 participants met inclusion criteria for the primary analysis (Table 1). Approximately 77% (n = 224) of participants who achieved SU goal < 6 mg/dL between weeks 36 and 48 were on the EasyAllo2 predicted dose or less. Younger age, lower kidney function, and higher SU were associated with requiring allopurinol doses higher than predicted by EasyAllo2 (Table 3). In secondary analysis using EasyAllo1, which includes baseline SU for prediction, younger age,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

higher baseline weight, and higher SU were associated with allopurinol doses higher than predicted. Considering all participants who ever achieved SU < 6 mg/dL, half (n=207, 51%) subsequently had SU that was not at goal (≥6 mg/dL). This occurred more frequently among participants on a study dose below the EasyAllo2 predicted dose relative to participants on a study dose at or above the EasyAllo2 dose prediction, though, this difference did not achieve statistical significance (55% v 45%, p = 0.06).

Table 1 Baseline Characteristics among Veterans Affairs Participants Randomized to Allopurinol in STOP-GOUT trial

	EasyAllo2 Cohort* (n = 291)	EasyAllo1 Cohort† (n = 181)
Age, years	63.1 (11.6)	63.7 (11.5)
Weight, kg	107.0 (23.5)	103.2 (21.7)
BMI, kg/m^2	34.1 (6.9)	33.1 (6.4)
Male	285 (98%)	178 (98%)

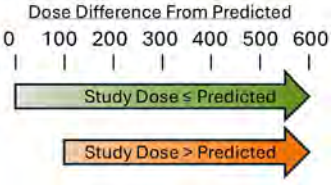
Black	60 (21%)	29 (16%)
Other	26 (9%)	17 (9%)
Missing	1 (<1%)	1 (1%)
CKD Stage 3	109 (38%)	61 (34%)
eGFR, mL/min/1.73 m^2	66.2 (18.8)	67.9 (18.4)
Hypertension	228 (78%)	144 (80%)
Diabetes Mellitus	103 (35%)	60 (33%)
Cardiovascular Disease	79 (27%)	41 (23%)
Serum Urate, mg/dL	8.5 (1.4)	8.8 (1.4)
Serum Urate >9.0 mg/dL	91 (31%)	71 (39%)
Duration of Gout, years	8.7 (10.2)	8.5 (9.8)
Diuretic Use	111 (43%)	65 (41%)
Baseline Allopurinol, mg/day		
None	181 (62%)	181 (100%)
50	3 (1%)	-
100	50 (17%)	-
150	3 (1%)	-
200	23 (8%)	-
300	31 (11%)	-

All values are mean (sd) or n (%). *The EasyAllo2 cohort is limited to participants without tophi at baseline who achieved goal SU <6 mg/dL and completed week 48 of the study to ensure adequate dose escalation and SU capture. †The EasyAllo1 cohort is further limited to participants not on baseline allopurinol to ensure baseline SU values do not reflect active treatment. Abbreviations: body mass index (BMI); chronic kidney disease (CKD); estimated glomerular filtration rate (eGFR)

Table 2 Final Allopurinol Study Dose versus EasyAllo2 Predicted Dose among Participants Achieving SU Goal

EasyAllo2* \ Final Study Dose	200	300	400	500	600	700	800
200	0	0	0	0	0	0	0
300	30	24	15	6	0	0	0
400	32	57	44	30	5	7	0
500	2	7	11	17	3	0	1
600	0	0	0	0	0	0	0



All doses represent mg per day of allopurinol. A total of 291 participants in the allopurinol group without baseline tophi met goal SU <6 mg/dL between weeks 36 and 48. Green represents participants in whom the final trial dose at the time of achieving SU goal <6 mg/dL was equal to (n = 85, 29%) or less than the EasyAllo2 predicted dose (n = 139, 48%). Orange represents participants whose final study dose was more than the EasyAllo2 predicted dose (n = 67, 23%). A total of 79% (n = 231) participants were on a study dose within 100 of the EasyAllo2 dose prediction. The weighted kappa, a measure of agreement where doses closer together are weighted more, was 0.27 using quadratic weighting. *EasyAllo2 dose predictions were calculated using participants baseline weight and creatinine clearance. Abbreviations: serum urate (SU)

White	159 (71%)	45 (67%)		97 (75%)	37 (71%)	
Black	46 (21%)	14 (21%)		20 (16%)	9 (17%)	
Other	18 (9%)	8 (12%)		12 (9%)	6 (12%)	
CKD Stage 3	80 (36%)	29 (43%)	0.26	45 (35%)	16 (31%)	0.76
eGFR, mL/min/1.73 m^2	67.6 (19.2)	61.6 (17.0)	0.02	66.5 (18.9)	71.4 (16.8)	0.11
Hypertension	178 (80%)	50 (75%)	0.40	106 (82%)	38 (73%)	0.17
Diabetes Mellitus	80 (36%)	23 (34%)	0.84	48 (37%)	12 (23%)	0.07
Cardiovascular Disease	57 (25%)	22 (33%)	0.24	33 (26%)	8 (15%)	0.14
Serum Urate, mg/dL	8.3 (1.3)	9.1 (1.6)	<0.01	8.9 (1.5)	8.4 (1.2)	0.03
Serum Urate > 9.0 mg/dL	57 (25%)	34 (51%)	<0.01	57 (44%)	14 (27%)	0.03
Duration of Gout, years	8.9 (10.3)	8.2 (9.8)	0.58	8.1 (9.3)	9.5 (10.9)	0.38
Diuretic Use	82 (41%)	29 (50%)	0.25	50 (43%)	15 (36%)	0.40

All values are mean (sd) or n (%) and p-values represent testing for association between baseline participant characteristics and SU goal attainment on the predicted allopurinol dose or lower at week 30 of the study. P-values represent t-test and chi-square test for continuous and categorical variables respectively. EasyAllo2 dose predictions were calculated using participants baseline weight and creatinine clearance and EasyAllo1 calculations also use baseline SU. Abbreviations: serum urate (SU); body mass index (BMI); chronic kidney disease (CKD); estimated glomerular filtration rate (eGFR)

Conclusion: Among participants who achieved SU < 6.0 mg/dL through protocolized allopurinol dose escalation, nearly 3 out of 4 would likely have achieved SU goal at the EasyAllo2 predicted dose. These findings suggest that EasyAllo2 would perform well in this population with a small proportion requiring additional dose escalation.

Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Calcium pyrophosphate deposition disease (CPPD) is a common cause of arthropathy over the age of 60. It can also manifest as a chronic polyarticular disease and may be mistaken for seronegative rheumatoid arthritis (RA). While previous retrospective cohort studies [1, 2] have explored the relationship between CPPD and RA, the potential role of specific hand joint space narrowing in the diagnosis or treatment response of CPPD has not been addressed.

We aimed to explore whether, in a cohort of patients with early non erosive RA, the presence of specific hand and wrist joint narrowing suggestive of CPPD is associated with distinct baseline features and whether it influences clinical outcomes over the first 60 months.

Methods: A retrospective analysis was conducted on RA patients from the Early Undifferentiated Polyarthritis (EUPA) cohort (1998–2023) [3].

EUPA inclusion criteria required a baseline SJC66 ≥3 and a symptom duration of one to twelve months. Patients with confirmed crystal-induced arthritis, connective tissue disease or vasculitis were excluded. For this analysis, only patients fulfilling the 1987 and/or 2010 RA classification criteria were included, while those with ≥1 erosions on hand or foot radiographs, as determined by the Sharp-van der Heijde score, were excluded.

Radiographs of hands and wrists were reviewed by two independent evaluators for the presence of at least one narrowing suggestive of CPPD such as bilateral radiocarpal, second or third metacarpophalangeal (MCP), scaphotrapeziotrapezoid (STT) joints without first carpometacarpal (CMC) involvement.

Patient characteristics were compared using descriptive statistics. Time-dependent outcomes were evaluated using generalized estimating equations (GEE) with repeated measures. Multivariable models were adjusted for baseline variables, including age, sex, BMI, smoking status, and seropositivity.

Table 1. Baseline variables of patients without (EUPA) and with (CPPD) at least one radiologic sign suggestive of CPPD

	EUPA (n=318)	CPPD (n=70)	p-value
Age	55.8 (42.4-65.4)	68.9 (60.5-73.1)	**<0.001**
Women, n (%)	216 (67.9)	41 (58.6)	0.134
BMI	26.2 (23-30.2)	26.9 (23-28.3)	0.621
Current smoker, n (%)	51 (16.8)	10 (14.7)	0.897
Race - White, n (%)	313 (98.4)	69 (100)	0.591
RDCI ≥ 1, n (%)	151 (47.5)	51 (72.9)	**<0.001**
Seropositive (RF and/or anti-CCP2), n (%)	146 (46.3)	26 (37.1)	0.161
ESR mm/h	24 (14-40)	32 (16-48)	**0.027**
CRP mg/L	9.8 (3.9-26.6)	7 (1.5-24.5)	0.370
66-Swollen joint count	12 (7-19)	12 (7-18)	0.782
≥ 1 swollen wrist, n (%)	228 (71.7)	57 (81.4)	0.095
SDAI	30.7 (20.2-46.3)	31.4 (23.4-43.7)	0.903
CDAI	29.4 (19.1-43.4)	29.2 (22.3-40.7)	0.948
M-HAQ (0-3)	0.8 (0.4-1.3)	0.9 (0.3-1.4)	0.580
Treatment Naive, n (%)	167 (52.5)	32 (45.7)	0.303
csDMARDs active, n (%)	66 (20.8)	18 (25.7)	0.362
Prednisone active, n (%)	52 (16.4)	12 (17.1)	0.872
bDMARDs active, n (%)	1 (0.3)	1 (1.4)	0.239

BMI, body mass index; RDCI, Rheumatic Disease Comorbidity Index; ESR, erythrocyte sedimentation rate; CRP, c-reactive protein; SDAI, Simplified Disease Activity index; CDAI, Clinical Disease Activity Index; M-HAQ, Modified Health Assessment Questionnaire; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; bDMARDs, biological disease-modifying antirheumatic drugs.

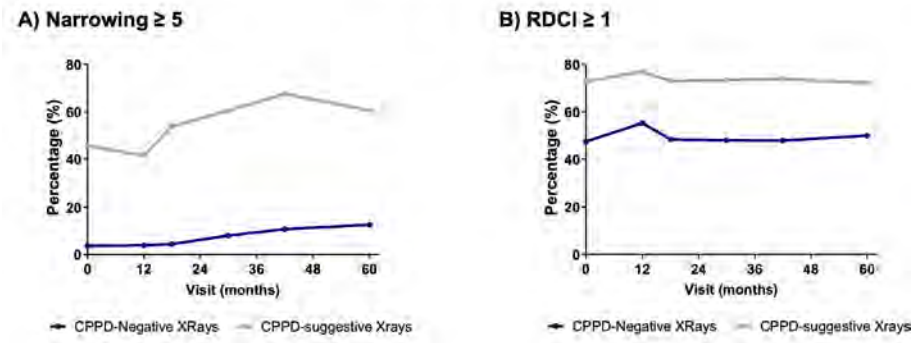
Figure 1. Evolution of narrowing ≥ 5 and RDCI ≥ 1 over 60 months



RDCI, Rheumatic Disease Comorbidity Index.

Table 2. Effect of CPPD on outcomes over 60 months according to univariate and multivariate analysis

	Univariate analysis		Multivariate analysis	
	RR (95% CI)	p-value	RR (95% CI)	p-value
Narrowing score ≥5	7.86 (5.28-11.71)	**<0.001**	5.02 (3.25-7.76)	**<0.001**
Swollen wrist	1.20 (1.00-1.43)	**0.049**	1.08 (0.88-1.32)	0.457
M-HAQ ≥ 1	1.43 (1.02-2.00)	**0.040**	1.10 (0.78-1.55)	0.579
RDCI ≥ 1	1.44 (1.21-1.70)	**0.002**	1.05 (0.89-1.23)	0.585
DMARDs active	1.12 (1.04-1.20)	**0.002**	1.14 (1.05-1.24)	**0.002**
DMARDs + Biologic	1.13 (1.06-1.21)	**<0.001**	1.17 (1.08-1.26)	**<0.001**
DMARDs + Biologic + Prednisone	1.15 (1.08-1.22)	**<0.001**	1.16 (1.08-1.25)	**<0.001**

Multivariable models were adjusted for the following baseline variables: age, sex, BMI, smoking status, and seropositivity.

Results: Among 966 EUPA patients, 388 met inclusion criteria, of which 70 (18%) exhibited at least one radiologic sign suggestive of CPPD. At baseline, CPPD+ patients were older, had higher comorbidity scores and slightly higher ESR (Table 1). The prevalence of CPPD was numerically higher among seronegative patients (20%) compared to seropositive patients (15%) (p=0.16).

Over 60 months of follow-up, CPPD+ patients were more likely to have a joint narrowing score ≥5 and a Rheumatic Disease Comorbidity Index (RDCI) ≥1 (Figure 1). They were also more likely to remain on conventional disease-modifying drug (DMARD) therapy and were more intensely treated with biologics combined with and without prednisone (Table 2). No significant differences were found in SDAI, CDAI, erosions, SJC66, TJC68, pain, or fatigue. Stratification by seropositivity yielded similar results.

Conclusion: Radiological signs of CPPD do not appear to influence RA disease trajectory, regardless of their seropositivity status. However, CPPD+ RA patients may require more intensive treatment, including biologics and prednisone. These changes in RA likely reflect a concomitant or preexisting condition rather than a distinct RA subtype. Further research is needed to enhance our understanding of this topic and its clinical implications.

Abstract Number: 1127

The Pathogenetic Role of Calcium Pyrophosphate and Basic Calcium Phosphate Crystals in Osteoarthritis: Associations with Synovial Fluid Cytokines and Clinical Indices

Francesca Oliviero[1], Chiara Baggio[2], Amelia Damasco[2], Federico Zorzi[3], Mariagrazia Lorenzin[2], Giacomo Cozzi[2] and Roberta Ramonda[4], [1]Rheumatology Unit, Department od Medicine - DIMED, University of Padova, Padova, Veneto, Italy, [2]Rheumatology Unit, Department of Medicine - DIMED, University of Padova, Padova, Veneto, Italy, [3]Center for Analysis and Certification Services (CEASC), University of Padova, Padova, Veneto, Italy, [4]Rheumatology Unit-DIMED-University of Padova ITALY, Padova, Padua, Italy

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

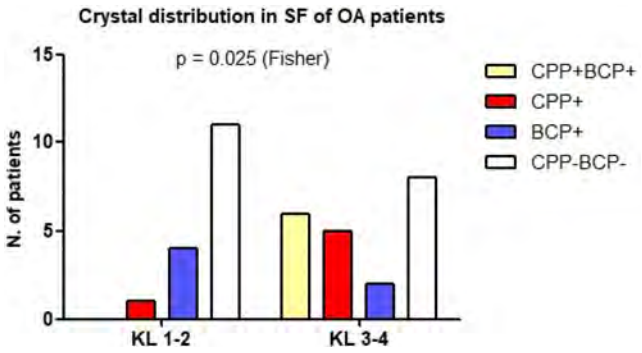
Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Calcium pyrophosphate (CPP) and basic calcium phosphate (BCP) crystals are frequent features of synovial fluid (SF) in patients with osteoarthritis (OA). Although these crystals have shown pro-inflammatory properties in vitro, their pathogenetic role is not completely clear. Our previous studies demonstrated that the presence of CPP in SF is associated with a mild inflammatory status and more advanced stages of the disease (Oliviero F, 2023; Frallonardo P, 2018). With this study we aimed to investigate SF cytokines and clinical indices of disease in a cohort of OA patients with or without CPP and BCP in their SF.

Methods: SF samples were collected from 40 patients with OA attending our outpatient clinic and analyzed as part of routine procedures. Patients were asked to complete the WOMAC and Lequesne questionnaires and a VAS scale for pain. OA severity was classified according to the Kellgren and Lawrence system. Total leucocytes, differential cell count and crystal search were performed in all the samples. CPP crystals were identified by polarized light microscopy (PLM) while BCP were assessed by Environmental Scanning Electron Microscopy (ESEM) and energy-dispersive X-ray (EDX) spectra, after samples centrifugation. Discarded SFs were stored for cytokine (IL-1, IL-18, IL-8, CCL23) determinations.

Results: ESEM analysis confirmed the presence of CPP in all SF positive at the PLM (n. 14) and in no additional samples. BCP have been found in 13 specimens, 7 of which were also positive to CPP. Given the low number of BCP+ SFs, we firstly compared the CPP+ and the CPP- groups. Patients with CPP showed higher WOMAC (p=0.04) and VAS pain (0.039). Although non-significant, IL-8 and CCL23 were higher in CPP+ samples. Examining data according to ESEM results, we found a significant distribution of CPP in the group of patients with a KL=3-4 and BCP in the group KL=1-2 (p=0.025)



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(Fig.1). Patients positive for both CPP and BCP had the worse clinical indices (WOMAC and pain 0.04). The levels of CLL23, which we demonstrated to be highly induced in vitro by CPP crystals (Baggio C, 2025), are similar in the groups CPP+ and CPP+BCP+, and decrease in the group BCP+, CPP-BCP-. IL-8 was higher in the group positive to both crystals but lower in the BCP+ group.

Conclusion: This study supports the concept that calcium crystals are not mere bystanders in OA, but rather play a pathogenetic role. CCL23 emerges as a new chemokine that warrants further exploration in OA research.

Association Between Leptin Levels, Body Mass Index and Health-related Quality of Life in Patients with Gout

Inna Orlova[1], Iryna Shapoval[2], Nataliia Shkolina[1], Nataliia Kuzminova[1] and Mykola Stanislavchuk[3], [1]National Pirogov Memorial Medical University, Vinnytsya, Vinnytsya, Ukraine, [2]National Pirogov Memorial Medical University, Vinnytsya (Ukraine), Vinnytsya, Ukraine, [3]National Pirogov Memorial Medical University, Vinnytsia, Vinnytsia, Ukraine

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Gout is s a disease with a high disability rate, resulting in severe social burden and is associated with reduced health-related quality of life (HRQoL). Several studies showed that the violation of adipokine status is factor in the development and progression of crystal-induced inflammation. Therefore, assessing the association between leptin levels, body mass index (BMI) and HRQoL is very relevant. This study aimed to investigate the BMI and HRQoL patients with gout and evaluate its association with leptin levels.

Methods: 151 patients were included; 100% were men. The mean age was (mean±SD) 52.4±9.2 years. The average BMI was 31.9±3.4 kg/m2. The mean disease-specific HRQoL was evaluated using a translated and validated Ukrainian version of the Gout Impact Scale (GIS; scale 0-100); HRQoL was assessed by the SF-36 and calculated summary physical (PCS) and mental component (MCS) scores of the SF-36. Leptin in serum was determined by ELISA using the "Human Leptin ELISA Kit" (DRG, Germany). Statistical analysis was performed using MS Excel and SPSS22 software (©SPSS Inc.).

Results: The PCS of the SF-36 was 34.0±7.7, MCS was 40.0±9.2. Total GIS was 51.1±27.5. The leptin level in patients with gout ranged from 2.06 to 18.15 ng/ml (95% CI) and the mean was 6.6±4.3 ng/ml. According to the quartile distribution of serum leptin level, patients with gout were divided into 4 groups: the 1st quartile (Q1) included 36 patients (with indicator level <3.44 ng/ml), the 2nd quartile (Q2) – 37 people (from 3.44 to 5.77 ng/ml), the 3rd quartile (Q3) – 36 people (from 5.77 to 7.49 ng/ml) and the 4th quartile (Q4) – 42 people (>7.49 ng/ml). With increasing leptin levels, there was a decrease in both physical and mental health in gout patients (Fig. 1). The PHS was 22% lower in the 4th quartile than in the 1st, while the MCS was 17% lower in the 4th quartile compared to the 1st quartile. At the same time, the final indicators of the physical and mental sphere in patients in the 4th quartile were significantly different from those in patients in the 1st and 2nd quartiles. The increase in leptin content was accompanied by an increase in the impact of gout on the GIS scale. The total GIS was higher in patients in the 4th quartile and was 35.6% higher than in patients in the 1st quartile. Besides, our analysis showed

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Fig.1. Characteristics of the total GIS, the total physical, mental component of the SF36 and BMI depending on the quartile distribution of leptin level. Note: * - p<0.05 relative to Q1; # - p<0.05 relative to Q2.

significant positive association between BMI and leptin level. In patients with leptin levels >7.49 ng/ml (Q4), BMI was significantly higher by 16.5% than in patients with leptin levels < 3.44 ng/ml (Q1).

Conclusion: An increased leptin level was associated with significant reductions in HRQoL in gout patients. A significant relationship is found between leptin and BMI. The results of this study support the role played by body composition and adipocytokines in HRQoL in gout patients.

Effectiveness of sodium-glucose cotransporter type 2 inhibitors and urate-lowering agents in patients with gout: data from a single-center specialised clinic

Jose Doménech Serrano[1], Ivana García Loiseau[2], Cristina RodrÍguez-Alvear[3], Pablo Riesgo Sanchis[1], Oscar Moreno Pérez[1] and Mariano Andrés[1], [1]Dr Balmis Alicante General University Hospital-ISABIAL, Alicante, Spain, [2]Miguel Hernández University, Alicante, Spain, [3]Virgen de la Peña General Hospital, Fuerteventura, Spain

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Sodium-glucose cotransporter type 2 inhibitors (SGLT2I) proved substantial benefits in diabetes mellitus (DM), heart failure (HF) and kidney disease (KD). In pivotal trials, SGLT2Is reduced serum urate (SU) levels, but the evidence in patients with gout under other urate-lowering drugs (ULD) in clinical grounds is scarce. The objective is to evaluate the urate outcomes in patients with gout treated with SGLT2I and ULD in clinical practice.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Retrospective, single-center observational study, enrolling patients with gout from a crystalarthritis specialised clinic. We selected those receiving combined treatment with ULD and SGLT2I, regardless of the indication. Cases with no serum urate levels available in the 6 months before andafter combined treatment or starting renal replacement therapy were excluded. The main variable of the study was SU level pre- and post-SGLT2I (mg/dL) statistically analized using Wilcoxon test as a non parametric continuous variable. As secondary variables, we measured the percentage achievement of SU target (< 6 mg/dL or < 5 mg/dL), the required allopurinol dose (mg) and pre-estimated dose according to the Easy-Allo tool (mg) [PMID 38359899].

Results: Forty-six patients were included: median age 76 years (IQR 15.25), 82.6% men, with high comorbidity (91.1% with DM, 58.7% with KD, 45.7% with HF) and 10 years (IQR 20) of gout duration. As ULD, 66.7% (n=30) of patients were treated with allopurinol, 28.9% (n=13) with febuxostat, and 4.4% (n=2) with benzbromarone. Regarding the SGLT2I, 58.7% (n=27) received dapagliflozin, 30.4% (n=14) empagliflozin, and 10.9% (n=5) canagliflozin. ULD were initially prescribed in 81.4% (n=35), while SGLT2I in the remaining 18.6% (n=8).

The target of SU < 6 mg/dL was achieved in 97.7% (95%CI 88.2-99.6%) of the patients, while 81.4% also reached < 5 mg/dL (95%CI 65.5-88.9%). The achievement of the < 5 mg/dL target was unrelated to the first prescribed medication (ULD 81.3% vs SGLT2I 87.5%, p=1.000) or the type of xanthine-oxidase inhibitor (allopurinol 79.3% vs febuxostat 91.7%, p=0.651).

The start of SGLT2I showed a median SU reduction of 0.85 mg/dL (IQR 3.02, p=0.001 for the before-after comparison) [Image 1]. The SU reduction was observed regardless of being already on ULD (median 0.80, IQR 2.90, p=0.021) or not (median 3.00, IQR 6.95, p=0.018) or of changes in diuretics use (p=0.692).

No significant differences in allopurinol dose were found pre- and post-SGLT2I use but with a trend toward a lower dosage than pre-estimated by the Easy-Allo tool [Image 2].

The use of SGLT2I showed significant reductions in fasting glucose, HbA1c, and C-reactive protein levels, increased urine glucose excretion, and no differences in urine albumin and glomerular filtration rate. We detected a significant reduction in diuretics use pre- and post- SGLT2I (60.9% vs 54.3%, p < 0.001).

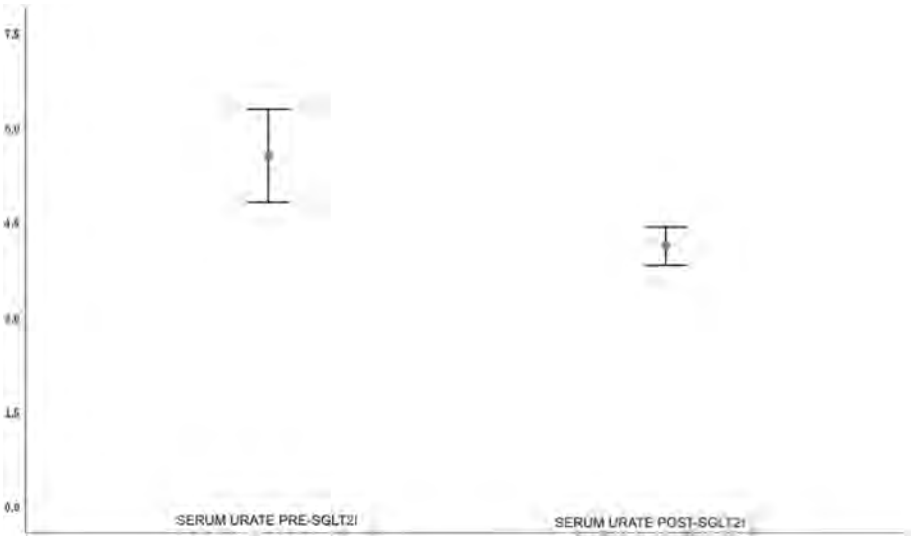

Image 1. Serum urate (SU) reduction in mg/dL after the start of SGLT2I. In brackets, 95%CIs. In the pre-SGLT2I serum urate category, the values are higher, with a mean close to 5.5 mg/dL and with regard to post-SGLT2I serum urate values these are lower, with a mean close to 4 mg/dL.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Image 2. Allopurinol dose pre-estimated and after the start of SGLT2I. Box-and-bar plot of Allopurinol dose comparison. The boxes represent the interquartile range (Q1 to Q3), the dark lines represent the median, and the brackets indicate the range of the data excluding outliers. We can observe a higher variability in the dose of allopurinol after the initiation of treatment with SGLT2I with a tendency towards the use of lower doses.

Conclusion: The combination of SGLT2I and ULD in patients with gout in clinical practice achieved significant SU level reductions and targets of SU < 6 mg/dL and < 5 mg/dL. A trend towards a lower dosage requirement of allopurinol was noted, along with a reduced use of diuretics.

These promising results require confirmation by further intervention studies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Obesity affects >50% of individuals with gout and is the most important modifiable risk factor for gout. Thus, novel anti-obesity medications (AOM, e.g., semaglutide and tirzepatide), which have revolutionized the medical management of obesity and associated cardiovascular-kidney-metabolic (CKM) comorbidities, are highly relevant for

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patients with gout. Researchers have associated weight loss through bariatric surgery or lifestyle changes with reduced serum urate (SU), but no study has examined how novel AOM affects SU. We sought to determine the SU change among patients with gout and baseline hyperuricemia treated with novel AOM.

Methods: Using the Mass General Brigham electronic health record (EHR) database, we identified all patients with gout with baseline hyperuricemia (SU ≥6 mg/dL) who had SU measurements available within 3 months before and >3 months after starting a novel AOM as part of routine clinical care. We defined novel AOM as semaglutide or tirzepatide. We identified patients with gout using an algorithm with a positive predictive value of 0.9 against the 2015 ACR/EULAR gout classification criteria. A rheumatologist and a trained research team member manually reviewed all charts and adjudicated any discrepant findings by consensus. We excluded patients who had SU measured in the setting of an acute gout flare and patients who started or changed the dose of urate-lowering therapy during the study period. We calculated the weight change for all individuals using measurements available in the EHR on dates closest to the SU measurements and grouped them into three categories (< 5%, 5-10%, or >10%). We used linear general estimating equations with robust variance to evaluate the association of baseline weight and weight change (either in absolute or categorical) with serum urate.

Results: Our study included 22 patients with gout who were started on a novel AOM. The mean age was 54.6 years, and the majority were male (77.3%) (**Table 1**). Mean BMI was 39.3 kg/m^2 at baseline. The primary indication for novel AOM treatment was obesity in 11 patients and type 2 diabetes (T2DM) in 11 patients, though many of those with T2DM also had comorbid obesity. Mean treatment duration was 258 days. There were 45.5%, 31.8%, and 22.7% of patients who lost < 5%, 5-10%, and >10% body weight, respectively. There was a significant association between weight and SU change (**-Table 2**, **Figure 1**). Each kg of weight loss was associated with a 0.13 mg/dL reduction in SU, while each BMI unit reduction

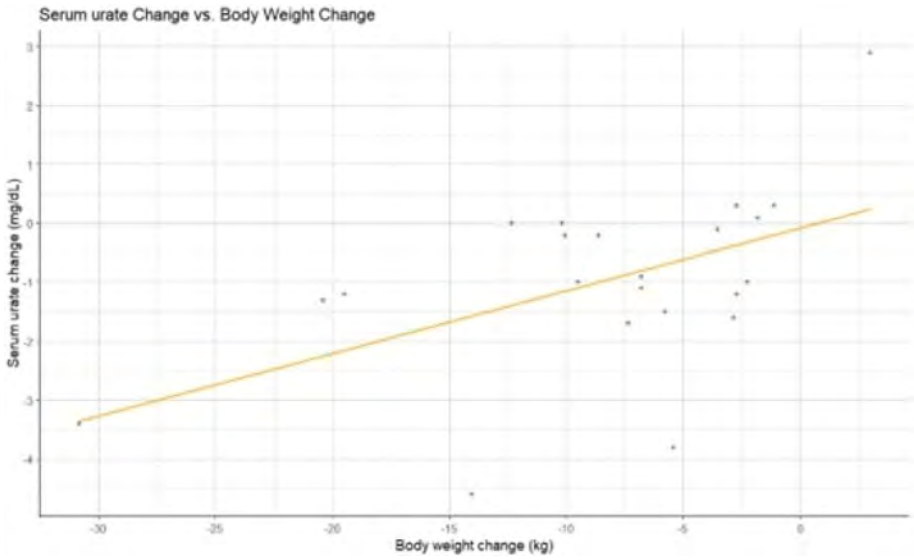

Figure 1. Body Weight Change and Serum Urate Change Among Patients with Gout and Baseline Hyperuricemia

was associated with a 0.41 mg/dL reduction in SU. Compared to those who lost < 5% of their body weight, those who lost 5-10% of their body weight had a 0.73 mg/dL greater reduction in SU, and those who lost >10% of their body weight had a 2.36 mg/dL greater reduction in SU (p for trend < 0.001) (**Table 2**).

Conclusion: In this retrospective study, novel AOM-induced weight loss was associated with a significant reduction in SU among patients with gout with baseline hyperuricemia. These results suggest that novel AOM may be a powerful multi-purpose medication for the many patients with gout and obesity and call for larger-scale studies to test this hypothesis.

Patient with tophi, WES, and pedigree: (A) The proband P1 (index case) in this study presented with tophi covering both hands. (B) Whole-exome sequencing revealed that the proband P1, his brother P2, and father P3 (not shown) all shared a heterozygous missense mutation in MIF (NM_002415.2):c.195C>G (p.Ile65Met) in exon 2. Additionally, proband P1 carried a homozygous missense mutation in MTHFR (NM_005957.5):c.665C>T (p.Ala222Val) in exon 5 and a heterozygous frameshift mutation in UBAP1 (NM_001171201.1):c.192dup (p.-Arg65SerfsTer18) in exon 1. (C) The pedigree chart showed that the proband's father (P3) and brother (P2) were also early-onset tophaceous gout patients, with all three (P1, P2, P3) carrying the heterozygous MIF mutation, while P1 has two asymptomatic sons (aged 6 and 4). (D) In vitro pulsed-field gel electrophoresis using human genomic DNA as the substrate was performed to assess the nuclease activity of DNase-I and MIF. (E) The results demonstrate that wild-type MIF exhibits DNA-degrading activity, whereas the nuclease activity of the MIF (I65M) mutant is significantly reduced compared to the wild type.

extracellular traps (aggNETs) constitute the primary structural component of tophi, the susceptible population for tophaceous gout remains poorly characterized. We investigated a familial case of early-onset tophaceous gout to elucidate novel mechanisms underlying tophus formation.

Methods: Whole-exome sequencing was performed on a multigenerational family with early-onset tophaceous gout affecting the proband, his father, and brother. Molecular cloning generated wild-type and mutant macrophage migration inhibitory factor (MIF) expression vectors, with subsequent structural and functional characterization using three-dimensional modeling and circular dichroism spectroscopy. Tophaceous mice administered by MIF or mutant MIF vectors, *Mif* knockout mice and in vitro models assessed tophus degradation dynamics. Transwell assays with fluorescence labeling evaluated macrophage-mediated phagocytosis and intracellular processing of aggNETs.

DNA Enzyme Intervention Promotes Tophus Resolution: (A) Classic MSU crystal-induced gouty arthritis model in mouse footpads: One footpad was injected with MSU crystals (40 μL, 25 mg/mL), while the contralateral side received an equal volume of PBS. Tophus-like material (red arrow) appeared at 8 h post-injection (d0+) and spontaneously resolved by day 8 (d8). (B) Daily footpad injection of DNase-I (20 μL, 1600 U/mL) after MSU crystal injection accelerated tophus resolution, with complete disappearance by day 6 (d6, red arrow). (C) Immunofluorescence staining of d2 tophus-like material revealed abundant NETs containing macrophages. (D) Joint swelling index in the MSU crystal-injected group returned to baseline (no statistical difference vs. d0) by day 8. (E) The DNase-I + MSU crystal group showed recovery of joint swelling index by day 6. (F) In vitro, aggNETs (formed by co-culturing neutrophils [1.2×10^7/mL] with MSU crystals [0.6 mg/10^6 cells]) were stained with Sytox (DNA). DNase-I treatment reduced aggNETs within 2 h, with near-complete dissolution at 4 h. (G, H) Uricase (10 U/mL, 50 U/mL) co-injection with MSU crystals failed to resolve tophi by day 8, with significantly higher arthritis indices vs. controls. (I, J) Combined uricase (50 U/mL) + DNase-I daily intervention achieved tophus resolution by day 5 and restored joint swelling index by day 3. (K, L) In MSU crystal-induced arthritis, MIF-treated mice showed tophus resolution at day 6.3, while MIF (I65M)-treated mice required 8 days (significantly delayed, **P<0.01, ****P<0.0001).

Results: We identified a pathogenic *MIF* variant (p.Ile65Met, hereafter referred to as I65M) segregating with disease in the affected family. Structural analysis revealed this mutation induces conformational changes in the PD-D/E(X)K domain. Functional studies demonstrated: (1) significantly reduced nuclease activity of MIF(I65M) compared to wild-type; (2) impaired tophus degradation capacity of MIF(I65M) in both murine models and in vitro systems; (3) preserved macrophage phagocytosis but defective cytoplasmic degradation of aggNETs through a lysosome-independent pathway.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. MIF Promotes Macrophage Phagocytosis of aggNETs and the Spatial Conformation of MIF (I65M): (A, C) THP-1-derived macrophages phagocytosing aggNETs. DNA (aggNETs) was stained with Sytox Green (intracellular live-cell DNA remains unstained). Over time, fluorescent signal appeared within macrophages, with gradually decreasing mean fluorescence intensity (MFI). (B) MIF-knockdown THP-1-derived macrophages exhibited significantly impaired phagocytosis of aggNETs. (D) MIF enhanced THP-1 phagocytosis of aggNETs, while MIF (I65M) showed reduced activity (peak phagocytosis at 4 h; MIF group displayed strongest intracellular green fluorescence, markedly weaker in MIF (I65M) group). (E) Schematic of human MIF's three PD-D/E(X)K domains (blue, green, purple) with amino acid sequences. Red "I→M" indicates the mutation site. (F) 3D structure of human MIF showing the mutation site (red) located in the 4th β-sheet between PD-E (blue) and PD-D (purple).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This study establishes a novel pathogenesis framework for familial tophaceous gout, demonstrating how MIF mutations lead to aggNETs accumulation through impaired clearance mechanisms. Our findings identify defective aggNETs degradation as a central pathophysiological process, offering new therapeutic targets for tophaceous gout management.

DDX3X Regulates Gout Inflammation via NLRP3 Inflammasome Activation and Macrophage Pyroptosis Crosstalk

Linrui Zhong, Tianyi Lei, Quanbo Zhang and Yufeng Qing, The Affiliated Hospital of North Sichuan Medical College, Nanchong, Sichuan, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

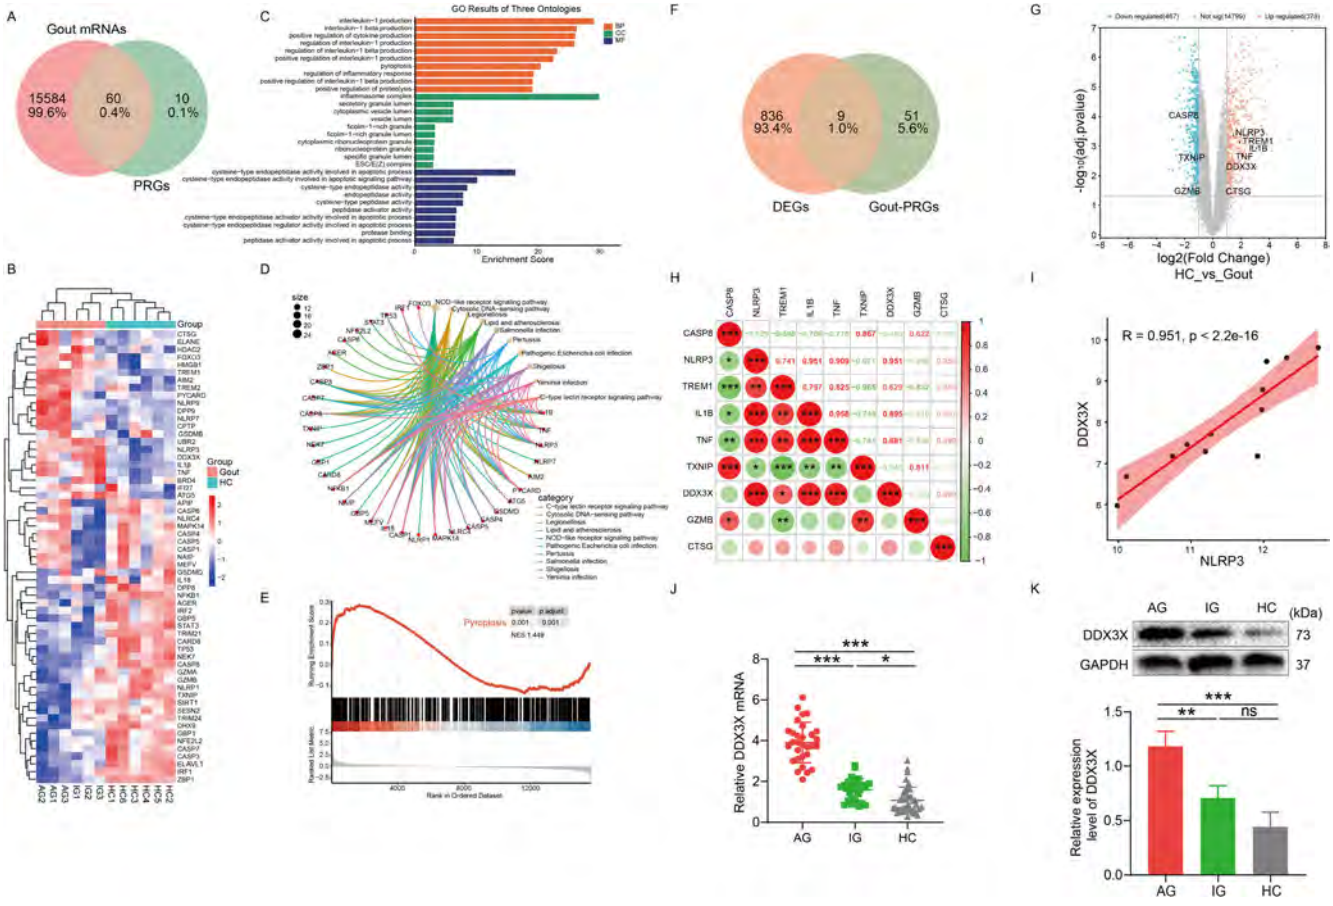

Figure1. DDX3X and pyroptosis play an important role in gout inflammation

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Pyroptosis is closely linked to acute flare-ups and spontaneous remission of gout. However, the specific mechanisms by which pyroptosis regulates gout inflammation remain unclear. This study aims to analyze the potential role of DDX3X as a hub molecule influencing pyroptosis to regulate gout inflammation.

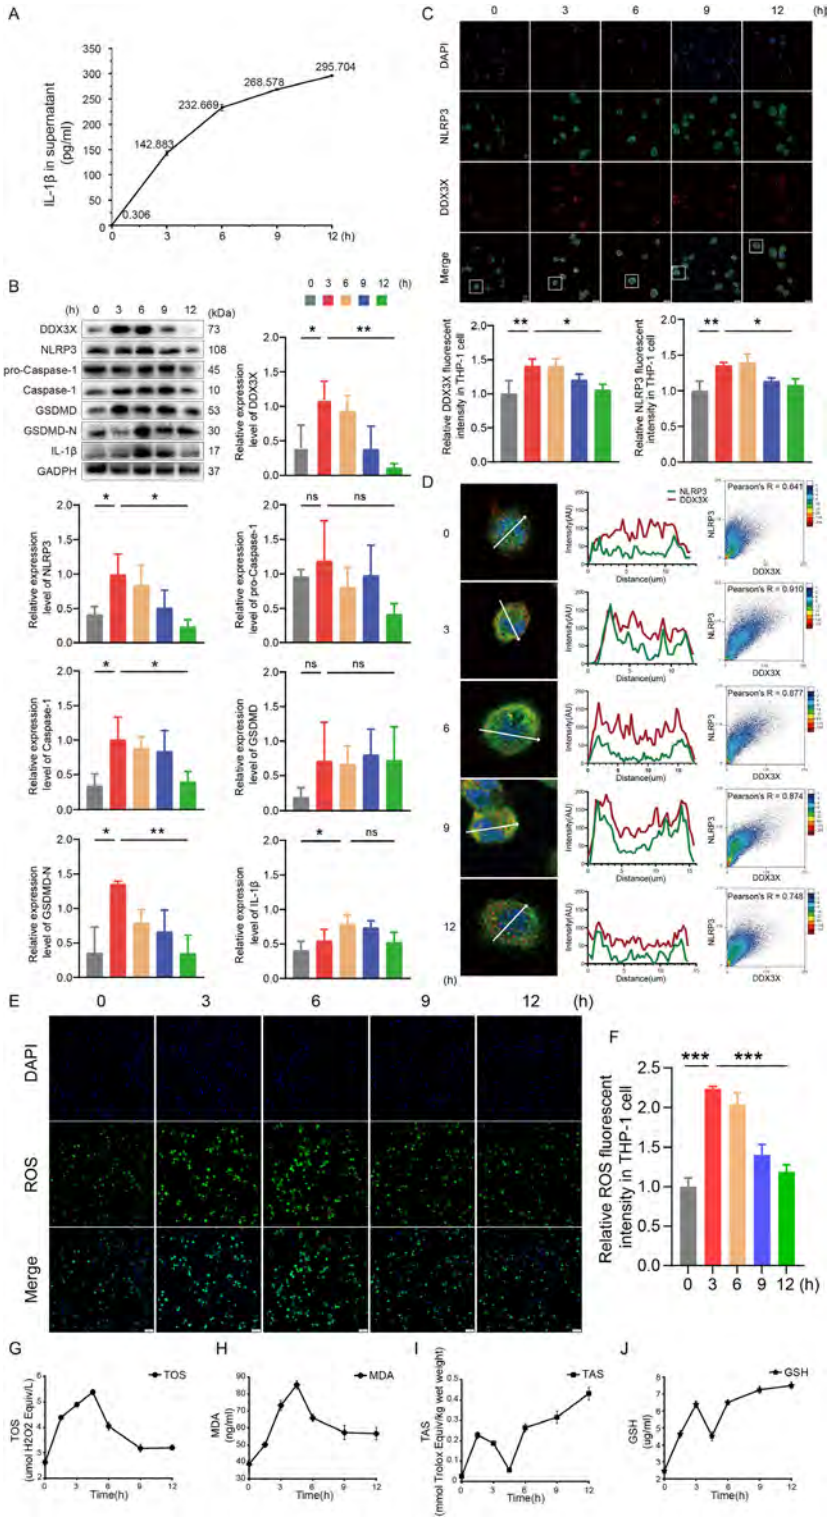

Figure2. DDX3X and pyroptosis were differentially expressed in gout and were closely related to inflammation levels and oxidative stress

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

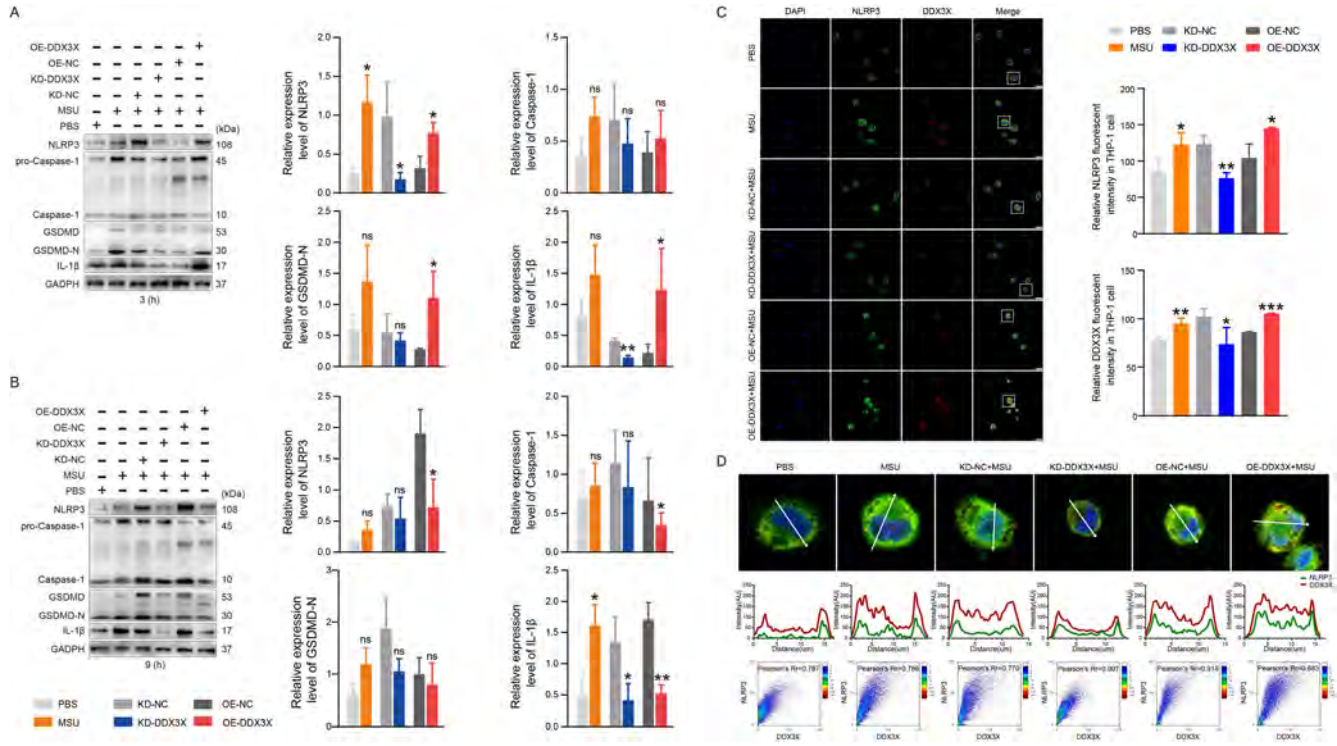

Figure2. DDX3X contributes to gout inflammation by mediating pyroptosis through modulating NLRP3 inflammasome assembly

Methods: Bioinformatics methods were used to explore whether pyroptosis is involved in regulating gout. Real-time quantitative PCR (RT-qPCR), Western blotting (WB), and immunofluorescence were employed to assess DDX3X, ROS levels, and changes in the NLRP3/Caspase-1/GSDMD pathway. The regulation of pyroptosis mediated by DDX3X under different conditions was observed.

Results: Bioinformatics analysis revealed that pyroptosis is involved in gout regulation, identifying nine (pyroptosis-related genes)PRGs with DDX3X closely related to NLRP3. DDX3X was significantly overexpressed in acute gout patients. In the time-gradient model of gout inflammatory cells, both the classical pyroptosis pathway and DDX3X showed significant nonlinear characteristics, leading to trends in IL-1β changes, with DDX3X interacting with NLRP3. After DDX3X expression intervention, pyroptosis and gout inflammation showed characteristic changes. At the 3h oxidative damage stage, DDX3X participated in activating the NLRP3 inflammasome to promote pyroptosis. At the 9h oxidative stress stage, DDX3X might respond to stress granule assembly, indirectly inhibiting pyroptosis, thereby protecting cell survival. This protective mechanism might initiate negative feedback regulation to inhibit IL-1β release.

Conclusion: DDX3X can regulate gout inflammation by activating the NLRP3 inflammasome and mediating macrophage pyroptosis. It mainly participates in early inflammation in gout and cell homeostasis maintenance in the later stages of inflammation.

Abstract Number: 1133

A Proteomic Analysis of Subclinical Synovial Inflammation Associated with Monosodium Urate Crystal Deposition

Mariano Andrés[1], María-Luisa Peral-Garrido[2], Samanta Ortuño[3], Rocío Caño[3], Silvia Gómez-Sabater[3], Alejandra Bermúdez[4], Teresa Lozano[5], Miguel Perdiguero[5], elena Caro-Martínez[6], Ruth Sánchez-Ortiga[5], Carolina Ruiz-García[7], Eliseo Pascual[8] and Rubén Francés[8], [1]Dr Balmis Alicante General University Hospital-ISABIAL, Alicante, Spain, [2]Vinalopó University Hospital, Novelda, Spain, [3]Alicante Institute for Health and Biomedical Research (ISABIAL), Alicante, Spain, [4]Rheumatology Department, Dr. Balmis General University Hospital, Alicante, Spain., Alicante, Spain, [5]Dr Balmis General University Hospital, Alicante, Spain, [6]HACLE San Vicente Hospital, San Vicente del Raspeig, Spain, [7]Campoamor Health Center, Alicante, Spain, [8]Miguel Hernandez University of Elche, Alicante, Spain

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Persistent subclinical inflammation from monosodium urate (MSU) crystals is present in gout and asymptomatic hyperuricemia (AH). The underlying mechanism is poorly understood. This study analyzes the articular inflammatory proteome linked to MSU crystal deposition in hyperuricemic patients without clinically active inflammation.

Methods: Observational, cross-sectional study. 100 participants with either AH (hyperuricemia as serum urate ≥7mg/dl) [n=77] or intercritical gout (2015 ACR/EULAR criteria, hyperuricemia, untreated) [n=23] underwent clinical assessment, blood testing, and lower limbs ultrasonography. In the case of effusion, synovial fluid (SF) was obtained (n=81). Samples underwent polarized microscopy for microcrystals (MSU, calcium pyrophosphate –CPP) and leukocytes (using a Neubauer chamber). The SF proteome was studied using Olink Inflammation panel in cell extracts from samples with enough volume after centrifugation (n=60). For these cases, paired serum proteome assessments were intended (n=28). Comparisons were conducted based on microcrystal deposition, identifying differential expression analysis of proteomics using Principal Component Analysis (PCA), represented by volcano plots. Also, we explored predictive models using SF features (proteome and leukocytes) to discriminate microcrystal deposition.

Results: Out of 100 participants, 81 had SF samples available for polarized microscopy; MSU and CPP crystals were detected in 5 (6.2%) and 11 samples (13.6%), respectively, while the others showed no crystals (65, 80.2%). Leukocyte

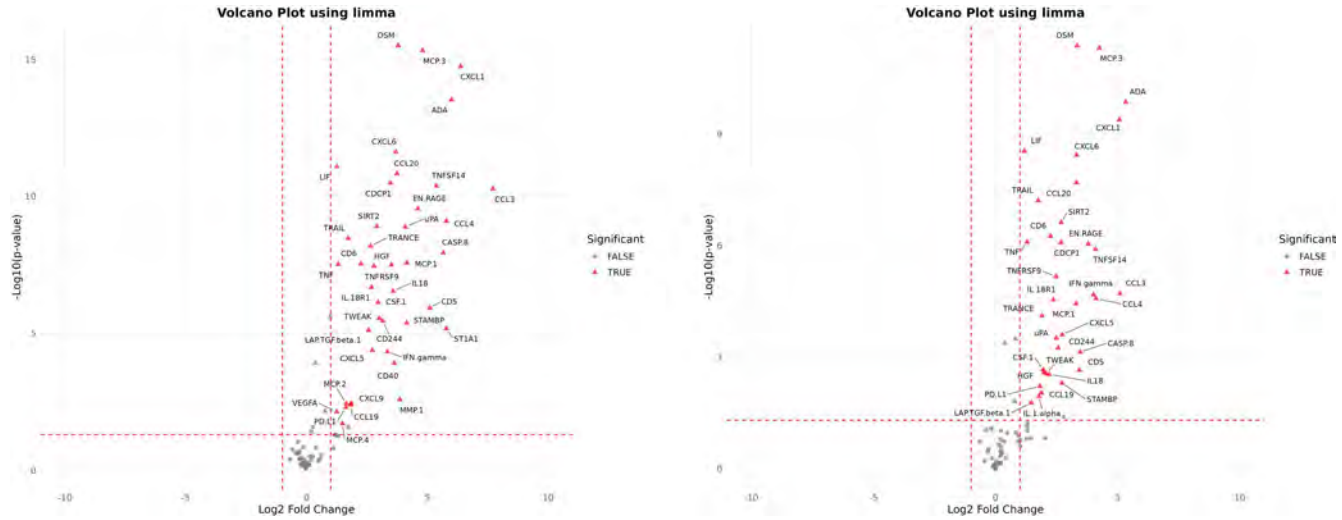

Figure 1. Volcano plot of differentially expressed proteins in SF samples (to the right favors MSU; to the left favors no crystals [left] or CPP [right]).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

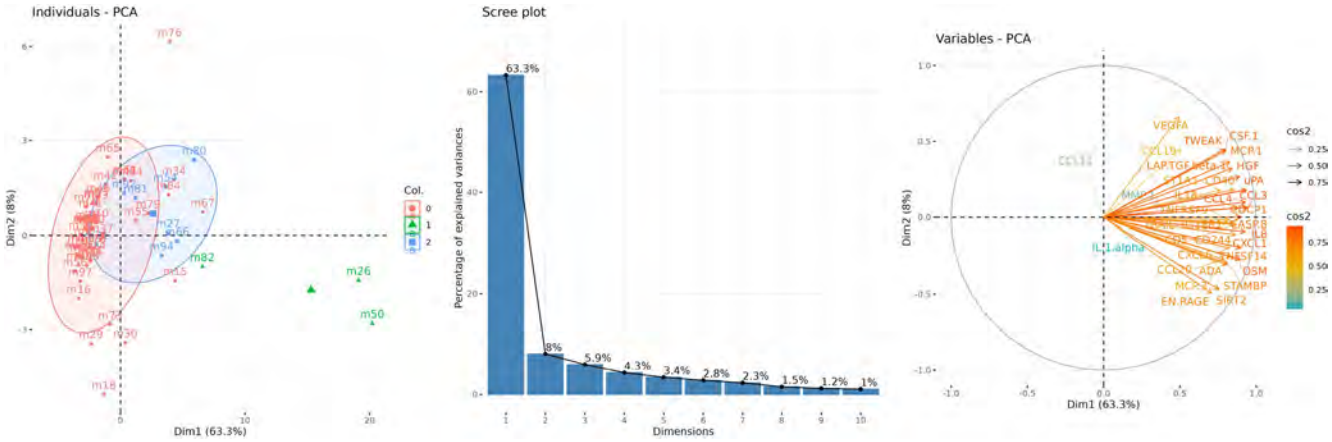

Figure 2. Left, PCA of statistically significant inflammatory proteins in synovial fluid, comparing the three patient groups, showing the distribution of patients' samples across dimensions 1 (dim1) and dim2 [red=no crystals; green=MSU; blue=CPP]. Middle, percentages of explained variances by dimensions. Right, protein distributions to dim1 and dim2 and their contribution.

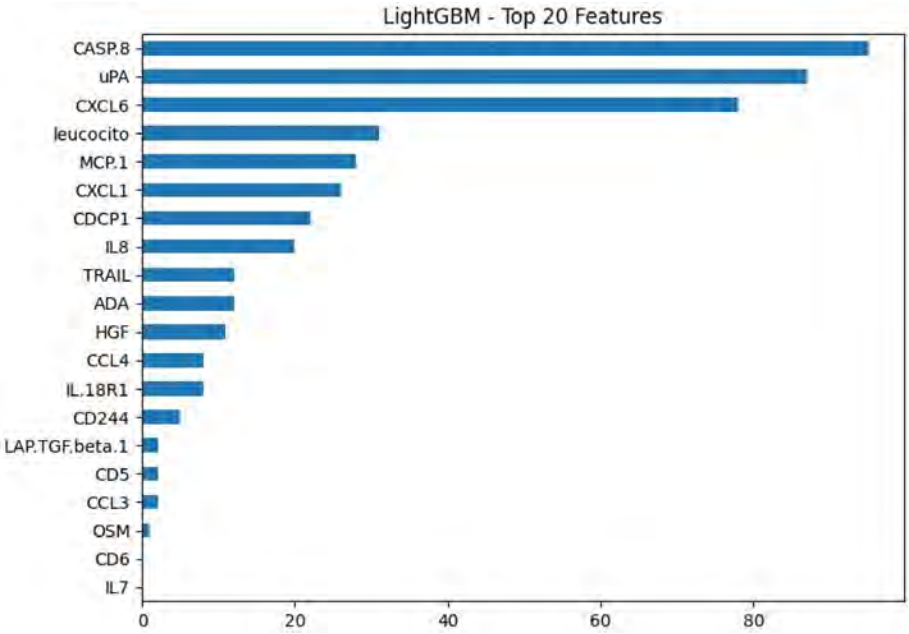

Figure 3. SF individual features and role in distinguishing the presence of microcrystals, using the lightGBM decision tree-based algorithm with KBest variable selection.

counts were significantly higher in samples with MSU (640/mm3, 245-875) compared to CPP (55/mm3, 43-203) or no crystals (40/mm3, 20-70), p< 0.001. Phagocytosis was seen in 32.4% (0-61.8%) and 8.3% (0-53.3%) of MSU and CPP samples [p=0.743]. SF leukocytes showed no correlation to serum urate, total leukocytes, or acute phase reactants.

Sixty samples underwent proteomic analysis (3 with MSU, 8 with CPP, 49 with no crystals). **Figure 1** shows the volcano plots comparing MSU versus CPP (left) and versus no crystals (right). Both comparisons yielded similar results: SF containing MSU crystals showed an increased relative expression of several inflammatory proteins. These proteins differentiated samples among the three groups (71.3% of explained variances [**Figure 2**]). Among different predictive models, lightGBM with variable selection by KBest showed the best performance (accuracy 0.83, AUC 0.8182). **Figure 3** shows the 20 features considered most relevant by the previously mentioned optimal model for prediction. Only IL-8 significantly correlated between SF and serum expression (r=+0.44, p=0.019) in paired sera [n=28].

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Subclinical inflammation associated with MSU crystal deposition involves elevated leukocyte counts and a distinctive proteomic profile, which can distinguish the presence of microcrystals. Our data also suggest that during asymptomatic stages, the subclinical inflammation appears localized and confined to the joint, the relevance of which requires further investigation.

Background/Purpose: Calcium Pyrophosphate Deposition Disease (CPPD) is a common inflammatory arthritis among older adults. Comorbidities often limit conventional treatment of acute CPPD flare. Anakinra, an interleukin-1 inhibitor, is a promising alternative. We aimed to evaluate the efficacy and safety of anakinra in acute CPPD flares.

Methods: We systematically searched studies from MEDLINE, EMBASE, and the Cochrane Database up until August 2024. The primary outcome was a positive treatment response between day 3 and day 5 after anakinra initiation. Secondary outcomes included changes in pain ratings assessed by the visual analog scales (VAS), C-reactive protein levels, tender joint counts (TJC), swollen joint counts (SJC) and corticosteroid usage.

Results: Six studies were included in our meta-analysis: five observational studies and one randomized controlled trial. A total of 84 patients were included in our analysis. Subjective physician assessments of clinical response were reported in all studies with a combined positive treatment response rate of 76% (95%CI: 61-86, I^2=0%). Our pooled analysis also showed a significant reduction of VAS scores by 48.12 mm (95% CI: 53.21 - 43.03, I^2=0%) and CRP levels by 62.09 mg/L (95% CI: 97.74-26.44, I^2=77%) from baseline. Reductions of TJC and SJC were also demonstrated, 4.86 (95% CI: 5.48 - 4.23, I^2=0%) and 3.65 (95% CI: -12.53-5.22, I^2=54%), respectively. Adverse reactions included injection site reaction, rash, bacterial pneumonitis, and neutropenia.

Conclusion: Anakinra is a promising alternative treatment for patients with acute CPPD flare as it showed desirable clinical responses and a favorable safety profile.

A Gain-of-function 5'UTR Variant in ANKH Causes Familial CPPD with Elevated Extracellular Ppi and Citrate

Richette Pascal[1], christophe Duranton[2], Thomas Pinna[3], Manon Ricquebourg[4], LATOURTE Augustin[5], Thomas Bardin[6], Valérie Bousson[7], Hang-Korng Ea[8], Isabelle Rubera[9] and Corinne Collet[10], [1]Rheumatology Department, Lariboisiere Hospital, Paris, Ile-de-France, France, [2]CNRS-UMR 7370 - Laboratoire de Physiomedecine moléculaire, Nice, Rhone-Alpes, France, [3]INSERM U1132, PARIS, Ile-de-France, France, [4]Lariboisiere Hospital, INSERM U1132, Paris, France, [5]Rheumatology Department, Lariboisiere Hospital, Paris, France, [6]Lariboisiere Hospital, Department of Rheumatology, Paris, France, [7]Radiology Department, Lariboisiere Hospital, Paris, France, [8]INSERM U1132, Lariboisiere Hospital, Paris, France, [9]CNRS-UMR 7370 - Laboratoire de Physiomedecine moléculaire, Nice, France, [10]Reference Center for Skeletal Dysplasia, INSERM UMR 1163, Paris, France

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

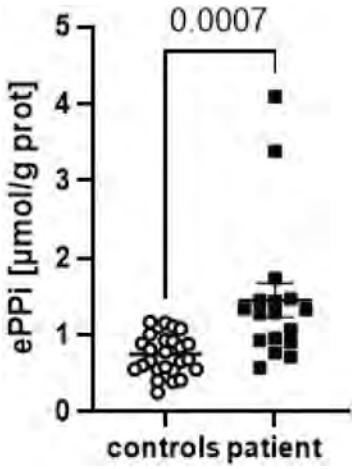
Session Time: 10:30AM–12:30PM

Background/Purpose: To identify novel pathogenic variants associated with chondrocalcinosis (CC), we systematically screened individuals with a family history of CPPD using an NGS panel. Among 26 index cases between 2016 and 2024, we identified a known mutation in the TNFRSF11B gene, a novel missense variant in the ANKH gene, and a novel mutation in the 5' untranslated region (5'UTR) of the ANKH gene, which we report here.

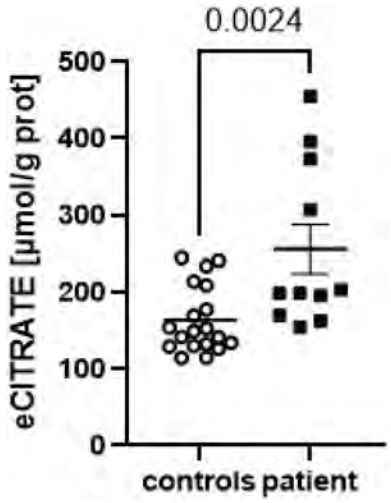
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Whole exome sequencing (WES) was performed to expand the search for pathogenic variants not detected by the targeted panel. Primary fibroblast cultures (skin biopsy) of the proband and three controls were established to assess protein levels and gene expression using Western blotting (WB), qRT-PCR, and immunocytochemistry (IC). Inorganic pyrophosphate (PPi) and ATP levels in the culture media were measured by enzymatic assay and citrate concentrations were determined by ion chromatography. Skeletal imaging of the proband was performed using a photon-counting computed tomography scanner.

Results: The proband experienced recurrent episodes of arthritis in the wrists, knees, and ankles since the age of 23. Microscopic analysis of SF confirmed the presence of CPP crystals. CT scan showed widespread calcium deposits in almost all joints without OA changes, as well as in the choroid (Figure 1). He is a member of a multiplex family in which CPPD follows a dominant mode of inheritance. Panel NGS revealed a previously unreported heterozygous variant in the 5' UTR (NM_054027.6: c.-113_-112delinsAT) introducing a novel ATG start codon in all affected individuals. WES confirmed that no other variant could explain this phenotype. This variant co-segregates with the CPPD phenotype and was further confirmed by Sanger sequencing. The plasma PPi level was elevated in the proband compared to the mean value measured in a control cohort (n=46): 2.40 μM vs. 1.61 ± 0.33 μM. In vitro, there were no differences in ANKH mRNA expression or protein expression (WB) between mutant and control fibroblasts. IC revealed both transmembrane and cytoplasmic localisation of the mutant protein. Notably, the levels of PPi and citrate in the fibroblast culture media (μmol/g protein) were significantly higher in the proband than in the controls: 1.45 vs. 0.77 for PPi ($p < 0.0007$) and 255.8 vs. 177.3 for citrate ($p = 0.0024$) (Figures 2-3). In contrast, no difference in extracellular ATP levels was observed. Treatment of fibroblasts with probenecid



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



(5 mM), an ANKH inhibitor, abolished the increased citrate levels observed in the proband's fibroblast culture media. mRNA expression of IL1, IL6, MMP1, PIT1 and TNAP was unchanged in the proband's fibroblasts. In contrast, ENPP1 expression was significantly increased by approximately 8-fold ($p < 0.001$) - a finding that was further confirmed at the protein level by WB and IC.

Conclusion: We describe a novel 5'UTR variant in the ANKH gene that generates an ectopic start codon. Functional studies showed increased extracellular levels of PPi and citrate and overexpression of ENPP1 without alterations in ANKH mRNA or protein levels, supporting a gain-of-function mechanism

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: A EULAR task force developed classification criteria (CC) for Haemochromatosis Arthropathy (HA) using a cohort of people with the C282Y homozygous mutation and arthropathy ***with*** iron overload requiring phlebotomy (1). The CC include 8 items covering age of symptom onset, clinical and X-ray features at MCP, DIP and ankle joints, and surgery of hips or ankles. A score of ≥5/11 provides 93.3% specificity and 71.4% sensitivity for classifying HA.

Two additional cohorts were recruited, both ***without*** iron overload; 1. Arthropathy and any HFE gene mutation, and 2. Disease mimics (OA, CPPD). This study aimed to assess the role of iron overload and HFE gene mutations on joint disease expression by comparing the performance of the HA CC and its individual items across the 3 cohorts.

Methods: The HA cohorts included 373 patients from 12 centres across 10 countries. Group 1 (G1, n=154): C282Y homozygous with arthropathy and iron overload; Group 2 (G2, n=99): any HFE mutation with arthropathy and no iron overload; Group 3 (G3, n= 120): disease mimics (OA, CPPD).

We compared features of arthropathy in G1 with G2, and G2 with G3, also with G2 subgroups: C282Y homozygous and heterozygous, H63D homozygous and heterozygous, C282Y/H63D compound heterozygous, any C282Y and compound heterozygotes, any H63D and compound heterozygotes. The total CC score, prevalence of the 8 items and proportion of patients scoring ≥5/11 to fulfil CC, was compared between groups using the Chi-square/Fisher's exact tests or the independent sample T-test, as appropriate.

Results: Six of eight CC items were significantly more prevalent in G1 vs G2, and 5 of 8 items in G2 vs G3. The mean total score in G1 was 6.0, G2 4.3, $p< 0.001$ (G1 vs G2), and G3 2.7, $p< 0.001$ (G2 vs G3). The CC for HA were met in 71.4% of G1, 37.4% of G2 and 6.7% of G3 ($p< 0.001$ G1 vs G2 and G2 vs G3).

Genotype-stratified analysis of G2 revealed a consistent hierarchy in prevalence of 5 of 8 of the individual CC items, total CC score and fulfilment of the CC overall. The highest prevalence was seen in people with H63D homozygous or heterozygous mutations combined, followed by any H63D and compound heterozygotes, followed by either any C282Y and compound heterozygotes or C282Y homozygous or heterozygous mutations alone (Table 1 & 2).

Conclusion: The discriminatory features of joint disease in HA, as defined by the CC, are significantly more prevalent in patients ***with*** iron overload and the C282Y homozygous HFE mutation than in patients ***without*** iron overload and any HFE genotype, supporting the major role of iron in disease expression.

In patients without iron overload and with any HFE mutation, the discriminatory features of HA are significantly more prevalent than found in OA and CPPD disease mimics, supporting an iron-independent effect of HFE mutations on arthropathy. This appears to be most evident in patients with any H63D mutation, though subgroup numbers are low.

Classification criteria met (Total score ≥5)	8 (6.7)	37 (37.4) p= <0.001	15 (31.9) p= <0.001	12 (44.4) p= <0.001	10 (40) p= <0.001	25 (34.7) p= <0.001	22 (42.3) p= <0.001

Overall, these findings increase our understanding of the interplay between HFE mutations and iron status in the pathogenesis of HA, where HFE mutations alone are associated with the phenotypic features of HA, becoming much accentuated with iron loading.

Increased Risk of Cardiovascular Events and Mortality Related to Diffuse Idiopathic Skeletal Hyperostosis (DISH): A Systematic Review and Meta-Analysis

Pitchaporn Yingchoncharoen[1], Nattanicha Chaisrimaneepan[2], Miriam Paz[3], Chanokporn Puchongmart[1], Ben thiravetyan[1], Panat Yanpiset[1] and Jerapas Thongpiya[4], [1]Texas Tech Health Sciences Center, Lubbock, TX, [2]Department of Medicine, Texas Tech University Health Sciences Center, Lubbock, TX, [3]Texas Tech University Health Sciences Center, Lubbock, [4]Texas Tech University Health Sciences Center at Lubbock Program, Lubbock, TX

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Diffuse Idiopathic Skeletal Hyperostosis (DISH) is characterized by ossification and calcification of the entheses with prevalence increasing with age. It has been reported to be associated with obesity and type 2 diabetes mellitus (DM). The prevalence of hypertension and hyperlipidemia is also higher in patients with DISH. These factors are components of metabolic syndrome and the atherosclerotic cardiovascular disease (ASCVD) risk calculation score. Previously published studies on the association between DISH and the risk of cardiovascular events and mortality have yielded conflicting findings. Our study aimed to identify the potential association by pooling all available publications.

Methods: We comprehensively searched the databases of MEDLINE and EMBASE from inception to March 2025 to identify studies evaluating the association between DISH and the risk of cardiovascular events and mortality. We identified all observational studies that compared the incidence or risk of developing cardiovascular events in DISH patients compared to non-DISH patients. Pooled risk ratios (RRs) and 95% confidence intervals (CIs) were calculated using a random-effects model, DerSimonian and Laird. Publication bias was analyzed with the Egger test.

Results: A total of 426 articles were identified. Following the PRISMA guidelines for study selection, 12 studies fulfilled the inclusion criteria and were included in the meta-analysis. Stratified analyses were conducted by event types: cerebrovascular accident (CVA; 8 studies), myocardial infarction/ischemic heart disease (MI/IHD; 9 studies), congestive heart failure (CHF; 6 studies), and cardiovascular mortality (3 studies).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The pooled results of the present meta-analysis showed that DISH was associated with an increased risk of CVA (RR = 1.80, 95% CI: 1.59–2.05, $P < 0.001$; $I^2 = 0\%$) and cardiovascular mortality (RR = 1.59, 95% CI: 1.21–2.09, $P < 0.001$; $I^2 = 0\%$).

However, the associations between DISH and increased risk of MI/IHD (RR = 1.59, 95% CI: 0.92–2.74, $P = 0.09$; $I^2 = 80.86\%$) and CHF (RR = 1.07, 95% CI: 0.79–1.44, $P = 0.66$; $I^2 = 23.59\%$) were not statistically significant. Publication bias assessed using Egger's test showed no evidence of small-study effects ($P > 0.05$).

Conclusion: This analysis found that DISH is associated with a higher risk of cerebrovascular accident, but not with other cardiovascular events. Further research is needed to determine a causal relationship

Efficacy of Pozdeutinurad (AR882) in Treatment Naïve and Suboptimally Treated Gouty Arthritis with Tophi

Robert Keenan[1], Puja Khanna[2], Zancong Shen[3], Sarah Morris[3], Pamela Mundell[4], Wen Wei[4], Elizabeth Polvent[5], Vijay Hingorani[6], Shunqi Yan[5] and Li-Tain Yeh[7], [1]Arthrosi Therapeutics, Raleigh, NC, [2]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [3]Arthrosi therapeutics, San Diego, CA, [4]Arthrosi Therapeutics Inc, San Diego, CA, [5]Arthrosi Therapeutics, Inc., San Diego, CA, [6]Vanguard Healthsciences, Inc., San Diego, CA, [7]Arthrosi Therapeutics, Inc., Irvine, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Pozdeutinurad (AR882, POZD) is a novel, selective URAT1 inhibitor currently in phase 3 clinical stage development for the treatment of gout and tophaceous gout. To date, only intravenous (IV) therapies such as pegloticase is indicated in urate-lowering (ULT) refractory patients and has demonstrated tophi dissolution by caliper measurement and Dual Energy Computer Tomography (DECT). However, IV therapy is not available or appropriate for the majority of patients given infusion costs, drug availability and potential toxicities from necessary use with concomitant immunosuppressives. POZD is an oral agent being evaluated for both urate control and dissolution of subcutaneous tophi.

This analysis explores the distinction between POZD 75 mg monotherapy or in combination with allopurinol in tophaceous gout patients who are either treatment naïve or suboptimally controlled.

Methods: The phase 2 trial recruited 42 patients with at least one subcutaneous tophus. Patients were eligible if they were either inadequately controlled on ULT with serum urate (sUA) > 6.0 mg/dL or were ULT naïve with sUA ≥ 7.0 mg/dL. After ULT washout (if applicable), patients were randomized to receive POZD 75 mg, POZD 50 mg + allopurinol, or allopurinol up to 300 mg. At 6 months all patients were able to opt into two subsequent 6-month extensions with treatment modifications. sUA, tophi measurements with calipers or urate crystal measurement using DECT were collected up to 18 months. Results for sUA response rates, complete resolution in target tophus and reduction in urate crystal volumes were analyzed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1: Complete resolution of at least 1 target tophus and reduction in crystal urate burden in tophaceous gout patients refractory or naïve to treatment

Endpoint	POZD 75 mg				POZD 75 mg + allopurinol			
	6-mo treatment		12-mo treatment		6-mo treatment		12-mo treatment	
	Refractory	Naïve	Refractory	Naïve	Refractory	Naïve	Refractory	Naïve
% with complete resolution of ≥1 target tophi	25% (2/8)	33% (2/6)	43% (3/7)	33% (1/3)	33% (3/9)	0 (0/2)	57% (4/7)	0 (0/2)
Mean reduction in crystal urate volume (cm^3)	-11.1	-0.3	-17.4	-0.92	-13.2	-0.31	-20.1	-0.03

Mo: month; POZD: pozdeutinurad

Results: Patients refractory to their pre-study ULT had a higher baseline sUA (9.5 to 9.8 mg/dL) than treatment naïve patients (7.6 to 8.5 mg/dL). Both populations had clinically significant and sustained sUA responses following treatment. In the 75 mg group, refractory patients had a 49% mean decrease in sUA levels, while the naïve patients achieved a 54% decrease. In the 75 mg + allopurinol group, the refractory patients had a 61% mean decrease in sUA levels, while the naïve patients achieved a 74% decrease. At 12 months, refractory patients demonstrated complete resolution of at least 1 target tophus in 43% and 57% of patients in the 75 mg group, and in 75 mg + allopurinol group, respectively. Although all ULT naïve patients had at least a partial response, only the 75 mg group had at least 1 target tophus fully resolved at 33% (**Table 1**). The refractory patients demonstrated greater reduction in their urate crystal burden compared to ULT naïve patients following 12 months treatments (-17.4 vs -0.92 cm3 for 75 mg; -20.1 vs -0.03 cm3 for 75 mg + allopurinol treatment) (**Table 1**).

Conclusion: Pozdeutinurad 75 mg monotherapy or in combination with allopurinol in tophaceous patients refractory and naïve to ULT were effective in sUA lowering, demonstrating high rates of complete resolution of target tophus and reduction in urate crystal burden. Pozdeutinurad alone or combination may provide an effective treatment option for patients with chronic tophi and inadequate response to their current treatment regimens.

Background/Purpose: Synovial fluid analysis is an essential diagnostic tool for evaluating crystalline and infectious arthritis. Traditionally, a leukocyte count threshold of >50,000 cells/μL has been used to help identify septic arthritis while awaiting culture results. However, no large or representative studies have systematically assessed the diagnostic performance of this leukocyte cutoff or characterized leukocyte counts across different causes of inflammatory synovial fluid.

Methods: A de-identified database from Froedtert Hospital and the Medical College of Wisconsin (1.9 million patients) was queried on March 17, 2023. All patients who underwent joint aspiration with synovial fluid analysis prior to March 1, 2023 were included. Structured and unstructured text were used to identify synovial fluid leukocyte count, crystal analysis, gram stain, and culture results. Demographic data were extracted; ICD-9-CM / ICD-10-CM codes were used to identify prevalent autoimmune diseases or crystalline diseases (1 year lookback) and prosthetic joint infections (PJI) (30 days before and after synovial fluid analysis).

Results: A total of 9,054 synovial fluid analyses from 6,690 patients were identified. The average age at first aspiration was 62.3 years (standard deviation (SD) 16.1 years) and most patients were male (53.4%) and white (74.6%) (Table 1). After categorizing synovial fluid aspiration results in a hierarchical fashion, the highest leukocyte counts occurred among fluid positive for staphylococcus or streptococcus infection (65,568, SD 81892) followed by other positive cultures (41,035, SD 55,259), MSU (20,966, SD 34,186), CPPD (13,202, SD 21,132), rheumatic diseases (12,827, SD 32,234), and negative for crystals or infection (9,822, SD 31,884) (Figure 1). Joints that had an over-representation of a crystal result included the ankle (50.6% MSU), knee (48.2% negative for crystals), shoulder (63.5% CPPD), and toe/foot (69.6% MSU) (Figure 2). A conventional leukocyte count cutoff of 50,000 had a low sensitivity (0.28) and a high specificity (0.95); a higher cutoff of 100,000 had an even lower sensitivity (0.10) and a higher specificity (0.99).

Table 1: Demographic and Clinical Characteristics of Included Patients, n = 6,687

Age at Aspiration, mean (SD)	62.3 (16.1)
Sex	-
Female	3,116 (46.6%)
Male	3,564 (53.4%)
Race/Ethnicity	-
White or Caucasian	4,983 (74.6%)
Black or African American	1,311 (19.6%)

PGG Suppresses MSU Crystal–Triggered Inflammation and Arachidonic Acid Production in PBMCs

Sadiq Umar[1], Poorna Chandra Rao Yalagala[2], Sugasini Dhavamani[2] and Sriram Ravindran[2], [1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois, Chicago, IL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Gout is the most prevalent inflammatory arthritis globally, with rising incidence in both developed and developing regions. It is driven by monosodium urate (MSU) crystal deposition in joints and bursae of hyperuricemic individuals, triggering intense pain and inflammation. Macrophage uptake of MSU crystals activates TLR2/4 signaling, promoting NLRP3 inflammasome formation and NF-κB–mediated pro-inflammatory cytokine production. Penta-O-galloyl-β-D-glucose (PGG), a naturally occurring polyphenol, exhibits anti-inflammatory and anti-proliferative properties. This study investigated PGG's effects on MSU-induced inflammatory responses and arachidonic acid (AA) metabolism in human PBMCs.

Methods: Human PBMCs were pretreated overnight with 5 μM PGG or 1 μM colchicine, followed by stimulation with 100 μg/mL MSU for either 30 minutes or 24 hours. Cytokine levels (IL-1β, IL-18, TNF-α, IL-6, IL-8, TGFβ) were measured by qPCR and ELISA. Phosphorylated MAPKs (p38, ERK, JNK) were assessed by immunoblotting. Phagocytosis was evaluated using the Vybrant™ Phagocytosis Assay. The fatty acid composition of PBMCs lipids was analyzed by GC/ MS after conversion to methyl esters. The analysis was carried out using a Shimadzu QP2010SE GC/MS equipped with a Supelco Omegawax column (30 m × 0.25 mm × 0.25 μ).

Results: PGG significantly reduced MSU-induced expression of IL-1β, IL-18, TNF-α, IL-6, and IL-8 and increased TGFβ ($p < 0.01$; n=4), with similar trends observed at the mRNA level. PGG also inhibited phagocytosis of MSU crystals, suggesting reduced upstream TLR signaling. Immunoblotting confirmed that PGG blocked MSU-induced phosphorylation of p38, JNK, and ERK. Furthermore, PGG and colchicine treatment markedly reduced elevated arachidonic acid levels in MSU-treated macrophages.

Conclusion: PGG mitigates MSU-induced inflammation in PBMCs by suppressing cytokine production, phagocytosis, MAPK activation, and arachidonic acid accumulation. Given AA's pro-inflammatory role as a precursor to eicosanoids. These findings suggest that PGG may represent a promising therapeutic candidate for targeting crystal-induced inflammation in gout.

Abstract Number: 1141

Modulation of Inflammatory Responses by Dental Pulp Stem Cell Extracellular Vesicles in Monosodium Urate-Stimulated Macrophages

Sadiq Umar[1], Kasey Leung[2] and Sriram Ravindran[2], [1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois, Chicago, IL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Gout is the most prevalent form of inflammatory arthritis, with rising global incidence. It results from the deposition of monosodium urate (MSU) crystals in joints, leading to severe inflammation and pain in individuals with hyperuricemia. Dental pulp stem cells (DPSCs), a type of mesenchymal stem cell (MSC), release extracellular vesicles (EVs) with intrinsic anti-inflammatory properties, which are further enhanced following inflammatory stimulation. This study aimed to evaluate the anti-inflammatory effects of EVs from both untreated (naïve) and MSU-preconditioned DPSCs on MSU-activated macrophages and to identify EV-associated microRNAs (miRNAs) mediating these effects.

Methods: DPSCs were obtained from Lonza. EVs were isolated from DPSCs cultured under normal conditions or after preconditioning with MSU, and characterized by immunoblotting and nanoparticle tracking analysis (NTA). The anti-inflammatory activity of EVs was assessed in vitro using human peripheral blood mononuclear cells (PBMCs) stimulated with 100 μg/mL MSU for 24 hours, with or without treatment with naïve or MSU-preconditioned DPSC EVs. Inflammatory gene and protein expression were analyzed by qRT-PCR and ELISA. Phagocytic activity was measured using the Vybrant™ Phagocytosis Assay Kit. miRNA profiles of naïve and preconditioned EVs were determined by sequencing and bioinformatics analysis. Statistical significance was assessed using one-way ANOVA followed by Tukey's post hoc test ($P < 0.05$).

Results: EVs from both naïve and MSU-preconditioned DPSCs displayed similar physical and molecular characteristics. Both EV types significantly reduced inflammatory responses in MSU-stimulated PBMCs. Notably, MSU-preconditioned DPSC EVs showed enhanced suppression of pro-inflammatory markers (IL-1β, TNF-α, iNOS) and increased expression of anti-inflammatory markers (IL-10, ARG1, TGF-β). Phagocytosis was also significantly reduced by preconditioned EVs. miRNA sequencing revealed upregulation of anti-inflammatory miRNAs in EVs from MSU-preconditioned DPSCs compared to naïve controls.

Conclusion: MSU-preconditioned DPSC EVs exhibit enhanced anti-inflammatory activity in MSU-activated PBMCs, including suppression of phagocytosis. These effects are likely mediated by specific EV-resident miRNAs, offering a promising platform for miRNA-based EV engineering in the treatment of inflammatory diseases like gout.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: CPPD has been associated with osteopenia of the metacarpal heads and a 2x increased risk for fracture of the wrist, hip, humerus or pelvis. Inorganic pyrophosphate is a known strong inhibitor of mineralization and a

Table 1. Osteoclast surface and number per bone surface from tibial plateau specimens with CPPD and controls matched on age, sex, and race

Pair	Sample ID	Osteoclast surface/bone surface (Oc.S/BS)	Osteoclast number/bone surface (Oc.N/BS)
A	CPPD-A	0.48	0.33
	Control-A	0.26	0.14
B	CPPD-B	1.08	0.61
	Control-B	0.02	0.01

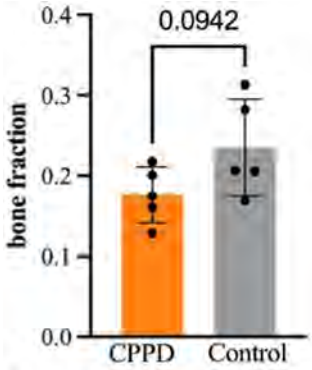

Figure 1. Tibial plateau trabecular bone volume/tissue volume (BV/TV) in 5 CPPD-control pairs matched on age, sex, and race

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

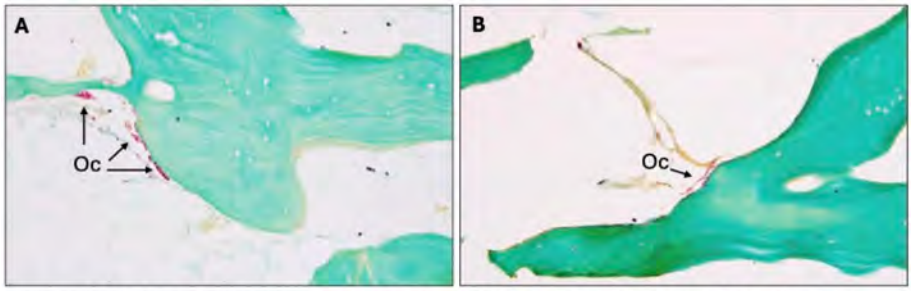

Figure 2. TRAP staining identified osteoclasts (Oc) in trabecular bone from the tibial plateau. Representative slides (20X) showing greater Oc abundance in a sample from an individual with CPPD (Panel A) than a control without CPPD matched on age, sex, and race (Panel B).

critical component of calcium pyrophosphate crystals. We conducted a pilot study testing for differences in tibial bone microstructure and histomorphometry in CPPD vs. controls.

Methods: Among patients undergoing total knee replacement surgery at a single academic medical center, we reviewed pre-operative radiographs for the presence of chondrocalcinosis in the knee, which defines the CPPD cohort. For each CPPD patient we identified one control matched on age (+/-5 years), sex, and race; controls were defined by absence of chondrocalcinosis on any joint radiograph. The tibial compartment analyzed (lateral or medial) was the same for each pair and was defined by the location of chondrocalcinosis in the CPPD patient and absence of Kellgren-Lawrence grade 4 in that compartment in both CPPD patients and controls. Microcomputed tomography (microCT) scanning was performed on formalin-fixed samples using a Scanco Medical mCT35 scanner with an isotropic voxel size of 20mm. A semi-automated contouring approach was used to exclude cortical bone and bone volume/tissue volume was calculated using software supplied by the manufacturer and a global threshold that set the bone/marrow cut-off at 398mg HA/cm^3. Following decalcification and paraffin-embedding, trabeculae in the subchondral region were traced using Osteomeasure to determine bone surface area. TRAP staining identified osteoclasts (Oc) and Safranin O staining highlighted articular cartilage. Mean Oc surface/bone surface (Oc.S/BS) and Oc number/BS (Oc.N/BS) were calculated from 3 segments per sample.

Results: We obtained samples from 5 CPPD-control pairs (4 lateral compartment pairs, 1 medial compartment pair). Mean age was 69.6 (SD 9.5) years, 2 pairs were female, and all were White. Tibial plateau BV/TV was lower in samples from individuals with CPPD than controls (p=0.09) (**Figure 1**). Histomorphometry was performed for 2 pairs; analysis of the 3 remaining pairs is ongoing. Oc.S/BS and Oc.N/BS were higher in tibial plateau subchondral trabecular bone from individuals with CPPD than controls (**Table 1, Figure 2**).

Conclusion: Tibial plateau trabecular bone had lower BV/TV and more abundant osteoclasts in knee compartments with chondrocalcinosis among patients undergoing knee replacement surgery. These preliminary findings are directionally consistent with prior cohort studies that reported a greater risk of osteopenia and fractures in CPPD, and suggest a link between localized inorganic pyrophosphate and compromised bone microstructure.

Annual Percentage Change in Gout and Renal Failure-Related Mortality by Year and Urban-Rural

data on the mortality rate due to renal disease or failure in patients with gout is not well established. Hence, we aim to assess the longitudinal trends in mortality rates attributed to renal disease in patients with gout. In addition, we aim to analyse for disparities in regard to race, sex, and geographical location in the United States.

Methods: Age-adjusted mortality rates (AAMR) per 100,000 individuals were obtained from the Centers of Disease Control and Prevention WONDER database from the years of 1999-2020. Joinpoint regression was applied to calculate the annual percentage change (APC) to evaluate significant differences in the change of AAMR over time.

Results: A total of 9263 deaths due to renal failure occurred in patients with Gout from 1999 to 2020. The AAMR from 1999 to 2012 insignificantly increased (APC 1.31) and sharply declined from 2012 to 2020 (APC -34.96). The same trend was reflected when stratified for females and males. The AAMR in urban areas had a trivial decline from 1999 to 2012 (APC 0.86) whereas significantly declined from 2012 to 2015 (APC -34.48). In rural areas, the AAMR initially significantly increased from 1999 to 2005 (APC 10.13), then decreased from 2005 to 2012 (APC -0.66) and subsequently significantly reduced from 2012 to 2015 (APC -32.79). The absolute AAMR for African Americans as compared to Whites were significantly different from 1999 to 2012. From 2012 to 2015, both subgroups had a statistically significant decline in AAMR, African Americans (APC -43.38 [-54.92, -21.89]) and Whites (APC -30.62 [-38.73, -3.42]). From 2015-2020, the AAMR remained fairly stable and similar in absolute numbers for both subgroups.

Conclusion: From 1999 to 2012, renal failure-related mortality in gout patients initially increased but had a significant drop from 2012 to 2015. Mortality rates reflected similarly in both sexes, females and males. Rural areas had an initial increase in mortality as compared to urban areas from 1999 to 2005. Blacks had a higher absolute mortality as compared to Whites until 2012 after which there was a sharp decline to similar rates from 2012 to 2015. These potential disparities warrant further research into quality of care delivered and phenotype of disease based on race and rural status. In addition, these findings may point towards improvement and standardization of care amongst different races and geographical areas after the introduction of the American College of Rheumatology (ACR) 2012 Gout guidelines.

Session Title: (1123–1146) Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: We previously described the frequent occurrence of an hyperechogenic pattern of the renal medulla following crystal deposition in untreated Vietnamese patients with severe tophaceous gout(1), without quantifying the medulla brightness. The aim of the present study was to quantify medulla brightness and investigate correlations with gout characteristics and renal function.

Methods: This prospective monocentric study analyzed baseline data of the first 250 patients enrolled in our ongoing prospective cohort at Vien Gut (a decicated medical center for diagnosis and treatment of gout in Vietnam), that aims at describing the effect of urate-lowering drugs (ULDs) on medulla echogenicity and renal function. Inclusion criteria were: i) gout according to the ACR/EULAR criteria, ii) residency in Ho Chi Minh City, Vietnam, iii) no use of ULDs at the time of enrollment and iv) signed informed consent. All patients underwent renal ultrasonography and renal medulla echogenicity assessment by two methods: 1) a semiquantitative scale (grade 0: no medullary hyperechogenic spot; 1: few spots in 1 or 2 pyramids; 2: hyper echoic pattern involving 40-60% of most pyramids; 3: hyper echoic pattern of > 60% of pyramids), and 2) image

analysis using image J software to quantify the cortex/medulla echogenicity ratio of the 2 best viewed pyramids. Clinical data were prospectively collected. Univariate proportional odds logistic regression models or linear regression models were used to compare the two methods of medulla rating and to look for correlations with patients 'features. Multivariable analysis included all statistically significant features, with model selection on the Akaike criterion (AIC).

Results: Median age and gout duration of patients (249 men) were 51 and 4 years respectively, 211 had clinical tophi, median eGFR and serum urate were 96.7 mmol/l and 529 mmol/l respectively. Medulla echogenicity was similar in both kidneys in all patients but 2, who differed by one grade; maximal grades were 0 in no patient, 1 in 146, 2 in 84, and 3 in 20 (table 1). Grades correlated negatively with corticex/medulla echogenicity ratios (p=0.0002) and positively with median maximum medulla echogenicity (p< 0.0001) (figure 1). By univariate analysis, medulla echogenicity grades correlated positively with medians of duration of gout, number of tophi, serum urate levels, and creatininemia, hypertension, MTP1 ultrasound features (double contours (graded 0 to 3) and tophus surfaces), and negatively with blood cortisol levels and eGFR; by multivariate analysis, correlations remained significant with numbers of clinical tophi, eGFR, cortisol levels, and MTP1 tophus surfaces (table 1). Median cortical/medullary echogenicity ratio correlated negatively with creatininemia.

Conclusion: The two ways of quantifying medulla echogenicity that we used provided consistent results and showed clinically meaningful correlations with patients 'features , especially renal function. Intersestingly, lower levels of cortisol were also associated, in line with the suspected effect of chronic exogenous steroid intake on tophi.

Background/Purpose: Gout is an inflammatory arthritis characterized by acute attacks, tophi formation, and bone destruction triggered by inflammatory responses to monosodium urate (MSU) crystals. Natural killer (NK) cells are key effectors of the innate immune system that recognize damage-associated molecular patterns (DAMPs) to initiate and amplify inflammatory responses. While MSU crystals deposited in the synovium may act as DAMPs and potentially activate NK cells, the role of these cells in gout pathophysiology remains unclear.

Methods: Peripheral blood and synovial fluid samples were collected from patients with gout and healthy controls (HCs). Flow cytometry was performed to analyze NK cells for their activation markers (CD69, PD-1, TIM-3), apoptosis (Annexin V), and cytokine/chemokine expression (IFN-γ, TNF-α, CCR2, CCR6, CXCR3, and CXCR4). NK cells were stimulated with MSU crystals and sorted by FACS sorter, while monocytes were isolated from PBMC using MACS. To evaluate osteoclastogenesis, MSU-stimulated NK cells and monocytes were cocultured in the presence of M-CSF, followed by TRAP staining. The expression of RANKL in MSU-stimulated NK cells was assessed using both flow cytometry and RT-PCR.

Results: The frequency of NK cells was decreased in the peripheral blood of gout patients, with intercritical stage patients showing a statistically significant reduction compared to HCs. These NK cells exhibited elevated annexin V expression, indicating late-stage apoptosis. Under PMA-IM stimulation, NK cells from both gout patients and HCs produced comparable levels of IFN-γ and TNF-α. In synovial fluid, the frequency of NK cells was significantly lower than in peripheral blood, but their CD69 and annexin V expression levels were higher. Chemokine receptor expression, including CCR2, CCR6, CXCR3, and CXCR4, tend to be elevated in synovial fluid-derived NK cells. Furthermore, NK cells stimulated with MSU crystals demonstrated increased CD69 and annexin V expression, suggesting activation by MSU. Notably, MSU-activated NK cells promoted osteoclastogenesis in both direct and indirect manners, as shown in co-culture experiments with or without transwell systems. These cells also exhibited elevated RANKL expression, confirmed by both flow cytometry and RT-PCR.

Conclusion: NK cells are numerically reduced and may undergo late-stage apoptosis in the peripheral blood of gout patients. In synovial fluid, NK cells show elevated expression of activation markers and chemokine receptors despite their decreased numbers, suggesting their apoptosis or migration from peripheral tissues to the synovium. MSU crystals activate NK cells, which in turn promote osteoclastogenesis, partly through increased RANKL expression. These findings suggest that NK cells play a key role in amplifying synovial inflammation and contributing to bone destruction in gout.

Background/Purpose: Previous studies have reported that walking is associated with a lower risk of several metabolic diseases; however, evidence of its association with gout, a metabolic condition, is lacking. We aimed to examine the relation of walking volume and intensity to the risk of incident gout.

Methods: Using data from the UK Biobank, a population-based cohort study was conducted to examine the relation of walking volume (total steps), walking intensity (peak 30-minute cadence), and their combination (purposeful steps, defined as average daily steps accumulated at a rate of exceeding 40 steps/minute) to the risk of incident gout. Participants aged 40-70 years, free of gout, and with valid accelerometer data at baseline were included. Hazard ratios (HRs) for incident gout were estimated across different walking activity metrics groups using Cox proportional hazard models, and the dose-response relationship was evaluated using restricted cubic spline regression. Three sensitivity analyses were conducted to assess the robustness of findings: (1) removing the accelerometer wear time from the multivariable adjusted model,

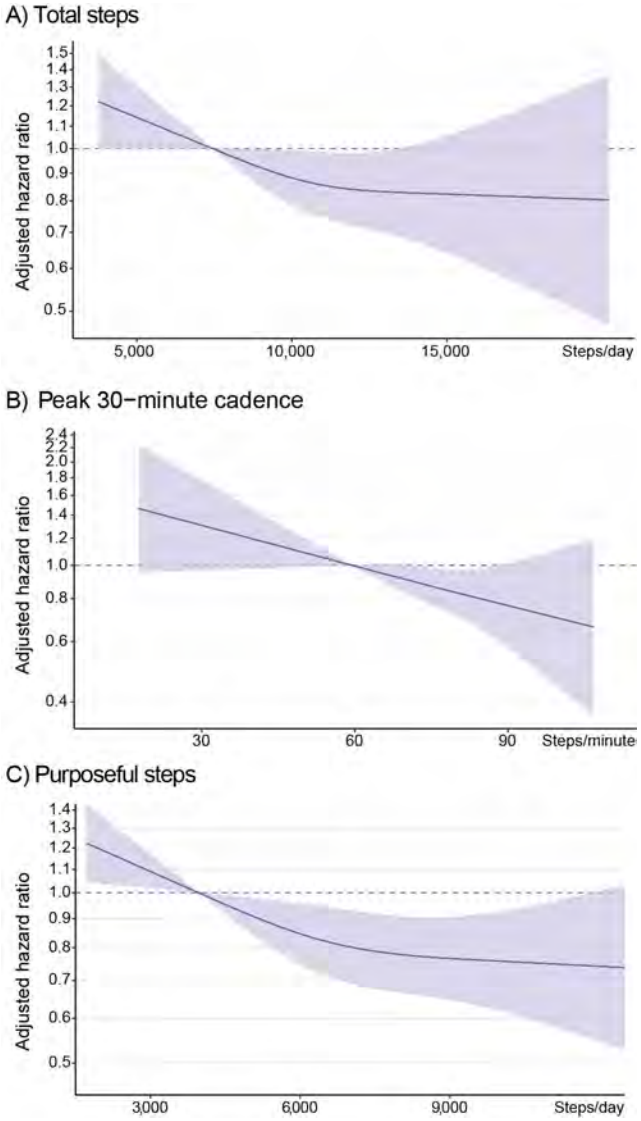

Figure 1. Associations Between Walking Activity and Incident Gout. Association between total steps (A), peak 30-minute cadence (B), and purposeful steps (C) and incident gout. Restricted cubic spline regression models fit with three knots placed at the median of three groups of categorical exposures. The y-axis is a log scale with the shaded area representing 95% confidence intervals. Hazard ratios are adjusted for age, sex, deprivation index, alcohol drinking status, coffee intake, red meat intake, poultry intake, fish intake, accelerometer wear time, body mass index, serum creatinine concentration, hyperuricemia, history of hypertension, history of diabetes, diuretic usage, and nonsteroidal anti-inflammatory drug usage at baseline. For total steps, models were further adjusted for peak 30-minute cadence (and vice versa).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(2) excluding incident gout cases within six months after the index date to mitigate potential reverse causation, and (3) restricting gout case confirmation to hospital inpatient records to minimize potential misclassification bias.

Results: Among 92,066 participants included in the current analyses, 706 developed incident gout during a mean follow-up period of 6.93 years. After adjustment for potential covariates, no significant association was observed between total steps or peak 30-minute cadence and the risk of incident gout (**Table 1**). However, compared with the low group (< 5,000 steps/day) of purposeful steps, the risk of incident gout was lower in the middle group (5,000-7,999 steps/day) and high (≥8,000 steps/day) group, with adjusted HRs and 95% confidence intervals of 0.78 (0.66–0.94) and 0.72 (0.58–0.90), respectively (P for trend =0.003) (**Table 2**). The associations remained consistent in sensitivity analyses, including when accelerometer wear time was excluded from models, those excluding incident gout cases occurring within the first six months of the index date, and those restricted to hospital-confirmed gout cases. Restricted cubic spline regression revealed significant linear inverse associations between purposeful steps and the risk of incident gout (**Figure 1**).

Conclusion: This large population-based cohort study demonstrates that higher purposeful steps, defined as the combined measure of walking volume and intensity, are associated with a lower risk of incident gout. These findings provide valuable insights for developing walking-based recommendations to prevent incident gout.

Renal Manifestations in VEXAS Syndrome: A Systematic Review of Clinical Features, Pathology, and Outcomes

Akhila Arya Perumangote Vasudevan[1], Vishnu Mulavini[2], Rasiya Hashim[3], Madhumitha Rondla[4] and Dileep C Unnikrishnan[5], [1]Yale University/Bridgeport Hospital, Stratford, CT, [2]Calicut Medical College, Stratford, [3]Franciscan Health Olympia & Chicago Heights, drrasiyahashim@gmail.com, IL, [4]Texas tech university health sciences center, El paso, El Paso, TX, [5]Bridgeport Hospital, Stratford, CT

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: VEXAS syndrome is a recently described, adult-onset autoinflammatory disease caused by somatic mutations in the UBA1 gene, typically affecting hematopoietic stem cells. Renal involvement was not prominently featured in early reports. The pathophysiology of VEXAS-associated kidney disease is not yet fully understood, but it is hypothesized that the UBA1-mutant myeloid clone directly infiltrates and damages renal tissue, as cytoplasmic vacuoles and UBA1-mutant cells have been identified in affected organs. Given that renal complications can lead to substantial morbidity, recognizing and characterizing kidney involvement in VEXAS is crucial.This review provides a comprehensive synthesis of the literature since VEXAS was first described, focusing on renal manifestations, biopsy findings, the frequency of kidney involvement, treatments used, and outcomes.

Methods: We searched PubMed/MEDLINE and Google Scholar for original articles with patient level data from 2020 on renal involvement in VEXAS syndrome. Key data was extracted from each report manually.The PRISMA diagram is shown below (Figure 1)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

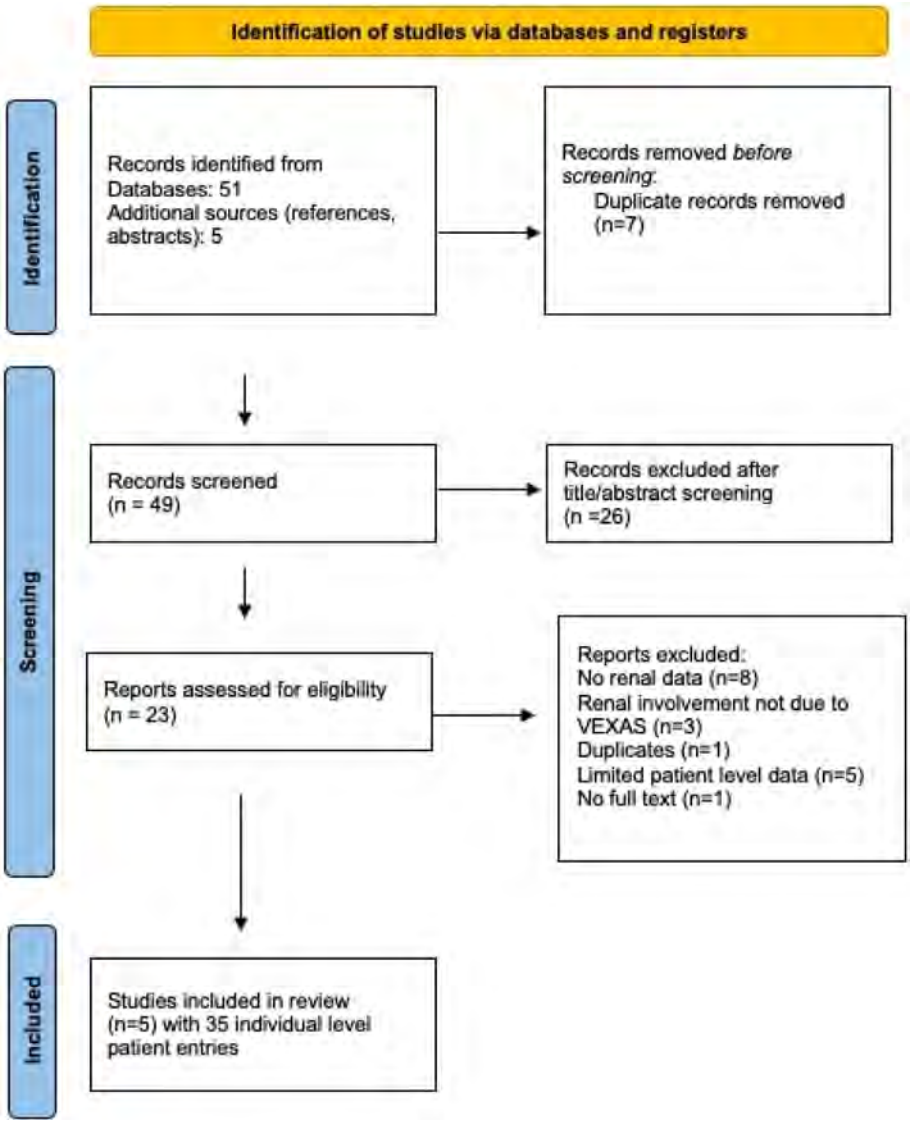

Figure 1: PRISMA diagram

Results: Kalantari et al. found AKI incidence of 6.2% at 1 year and 39% by year 10. A Dutch series showed 2 of 12 men had renal involvement; a Swiss series had 1 of 17 with AKI. In a French study, only 11 of 303 patients (3.6%) underwent biopsy. True prevalence may be higher due to avoided biopsies and empirical treatment.Patients (all male, aged 47–86) presented with CKD or abrupt AKI. Proteinuria was common; 5 of 11 French cases had nephrotic-range proteinuria. Hematuria and pyuria occurred in ∼50%. Table 1 summarises biopsy findings.The association with VEXAS flares was unclear—only 3 of 11 had flare-associated AKI. However, AKI often improved with immunosuppression. CRP elevation correlated with AKI onset in the Mayo cohort. Glucocorticoids remain first-line. In the Mayo cohort, all responded with improved kidney function and inflammation. Relapses with tapering necessitated steroid-sparing agents: cyclophosphamide, methotrexate, azathioprine, MMF. Targeted agents (tocilizumab, anakinra, JAK inhibitors) were used in refractory cases. Azacitidine may reduce inflammation by suppressing mutant clones. HSCT may induce remission; of two Mayo cases, one recovered, one had stable CKD post HSCT.AKI often improved with treatment; dialysis was rare.The role of renal disease in mortality remains unclear.

Conclusion: Kidney involvement in VEXAS can take diverse forms—most commonly interstitial nephritis and vasculitic glomerulonephritis, often parallel the activity of the systemic disease. Biopsy findings of plasma cell and neutrophil infiltration in the kidneys, along with UBA1 mutation positivity, suggest direct tissue damage by infiltrating mutant myeloid clones.The mainstay of treatment for VEXAS flares, including renal involvement, is glucocorticoids. Adjunctive therapies are frequently

Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Mixed connective tissue disease (MCTD) is a rare autoimmune condition defined by the presence of anti-U1-ribonucleoprotein (RNP) antibodies and clinical features of at least two other connective tissue diseases (CTDs). Pulmonary complications, including interstitial lung disease (ILD), are the leading causes of morbidity and mortality in this population. The clinical phenotype, natural history, and risk factors for ILD in MCTD remain poorly characterized. This study aims to evaluate the prevalence of MCTD and characterize clinical differences between MCTD patients with and without ILD.

Methods: We conducted a retrospective review of patients seen within the UCLA Health System between April 1, 2005, and April 1, 2025. Eligible patients had a CTD ICD-10 code of either M35.1 or M35.9, were at least 18 years of age, and had a

Table 1. Characteristics of patients with MCTD with and without ILD (N=581)

	ILD (N= 120)	No ILD (N= 461)
Age, Mean (SD)	58 (±18)	48 (±17)
Age <55, N (%)	49 (41%)	292 (63%)
Age >/=55, N (%)	71(59%)	169 (37%)
Female N (%)	101(84%)	405 (88%)
BMI, Mean (SD)	26.2 (±7.13)	25.9 (±6.3)
Current Smoker, N (%)	2 (2%)	10 (2%)
Former Smoker, N (%)	22 (18%)	76 (17%)
Never Smoker, N (%)	93 (78%	357 (77%)
Smoker Status Unknown, N (%)	3 (2%)	18 (4%)
Race, N (%)		
Caucasian	45 (38%)	159 (34%)
African American/Black	26 (22%)	81 (18%)
Asian/Pacific islander	18 (15%)	73 (16%)
Native American	3 (2%)	3 (1%)
Other/Decline to Answer	28 (23%)	145 (31%)
Ethnicity, N (%)		
Hispanic	36 (30%)	75 (16%)
Non-Hispanic	84 (70%)	386 (84%)
GERD, N (%)	73 (61%)	137 (30%)
Dysphagia, N (%)	39 (33%)	63 (14%)
Pulmonary Hypertension, N (%)	47 (39%)	38 (8%)

positive anti-U1-RNP antibody. Individuals with a medical history of systemic sclerosis, rheumatoid arthritis, systemic lupus erythematosus, or inflammatory myositis were excluded. Patients with ILD were identified based on diagnosis documentation in the electronic medical record. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated to assess differences in clinical and demographic characteristics between MCTD patients with and without ILD.

Results: A total of 581 patients with MCTD were included in the study. The majority were female (86.9%) with a mean age of 50 years (range: 18–96) (Table 1). The cohort was racially diverse, with 35.3% identifying as Caucasian, 18.4% as Black/African American, and 15.7% as Asian/Pacific Islander. ILD was present in 120 patients (20.7%). Patients with and without ILD did not differ significantly in terms of sex, body mass index (BMI), race, or smoking status. However, patients with MCTD and ILD were significantly more likely to be over the age of 55 (OR 2.50; 95% CI: 1.62–3.86), ethnically Hispanic (OR 2.21; 95% CI 1.40-3.49), report dysphagia (OR 3.03; 95% CI: 1.85–4.95), and have documented diagnoses of gastroesophageal reflux disease (GERD) (OR 3.66; 95% CI: 2.37–5.70), as well as pulmonary hypertension (PH) (OR 7.13; 95% CI: 4.24–12.10).

Conclusion: This study represents the largest evaluation of patients with MCTD and underscores the notable burden of ILD in this population. Universal screening for ILD in MCTD remains controversial. The present study sheds light on the distinguishing clinical features of patients with MCTD-ILD (e.g., older age, Hispanic, GERD, dysphagia, PH) that if present, could prompt evaluation for ILD and lead to earlier diagnosis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1147–1190) Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patient symptoms are important in the assessment of disease activity. The Patient Acceptable Symptom State (PASS) is defined as the minimum symptom score beyond which patients consider themselves to be well. The PASS reflects symptom control from the patient's perspective. We analyzed between group differences for PASS+ and PASS- subjects, and we performed a longitudinal response profile analysis and assessed validity of patient-reported outcomes (PRO) for PASS in adults with SAPHO-CNO.

Table 1. Baseline demographics, clinical characteristics and patient-reported outcome measures by the patient symptom state in adults with SAPHO-CNO (n=59).

	PASS+, n=37	PASS-, n=22
Age at enrollment, mean (SD), years	35 (14)	43 (17)
Age at diagnosis, mean (SD), years	28 (15)	36 (19)
Female biological sex, count (%)	30 (81)	20 (91)
Non-Hispanic, count (%)	36 (97)	21 (95)
Race by self-report, White, count (%)	33 (89)	20 (91)
SAPHO-CNO Disease characteristics		
Disease duration, mean (SD), years	7 (6)	6 (6)
Time to diagnosis, mean (SD), years	4 (4)	8 (10)
Symptom duration, mean (SD), years	11 (6)	15 (10)
Musculoskeletal involvement, count (%)	37 (100)	22 (100)
Inflammatory arthritis (ever), count (%)	14 (38)	15 (68)
Spine involvement (ever), count (%)	12 (32)	12 (59)
Skin involvement – any, count (%)	15 (41)	9 (40)
PPP, count (%)	7 (19)	6 (27)
PsV, count (%)	7 (19)	4 (18)
Severe Acne, count (%)	3 (8)	4 (18)
HS, count (%)	1 (3)	3 (14)
Patient-reported Disease Activity by NRS		
Overall SAPHO-CNO (PATDAM), mean (SD)	2.1 (1.8)	6.2 (2.0)
MSK SAPHO-CNO, mean (SD)	2.4 (2.4)	6.3 (2.1)
Skin SAPHO-CNO*, mean (SD)	1.5 (1.8)	4.0 (2.9)
Patient-reported Outcome Measure		
PAIN		
Patient global assessment by NRS, mean (SD)	2.8 (2.5)	6.7 (2.3)
PROMIS Pain Interference, mean (SD)	51.8 (7.4)	65.3 (6.7)
SF-36 Pain, mean (SD)	70.3 (15.4)	38.8 (19.6)
PHYSICAL FUNCTION		
Patient global assessment by NRS, mean (SD)	1.7 (1.9)	5.8 (2.2)
PROMIS Physical Function, mean (SD)	47.6 (8.1)	35.9 (6.4)
SF-36 Physical Functioning, mean (SD)	78.1 (19.6)	39.3 (24.9)
FATIGUE		
Patient global assessment by NRS, mean (SD)	3.4 (2.9)	7.0 (2.7)
PROMIS Fatigue, mean (SD)	51.8 (9.9)	62.1 (11.0)
SF-36 Energy/Fatigue, mean (SD)	51.6 (23.1)	25.5 (19.5)
GLOBAL HEALTH		
Patient global assessment by NRS, mean (SD)	2.7 (2.2)	5.2 (2.5)
PROMIS Global Health – Physical score, mean (SD)	46.5 (7.9)	35.8 (6.5)
SF-36 General Health, mean (SD)	52.7 (17.6)	35.0 (19.7)

Means (standard deviation) and counts (percentage) are presented unless otherwise stated. SAPHO: Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis; CNO: chronic nonbacterial osteomyelitis; PASS: Patient Acceptable Symptom State; PPP: Palmoplantar pustulosis; PsV: Psoriasis vulgaris; HS: Hidradenitis suppurativa; NRS: numeric rating scale, with range 0 (no pain, no limitations, no fatigue) to 10 (severe pain, severe limitations, severe fatigue); PATDAM: patient-reported disease activity overall in SAPHO-CNO by NRS, with range 0 (well controlled) to 10 (poor y controlled); MSK: Musculoskeletal; PROMIS: Patient-Reported Outcomes Measurement Information System; SF-36: 36-item Short Form survey.
*For subjects with current SAPHO-CNO related scin manifestations (n=24).

SAPHO: Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis; CNO: chronic nonbacterial osteomyelitis; PASS: Patient Acceptable Symptom State, with red line indicating PASS+ group (reference) and blue line indicating PASS- group. NRS: numeric rating scale, with range 0 (better) to 10 (worse). PROMIS: Patient-Reported Outcomes Measurement Information System, with higher scores reflecting higher pain and fatigue, and higher function and overall health by their respective scales. SF-36: 36-item Short Form survey, with lower scores being worse (from 0) and higher scores being better (to 100).

Figure 1. Response Profile Analysis of Patient-reported Outcome Measures by the Patient Acceptable Symptom State group over 1 year of follow-up in Adults with SAPHO-CNO (n=59).

Methods: Adults (≥18 years) enrolled in the SAPHO-CNO Study, a prospective longitudinal observational study, completed the PASS question: "*Think about all the ways that your SAPHO/CNO has affected you during the last week. If you were to remain for the next few months as you were in the last week, would this be acceptable to you?*". The PASS has a binary response: acceptable (PASS+) or unacceptable (PASS-). We collected serial questionnaires on patient-reported disease activity (PATDAM) measured by the numeric rating scale (NRS, range 0-10), and PROs for pain, function, fatigue, and global health assessed by the patient NRS (range 0-10), 36-item Short Form survey (SF-36), and Patient-Reported Outcomes Measurement Information System (PROMIS) instruments.

Subject baseline characteristics were summarized as means (standard deviation) or counts (proportion) stratified by PASS. We performed a response profile analysis with longitudinal modeling to account for both the mean and the covariance of repeated measures over time. We sought to characterize changes in the mean PROs over time, and to determine whether the mean outcome differs between PASS groups. Dependent variables (responses) were PRO measures; independent

	Proportion of PASS+ vs. PASS- subjects over 5 timepoints	
Timepoint	PASS+ group, n=37	PASS- group, n=22
Baseline	63%	37%
3-month	68%	32%
6-month	69%	31%
9-month	71%	29%
12-month	70%	30%

SAPHO: Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis; CNO: chronic nonbacterial osteomyelitis; PATDAM: patient-reported disease activity overall in SAPHO-CNO by numeric rating scale (NRS), with range 0 (well controlled) to 10 (poorly controlled); PASS: Patient Acceptable Symptom State, with red line indicating PASS+ group (reference) and blue line indicating PASS- group.

Figure 2. Response Profile Analysis of Patient-reported Disease Activity by the Patient Acceptable Symptom State group over 1 year of follow-up in Adults with SAPHO-CNO (n=59).

variables were time, group and time*group interaction term. Time was alternatively treated as categorical, linear, or quadratic, and model fit was evaluated by Akaike Information Criterion. All analyses were performed using SAS (v.9.4).

Results: Differences in baseline characteristics of PASS- and PASS+ subjects (n=59) are summarized in Table 1. PASS- subjects were slightly older at diagnosis, with a longer time to diagnosis and longer symptom duration. Spine involvement and skin features (PPP, acne) were more common, and mean PRO scores were higher in PASS- subjects. Mean response profiles for pain, function, and fatigue, but not global health, were significantly different between PASS groups ($p < 0.05$ for all time*group interaction terms) (Figure 1). Over time, longitudinal trajectories for all PROs remained stable in the PASS+ group, while they tended to improve in the PASS- group. Similarly, mean patient-reported disease activity (by PATDAM) was significantly different between PASS groups; it improved in PASS- subjects over time ($p< 0.05$) (Figure 2). Hence, PRO measures for pain, function and fatigue, demonstrate content validity, and PATDAM shows content and construct validity for disease activity as reflected by longitudinal changes in PASS groups.

Conclusion: The PASS identifies two distinct groups of adult SAPHO-CNO patients with differing levels of disease activity, pain, function and fatigue over time. We demonstrated the validity of PATDAM and key PROs with PASS longitudinally.
