Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: In patients with axial spondyloarthritis (axSpA), high disease activity is a key indication for biological disease-modifying antirheumatic drug (bDMARD) initiation. The Axial Spondyloarthritis Disease Activity Score (ASDAS) criterion (ASDAS≥2.1) is recommended for defining high disease activity, but the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) criterion (BASDAI≥4) can be used if ASDAS is unavailable [1]. We aimed to compare a newly proposed BASDAI cut-off for high disease activity (BASDAI≥2.5) [2] with ASDAS≥2.1 as an eligibility criterion for bDMARD initiation.

Methods: Prospectively collected real-world data from registries participating in the European Spondyloarthritis (EuroSpA) collaboration were analysed. Patients with axSpA initiating a tumour necrosis factor inhibitor or an interleukin-17A inhibitor as their first bDMARD between 2015 and 2023 were included. Analyses were limited to patients who had complete data on ASDAS and BASDAI at baseline and had attended a 6-month visit. Patients were categorised into 4 subgroups according to baseline ASDAS (≥2.1) and BASDAI (≥2.5) cut-offs for high disease activity. Treatment effect was assessed at 6 months by the Assessment of SpondyloArthritis international Society (ASAS) response measures (ASAS20 and ASAS40). Logistic regression analyses were performed to compare the achievement of treatment effect according to the ASDAS (≥2.1) and BASDAI (≥2.5) cut-offs for high disease activity.

Results: We analysed data from 6,329 patients with axSpA from 9 European registries. Most patients (n=5,753; 91%) fulfilled both ASDAS (≥2.1) and BASDAI (≥2.5) eligibility criteria at baseline, while 243 (4%) patients fulfilled neither of them (Table 1). The number of patients fulfilling either ASDAS or BASDAI criterion alone were 161 (3%) and 172 (3%), respectively. Baseline patient characteristics in the overall cohort and in subgroups are presented in Table 1. The subgroup fulfilling both eligibility criteria demonstrated the highest ASAS20 and ASAS40 responses at 6 months (68% and 52%, respectively) (Table 2). Among patients who only fulfilled the ASDAS or BASDAI criterion alone, similar ASAS20 (37% and 39%) and ASAS40 (17% and 15%) responses were achieved. The results of the regression analyses showed that fulfilling either ASDAS or BASDAI criterion was significantly associated with achieving ASAS20 and ASAS40 responses (Figure 1). When both criteria were included in the regression analyses, ASDAS≥2.1 and BASDAI≥2.5 were positive predictors of treatment effect at 6 months.

Table 1. Baseline patient characteristics in overall cohort and in subgroups according to baseline ASDAS and BASDAI cut-off values for high disease activity

Patient characteristic	Overall cohort n=6,329	ASDAS≥2.1 and BASDAI≥2.5 n=5,753 (91%)	ASDAS≥2.1 and BASDAI<2.5 n=161 (3%)	BASDAI≥2.5 and BASDAI≥2.5 n=172 (3%)	ASDAS<2.1 and BASDAI<2.5 n=243 (4%)
Age at treatment start, years	42 (33-51)	42 (33-51)	40 (31-49)	40 (33-48)	40 (32-49)
Time since diagnosis, years	2 (1-8)	2 (1-8)	2 (1-8)	3 (1-7)	3 (1-8)
Time since symptom onset, years	8 (3-16)	8 (3-16)	8 (2-14)	8 (3-14)	6 (2-13)
Male, n (%)	3,807 (60%)	3,438 (60%)	112 (70%)	93 (54%)	164 (67%)
BMI, kg/m²	26.2 (23.2-29.3)	26.3 (23.3-30.0)	24.8 (22.2-27.7)	25.0 (23.1-27.3)	25.1 (22.6-27.5)
Smoking status, current, n (%)	1,841 (31%)	1,709 (32%)	43 (29%)	37 (23%)	52 (24%)
Radiographic axSpA*, n (%)	2,723 (84%)	2,621 (84%)	38 (78%)	29 (67%)	35 (71%)
Concomitant csDMARD, n (%)	1,612 (28%)	1,449 (27%)	50 (34%)	51 (32%)	62 (29%)
HLA-B27 positive, n (%)	4,459 (78%)	4,067 (78%)	108 (77%)	115 (82%)	169 (79%)
CRP, mg/l	10.7 (4.0-21.0)	11.1 (4.2-22.0)	18.0 (11.0-30.0)	1.8 (1.0-3.0)	3.0 (1.0-6.0)
Patient pain assessment, 0-10	7 (5-8)	7 (5-8)	3 (2-4)	3 (2-4)	2 (1-3)
Patient fatigue assessment, 0-10	7 (5-8)	7 (6-8)	2 (1-4)	4 (3-6)	2 (1-3)
Patient global assessment, 0-10	7 (5-8)	7 (6-8)	3 (2-5)	3 (2-4)	2 (1-3)
Physician global assessment, 0-10	6 (3-7)	6 (4-7)	4 (2-6)	3 (2-5)	2 (1-5)
HAQ, 0-3	1.0 (0.6-1.4)	1.0 (0.6-1.4)	0.6 (0.2-0.8)	0.5 (0.2-0.8)	0.2 (0.1-0.5)
BASDAI, 0-10	6.0 (4.6-7.3)	6.2 (5.0-7.4)	1.9 (1.5-2.3)	3.4 (2.9-3.9)	1.5 (0.9-1.9)
BASFI, 0-10	4.9 (2.8-6.7)	5.2 (3.3-6.9)	1.4 (0.6-2.4)	2.2 (1.0-3.4)	0.9 (0.3-1.7)
ASDAS	3.6 (3.0-4.3)	3.7 (3.2-4.3)	2.5 (2.3-2.9)	1.9 (1.7-2.0)	1.5 (1.2-1.8)

Values are given as median (25th-75th percentile) unless otherwise stated. Results were calculated based on available data. *Radiographic axSpA was defined by bilateral grade 2–4 or unilateral grade 3–4 sacroiliitis on plain radiographs, according to the modified New York criteria (30).

ASAS: Assessment of SpondyloArthritis international Society, ASDAS: Axial Spondyloarthritis Disease Activity Score based on CRP, BASDAI: Bath Ankylosing Spondylitis Disease Activity Index, BASFI: Bath Ankylosing Spondylitis Functional Index, bDMARD: biologic Disease-Modifying Anti-Rheumatic Drug, BMI: Body Mass Index, csDMARD: conventional synthetic Disease-Modifying Anti-Rheumatic Drug, CRP: C-reactive protein, HAQ: Health Assessment Questionnaire, HLA-B27: Human Leukocyte Antigen B27, GDP: gross domestic product.

Table 2. Treatment effect at 6 months in overall cohort and in subgroups according to baseline ASDAS and BASDAI cut-off values for high disease activity

	Overall cohort	ASDAS≥2.1 and BASDAI≥2.5	ASDAS≥2.1 and BASDAI<2.5	BASDAI≥2.5 and BASDAI≥2.5	ASDAS<2.1 and BASDAI<2.5
Response measure	n=6,329	n=5,753 (91%)	n=161 (3%)	n=172 (3%)	n=243 (4%)
ASAS20	3,767 (65%)	3,611 (68%)	53 (37%)	61 (39%)	42 (19%)
ASAS40	2,824 (48%)	2,759 (52%)	25 (17%)	24 (15%)	16 (7%)

Values are given as number (percentage). Percentages were calculated based on available ASAS20 and ASAS40 data at 6 months.

ASAS: Assessment of SpondyloArthritis International Society; ASDAS: Axial Spondyloarthritis Disease Activity Score based on CRP; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index.

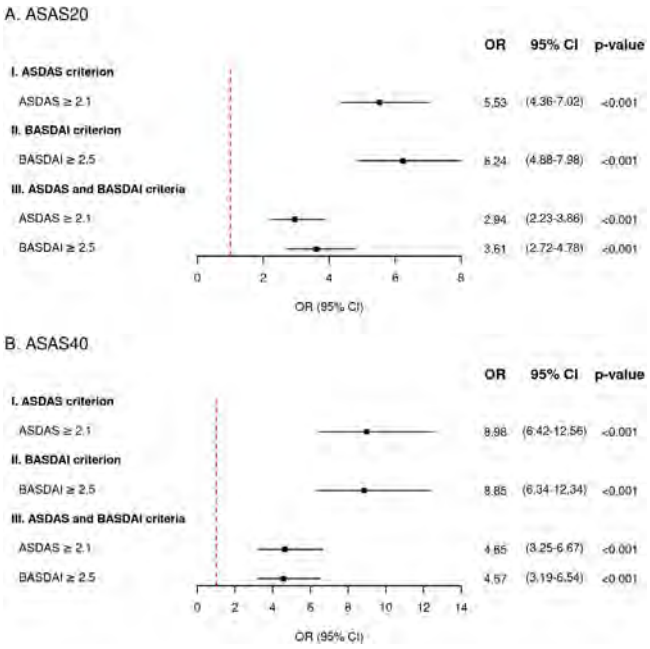

Figure 1. Forest plots of odds ratios with 95% confidence intervals for achieving ASAS 20 and ASAS40 at 6 months derived by logistic regression models including I. ASDAS criterion alone, II. BASDAI critetion alone, and III. both ASDAS and BASDAI criteria. Logistic regression analyses were adjusted for sex, age and GDP per capita (1,000$), as a proxy for socio-economic status of registries. ASAS: Assessment of SpondyloArthritis international Society; ASDAS: Axial Spondyloarthritis Disease Activity Score based on CRP; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; CI: confidence interval; OR: odds ratio.

Conclusion: In a multinational European cohort, similar numbers of patients were eligible for treatment with bDMARDs when applying either ASDAS≥2.1 or BASDAI≥2.5 as the eligibility criterion. Patients with ASDAS≥2.1 and BASDAI≥2.5 demonstrated the best response to bDMARD treatment. These findings support the use of BASDAI≥2.5 as an indication for biologic treatment in axSpA, particularly when ASDAS is not available.

Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial involvement in psoriatic arthritis (PsA) is variable and influences treatment choices. Data on axial PsA in Indian patients, especially its clinical and radiographic features, are limited. We aimed to describe these features and their association with radiographic sacroiliitis in an Indian PsA cohort.

Methods: Patients with PsA fulfilling CASPAR criteria were enrolled between April 2024 and March 2025. Demographic, clinical, and laboratory data were collected. Pelvis and spine radiographs were independently scored for sacroiliitis (modified New York criteria) and spinal damage by modified Stokes ankylosing spondylitis score (mSASSS). Patients were stratified by sacroiliitis status, and group comparisons were made using appropriate statistical tests and odds ratios (ORs).

Results: Of 182 consecutively enrolled patients (table 1), radiographic sacroiliitis was present in 85 (46.7%). Thirty of these 85 (35%) radiographic sacroiliitis patients had no clinical axial symptoms. Asymmetric oligoarthritis was the most common pattern of presentation observed as per Moll and Wright Classification (figure-1A). Radiographic sacroiliitis patients were older (mean age 49.6 vs. 45.3 years, p=0.01), had longer disease duration (median 6 vs. 3 years, p=0.01). Axial symptoms (spondylitis ± inflammatory back pain) were more frequent in the sacroiliitis group (51.9% vs. 29.9%, p=0.04; OR 2.5, 95% CI 1.3–4.6), including *HLA-B*27* positivity (16.9% vs. 1.0%, p< 0.001; OR 19.2, 95% CI 2.4–151.0). Other clinical features, including peripheral disease patterns, nail changes, enthesitis, dactylitis, and inflammatory markers did not significantly differ.

On spinal radiography (table 2), lumbosacral (LS) spine bridging syndesmophytes were significantly more frequent (35.3% vs. 8.0%, p< 0.001; OR 6.3, 95% CI 2.5–15.0), and LS spine mSASS were higher (median 8 vs. 4, p=0.001). Cervical spine syndesmophytes were also more common in the sacroiliitis group (70.6% vs. 54.4%, p=0.03). The C5, C6, and L4 vertebrae were most frequently involved, and were also frequently damaged with syndesmophytes including non-marginal bridging

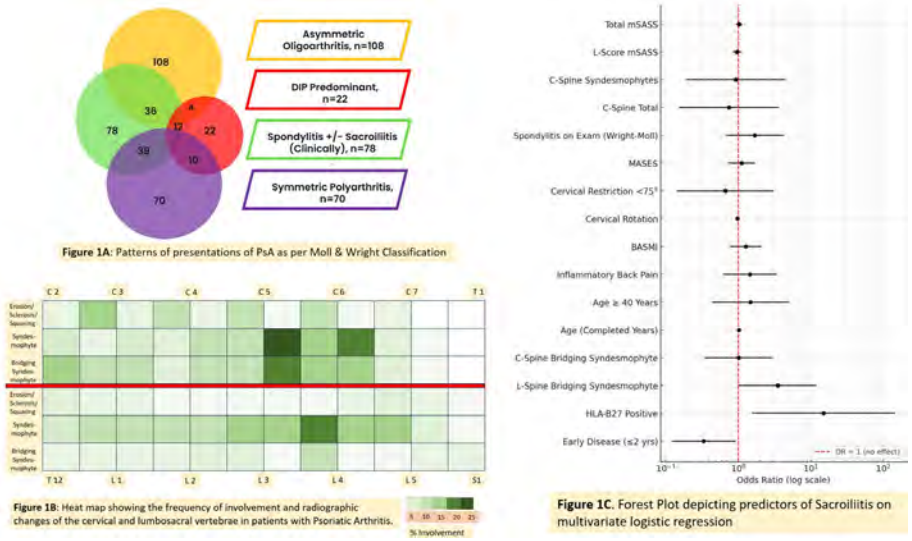

Figure 1A: Patterns of presentations of PsA as per Moll & Wright Classification Figure 1B: Heat map showing the frequency of involvement and radiographic changes of the cervical and lumbosacral vertebrae in patients with Psoriatic Arthritis. Figure 1C. Forest Plot depicting predictors of Sacroiliitis on multivariate logistic regression

regression only *HLA-B*27*, LS spine bridging syndesmophytes emerged as independent predictors of radiographic sacroiliitis (figure-1C), while shorter disease duration was associated with low odds of radiographic sacroiliitis.

Conclusion: Radiographic sacroiliitis was prevalent in nearly 47% patients in this Indian PsA cohort, often occurring without clinical axial symptoms. *HLA-B*27* positivity, and LS spine bridging syndesmophytes were significantly associated with sacroiliitis, while those with disease duration < 2 years had a lower odds of sacroiliitis. These findings support the role of early routine imaging to detect subclinical axial involvement and guide management.

HLA-B27	0.073	-0.492, 0.639	0.799			
Proportion of TNF-α blocker Exposure	-0.09	-0.343, 0.162	0.482			
Early axial Spondyloarthritis (ASAS definition)	-0.201	-0.448, 0.046	0.111	-0.147	-0.399, 0.105	0.253

axSpA: axial spondyloarthritis; CRP: C reactive protein; HLA: human leukocyte antigen; mSASSS: the modified Stokes AS Spinal Score; TNF: tumor necrosis factor.

Background/Purpose: This study evaluates the impact of the ASAS definition of early axial spondyloarthritis (axSpA) on radiographic progression over a 12-year period, utilizing the Modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) to compare early and established disease stages.

Methods: Data from the Korean spondyloarthropathy registry were used in this retrospective observational study to categorize patients into early or established axSpA according to the ASAS criteria. Radiographic progression was assessed through annual changes in mSASSS, scored independently by two radiologists. Linear regression and other statistical analyses were performed to examine the correlation between early axSpA status and radiographic progression, adjusting for relevant covariates.

Results: The study included time intervals at 0-4, 0-6, 0-8, 0-10, and 0-12 years, involving 445 patients. Results showed no statistically significant differences in mSASSS changes between the early and established axSpA groups, suggesting similar rates of progression irrespective of TNF-α blocker therapy. Both univariable and multivariable analyses demonstrated that early axSpA status did not significantly impact changes in mSASSS.

Conclusion: Our findings indicate that the ASAS criteria for early stage axSpA do not significantly affect long-term radiographic outcomes, challenging the assumption that early identification and treatment of axSpA based on these criteria alter radiographic progression.

Abstract Number: 1433

Identifying Predictors of Difficult-to-Manage Axial Spondyloarthritis: Real-World Insights from a Taiwanese Registry Cohort

Yen-An Chang and Ming-Han Chen, Division of Allergy, Immunology & Rheumatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, Taipei, Taiwan (Republic of China)

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1405–1433) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The concept of Difficult-to-Manage Axial Spondyloarthritis (D2M-ax-SpA) was recently introduced by the Assessment of Spondyloarthritis International Society (ASAS). According to this new definition, D2M-ax-SpA is characterized by (a) failure of ≥2 biologic or targeted synthetic DMARDs (b/tsDMARDs) with different mechanisms of action (MOAs), (b) persistent disease activity, and (c) symptoms considered problematic by either the patient or rheumatologist.

This study is among the first to evaluate the real-world prevalence and clinical predictors of D2M-ax-SpA using this newly proposed definition.

Methods: We conducted a retrospective cohort study of patients with axial spondyloarthritis (ax-SpA) enrolled between January 2009 and December 2021 at Taipei Veterans General Hospital. Inclusion criteria included fulfillment of the ASAS classification criteria and ≥6 months of follow-up. Patients were categorized into three groups: D2M-ax-SpA (per ASAS definition), those treated with b/tsDMARDs with only one MOA, and those who never received b/tsDMARDs. Demographic, radiographic, and laboratory data were analyzed. Group comparisons were performed using the Mann–Whitney U and Fisher's exact tests. Univariate and multivariate logistic regression were conducted to identify predictors of D2M-ax-SpA, and ROC curve analysis was applied to assess the predictive performance of laboratory markers.

Results: Among 560 patients with ax-SpA (all HLA-B27 positive), 20 (3.6%) met the criteria for D2M-ax-SpA. Ninety-four patients received b/tsDMARDs with a single MOA, while 446 were treatment-naïve to b/tsDMARDs. Compared to the other groups, patients with D2M-ax-SpA had significantly longer disease duration (median 3890 vs. 3292 and 2034 days, $p< 0.01$), more frequent peripheral arthritis ($p< 0.01$), higher grades of sacroiliitis on plain radiography ($p< 0.01$), and elevated ESR and CRP levels ($p< 0.01$). In multivariate analysis, peripheral arthritis emerged as an independent predictor of D2M-ax-SpA (OR: 4.68, 95% CI: 1.74–12.60, $p=0.0022$). ROC analysis demonstrated that ESR and CRP were strong predictive markers, each with an AUC of 0.785 ($p< 0.0001$), and optimal thresholds identified as ESR >20 mm/hr and CRP >0.99 mg/dL.

	D2M (n=20)	MOA1 (n=94)	no biologics (n=448)	P value

CRP	0.785	<0.0001	>0.99

Receiver Operating Characteristic (ROC) Curve Analysis of Laboratory Markers Predicting D2M-ax-SpA

Conclusion: This study provides the first real-world evidence on the clinical characteristics and predictors of D2M-ax-SpA using the newly proposed ASAS criteria. Peripheral arthritis and elevated inflammatory markers (ESR, CRP) were strongly associated with treatment resistance. These findings highlight the importance of early identification of high-risk patients, which may inform treatment selection and improve long-term outcomes. Further prospective studies in larger, multi-ethnic cohorts are warranted to validate these results.

Safety of Prescription NSAIDs in Adults with IBD: Data from a Large Administrative Claims Cohort

Adam Mayer[1], Rui Xiao[2], Meenakshi Bewtra[3], Michael George[4] and Pamela Weiss[5], [1]University of Pennsylvania/ Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, [4]University of Pennsylvania, Philadelphia, PA, [5]Childrens Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The potential that nonsteroidal anti-inflammatory drugs (NSAIDs) may precipitate flares of inflammatory bowel disease (IBD) has limited their use in managing joint pain in this population. We tested whether use of NSAIDs is associated with a clinically important risk of IBD-related hospitalization using a non-inferiority design.

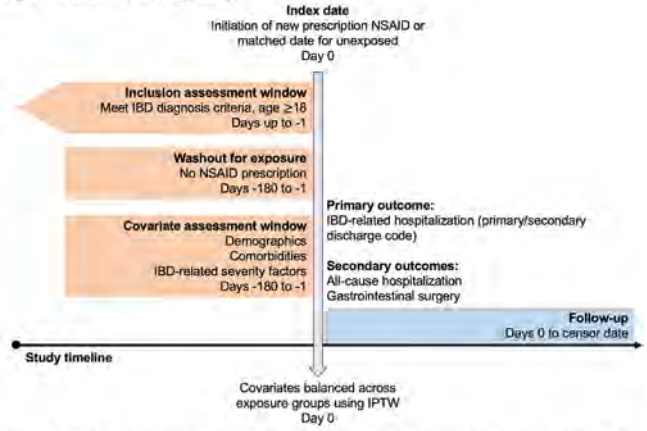
Figure 1. Overview of study design



Legend: NSAID: Nonsteroidal anti-inflammatory drug; IBD: inflammatory bowel disease; IPTW: inverse probability of treatment weighting. Subjects were censored at the end of continuous enrollment, end of study period, or ≥6 months from last NSAID fill. Cox proportional hazards models for primary and secondary outcomes were adjusted for covariates that did not achieve balance by propensity scores.

Methods: This retrospective cohort study of IBD patients used administrative claims data from Optum's de-identified Clinformatics Data Mart Database (2000-2022). Patients with a new NSAID prescription fill ("exposed") were matched to those without an NSAID fill during the study period ("unexposed") by age and calendar year when IBD criteria were met (**Figure 1**). The index date for exposed patients was date of first NSAID fill; unexposed patients were assigned a matched index date based on time from meeting IBD criteria. A propensity score was calculated to balance covariates across exposure groups. The primary outcome was IBD-related hospitalization, defined as any hospitalization >1 day duration with an IBD diagnosis code as the primary or secondary discharge code. Secondary outcomes included all-cause hospitalization and gastrointestinal surgery, defined by Current Procedural Terminology codes. Propensity score-based inverse probability of treatment weighted (IPTW) Cox proportional hazards models evaluated the association between NSAID exposure and time to each primary and secondary outcome across IBD subtypes. A hazard ratio (HR) of 1.2 was set as the pre-specified non-inferiority margin based on discussions with IBD content experts on acceptable risk.

Results: Among 269,304 patients with IBD, 29.7% were NSAID exposed (**Table 1**). In the IPTW-weighted Cox model, NSAID exposure was associated with a small increase in IBD-related hospitalization in the overall IBD cohort (HR 1.08, 95% CI 1.05-1.11; **Figure 2**) but demonstrated non-inferiority (upper limit of confidence interval < 1.20). Exposed patients experienced an adjusted 0.06 IBD-related hospitalizations/person-year versus 0.05 events/person-year in the unexposed

Table 1. Unweighted cohort characteristics stratified by NSAID exposure

Factor	Total N (%) (N=269,304)	NSAID Exposed N (%) (N=79,872)	Unexposed N (%) (N=189,432)
Age, median (IQR)	52 (39, 66)	52 (40, 65)	52 (39, 66)

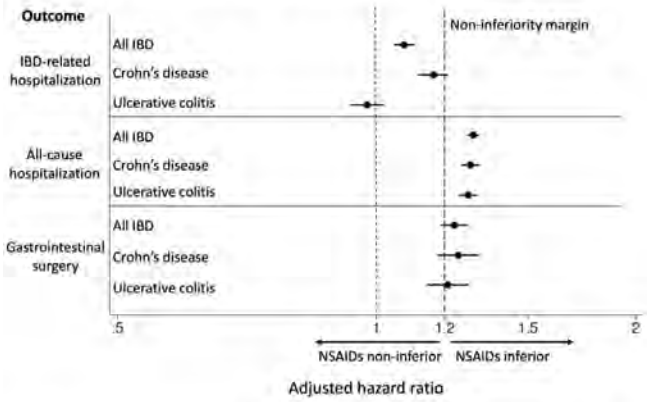
Opioid use	64,378 (23.9)	26,603 (33.3)	37,775 (19.9)
Glucocorticoid use	76,393 (28.4)	27,787 (34.8)	48,606 (25.7)
csDMARD use	111,161 (41.3)	33,028 (41.4)	78,133 (41.2)
b/tsDMARD use	39,286 (14.6)	11,297 (14.1)	27,989 (14.8)
Joint pain	106,147 (39.4)	39,643 (49.6)	66,504 (35.1)
Chronic pain	116,967 (43.4)	45,737 (56.0)	71,230 (36.9)
Gastrointestinal bleed	66,809 (24.8)	22,047 (27.6)	44,762 (23.6)

Legend: NSAID: Nonsteroidal anti-inflammatory drug; IQR: interquartile range; yrs: years; CD: Crohn's disease; UC: ulcerative colitis; CCI: Charlson comorbidity index; csDMARD: conventional synthetic disease modifying anti-rheumatic drug; b/tsDMARD: biologic/targeted synthetic disease modifying anti-rheumatic drug

Figure 2. Association between prescription NSAID exposure and time to IBD-related hospitalization, all-cause hospitalization, and gastrointestinal surgery across IBD subtypes.



Legend: Vertical dashed lines indicate: 1) null hazard ratio 1.0 and 2) the prespecified non-inferiority margin of hazard ratio 1.2 based on clinically-acceptable risk defined by IBD content experts. X-axis is log-transformed. NSAID: Nonsteroidal anti-inflammatory drug; IBD: inflammatory bowel disease

group (absolute risk difference 0.007, number needed to harm 137). No significant increase in IBD-related hospitalization was seen in the ulcerative colitis subgroup (HR 0.96, 95% CI 0.91-1.01), but there was a significant increase in those with Crohn's disease (HR 1.16, 95% CI 1.11-1.21), with non-inferiority not met. There were significantly higher rates of gastrointestinal surgery (overall HR 1.23, 95% CI 1.19-1.28) and all-cause hospitalization (overall HR 1.30, 95% CI 1.28-1.32) with neither meeting non-inferiority.

Conclusion: Prescription NSAID exposure was associated with a numerically small risk of IBD-related hospitalization below the pre-specified non-inferiority threshold. Risk was not seen in patients with ulcerative colitis, while small magnitude risks were present in those with Crohn's disease. These results challenge the current paradigm of avoiding NSAIDs in all patients with IBD and suggest that the benefits of NSAIDs may outweigh small possible risks for many patients with significant joint disease.

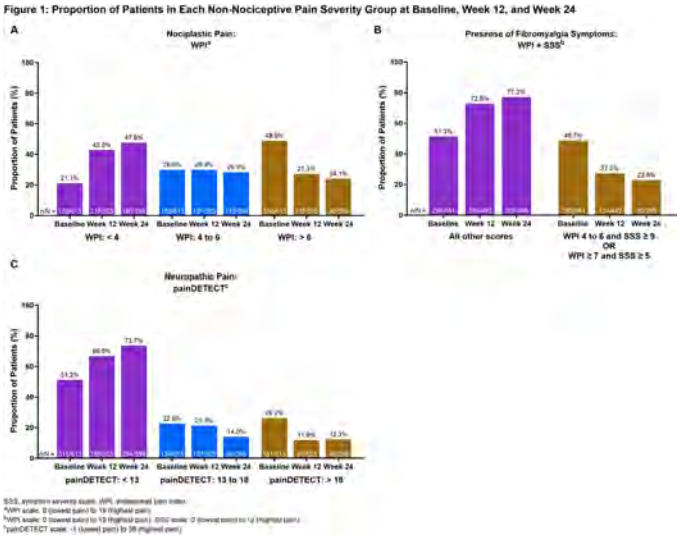
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Upadacitinib (UPA), an oral JAK inhibitor, has demonstrated improvements in inflammation and nociceptive pain in late phase clinical trials of patients with axSpA.[1,2,3] However, patients may also experience non-nociceptive pain via altered central nervous system modulation (nociplastic), including fibromyalgia (FM), or peripheral nervous system damage (neuropathic). This post hoc analysis of a real-world study in patients with axSpA examined the impact of UPA treatment on non-nociceptive pain and the association of non-nociceptive pain with residual symptoms, sleep disturbance, anxiety, and depression.

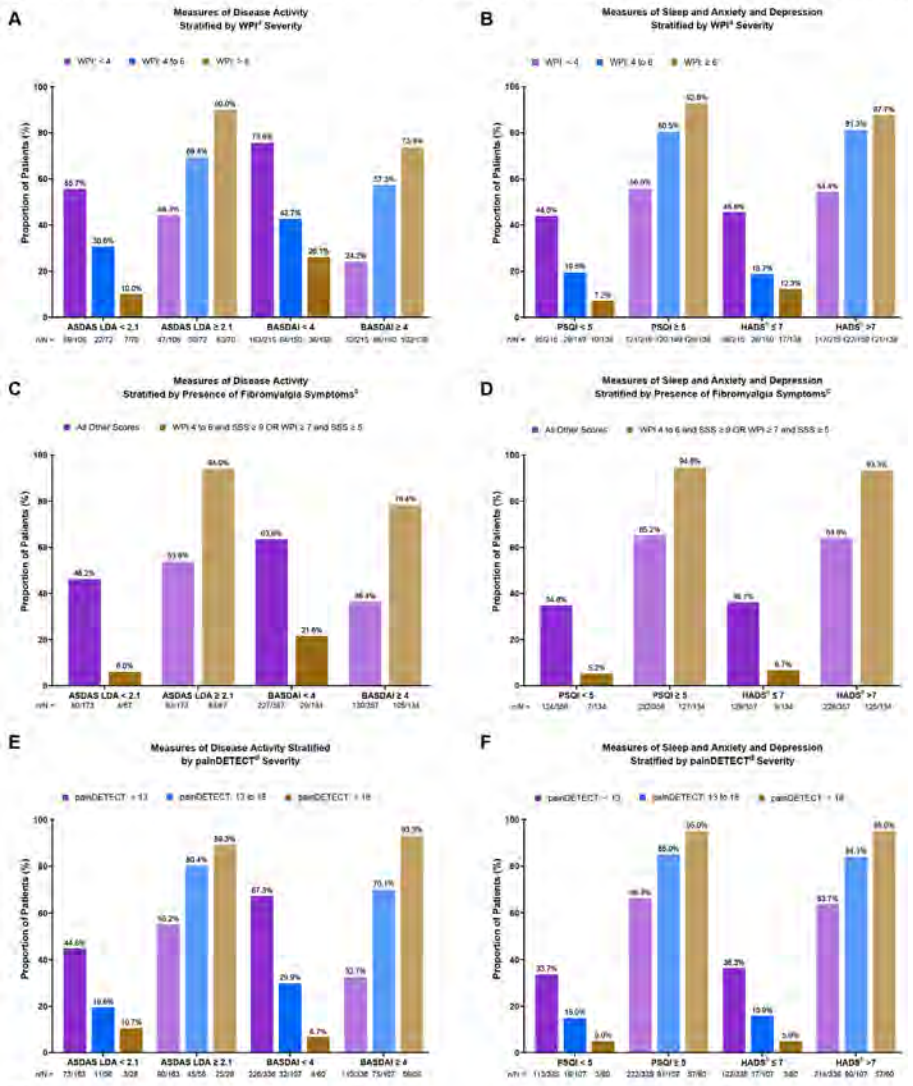
Methods: UPSTAND was a 12-month, multicountry, noninterventional, observational study evaluating the effectiveness of UPA on pain in adult patients with axSpA. Safety from UPSTAND has been previously analyzed.[4] This analysis used interim data collected after all patients completed at least week (wk) 12. Patients were grouped by severity of neuropathic pain, as captured by painDETECT (< 13, 13-18, and > 18) or severity of nociplastic pain, as captured by widespread pain index (WPI: < 4, 4-6, and > 6). While patients demonstrating active symptoms of FM per clinical diagnosis were excluded from UPSTAND, WPI and symptom severity score (SSS) were used together to assess the presence of nociplastic pain fulfilling FM criteria as per Wolfe et al. 2016: WPI 4-6 and SSS ≥ 9 or WPI ≥ 7 and SSS ≥ 5.[5] All other scores (absence of FM) were grouped together. The proportion of patients in each group was reported at baseline (BL) and wk 12. For those with available data, the proportion of patients in each group was reported at wk 24. The association of non-nociceptive pain with measures of disease activity, sleep quality, and symptoms of anxiety/depression was assessed by analyzing the proportion of patients in each group at wk 12 that did or did not achieve ASDAS low disease activity (ASDAS LDA; < 2.1), BASDAI < 4, Pittsburgh Sleep Quality Index Score < 5, and Hospital Anxiety and Depression Scale ≤ 7 at wk 12. The change from BL in total back pain, nocturnal back pain, fatigue (BASDAI question 1), and BASFI at wk 12 was reported for each group.

Figure 1: Proportion of Patients in Each Non-Nociceptive Pain Severity Group at Baseline, Week 12, and Week 24



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2: Achievement of Response at Week 12 Stratified by Non-Nociceptive Pain Severity at Week 12



SSS, symptom severity scale; WPI, widespread pain index.
[a]WPI scale: 0 (lowest pain) to 19 (highest pain).
[b]HADS ≤ 7 indicates no depression. Scale: 0 to 21.
[c]WPI scale: 0 (lowest pain) to 19 (highest pain); SSS scale: 0 (lowest pain) to 12 (highest pain).
[d]painDETECT scale: −1 (lowest pain) to 38 (highest pain).

Results: Overall, UPA treatment was associated with a reduction in the burden of nociplastic and neuropathic pain over time (**Figure 1**). The proportion of patients in the least severe pain groups increased from BL over time; the proportion of patients in the more severe pain groups or meeting criteria for FM decreased over time. Non-nociceptive pain at wk 12 was associated with residual symptoms, anxiety/depression, and poor sleep (**Figure 2**). The presence of non-nociceptive pain was associated with smaller improvements in total back pain, nocturnal back pain, fatigue, and BASFI from BL to wk 12 (**Figure 3**).

Conclusion: In patients with axSpA, treatment with UPA was associated with improvements in non-nociceptive pain. Non-nociceptive pain was associated with residual symptoms, sleep disturbance, signs of anxiety/ depression, and fatigue.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Difficult to treat (D2T) psoriatic arthritis (PsA) presents a state of active inflammatory disease manifestations despite therapy with at least two biologic disease modifying anti-rheumatic drugs (bDMARDs) or targeted synthetic DMARDs (tsDMARDs) with two different mechanisms of action. Inflammation and angiogenesis are interlinked processes. EMMPRIN/CD147, a multi-functional protein that can induce the expression of the pro-angiogenic matrix metalloproteinases (MMPs) and vascular-endothelial-growth factor (VEGF), also regulates the expression of the anti-angiogenic factor endostatin.

We aimed to assess the levels of pro- and anti-angiogenic factors in patients with D2T PsA patients compared to non-D2T PsA patients.

Methods: We determined the serum levels of the pro-angiogenic factors EMMPRIN/CD147, VEGF, MMP-9, MMP-9 activity, and the anti-angiogenic factors endostatin and Thrombospondin-1 (Tsp-1) in D2T PsA patients and in non-D2T controls who were stratified into two subgroups based on exposure to bDMARDs / tsDMARDS or to conventional DMARDs (biologic naïve) from a well-defined database. Each patient with D2T PsA was matched with at least one non-D2T patient of similar age and disease duration. The visit with the highest scores of articular and skin manifestations in the database was chosen for each patient. The serum levels of the biomarkers were evaluated using sandwich ELISA, and the MMP-9 activity was determined by the cleavage of its fluorescent substrate. The three patient groups were compared using Kruksal-Wallis ANOVA followed by Dunn's multiple comparisons test.

Results: 23 patients with D2T PsA, accounting for 6.7% of the database population, were matched with 25 non-D2T bDMARDs /tsDMARDs-experienced PsA controls and to 25 non-D2T biologic naive patients. The mean age of the study groups was 62.32±15.48 years with a disease duration of 19.38±11.12 years. All patients had active disease, but the D2T group had higher scores of enthesitis compared to the non-D2T bDMARDs/tsDMARDs group and higher tender and swollen joint counts and HAQ scores compared to the non-D2T biologic naïve group. No significant differences were observed in the mean dactylitis or psoriasis area and severity index (PASI) scores, nor in other patient-related outcomes among the three groups. Comparing between the D2T patients, the non-D2T biologic experienced patients, and the non-D2T biologic-naïve patients, higher levels of EMMPRIN/CD147 (26.4±1.4, 19.4±0.88, 19.7±0.86 ng/ml, respectively, $p< 0.001$), endostatin (60.9±2.8, 52.1±1.56, 50.1±1.4 ng/ml, respectively, $p< 0.048$), and of MMP-9 activity (123,861±9,446, 90,067±5,620, 89,328±6,258 RFU, respectively, $p< 0.017$) were found in the DTT group. No statistically significant differences were found in the levels of VEGF and Tsp-1 between the three groups.

Conclusion: Higher level of CD147, and increased activity of MMP-9, which we have previously linked to the regulation of the anti-angiogenic factor endostatin, were detected in D2T PsA patients' serum, suggesting their possible use as biomarkers, and indicating the complexity of the angiogenetic process in these patients, which merit further investigation.

Abstract Number: 1437

Characterization of ORKA-002, a Novel Extended Half-life Monoclonal Antibody Targeting IL-17A/F for the Treatment of Psoriasis and Other Indications

Byron Kwan[1], Joseph Merola[2], Andrew Blauvelt[3], Daniel Rios[1], Joana Ministro[1], Jacob Milligan[1], Ghassan Fayad[1], Christopher Finch[4], **Eugenia Levi**[5], Joseph Senn[5], Jason Oh[1] and Hussam Shaheen[1], [1]Paragon Therapeutics, Waltham, MA, [2]UT Southwestern Medical Center, Dallas, TX, [3]Blauvelt Consulting, LLC, Annapolis, MD, [4]Oruka Therapeutics, Menlo Park, CA, [5]Oruka Therapeutics, Waltham, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin 17 (IL-17) is a pro-inflammatory cytokine that has been implicated in the pathogenesis of multiple autoimmune conditions, including psoriasis and psoriatic arthritis (PsA). The IL-17 family of cytokines includes 6 members (IL-17A to IL-17F). Both IL-17A and IL-17F are key drivers in the pathogenesis of psoriatic disease, being highly overexpressed in psoriatic plaques and the inflamed synovium of patients with PsA. Recently, a biologic targeting both IL-17A and IL-17F, bimekizumab (BIME), has demonstrated high efficacy that exceeds therapies targeting IL-17A only. ORKA-002 is a novel, extended half-life, humanized, monoclonal antibody that binds to IL-17A/F with high affinity. ORKA-002 has been engineered to have optimized properties with the aim of delivering an enhanced clinical profile compared to currently available treatments for psoriasis and other inflammatory diseases.

Methods: ORKA-002 was evaluated across multiple *in vitro* and *ex vivo* assays alongside BIME. Binding affinity to IL-17A and IL-17F was determined by surface plasmon resonance (SPR). Antagonism of IL-17A and IL-17F signaling was assessed through NFκB activation assays in reporter cell lines. Inhibition of IL-17A-induced or IL-17F-induced IL-6 secretion was measured *in vitro* using normal human dermal fibroblasts. Half-life extension was evaluated via pharmacokinetic (PK) analysis in cynomolgus monkeys following a single bolus dose of ORKA-002.

Results: ORKA-002 bound specifically to human IL-17A and IL-17F with high affinity. IL-17A/F binding affinity and functional potencies for IL-17A/F antagonism were comparable to BIME. In cynomolgus monkeys, ORKA-002 demonstrated a significantly extended half-life relative to BIME. Predictive simulations, based on allometric scaling of ORKA-002 PK parameters, suggest that in humans, subcutaneous maintenance dosing every four to six months could sustain high antibody exposures.

Conclusion: ORKA-002 exhibits high selectivity and affinity for IL-17A and IL-17F *in vitro*, potent inhibition of downstream cellular signaling *ex vivo*, and an extended half-life in non-human primates compared to BIME. These characteristics could result in comparable or increased efficacy compared to BIME with just two to three doses of ORKA-002 a year. Pre-clinical evidence for ORKA-002 reported here may lead to therapeutic improvements for psoriatic disease and other inflammatory conditions amenable to IL-17 inhibition. Clinical studies are planned to explore this potential.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease mainly affecting the sacroiliac joints and spine.[1] Peripheral manifestations are common, contributing to disease burden.[2] Two clinical axSpA endotypes have been identified by cluster analyses: patients (pts) with predominantly axial disease (i.e., Endotype A), and pts with axial and peripheral manifestations (i.e., Endotype B; associated with higher disease activity and reduced quality of life).[3–5]

Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has shown sustained efficacy and safety to Week (Wk) 104 across the full disease spectrum of axSpA in the phase 3 studies BE MOBILE 1 and 2 and their open-label extension (OLE).[6] Here, we report efficacy and safety of BKZ to Wk 104 by endotype to evaluate differences in treatment response.

Methods: Study designs of BE MOBILE 1 (NCT03928704; non-radiographic axSpA), BE MOBILE 2 (NCT03928743; radiographic axSpA) and their OLE (NCT04436640) have been reported previously.[7] From Wk 16, all pts received subcutaneous BKZ 160 mg every 4 weeks. At Wk 52, eligible pts could enroll in the OLE.

Pts pooled across studies were categorized into endotypes by a validated classification and regression tree (CART) clustering algorithm using baseline characteristics.[3]

Retention and efficacy data to Wk 104 are reported for all randomized pts (N=586). ASAS40 response and ASDAS major improvement (ASDAS-MI) are reported with non-responder imputation (NRI); ASDAS low disease activity (LDA) and ASDAS change from baseline are reported with multiple imputation (MI). Safety data are reported in pts receiving ≥1 BKZ dose (N=574).

Results: Of the 586 pts in BE MOBILE 1 and 2 and their OLE, 402 (68.6%) were categorized into Endotype A, and 184 (31.4%) into Endotype B. Baseline characteristics by endotype are shown in the **Table**. Kaplan-Meier retention rate at Wk 104 was 83.9% in both endotypes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table. Patient demographics and baseline characteristics, stratified by endotype

	Endotype A *Predominantly Axial Manifestations*		Endotype B *Axial and Peripheral Manifestations*		Overall
Mean (SD) unless otherwise specified	PBO → BKZ 160 mg Q4W n=169	BKZ 160 mg Q4W n=234	PBO → BKZ 160 mg Q4W n=69	BKZ 160 mg Q4W n=115	N=586
Age, years	39.0 (11.6)	40.5 (11.4)	40.2 (13.4)	40.4 (12.6)	40.0 (11.9)
Sex, male, n (%)	110 (65.5)	161 (68.8)	35 (50.7)	72 (62.6)	378 (64.5)
HLA-B27 positive, n (%)	132 (78.6)	197 (84.2)	55 (79.7)	97 (84.3)	481 (82.1)
Symptom duration, years	9.9 (8.4)	12.5 (10.8)	11.4 (10.0)	12.1 (10.0)	11.5 (9.9)
Age at axSpA onset, years	29.6 (8.6)	28.6 (8.3)	29.3 (8.4)	28.8 (8.6)	29.0 (8.5)
ASDAS	3.6 (0.7)	3.6 (0.8)[b]	3.8 (0.8)	4.0 (0.8)	3.7 (0.8)[b]
BASFI	5.0 (2.2)	5.1 (2.2)	5.8 (2.0)	5.9 (2.1)	5.3 (2.2)
ASQoL	8.4 (4.2)	8.8 (4.7)	10.5 (4.4)	10.1 (4.6)	9.1 (4.5)
SF-36 PCS	35.2 (8.6)	34.7 (8.3)[a]	31.3 (8.4)	32.5 (8.4)	34.0 (8.5)[a]
hs-CRP, mg/L, median (Q1, Q3)	7.0 (2.7, 13.2)	6.2 (1.8, 15.5)	5.9 (1.7, 19.8)	9.1 (2.6, 21.0)	7.0 (2.2, 15.9)
History of peripheral manifestations, n (%)					
Peripheral arthritis	24 (14.3)	21 (9.0)	69 (100)	115 (100)	229 (39.1)
Enthesitis[c]	94 (56.0)	133 (56.8)	65 (94.2)	93 (80.9)	385 (65.7)
Dactylitis	5 (3.0)	8 (3.4)	11 (15.9)	18 (15.7)	42 (7.2)
Uveitis	30 (17.9)	31 (13.2)	15 (21.7)	21 (18.3)	97 (16.6)
Psoriasis	10 (6.0)	13 (5.6)	7 (10.1)	12 (10.4)	42 (7.2)
Inflammatory bowel disease	2 (1.2)	3 (1.3)	0	3 (2.6)	8 (1.4)

Randomized sets. The Classification and Regression Tree (CART) clustering algorithm used to stratify patients into endotypes was based on the following baseline characteristics: sex, onset age <40 years, disease duration <2 years, HLA-B27 status and presence of arthritis, enthesitis, dactylitis, uveitis, psoriasis, and inflammatory bowel disease. Unlike the published algorithm, buttock pain, triggering infection and NSAID response were not used to determine endotype, as these data were not collected in BE MOBILE 1 and 2. [a] n=233; [b] n=585; [c] Enthesitis is defined as MASES >0 at baseline. ASDAS: Axial Spondyloarthritis Disease Activity Score; ASQoL: Ankylosing Spondylitis Quality of Life; axSpA: axial spondyloarthritis; BASFI: Bath Ankylosing Spondylitis Functional Index; BKZ: bimekizumab; CART: Classification and Regression Tree; hs-CRP: high sensitivity C-reactive protein; HLA: human leukocyte antigen; MASES: Maastricht Ankylosing Spondylitis Enthesitis Score; NSAID: non-steroidal anti-inflammatory drug; PBO: placebo; PCS: physical component summary; Q: quartile; Q4W: every four weeks; SD: standard deviation; SF-36: 36-Item Short Form Health Survey.

At Wk 16, higher ASAS40 response rates were observed with BKZ vs PBO in both endotypes, sustained to Wk 104 with continuous BKZ (Endotype A: 49.1%; Endotype B: 56.5%; **Figure 1A**). Trends were largely similar for ASDAS-MI and ASDAS LDA (**Figure 1B–C**).

Reductions from baseline in ASDAS were greater in both endotypes with BKZ vs PBO at Wk 16 and sustained to Wk 104 with continuous BKZ (A: –1.7; B: –2.0; **Figure 1D**). Greater differences in responses with BKZ vs PBO were observed in Endotype B vs Endotype A.

The safety profile of BKZ was consistent across endotypes (treatment-emergent adverse events [TEAEs]: A: 89.1% [352/395], B: 90.5% [162/179]; serious TEAEs: A: 12.2% [48/395], B: 13.4% [24/179]).

Conclusion: BKZ showed comparable retention, efficacy, and safety to Wk 104 in pts with predominantly axial disease and with axial and peripheral manifestations. These data suggest pts with axSpA have improved outcomes with BKZ regardless of endotype.

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Bimekizumab, a dual IL-17 A and F blocker, has recently been added in the therapeutic rheumatologist's armamentarium of PsA, but real-world evidence is lacking. Phase 3 trials have suggested that its efficacy between TNFi-naïve and TNFi experienced patients is not significantly different. In this nationwide study we aimed to comparatively examine the efficacy of bimekizumab in biologic(b)/ targeted synthetic(ts)-DMARD-naive and IL-17Ai-experienced PsA patients.

Methods: Consecutive PsA patients, either b/ts-DMARD-naïve (Group 1) or IL-17Ai- experienced (Group 2) followed up from October 2024 – January 2025 were prospectively included and assessed at time-0 (commencement of bimekizumab) and at month-3. There were no exclusion criteria. The following characteristics were recorded: demographics, clinical

Table-1: Demographic and clinical characteristics of b/tsDMARD-naive and IL-17A experienced PsA patients included in the study

	PsA (n=33)		
	b/tsDMARD-naive (n=14)	IL-17A experienced (n=19)	p-value
Demographics			
Sex (females), n (%)	6 (42.9)	12 (63.2)	0.247
Age (years) mean ± S.D.	48.9 ± 14.0	53.7 ± 10.2	0.262
BMI (kg/m²) median (Q3-Q1)	25.2 (39.4-23.2)	30.7 (38-21)	0.328
Current Smoking, n (%)	3 (21.4)	9 (47.4)	0.126
Clinical			
Axial involvement, n (%)	3 (21.4)	7 (36.8)	0.309
Enthesitis, n (%)	4 (36.4)	12 (63.2)	**0.049**
Dactylitis, n (%)	4 (36.4)	3 (15.8)	0.375
Skin, n (%)	13 (92.9)	18 (94.7)	0.823
Nail disease, n (%)	4 (36.4)	12 (63.2)	**0.049**
Eye involvement, n (%)	0 (0.0)	1 (5.3)	0.383
IBD, n (%)	0 (0.0)	0 (0.0)	1.000

b/tsDMARD: biologic/target synthetic DMARD; IBD: Inflammatory bowel disease

features (peripheral arthritis, axial involvement, dactylitis, enthesitis, psoriasis, nail-, eye- and bowel- involvement) present throughout the disease , as well as laboratory parameters, clinical features and disease activity scores at time-0 and at month-3. Treatment characteristics (concurrent conventional synthetic (cs) DMARDs, previous bDMARDs treatment if any and reason for bimekizumab discontinuation, if so) were also recorded. Difference between scores was expressed as Delta (Δ) (score at time-0 minus score at month-3).

Results: In total 33 patients were enrolled. Fourteen patients were b/tsDMARD-naïve (Group 1) and 19 were IL-17Ai-experienced (Group 2). csDMARDs were co-administered in 50% and 42.1% of patients, respectively. In Group 2, 7 were switched directly from another IL-17Ai to bimekizumab, while 12 received other b/tsDMARDs in-between. Of note, 42.1% of patients in Group 2 had failed in two different IL-17A-inhibitors.

No significant differences were detected in the characteristics between the two groups apart from enthesitis and nail disease which were slightly more common in the latter (Table-1). At month 3, Disease Activity index for PsA (DAPSA) was significantly improved in both groups (Group 1; p=0.001, Group 2; p=0.002) (Table-2), while ΔDAPSA was comparable (Group 1; 10.8 ±14.6, Group 2; 15.5 ±13.1, p=0.258). Number of tender count joints (TJC)/ swollen count joints (SJC), as well as Body Surface Area (BSA) and ESR were also significantly improved for both groups (Table-2). ΔESR (Group 1; 12.0±12.5, Group 2;

16.6 ±28.8, p=0.813), as well as ΔTJC (Group 1; 4.2±6.0, Group 2; 4.8±4.8, p=0.741) and ΔSJC (Group 1; 2.3±3.7, Group 2; 3.5±3.6, p=0.338) were comparable between groups. ΔBSA was significantly higher for the Group 1 (Group 1; 5.6±4.2, Group 2; 2.6±6.5, p=0.007). Finally, in the whole cohort, Ankylosing Spondylitis Disease Activity Score was also significantly improved (time-0; 2.64±0.75, month-3; 1.95±0.96, p=0.01), This was also evident when Group 2 was analyzed separately, as Group 1 included only 3 patients with axial disease (Table-2). Two patients (6.1%) developed oral candidiasis.

Conclusion: In this real-world prospective study, we found that at 3 months bimekizumab is equally effective in b/tsDMARDs and IL-17A-experienced patients in almost all aspects of PsA. Also, bimekizumab was found to be effective for axial-PsA.

Comparison of standard and tapered dose of biologic treatments in patients with axial spondyloarthritis

MÜSLÜM FIRAT İKİKARDEŞ[1], EMRAH KOÇ[1], **GEZMIS KIMYON**[2], EMİNE DUYGU ERSOZLU[1] and TAYYIBE SALER[1], [1]ADANA SEHİR HASTANESİ, ADANA, Turkey, [2]MUSTAFA KEMAL UNIVERSITY, HATAY, Turkey

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: We aimed to compare the demographic and clinical characteristics of the patients with axial spondyloarthritis (aSpA) receiving standard-dose versus tapered-dose biologic disease-modifying antirheumatic drugs (bDMARD).

Methods: The patients with aSpA who visited the rheumatology outpatient clinics at our hospital between 1 October 2017 and 31 October 2023 were retrospectively analyzed. The patient's data were collected between 1 December 2023 and 30 November 2024. The demographic and clinical characteristics of the patients were compared between groups.

Results: A total of 251 patients were included in the study, with 105 patients in bDMARD tapered dose group (TDG) and 146 patients in standard dose group (SDG). Compared to SDG, there were more male patients in the TDG (75.2% vs. 57.5%, p=0.004). In the TDG, lower rates of obesity (27.6% vs. 47.9%, p=0.001), chronic disease (55.2% vs. 68.5%, p=0.032), fibromyalgia syndrome (FMS) (1.9% vs. 10.3%, p=0.009), ≥3 different bDMARDs usage (4,8% vs 26%, p=0,000), and nonsteroidal anti-inflammatory drug usage (23,8% vs 48,6%, p=0,000) were found. The TDG had a longer disease duration (median: 152 vs. 130 months, p=0.009), lower erythrocyte sedimentation rate (median: 5 mm/h vs. 8 mm/h, p=0.000), C-reactive protein (median: 3,1 mg/L vs 4,05 mg/L, p=0,033), current ankylosing spondylitis disease activity score-C-reactive protein level (median: 1.2 vs. 1.7, p=0.000), and a higher remission rate (87.6% vs. 58.2%, p=0.000). The most frequently used bDMARD in the TDG was etanercept (31,4%, 25 mg and 50 mg forms), and the second

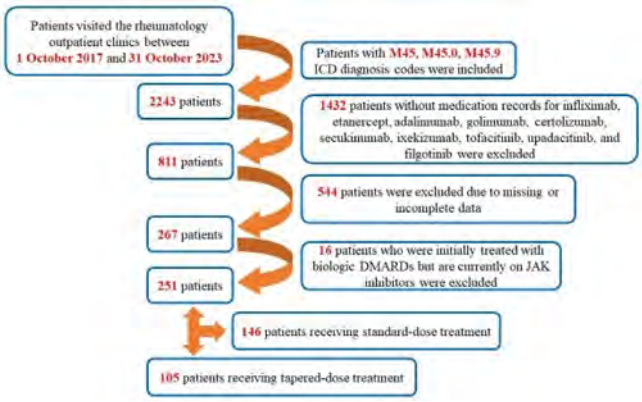

Figure 1: Flowchart of the study population selection

most commonly used was golimumab (%21,9). Compared to other bDMARDs, maintenance duration at the tapered dose of etanercept was longer (median: 102 vs 61 months, p=0.002).

Conclusion: bDMARD tapering was more frequently performed in male patients who do not have obesity, chronic diseases, or FMS. Etanercept was a drug that was most commonly tapered.

Table 1: Comparison of baseline characteristics between the tapered-dose and standard-dose groups

Efficacy and Safety of Vunakizumab in Patients with Active Ankylosing Spondylitis by Cigarette Smoking Status: A Post Hoc Analysis of a Randomized, Double-blind, Phase 2/3 Study

Hongbin Li[1] and Huilin Li[2], [1]Affiliated Hospital of Inner Mongolia Medical University, Hohhot, Nei Mongol, China (People's Republic), [2]Affiliated Hospital of Inner Mongolia Medical University, Hohhot, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Vunakizumab, a humanized anti-interleukin-17A monoclonal antibody, has shown significant efficacy and favorable safety in patients with active ankylosing spondylitis (AS), leading to its approval in China. This analysis aims to evaluate the impact of cigarette smoking status on the efficacy and safety of vunakizumab in patients with active AS.

Methods: This post hoc analysis used data from a randomized, double-blind, adaptive, seamless, phase 2/3 trial (NCT04840485) of vunakizumab in adult patients with active AS who were confirmed by radiographic evidence and met the modified New York criteria. In phase 2, eligible patients were randomized (2:2:1) to receive subcutaneous vunakizumab 120 mg, 240 mg, or placebo at weeks 0, 2, 4, 8, and 12. In phase 3, patients were randomized (2:1) to receive vunakizumab 120 mg (the optimal dose selected from phase 2) or placebo. In both phases, all patients continued to receive subcutaneous vunakizumab every 4 weeks from week 16 to week 32. The primary endpoint was the proportion of patients with at least 20% improvement in Assessment of SpondyloArthritis International Society (ASAS20) response criteria at week 16. This analysis pooled baseline, efficacy and safety data for patients receiving vunakizumab 120 mg or placebo in phase 2 and 3. Subgroup analyses were performed based on smoking status (never/former smoker or current smoker). Efficacy outcomes included ASAS20, ASAS40 and ASAS5/6. Logistic regression models were used to estimate the treatment difference in each subgroup, with stratification factors (weight, prior exposure to tumor necrosis factor-α inhibitors) as covariates. Safety was also assessed.

Results: A total of 440 patients were included in the analysis. Of these, 279 patients were never/former smokers (vunakizumab, n=182; placebo, n=97), and 161 patients were current smokers (vunakizumab, n=112; placebo, n=49). Baseline demographics and clinical characteristics were comparable between treatment arms within smoking status subgroups. The efficacy outcomes (ASAS20, ASAS40, ASAS5/6) from week 2 to week 16 are presented in Table 1. At week 16, among

Notes: ASAS20 response was defined as at least 20% improvement in ASAS criteria; ASAS40 response was defined as at least 40% improvement in ASAS criteria; ASAS5/6 response was defined as at least 20% improvement in five of the six ASAS domains; ASAS domains comprised Bath Ankylosing Spondylitis Functional Index, total back pain, patient global assessment, inflammation/morning stiffness, spinal mobility, and high-sensitive C-reactive protein. ASAS, Assessment of SpondyloArthritis International Society.

If patients withdrew from the study before 16 weeks, missing data were imputed using the Non-Responder Imputation (NRI) method.

For each visit, odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using a logistic regression model, with stratification factors (weight, prior exposure to tumor necrosis factor-α inhibitors) as covariates.

One-sided interaction P values were calculated using a logistic regression model, adjusting for stratification factors (weight, prior exposure to tumor necrosis factor-α inhibitors), subgroups (smoking status), and treatment-subgroup interactions.

never/former smokers, the ASAS20 response rates were 67.58% for vunakizumab and 46.39% for placebo (OR: 2.44; 95% confidence interval [CI]: 1.47, 4.06; nominal P=0.0006); among current smokers, the ASAS20 response rates were 62.50% for vunakizumab and 34.69% for placebo (OR: 3.26; 95% CI: 1.61, 6.63; nominal P=0.0011). Moreover, vunakizumab showed a rapid onset of action, with a higher ASAS20 response rate observed as early as week 2 compared to placebo in both subgroups. This elevated ASAS20 response was sustained through week 32 in both subgroups (Figure 1). Furthermore, no treatment-subgroup interaction term was observed for ASAS20, ASAS40 and ASAS5/6 responses from week 2 to week 16 (Table 1). The incidence of treatment-emergent adverse events (TEAEs) was similar across treatment arms within smoking status subgroups. During the 32-week treatment period, the majority of TEAEs were mild to moderate in severity.

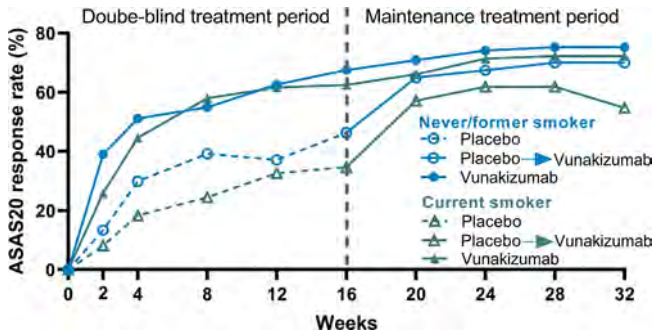

Figure 1. ASAS20 response rate from week 0 to week 32 by smoking status. Patients who received placebo from week 0 to week 16 were switched to receiving vunakizumab 120 mg after week 16 and those initially receiving vunakizumab 120 mg continued receiving vunakizumab 120 mg. ASAS20 response was defined as at least 20% improvement in ASAS criteria. ASAS, Assessment of SpondyloArthritis International Society.

Conclusion: Vunakizumab 120 mg showed significant efficacy and favorable safety in patients with active AS, regardless of cigarette smoking status.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: As a chronic inflammatory disease, PsA is marked by cartilage and bone turnover and articular inflammation. Accordingly, elevated levels of inflammation and bone metabolism are observed in PsA. Zasocitinib (TAK-279) is an oral, allosteric, highly selective and potent tyrosine kinase 2 (TYK2) inhibitor under clinical investigation for PsA treatment. In a phase 2b study in patients with active PsA (NCT05153148), ACR20 response rates were significantly greater with zasocitinib 15 mg or 30 mg once daily versus placebo (PBO) at Week 12 (primary endpoint; both $p = 0.002$). This study evaluated the longitudinal impact of zasocitinib on biomarkers of cartilage and bone turnover and inflammation in patients with active PsA, including associations between biomarker changes and clinical response.

Methods: In this multicenter, double-blind, PBO-controlled, dose-ranging phase 2b study, patients with active PsA were randomized 1:1:1:1 to zasocitinib 5, 15 or 30 mg or PBO, once daily for 12 weeks. Blood samples were collected at baseline (day 1), Week 4 and Week 12 (pre-dose, if applicable). Plasma biomarkers, including IL-6, colony stimulating factor 1 (CSF1), vascular endothelial growth factor A (VEGF-A), monocyte chemoattractant protein-2 (CCL8), tumor necrosis factor-like weak inducer of apoptosis (TWEAK), type VI collagen degradation marker (C6M), and matrix metalloprotease 3 (MMP3) were measured using the Olink Explore HT or Nordic (C6M) platforms. Longitudinal biomarker changes were modeled using a mixed-effect model, with baseline value, treatment, time and treatment–time interaction as fixed effects and patient as a random effect. Associations with clinical response (ACR20) were measured using absolute area under the receiving operator characteristic curve (abs AUC), adjusted for permutation.

Results: Overall, among 290 treated patients (zasocitinib or PBO), least-squares mean reductions in IL-6 and CSF1 at Week 4 and VEGF-A at Week 12 were associated with ACR20 response (abs AUC: 0.637, 0.627 and 0.637, respectively; $p = 0.018$, 0.036 and 0.018, respectively). Among ACR20 responders, zasocitinib-treated patients generally showed dose-dependent reductions from baseline in IL-6, VEGF-A, CCL8 and TWEAK at both Weeks 4 and 12 (**Figure 1**); in contrast, reductions from baseline in these parameters were not consistently observed in ACR20 non-responders, suggesting a link to intercurrent disease activity. At Week 4, dose-dependent C6M reductions were seen in patients receiving zasocitinib

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Zasocitinib treatment resulted in dose-dependent reductions in IL-6 (a), VEGF-A (b), CCL8 (c) and TWEAK (d) in ACR20 responders from baseline to Week 12.

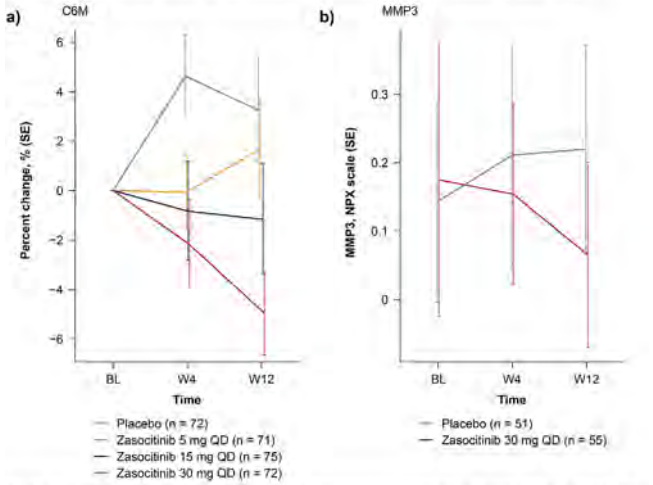
Biomarker levels, reported on a relative and log2 scale as normalized protein expression values, in each treatment group were quantified at different time points and were compared between treatment groups. To calculate change from baseline, the normalized protein expression for biomarkers of interest at baseline was subtracted from the normalized protein expression at each time point (baseline, Week 4 and Week 12) for each patient. The longitudinal change from baseline for each biomarker was modeled using a mixed effect model, with baseline value, treatment, time and treatment–time interaction as fixed effects, and the patient as the random effect. The least-squares mean and standard error were plotted for each biomarker at each time point. ACR20 responders were defined as patients who achieved ACR20 response at Week 12.
ACR, American College of Rheumatology; BL, baseline; CCL8, monocyte chemoattractant protein-2; IL-6, interleukin 6; QD, once daily; SE, standard error; TWEAK, tumor necrosis factor-like weak inducer of apoptosis; VEGF-A, vascular endothelial growth factor A; W, Week.

Figure 2. Dose-dependent reductions were observed in serum C6M in patients receiving zasocitinib 15 mg and 30 mg at Week 12, compared with placebo (a). Zasocitinib 30 mg reduced serum levels of MMP3 at Week 12 (b).



To calculate change from baseline, the normalized protein expression for biomarkers of interest at baseline was subtracted from the normalized protein expression at each time point (baseline, Week 4 and Week 12) for each patient. The longitudinal change from baseline for each biomarker was modeled using a mixed effect model, with baseline value, treatment, time and treatment–time interaction as fixed effects, and the patient as the random effect. The least-squares mean and standard error were plotted for each biomarker at each time point.
BL, baseline; C6M, type VI collagen degradation marker; MMP3, matrix metalloprotease 3; NPX, normalized protein expression; QD, once daily; SE, standard error; W, Week.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

15 mg and 30 mg, with significant reductions versus PBO (0.94-fold [$p < 0.05$] and 0.93-fold [$p < 0.01$], respectively); at Week 12 zasocitinib 30 mg had significant reductions in plasma C6M versus PBO (0.92-fold, $p < 0.01$; **Figure 2a**) and from baseline (5% reduction, $p < 0.01$). Zasocitinib 30 mg also reduced plasma MMP3 levels at Week 12 (**Figure 2b**).

Conclusion: Zasocitinib modulates biomarkers of cartilage and bone turnover and articular tissue inflammation in patients with active PsA as early as Week 4, with changes linked to ACR20 clinical response. Zasocitinib 30 mg significantly reduced bone turnover biomarkers at Week 12 versus PBO. Ongoing phase 3 studies (NCT06671483 and NCT06671496) are examining TYK2 inhibition in PsA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: We evaluated safety and efficacy of upadacitinib (UPA) versus adalimumab (ADA) at week 260 (5-years) from the long-term extension of SELECT-PsA 1.

Methods: Randomized patients with PsA received UPA 15mg once daily, UPA 30mg once daily, ADA 40mg every other week, or placebo for 24 weeks. At week 24, placebo groups switched to UPA15 or UPA30. Following approval of UPA15, patients on UPA30 switched to UPA15; earliest switch at week 104; data not presented). TEAEs were summarized for patients who received ≥1 dose of the drug using all 5-year data. Safety data are presented as exposure-adjusted event rates (EAERs; events per 100 patient-years) and exposure-adjusted incidence rates (EAIRs; patients per 100 patient-years). Efficacy endpoints were analyzed using nonresponder imputation (NRI) and as observed (AO) (binary endpoints), or mixed-effect model repeated measures and AO (continuous endpoints; P values are nominal).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure: Exposure-Adjusted Event Rates of Treatment-Emergent Adverse Events at Week 260 (5 Years)[a]

ADA, adalimumab; CPK, creatine phosphokinase; E, event; EAER, exposure-adjusted event rate; EAIR, exposure-adjusted incidence rate; EOW, every other week; GI, gastrointestinal; IBD, inflammatory bowel disease; MACE, major adverse cardiovascular event; NMSC, nonmelanoma skin cancer; PY, patient-year; QD, once daily; TB, tuberculosis; UPA, upadacitinib; VTE, venous thromboembolism.

[a]Treatment-emergent adverse events are defined as psoriasis events with onset on or after the first dose of study drug and ≤ 30 days after the last dose for UPA or ≤ 70 days for ADA.

[b]Includes patients treated with placebo that switched to UPA.

[c]Following a protocol amendment, all patients on UPA 30 mg switched to UPA 15 mg (earliest switch at week 104). For patients who switched from UPA 30 mg to UPA 15 mg, adverse events and exposure to UPA 30 mg were censored at the time of dose switch.

[d]Data are presented as EAERs (defined as E/100 PYs [95% CI] [number of E]) or as EARs (derived as n/100 PY [95% CI]) for a subset of treatment-emergent adverse events. For EAERs, total patient exposure was used with multiple events in the same patient included. For EARs, patients were censored at the time of the first event.

[e]Opportunistic infections excluding tuberculosis and herpes zoster.

[f]There was one case of abnormal lymphocyte morphology with UPA 15 mg, which is reported here, as this preferred term is included in the Malignant Lymphoma Standardised MedDRA Query, but it was not confirmed to be a true lymphoma.

[g]Defined as cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke.

[h]Includes deep vein thrombosis and pulmonary embolism (fatal and non-fatal).

Both treatment-emergent and nontreatment-emergent deaths are included. Deaths (listed by preferred term) include 20 with UPA 15 mg (1 cardiovascular death, 4 COVID-19, 3 COVID-19 pneumonia, 1 haematemesis, 1 lower respiratory tract infection, 1 metastatic lung cancer, 1 multiple organ dysfunction syndrome, 1 myocardial infarction, 1 pulmonary embolism, 1 road traffic accident, 1 sepsis, shock, 1 sudden cardiovascular death, 3 sudden death), 12 with UPA 30 mg (1 arteriosclerosis of coronary artery, 1 cardiac arrest, 1 circulatory collapse, 1 COVID-19, 5 COVID-19 pneumonia, 1 interstitial lung disease, 1 myocardial infarction, 1 pulmonary embolism), and 5 with ADA (1 acute myocardial infarction, 1 COVID-19 pneumonia, 1 drowning, 1 road traffic accident, 1 suicide).

Table. Efficacy Endpoints at Week 260 (5 Years)

ACR20/50/70, ≥ 20%/50%/70% improvement in ACR criteria; ADA, adalimumab; AO, as observed; EOW, every other week; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; LS mean, least squares mean; MDA, minimal disease activity; MMRM, mixed effected model repeated measurement; mTSS, modified total Sharp/van der Heijde Score; NRI, nonresponder imputation; NRS, numeric rating scale; PASI75/90/100, ≥ 75%/90%/100% improvement in PASI; QD, once daily; UPA, upadacitinib.

[a]Following a protocol amendment, all patients on UPA 30 mg switched to UPA 15 mg (earliest switch at week 104); data are presented by originally randomized treatment.

[b]In patients with psoriasis affecting ≥ 3% of body surface area at baseline.

[c]In patients with LEI > 0 at baseline; resolution LEI = 0.

[d]In patients with LDI > 0 at baseline; resolution LDI = 0.

[e]Data shown as LS Mean (95% CI) for MMRM and mean (SD) for AO.

[f]In patients with psoriatic spondylitis at baseline.

For NRI and MMRM analyses, nominal *P < .01 UPA 15 mg versus ADA; nominal #P < .05, ###P < .001 UPA 30 mg versus ADA.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 1704 patients received ≥1 dose and 983 (57.7%) completed 260 weeks. Most common reasons for discontinuation were AEs (8.4%), withdrawal of consent (6.2%), and lack of efficacy (4.7%). UPA's safety profile through week 260 (5-years) was comparable to ADA and consistent with week 104 and 152 data. Rates of malignancy excluding nonmelanoma skin cancer (NMSC), VTE, and MACE were low compared to historical comparators and generally similar across treatments. Serious infection, herpes zoster, anemia, lymphopenia, creatine phosphokinase (CPK) elevation, and NMSC rates were higher with UPA versus ADA; serious infection, herpes zoster, anemia, neutropenia, and CPK elevation were higher with UPA30 versus UPA15. Death rates (EAERs) were the same across UPA treatment groups and similar (< 1.0 difference) with ADA; COVID-19/COVID-19 pneumonia was the most common cause. UPA15 achieved ≥20%/50%/70% improvement in ACR response criteria (ACR20/50/70) and minimal disease activity (MDA) comparable to ADA at week 260 (AO). PASI (PASI75/90/100) improvements were also comparable between UPA15 and ADA at week 260 (AO). Using the more conservative NRI, responses were comparable for UPA15 versus ADA at week 260. HAQ-DI and patient assessment of pain changes were consistent through week 260 and comparable between UPA15 versus ADA (AO). Mean change in modified total Sharp/van der Heijde Score (mTSS) at week 260 was similar across treatments.

Conclusion: In patients with PsA and inadequate response/intolerance to ≥1 non-biologic DMARD, no new safety risks were identified with UPA up to 5 years; its safety profile remained consistent with ADA. Efficacy responses were generally maintained over time and comparable to ADA at 5 years.

Abstract Number: 1444

Real-world comparative effectiveness of tofacitinib, tumor necrosis factor inhibitors, and interleukin-17 inhibitors among patients with axial spondyloarthritis

Jeffrey Curtis[1], Genevieve Gauthier[2], Lara Fallon[3], David Gruben[3], You-Li Ling[4], Matthew Brouillette[3], Arne Yndestad[5], Yu hong[6] and Mona Kelkar[6], [1]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL, [2]Pfizer Canada ULC, Kirkland, QC, Canada, Montreal, Canada, [3]Pfizer Inc, New York, NY, USA, New York, [4]Pfizer Inc, New York, NY, USA, New York, NY, [5]Pfizer Inc, Oslo, Norway, Oslo, Norway, [6]Genesis Research Group, Hoboken, NJ, USA, New York

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: : In the context of an expanding therapeutic landscape and absence of head-to-head trials in axial spondyloarthritis (axSpA), data on direct comparison of effectiveness between the JAK inhibitor tofacitinib (TOFA) and other advanced therapies (AT), i.e., inhibitors of tumor necrosis factor (TNFi) and interleukin-17 (IL-17i) in patients (pts) with axSpA is lacking.

To compare real-world effectiveness of TOFA, TNFi, and IL-17i using an adapted version of a claims-based treatment (tx) effectiveness algorithm applied to the Komodo Healthcare Map®, a large US administrative claims database.

Methods: Adults with axSpA who initiated ≥1 selected AT on/after Dec 14 2021 (tofacitinib FDA approval date for ankylosing spondylitis) were selected and required to have continuous healthcare enrollment for ≥12 months before and ≥6 months after the index date (date of AT initiation). Pts could contribute multiple tx episodes of the analysis (i.e. multiple index dates) if they switched to a different AT over the study period. Pts with >1 AT administered/prescribed on the index date were excluded. Pts were classified into cohorts based on the AT initiated on each index date: (1) TOFA (2) TNFi (adalimumab, golimumab, infliximab, etanercept, certolizumab) and (3) IL-17i (ixekizumab, secukinumab). Propensity score weighting (PSW) was used to adjust for baseline confounders.

The proportion of pts fulfilling all effectiveness criteria over the 6-month study period was reported. Lack of effectiveness (i.e. not meeting all 8 effectiveness criteria) was compared between TOFA vs TNFi and TOFA vs IL-17i cohorts using Cox Proportional Hazards model with robust variance estimator to account for within patient correlation (multiple tx episodes). Results were reported as weighted hazard ratios (HR) and 95% confidence intervals.

Results: A total of 829 TOFA, 14,056 TNF and 4,472 IL-17i pts were included. Mean age at index ranged from 47 to 48 years; proportion of female range from 65% to 69%. In the pre-index period, 60% of TOFA pts had used ≥2 prior ATs, vs. 14% for the TNFi and 40% for the IL-17i cohort. Prior to PS weighting, use of steroid, opioid, non-opioid pain medications and csDMARDs at baseline was higher in the TOFA vs the TNFi and IL-17i cohorts.

After PS weighting, 28%, 32%, and 28% of pts in the TOFA, TNFi, and IL-17i cohorts met all effectiveness criteria. No difference in risk of effectiveness failure was found between cohorts: TNFi vs TOFA: HR=0.92 (0.84-1.01); IL-17i vs TOFA: HR=1.00 (0.89-1.11). Most common events associated with effectiveness failure were: use of a new pain medication class, low adherence to index tx, and switching/adding another non-index AT for axSpA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Effectiveness failure within 6 months in patients with axSpA initiating treatment with tofacitinib *versus* TNFi or IL-17i.

Weighting by odds, i.e. the standardized mortality ratio weight, was used to control for confounders when comparing outcomes between cohorts. Variables with SMD ≥0.1 were incorporated into the weighting and included demographics, treatment history, comorbidities and healthcare resource utilization and costs. Risk of failing effectiveness criteria were estimated using Cox proportional hazard model with robust (sandwich) variance estimator to account for within patient correlation. Variables with post-weighting SMD ≥0.1 were included as covariates in the model: Year of index, BL hypertension (yes/no), BL any cardiovascular disease (yes/no), and number of distinct advanced medications in pre-index history.

aHR, adjusted hazard ratio; AT, advanced therapy; axSpA, axial spondyloarthritis; BL, baseline; CI, confidence interval; csDMARD, conventional synthetic disease modifying antirheumatic drug; GC, glucocorticoid; IL-17i, interleukin-17 inhibitor; PDC, proportion of days covered; SMD, standardized mean difference; TNFi, tumor necrosis factor; TOFA, tofacitinib.

Conclusion: In this study using real-world data, pts with axSpA who initiated TOFA, TNFi, or IL-17i had similar effectiveness within the first 6 months of tx initiation. Overall response rate to TOFA in this real-world cohort, assessed using a claims-based effectiveness algorithm, was comparable ASDAS major improvement rates and numerically lower than ASAS40 response rates observed in published tofacitinib AS clinical trials. Longer term follow-up will allow confirmation of the robustness of these conclusions.

Abstract Number: 1445

Patient Characteristics, and Physician-Reported Treatment Effectiveness and Treatment Satisfaction with Bimekizumab for Axial Spondyloarthritis in the United States: Interim Analysis from a Real-World Study

Jessica A. Walsh[1], Abhijeet Danve[2], Isabel Truman[3], Dan Twigg[3], Hervé Besson[4] and Helena Roque[5], [1]Division of Rheumatology, Salt Lake City Veterans Affairs Health and University of Utah Health, Salt Lake City, UT, [2]Section of Rheumatology, Department of Medicine, Yale School of Medicine, New Haven, CT, [3]Adelphi Real World, Bollington, United Kingdom, [4]UCB, Breda, Netherlands, [5]UCB, Brussels, Belgium

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory condition affecting the sacroiliac joints and spine.[1] Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A and has demonstrated long-term clinical efficacy and safety in patients (pts) with axSpA across the full disease spectrum (non-radiographic [nr-]axSpA and radiographic [r-]axSpA).[2,3] BKZ was approved for axSpA treatment in the US in September 2024.[4]

This first presentation of BKZ real-world clinical data from the US describes physician-reported pt characteristics, including treatment history and disease severity, of pts with axSpA initiating BKZ in routine clinical practice in the US, and physician-reported effectiveness of BKZ treatment and satisfaction with disease control.

Methods: Interim data were drawn from the Adelphi Real World BKZ axSpA Plus Disease Specific Programme™, an ongoing cross-sectional survey in Canada, France, Germany, Italy, Japan, Spain, the UK and the US. Physician questionnaires on pts with PsA or axSpA undergoing BKZ treatment began in July 2024, staggered by country based on BKZ reimbursement; completion expected September 2025. Interim data from the US axSpA population are reported (data cut April 22 2025).

Physicians completed a questionnaire per patient at most recent visit including current and retrospective questions (answered as perceived by physicians and/or by medical records). We present pt characteristics at BKZ initiation, physician-reported overall disease severity (mild, moderate or severe; as perceived by physicians) at BKZ initiation and most recent visit, and physician satisfaction with disease control, at most recent visit (stratified by BKZ treatment duration [TD]: < 3, 3–6 or >6 months).

Pts with mild axSpA at BKZ initiation were excluded and no TD-related inclusion criteria were imposed. All analyses are descriptive; observed data reported.

Results: At interim data cut, 10 physicians provided data for 43 BKZ-treated pts with axSpA and available TD information **(Table)**.

Between BKZ initiation and most recent visit, physicians reported overall disease severity improvements with BKZ for all TDs including < 3 months, suggesting rapid treatment response. By the most recent visit, most pts had mild overall disease severity and none had severe disease severity **(Figure 1)**, demonstrating sustained improvements in disease control. At the most recent visit, physicians were satisfied/very satisfied with treatment for almost all pts across TD groups **(Figure 2)**.

Table. Characteristics and demographics of patients with available BKZ treatment duration data, at BKZ initiation, in the Adelphi Real World BKZ axSpA Plus Disease Specific Programme™

Baseline characteristic *(mean [SD] unless otherwise stated)*	**All patients in interim analysis[a]**
Age, years	39.5 (13.3)
Sex, n (%)[b]	
Male	26 (60)
Female	17 (40)
Diagnosed axSpA subtype, n (%)	
nr-axSpA	20 (47)
r-axSpA	23 (53)
Ethnicity, n (%)	
White	37 (86)
Black	2 (5)
South or Central American Native	1 (2)
East or Southeast Asian	1 (2)
South Asian	1 (2)
Middle Eastern or North African	1 (2)
Time since onset of axSpA symptoms,[c] years	5.6 (7.9)
Time since axSpA diagnosis,[d] years	2.6 (2.5)
Physician-reported overall disease severity at initiation, n (%)	
Moderate	29 (67)
Severe	14 (33)
BKZ treatment duration, months	7.6 (6.3)
BKZ treatment duration categories, n (%)	
<3 months	7 (16)
3–6 months	17 (40)
>6 months	19 (44)
Current advanced therapy treatment line,[e] n (%)	
1st line[f]	17 (40)
2nd line	20 (47)
3rd line or later	6 (14)
csDMARD prescribed concomitantly, yes, n (%)	11 (26)

Includes all patients with available treatment duration data. For each recruited patient, physicians completed Patient Reported Forms at most recent physician visit; baseline characteristics and demographics were collected retrospectively using physician-reported information and details from patients' medical records. [a] N=43 unless otherwise stated; [b] Biological sex, as recorded on patient medical records; categories were male, female and intersex, no patients were reported as intersex; [c] n=30; [d] n=42; [e] An advanced therapy is considered to be a prior biologic DMARD, targeted synthetic DMARD or JAK inhibitor; [f] No prior exposure to advanced therapy. axSpA: axial spondyloarthritis; BKZ: bimekizumab; csDMARD: conventional synthetic DMARD; DMARD: disease-modifying antirheumatic drug; nr-axSpA: non-radiographic axSpA; r-axSpA: radiographic axSpA; SD: standard deviation.

Conclusion: In real-world settings, physician-reported disease severity improved over time in BKZ-treated pts with axSpA regardless of TD. Physicians were satisfied/very satisfied with almost all pts' disease control on BKZ treatment across all TD groups. These results from routine clinical practice complement the rapid and sustained effectiveness of BKZ in pts with axSpA previously observed in phase 3 trials.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Failure of a first-line anti-TNF in axial spondyloarthritis (axSpA) is common, and when it occurs, there are no randomized clinical trials (RCTs) comparing the option of switching to a drug with a different mechanism of action (MoA) or cycling to a different anti-TNF. The aim of this study is to evaluate whether these treatment strategies influence the retention to second-line therapy after failure of first-line anti-TNF.

Methods: Data were obtained from the nationwide prospective registry BIOBADASER (Spanish Registry of Adverse Events of Targeted Therapies in Rheumatic Diseases). Patients diagnosed with axSpA who had failed a first TNFi and were starting a second advanced treatment (anti-TNF, IL17 inhibitors or JAK inhibitors) after 2016 were included in the study. Demographic variables, presence of HLA-B27, axSpA manifestations, as well as start and end dates of treatment and reasons for discontinuation were included in the study. Retention rates of the different drugs were estimated using Kaplan-Meier curves and Log rank test, considering discontinuation due to inefficacy or loss of efficacy as a completion event. Predictors of discontinuation were examined using the Cox multivariate regression model.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

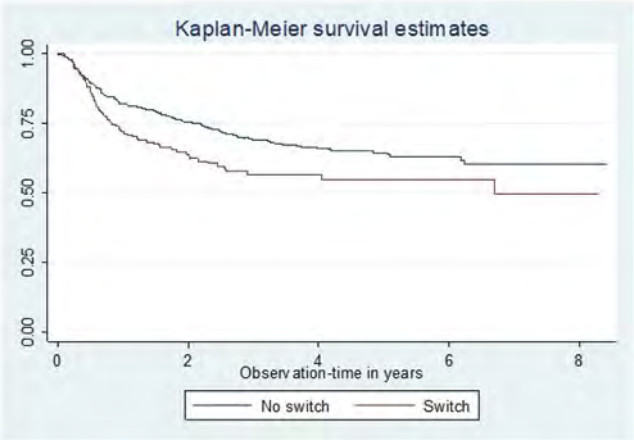

Figure 1. Kaplan - Meier survival estimates

Results: A total of 827 axSpA patients who met inclusion criteria were included in the analysis, 603 (72.9%) continued to another TNFi and 224 (27.1%) switched to different MoA (90.6% to an IL-17 inhibitor). Of all patients, 306 (37.0%) were female, mean (SD) age at treatment initiation was 48.4 (13.0) years, 697 (84.3%) had radiographic axSpA and 547 (66.1%) were HLA-B27 positive, with a mean disease duration of 9.8 (9.8) years.

No statistically significant differences in baseline characteristics were found between the two groups, except for a higher percentage of patients initiating second-line treatment after 2020 in the switch cohort versus the cycling cohort (60.3% vs 45.4%; $p < 0.001$).

The one-year retention rate until inefficacy was significantly higher in the cycling cohort compared to the switching cohort (82.3%; 95%CI [78.8 - 85.4] vs 71.3% [64.5 - 77.1]; Log Rank < 0,01) (Figure 1).

In the univariate analysis, switching to a different MoA was associated with a higher probability of treatment discontinuation (HR: 1.49 [1.14 - 1.90]; p = 0.004) (Table 1). This finding was confirmed in the multivariate analysis (HR: 1.50 [1.14–1.98]; p = 0.004). Other significant predictors of increased risk of discontinuation were obesity (HR: 1.57 [1.11–2.23]; p = 0.011) and nr-axSpA diagnosis (HR: 1.74 [1.23 - 2.44]; p = 0,002). In contrast, HLA-B27 positivity (HR: 0.70 [0.52–0.94]; p = 0.017) and second-line treatment initiation after 2020 (HR: 0.61 [0.46 - 0.80]; p < 0,001) were associated with a lower probability of discontinuation, suggesting a protective effect (Table 1).

Table 1. Univariate and Multivariate models.

	Univariate		Multivariate	
	HR (95% CI)	p-value	HR (95% CI)	p-value
Switch (reference: no switch)	1.49 (1.14 - 1.95)	**0.004**	1.50 (1.14 - 1.98)	**0.004**
Female (reference: male)	1.13 (0.87 - 1.47)	0.345	0.98 (0.74 - 1.30)	0.891
Rx axSpA (reference: No Rx axSpA)	1.81 (1.33 - 2.46)	**<0.001**	1.74 (1.23 - 2.44)	**0.002**
Age at treatment initiation	1.00 (0.99 - 1.01)	0.901	1.00 (0.99 - 1.01)	0.687
HLA-B27 positive (reference: HLA-B27 negative)	0.62 (0.47 - 0.83)	**0.001**	0.70 (0.52 - 0.94)	**0.017**
Obesity (BMI > 30) (reference: BMI < 25)	1.61 (1.15 - 2.26)	**0.006**	1.57 (1.11 - 2.23)	**0.011**
Year of second-line treatment initiation 2021-2024 (reference 2016-2020)	0.68 (0.51 – 0.89)	**0.005**	0.61 (0.46 - 0.80)	**<0.001**
Tobacco use: current (reference never)	0.94 (0.69 - 1.27)	0.676		
First line anti-TNF (reference adalimumab)				
Etanercept	1.12 (0.82 - 1.53)	0.463		
Infliximab	0.74 (0.49 - 1.13)	0.161		
Certolizumab pegol	0.91 (0.50 - 1.66)	0.770		
Golimumab	1.27 (0.84 - 1.92)	0.253		

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion:

1. In patients with axSpA, cycling to another anti-TNF agent after first-line anti-TNF failure is associated with a lower risk of discontinuation compared to switching to a treatment with a different mechanism of action.
2. HLA-B27 positivity and treatment initiation after 2020 were also associated with a lower risk of discontinuation.
3. In contrast, obesity and nr-axSpA diagnosis were associated with higher risk of discontinuation.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Secukinumab is a fully human monoclonal antibody that selectively inhibits interleukin-17A, demonstrating robust and sustained efficacy in moderate to severe psoriasis (PsO) and psoriatic arthritis (PsA) with a good safety profile in long-term trials.[1-3] Besides its efficacy in PsA, secukinumab may have a preventive effect in patients with PsO without clinical signs of PsA. Pooled clinical trials of secukinumab (ERASURE, FIXTURE and SCULPTURE) provide valuable data sets that can help in understanding PsA prevention with secukinumab treatment. This study aimed to explore the efficacy of secukinumab in preventing PsA in patients with PsO using pooled data from the ERASURE, FIXTURE and SCULPTURE trials and to indirectly compare these data with historical data in patients who were biologic-naïve.[4]

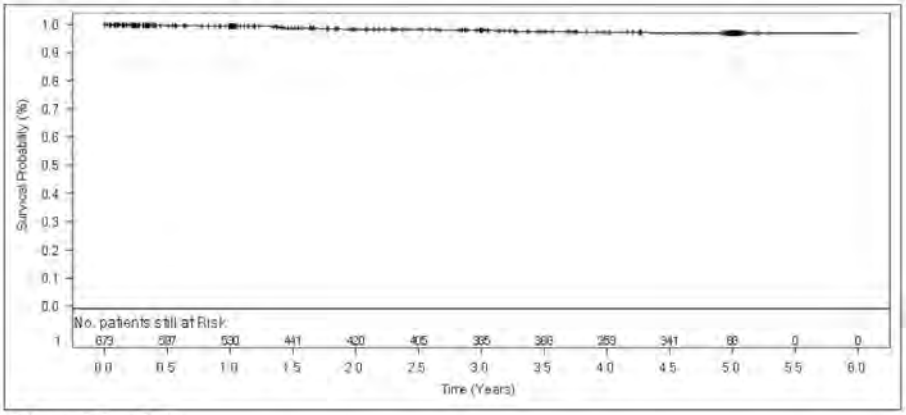
Methods: Patients with moderate to severe PsO (with no medical history of PsA at baseline) who were treated with secukinumab 300 mg through up to 5-year follow-up were included in this analysis. The incidence of PsA within the studies was assessed using exposure-adjusted incidence rates (EAIRs; incidence rate/100 patient-years [PY]). The preferred term 'psoriatic arthropathy' in the reported adverse events was used to capture the incident PsA. The time to develop PsA was estimated using Kaplan-Meier analysis. Efficacy was measured using Psoriasis Area and Severity Index (PASI) 90 and 100 responders (as observed data).

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Efficacy of secukinumab in patients with psoriasis without PsA at baseline over a 5-year follow-up period.

Endpoints	Study population (N)	Year 1	Year 2	Year 3	Year 4	≥Year 5
PASI 100 n/M (%)	673	242/570 (42.5)	139/334 (41.6)	115/316 (36.4)	107/290 (36.9)	92/252 (36.5)
PASI 90 n/M (%)	673	407/570 (71.4)	217/334 (65.0)	187/316 (59.2)	188/290 (64.8)	161/252 (63.9)

M, number of patients under evaluation; n, number of responders; N, number of patients in the study population; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis.



PsA, psoriatic arthritis.

Figure 1: Kaplan-Meier Curve for PsA development in patients with psoriasis without PsA at baseline over a 5-year follow-up period.

Results: Overall, 673 patients with active PsO without PsA were included in the analysis (mean age: 45.2 years; male: 71.8%; mean body mass index: 28.9 kg/m^2; mean time since diagnosis: 16.1 years). In total, 8% (N=54), 11.3% (N=76), 34.5% (N=232) and 46.2% (N=311) patients had < 2, 2-< 5, 5-< 15 and ≥15 years of disease duration, respectively. Overall, 18.3% of patients were biologic-experienced before the start of secukinumab. All patients had a PASI score of ≥10. After 5 years of treatment and a total exposure of 1831 PY, most patients (659/673 patients; 97.9%) did not experience PsA (**Fig. 1**). This translates into an EAIR of 0.76 (95% CI: 0.42,1.28). An 8-year prospective observational study previously reported a yearly PsA incidence rate of 2.7/100 patients in biologic-naïve patients with PsO without PsA.[4] When we indirectly compared these data with current data from pooled clinical trials, we found that incidence rate of PsA development was ~72% lower with secukinumab. At Year 5 of secukinumab treatment, 36.5% and 63.9% of patients achieved skin clearance (PASI 100) and PASI 90, respectively (**Table 1**).

Conclusion: These findings support the hypothesis that secukinumab may prevent PsA development in patients with PsO and suggest a potential protective effect against PsA. Additionally, secukinumab-treated patients demonstrated effective and sustained long-term control over skin clearance.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic disease, including psoriasis (Pso) and psoriatic arthritis (PsA), seems to affect male and female patients differently in clinical presentation, disease progression and advanced treatment response[1]. Sex influence on biologics has been described in bio-naive PsA population[2] previously, and this study investigates the sex impact on guselkumab (GUS) persistence in overall, bio-naive and bio-experienced Pso and/or PsA patients.

Methods: This study used data from the French administrative healthcare claims database (SNDS) on all adults with psoriatic disease who received their first GUS dispensation (index date) between 2019 and 2022. Patients were followed until death, treatment discontinuation or the end of the study period (12/31/2023). Two sub-groups were identified in the overall population of patients with a psoriatic disease, using surrogate markers of diagnosis: i) Pso patients (without PsA) and ii) PsA patients (with or without Pso). Treatment persistence for GUS depending on sex (i.e., the duration of treatment from initiation to discontinuation, defined as a drug-free interval of at least 120 days after the last dispensation of GUS) was estimated using the Kaplan-Meier method.

Results: Among the 9,478 patients who received at least one dispensation of GUS between 2019 and 2022, a total of 8,603 adult patients initiated treatment for psoriatic disease: 6,872 (79.9%) were Pso patients and 1,731 (20.1%) PsA patients. Males represented 55.6%, 58.2% and 54.8% of the overall, Pso and PsA populations, respectively. During the 5-year period before GUS initiation, 59.7% of patients had received at least one conventional disease-modifying antirheumatic drug

Table: Persistence of guselkumab

Population	Stratification	N (%)	Persistence (%) - 95% CI					
			12 months		24 months		36 months	
Psoriatic disease	Overall	8603 (100)	71.8	70.3-73.2	58.2	56.6-59.7	49.8	48.1-51.4
	Male	4783 (55.6)	74.4	72.4-76.3	60.8	58.7-62.7	52.5	50.2-54.8
	Female	3820 (44.4)	68.5	66.2-70.6	54.9	52.6-57.2	46.4	43.8-48.9
Pso	Overall	6872 (100)	73.6	72-75.2	59.6	57.9-61.3	51.2	49.3-53
	Male	4001 (58.2)	75.9	73.7-78	61.8	59.5-63.9	53.4	51-55.7
	Female	2871 (41.8)	70.4	67.8-72.9	56.6	54-59.2	48.1	45.1-51
PsA	Overall	1731 (100)	64.4	61-67.5	52.5	49-55.9	44.1	-*
	Male	782 (45.2)	66.5	61.4-71.1	56.0	50.8-60.9	48.0	-*
	Female	949 (54.8)	62.6	58-66.8	49.7	44.9-54.1	40.7	-*

*The follow-up of the PsA population was not sufficient to evaluate robustly the persistence at 36 months.

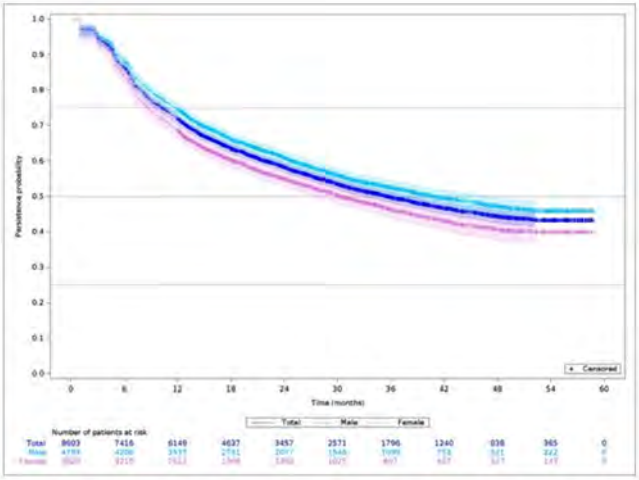

Figure: Persistence of guselkumab according to sex in psoriatic patients (overall population)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(DMARD) (Pso: 58.2%; PsA: 65.8%), and 61.8% had received at least one biologic DMARD (Pso: 57.2%; PsA: 79.8%). For overall population, persistence rates of GUS treatment at 12 months, 24 months, and 36 months were 71.8%, 58.2%, and 49.8% respectively, with 74.4%, 60.8%, and 52.5% for males and 68.5%, 54.9%, and 46.4% for females. For the Pso population, persistence rates were 73.6% at 12 months, 59.6% at 24 months and 51.2% at 36 months, with respectively 75.9%, 61.8% and 53.4% for males and 70.4%, 56.6% and 48.1% for females. For the PsA group, persistence rates were 64.4% at 12 months and 52.5% at 24 months, with respectively 66.5% and 56.0% for males and 62.6% and 49.7% for females. (Figure & Table). The median times to discontinuation were 35.6 months [95% CI: 33.6-38.0] for the overall population, 40.7 months [95% CI: 37.9-45,8] for males and 30.2 months [95% CI: 28.0-33.0] for females.

Conclusion: Consistent with previous findings showing that TNFi and IL-17i treatment persistence was lower for female PsA patients than for male, our results highlight the sex influence on GUS persistence in psoriatic disease, including PsO and PsA patients. These findings suggest that sex-related factors may influence treatment outcomes, emphasizing the need for tailored treatment strategies to enhance persistence in psoriatic disease management.

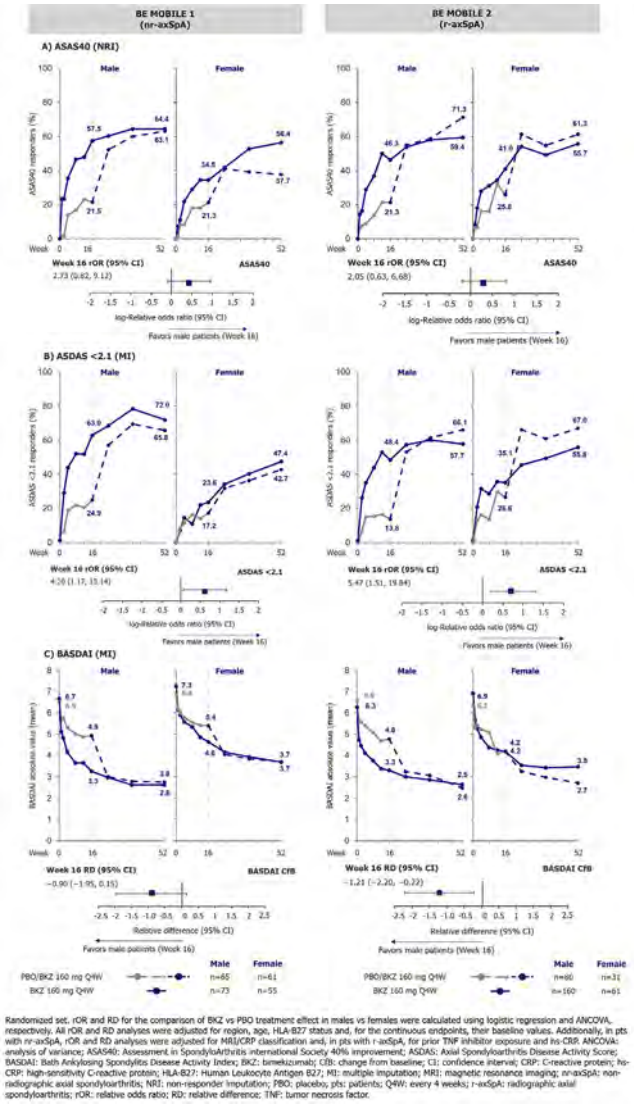
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. BKZ has shown sustained efficacy to Week (Wk) 52 in patients (pts) with non-radiographic/radiographic axial spondyloarthritis (nr-/r-axSpA) in the BE MOBILE 1 and 2 studies.[1,2] Studies have shown male and female pts with axSpA can experience different disease manifestations, clinical burden and treatment efficacy.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Randomized set. rOR and RD for the comparison of BKZ vs PBO treatment effect in males vs females were calculated using logistic regression and ANCOVA, respectively. All rOR and RD analyses were adjusted for region, age, HLA-B27 status and, for the continuous endpoints, their baseline values. Additionally, in pts with nr-axSpA, rOR and RD analyses were adjusted for MRI/CRP classification and, in pts with r-axSpA, for prior TNF inhibitor exposure and hs-CRP. ANCOVA: analysis of variance; ASAS40: Assessment in Spondyloarthritis international Society 40% improvement; ASDAS: Axial Spondyloarthritis Disease Activity Score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BKZ: bimekizumab; CfB: change from baseline; CI: confidence interval; CRP: C-reactive protein; hs-CRP: high-sensitivity C-reactive protein; HLA-B27: Human Leukocyte Antigen B27; MI: multiple imputation; MRI: magnetic resonance imaging; nr-axSpA: non-radiographic axial spondyloarthritis; NRI: non-responder imputation; PBO: placebo, pts: patients; Q4W: every 4 weeks; r-axSpA: radiographic axial spondyloarthritis; rOR: relative odds ratio; RD: relative difference; TNF: tumor necrosis factor.

Figure 1. ASAS40, ASDAS <2.1 and BASDAI to Week 52 and relative odds ratios and relative differences at Week 16, stratified by sex

Here, we assess efficacy of BKZ treatment to Wk52 in pts across the full axSpA disease spectrum, focusing on potential sex-based differences.

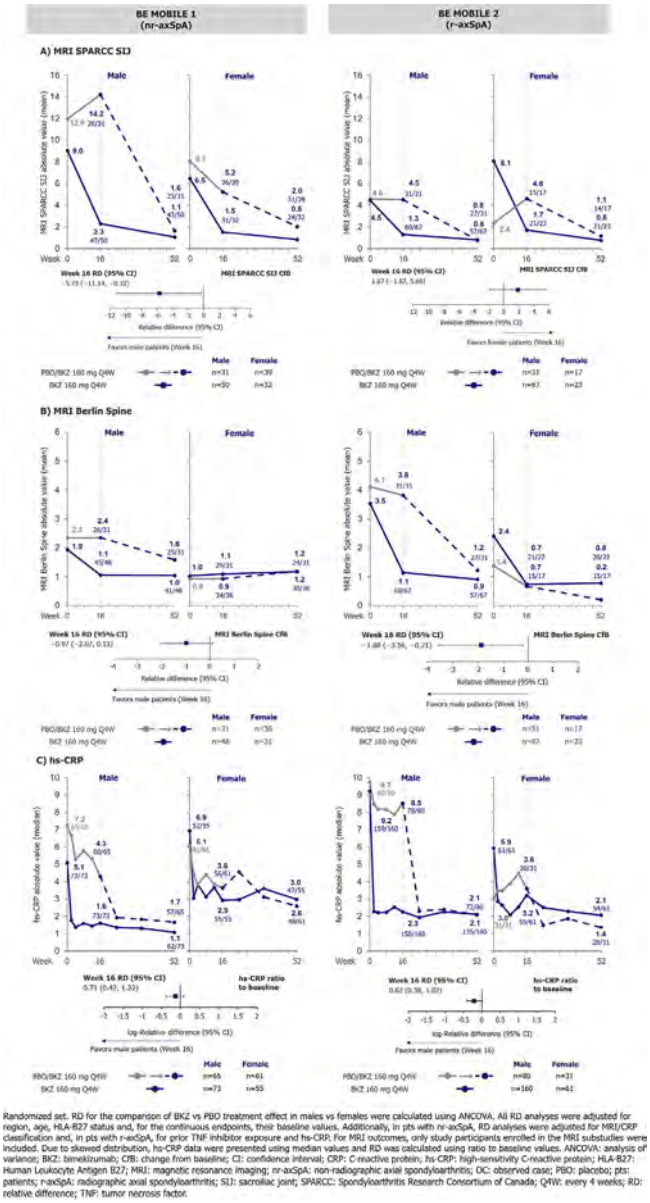
Methods: BE MOBILE 1 (NCT03928704) and 2 (NCT03928743) both comprised a 16-wk double-blind and 36-wk maintenance period. Pts were randomized to receive subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO); from Wk16, all received BKZ 160 mg Q4W.

Outcomes reported to Wk52, stratified by sex, include ASAS40, ASDAS < 2.1, BASDAI, Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) and objective signs of inflammation (OSI; MRI SPARCC SIJ, MRI Berlin spine and hs-CRP).

Results: 254 pts (M=138, F=116) were randomized in BE MOBILE 1 and 332 pts (M=240, F=92) were randomized in BE MOBILE 2; of these, 220/254 and 298/332 completed to Wk52.

Baseline (BL) differences between males and females included longer mean symptom duration (years) in females (**nr-axSpA**: 7.2 vs 11.1; **r-axSpA**: 12.9 vs 15.0) and lower HLA-B27 positivity (%) in females (**nr-axSpA**: 84.8 vs 69.0; **r-axSpA**: 88.3 vs 78.3). Across BKZ and PBO-randomized pts at BL, males had lower mean ASQoL scores vs females (**nr-axSpA:** BKZ: 8.5

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Randomized set. RD for the comparison of BKZ vs PBO treatment effect in males vs females were calculated using ANCOVA. All RD analyses were adjusted for region, age, HLA-B27 status and, for the continuous endpoints, their baseline values. Additionally, in pts with nr-axSpA, RD analyses were adjusted for MRI/CRP classification and, in pts with r-axSpA, for prior TNF inhibitor exposure and hs-CRP. For MRI outcomes, only study participants enrolled in the MRI substudies were included. Due to skewed distribution, hs-CRP data were presented using median values and RD was calculated using ratio to baseline values. ANCOVA: analysis of variance; BKZ: bimekizumab; CfB: change from baseline; CI: confidence interval; CRP: C-reactive protein; hs-CRP: high-sensitivity C-reactive protein; HLA-B27: Human Leukocyte Antigen B27; MRI: magnetic resonance imaging; nr-axSpA: non-radiographic axial spondyloarthritis; OC: observed case; PBO: placebo; pts: patients; r-axSpA: radiographic axial spondyloarthritis; SIJ: sacroiliac joint; SPARCC: Spondyloarthritis Research Consortium of Canada; Q4W: every 4 weeks; RD: relative difference; TNF: tumor necrosis factor.

Figure 2. MRI SPARCC SIJ, MRI Berlin spine score and hs-CRP absolute values to Week 52 and relative differences at Week 16, stratified by sex (OC)

vs 10.8, PBO: 8.6 vs 10.2; **r-axSpA:** BKZ: 8.3 vs 11.1, PBO: 8.4 vs 9.0), and generally had higher mean OSI values.

Across ASAS40, ASDAS < 2.1 and BASDAI change from BL (CfB), a pattern of higher BKZ vs PBO treatment effect in males vs females at Wk16 was reflected in the relative odds ratios (rORs) and relative differences (RDs) at this timepoint (**Figure 1**). At Wk52, response rates were higher/comparable in males vs females with nr-axSpA/r-axSpA respectively. Full results of ASAS40, ASDAS < 2.1 and BASDAI can be seen in **Figure 1**.

For ASQoL, males and females showed improvements with BKZ at Wk16 (**nr-axSpA**: –5.5 vs –4.8; **r-axSpA**: –4.8 vs –5.5) compared with PBO (**nr-axSpA**: –2.1 vs –2.9; **r-axSpA**: –3.1 vs –3.7). Improvements continued to Wk52 with BKZ (**nr-axSpA:** BKZ: –5.7 vs –6.2, PBO/BKZ: –5.5 vs –5.1; **r-axSpA:** BKZ: –5.4 vs –6.5, PBO/BKZ: –5.5 vs –5.8).

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

For CfB in OSI outcomes, RDs generally indicated a higher BKZ vs PBO treatment effect in males vs females at Wk16 (-**Figure 2**). However, absolute OSI values in males and females were generally comparable at Wk16, with values maintained or improved to Wk52 (**Figure 2**).

Conclusion: The treatment effect of BKZ vs PBO at Wk16 tended to be higher among male vs female pts with axSpA. However, at Wk52 female pts showed marked improvement and comparable efficacy to male pts following longer-term treatment with BKZ. Overall, efficacy of BKZ in clinical, patient-reported, and OSI outcomes was demonstrated in both pt populations across the full axSpA disease spectrum.

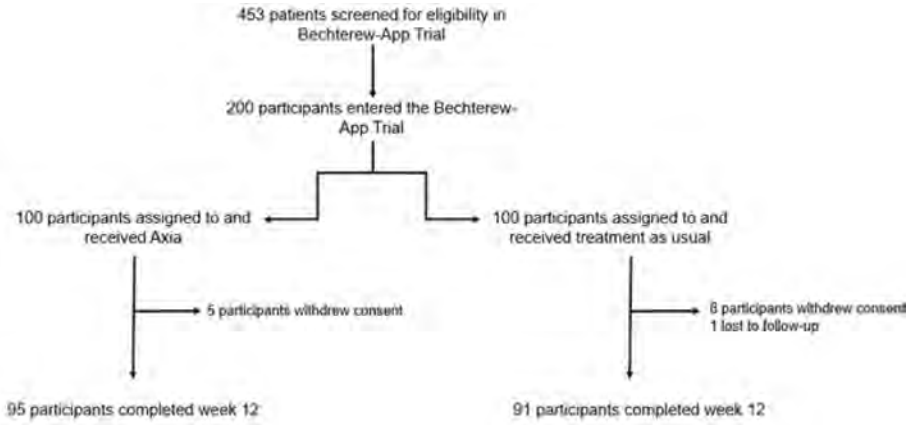
Baseline characteristics of the study population



Flowchart and trial design of the Bechterew-App Trial

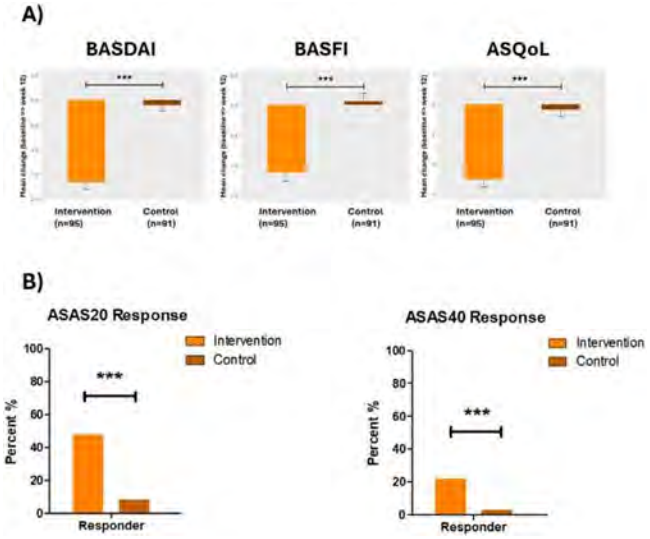
intervention combining individualized home exercise programs, patient education, and comprehensive disease management, incorporating structured gamification elements to support long-term adherence. To date, no DTx targeting rheumatic diseases has been convincingly demonstrated to improve disease activity.

The Bechterew-App Trial was designed as a nationwide, randomized, controlled interventional trial (RCT) to assess the efficacy of Axia over a 12-week period in German axSpA patients with stable pharmacotherapy.

Methods: In this 12-week RCT, 200 patients with axSpA receiving stable pharmacotherapy were randomized (1:1) to either using Axia (intervention group) or treatment as usual (control group) (Figure 1 and Figure 2). The primary endpoints are improvements in disease activity, measured by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI); disease-specific functionality, assessed by the Bath Ankylosing Spondylitis Functional Index (BASFI); and disease-specific quality of life, evaluated using the Ankylosing Spondylitis Quality of Life questionnaire (ASQoL). Secondary endpoints include responder analyses based on the Assessment of Spondyloarthritis International Society (ASAS)20 and ASAS40 response criteria.

Results: Of the 200 axSpA patients enrolled in the trial, 186 participants (95 in the intervention group and 91 in the control group) completed the study (Figure 2). Apart from a slightly higher proportion of female participants, no significant differences were observed between the groups at baseline (Figure 1). Participants in the Axia intervention group demonstrated significant and clinically meaningful improvements in disease activity (BASDAI: –1.66 [SD 1.41] vs. control: –0.11 [1.15];

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Results of the Bechterew-App Trial A) The intervention group showed improvements in mean BASDAI, BASFI and ASQoL The analysis was conducted using ANCOVA, adjusted for baseline values and sex. ***: p < 0.001. Abbreviations: ASQoL, Ankylosing Spondylitis Quality of Life Questionnaire; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index. B) Efficacy of Axia assessed by ASAS20 and ASAS40 response criteria. ASAS20 response was defined as an improvement of at least 20% and at least 1 unit (on a 0–10 scale) from baseline in three of four domains (spinal pain [BASDAI question 2], spinal inflammation [mean of BASDAI questions 5 and 6], physical function [BASFI], and patient global assessment by visual analogue scale [VAS]), with no worsening in the remaining domain (defined as a deterioration of ≥20% or ≥1 unit). ASAS40 response required an improvement of at least 40% and 2 units in three of the four domains without worsening in the fourth. ***: p < 0.001. Abbreviations: ASAS, Assessment of Spondyloarthritis International Society; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index.

p< 0.001), functional status (BASFI: −1.12 [1.40] vs. control: 0.06 [1.31]; p< 0.001), and disease-specific quality of life (ASQoL: –2.51 [2.55] vs. control: –0.16 [2.26]; p< 0.001), without meaningful changes in the control group (Figure 3A). Furthermore, a significantly higher proportion of patients in the intervention group achieved an ASAS20 response compared to the control group (51% vs. 9%; p< 0.001), and the ASAS40 response rate was also markedly higher (23% vs. 3%; p< 0.001) (Figure 3B). No concerning safety signals were detected.

Conclusion: In this 12-week RCT involving axSpA patients receiving stable pharmacotherapy, the DTx Axia significantly improved disease activity, functional status, and disease-specific quality of life. These findings support the potential of Axia as a novel therapeutic option for patients with axSpA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

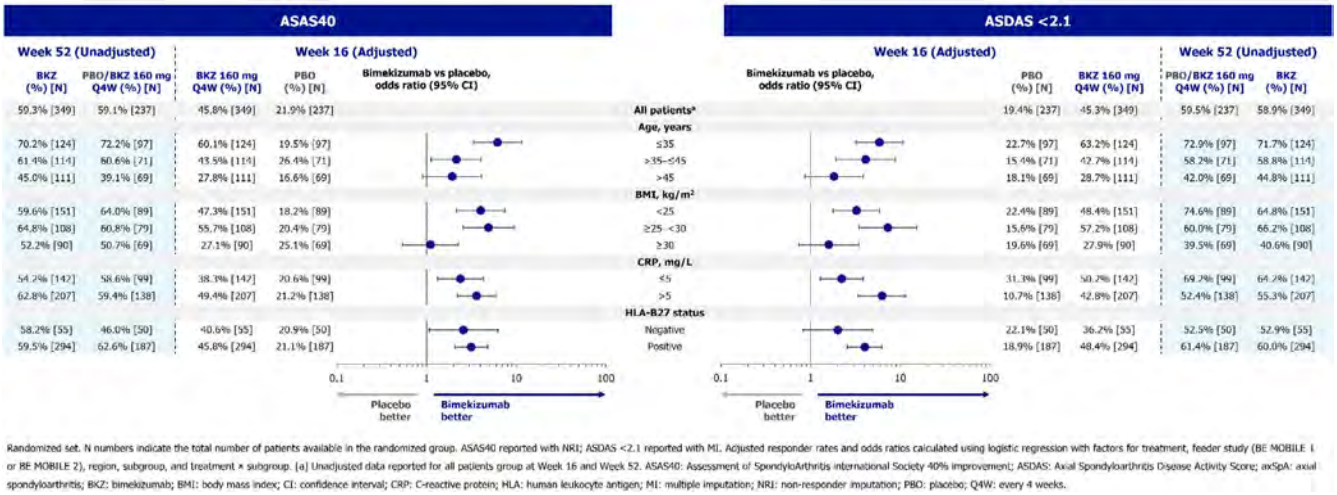
Background/Purpose: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has shown efficacy to Week (Wk) 52 in patients (pts) with axial spondyloarthritis (axSpA).[1] BKZ has shown comparable efficacy to 1 year (yr) across sexes,[2] and to 2 yrs in differing symptom durations;[3] the effect of other pt characteristics has not yet been reported. We report BKZ clinical outcomes to 1 yr in pts with axSpA stratified by age, BMI, CRP, and HLA-B27 status.

Methods: In BE MOBILE 1 and 2 (NCT03928704; NCT03928743), pts were randomized to subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO); all pts received BKZ Q4W from Wk 16–52.

To Wk 52, we analyzed proportions of pts achieving ASAS40 and ASDAS < 2.1, and change from baseline (CfB) in ASDAS, BASDAI, ASQoL, and objective signs of inflammation (OSI; MRI SPARCC SIJ and MRI Berlin Spine). Pooled pts were stratified by baseline age (≤35, >35–≤45, >45 yrs), BMI (< 25, ≥25–< 30, ≥30 kg/m^2), CRP (≤5, >5 mg/L), and HLA-B27 status (negative, positive). Binary endpoints used non-responder imputation; continuous endpoints used multiple imputation. OSI measures used observed case.

To compare Wk 16 BKZ treatment effect vs PBO stratified by subgroup, adjusted odds ratios and least squares (LS) mean differences were calculated using logistic regression and ANCOVA, respectively. No p values are provided due to the post hoc nature of analyses.

Results: Of 586 pooled pts, 349 and 237 were randomized to BKZ and PBO at baseline, respectively. Generally, larger improvements in clinical outcomes were seen for BKZ vs PBO across all subgroups at Wk 16; improvements were sustained/further improved to Wk 52 in all pts (**Figures 1–3**).



Randomized set. N numbers indicate the total number of patients available in the randomized group. ASAS40 reported with NRI; ASDAS <2.1 reported with MI. Adjusted responder rates and odds ratios calculated using logistic regression with factors for treatment, feeder study (BE MOBILE 1 or BE MOBILE 2), region, subgroup, and treatment × subgroup. [a] Unadjusted data reported for all patients group at Week 16 and Week 52. ASAS40: Assessment of SpondyloArthritis international Society 40% improvement; ASDAS: Axial Spondyloarthritis Disease Activity Score; axSpA: axial spondyloarthritis; BKZ: bimekizumab; BMI: body mass index; CI: confidence interval; CRP: C-reactive protein; HLA: human leukocyte antigen; MI: multiple imputation; NRI: non-responder imputation; PBO: placebo; Q4W: every 4 weeks.

Figure 1. Patients achieving ASAS40 (NRI) and ASDAS <2.1 (MI) at Week 16 and Week 52, stratified by baseline characteristic subgroups

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

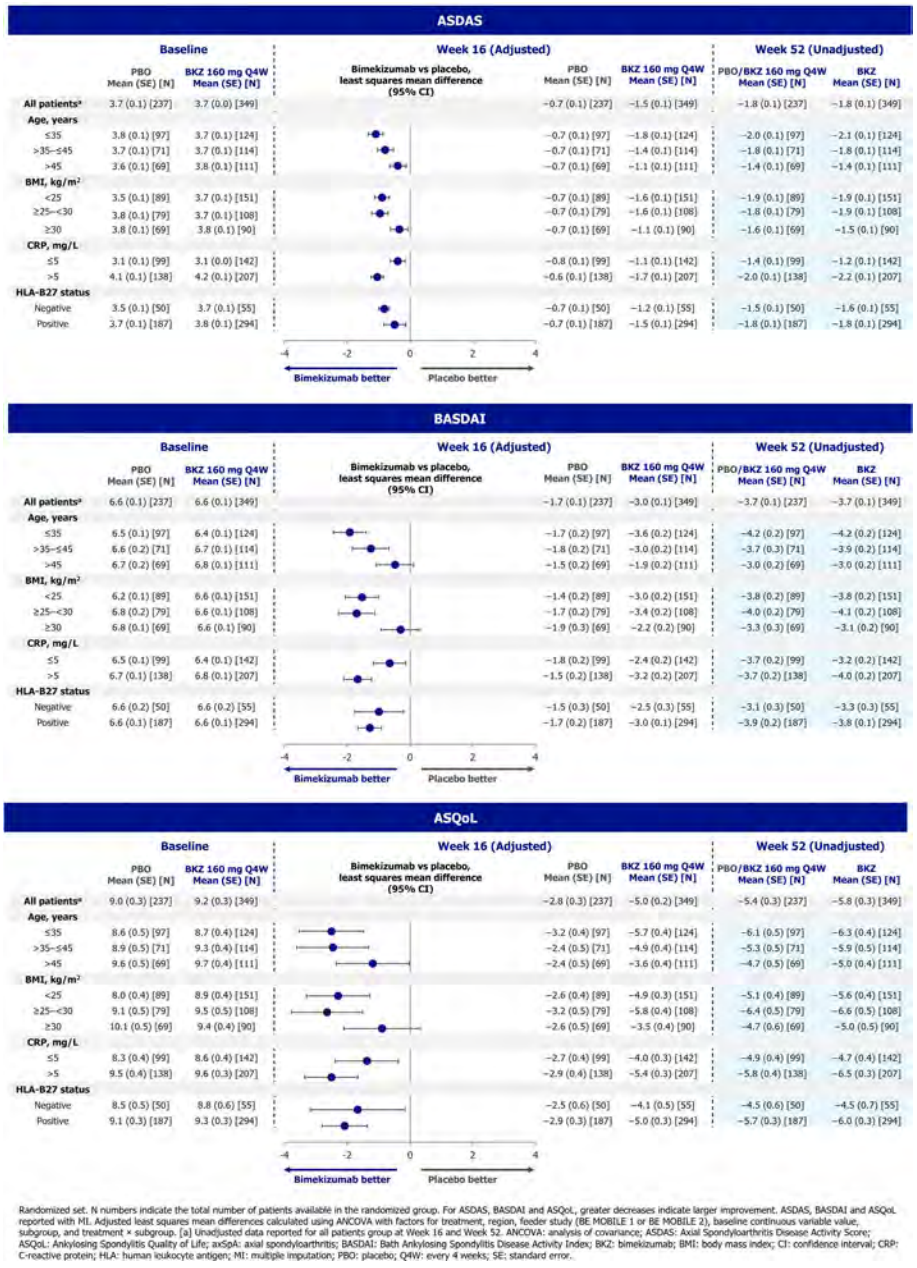


Figure 2. Mean change from baseline in ASDAS, BASDAI and ASQoL at Week 16 and Week 52, stratified by baseline characteristic subgroups (MI)

For ASAS40/ASDAS < 2.1, numeric differences in the proportions of pts achieving outcomes were detected between BKZ vs PBO at Wk 16 across subgroups except age >45 yrs, BMI ≥30 kg/m^2, and HLA-B27 negativity (ASDAS < 2.1 only). Within respective subgroups, at Wk 52, proportions achieving ASAS40/ASDAS < 2.1 were numerically higher in BKZ-randomized pts with age ≤35 yrs, BMI ≥25–< 30 kg/m^2, or HLA-B27 positivity (**Figure 1**).

For ASDAS/BASDAI/ASQoL, numeric differences in LS mean CfB were detected for BKZ vs PBO at Wk 16 across most subgroups except for age >45 yrs (BASDAI only), and BMI ≥30 kg/m^2 (BASDAI/ASQoL only). Within respective subgroups, at Wk 52, numerically larger improvements in mean CfB ASDAS/BASDAI/ASQoL were observed in BKZ-randomized pts with age ≤35 yrs, BMI ≥25–< 30 kg/m^2, CRP >5 mg/L, and HLA-B27 positivity (**Figure 2**).

For OSI, numeric differences in LS mean CfB were detected for BKZ vs PBO at Wk 16 across subgroups except for age >45 yrs and HLA-B27 negativity, BMI ≥30 kg/m^2 (MRI SPARCC SIJ only), and BMI < 25 kg/m^2 and CRP ≤5 mg/L (MRI Berlin

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

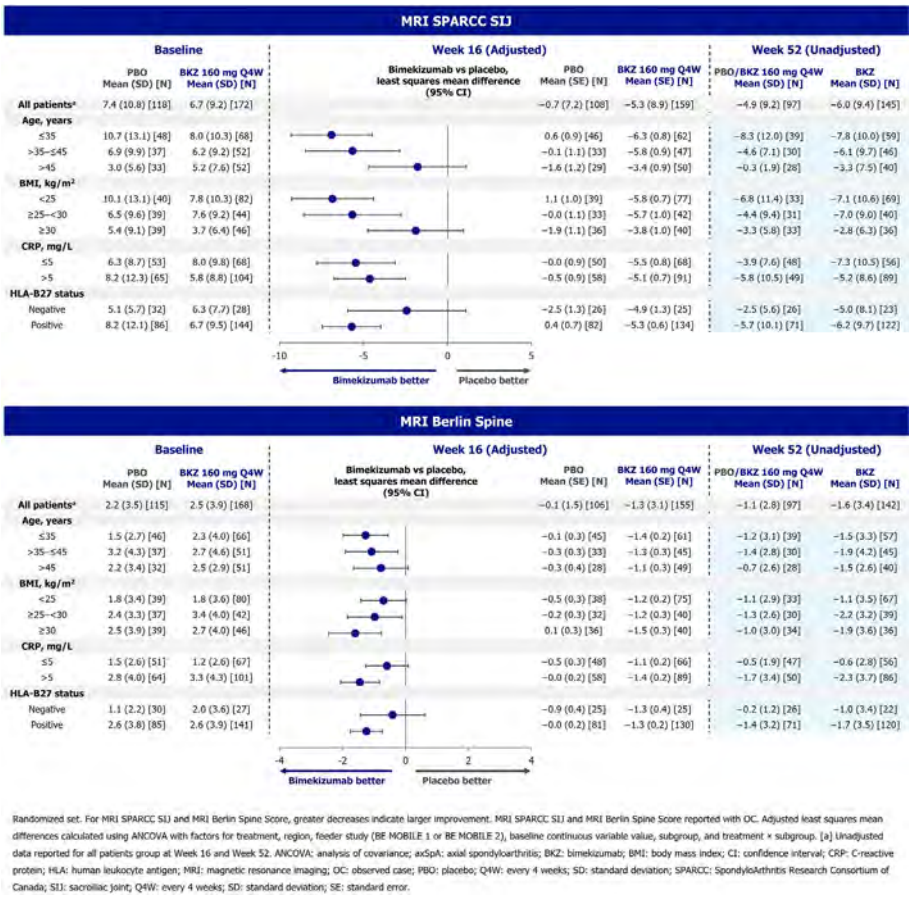

Figure 3. Mean change from baseline in MRI SPARCC SIJ and MRI Berlin Spine Score at Week 16 and Week 52, stratified by baseline characteristic subgroups (OC)

Spine only). Within respective subgroups, at Wk 52, numerically larger OSI improvements were seen in HLA-B27 positive pts only (**Figure 3**).

Conclusion: BKZ generally demonstrated greater improvements in clinical outcomes vs PBO at Wk 16. Improvements were sustained to 1 yr in pts with axSpA, regardless of pt demographics and baseline clinical presentation.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (AxSpA) is a chronic inflammatory disease that significantly impairs quality of life. Although biologic and targeted synthetic DMARDs (b/tsDMARDs) have improved disease control, a subset of patients remains treatment-refractory (TR), failing to achieve effective control of inflammation despite sequential use of multiple advanced therapies. This TR subgroup forms part of the broader group of difficult-to-manage (D2M) AxSpA patients. ASAS recently proposed a definition for both D2M and TR to guide research into these special populations [1].

Objectives: To describe the demographic and clinical features of treatment-refractory AxSpA patients in Greece and compare them with the non-TR subgroups.

Methods: Data were retrieved from the Greek AxSpA Registry, a prospective cohort (2022–2023) including patients fulfilling the 1984 modified New York criteria for radiographic AxSpA or the 2009 ASAS criteria for non-radiographic AxSpA. Patients were classified into three groups: non-D2M, D2M non-TR, and TR. TR patients met both of the following criteria: (1) inadequate response, defined as ASDAS ≥2.1 despite treatment with ≥2 b/tsDMARDs with different mechanisms, and (2) objective evidence of persistent inflammation (CRP >0.5 mg/dL). Demographics, clinical, radiographic features and comorbidities were compared among groups.

Table 1. Comparison of characteristics between Treatment Refractory (TR), non-TR Difficult-to-manage (D2M) and non-D2M patients with AxSpA

Variable	Non-D2M (n=355)	Non-TR D2M (n=18)	TR D2M (n=22)	p-value
Age, mean±SD, years	49.7 ± 14.6	51.2 ± 12.3	53.9 ± 9.7	0.387
Male gender, *n (%)*	250 (70)	11 (61)	13 (59)	0.395
Unemployed, *n (%)*	22 (6)	**5 (28)***	3 (14)	**0.008**
Radiographic AxSpA, *n (%)*	241 (70)	10 (56)	17 (77)	0.304
Disease duration since diagnosis, median (IQR), years	9 (4–17)	7 (5–12)	17 (8–23)	0.068
HLA-B27 positive, *n (%)*	192 (78)	**8 (57)****	13 (100)	0.026
BASDAI, median (IQR)	1.6 (0.6–2.8)	**4.9 (4.0–6.0)***	**4.4 (3.6–6.1)***	**<0.001**
ASDAS, median (IQR)	1.3 (0.9–1.7)	**2.9 (2.4–3.1)***	**3.1 (2.3–4.1)***	**<0.001**
BASFI, median (IQR)	1.8 (0.5–3.0)	**5.0 (4.4–6.2)***	**4.9 (3.9–8.0)***	**<0.001**
Global VAS, median (IQR)	1 (1–3)	**6 (4–7)***	**4 (3–8)***	**<0.001**
Pain VAS, median (IQR)	1 (0–2)	**5 (4–8)***	**4 (3–7)***	**<0.001**
CRP, median (IQR), mg/dL	0.3 (0.2–0.7)	0.4 (0.3–1.9)	**1.1 (0.9–2.1)***	**<0.001**
Syndesmophytes, *n (%)*	139 (39)	5 (28)	**15 (68)*****	**0.014**
Spine sections with syndesmophytes, median (IQR)	0 (0 – 2)	0 (0 – 1)	**1 (0 – 2)*****	0.012
Hip involvement (ever), *n (%)*	87 (25)	8 (44)	**10 (45)***	**0.021**
BMI ≥25 kg/m², n (%)	192 (59)	11 (69)	**19 (95)***	**0.005**
Current smokers, *n (%)*	114 (33)	7 (44)	**13 (65)***	**0.012**
Depression, *n (%)*	45 (13)	**7 (39)***	6 (30)	**0.002**
Number of comorbidities†, median (IQR)	0 (0–1)	**2 (1–3)***	**3 (1–3)***	**0.004**
Number of prior b/tsDMARDs, median (IQR)	0 (0–1)	**1 (1–3)***	**2 (1–3)***	**<0.001**

† Includes BMI ≥25 kg/m², arterial hypertension, dyslipidemia, diabetes mellitus, atherosclerotic disease, chronic obstructive pulmonary disease, osteoporosis, cancer
*Asterisks denote significant difference: * vs non-D2M, ** vs non-D2M AND TR, ***vs non-D2M AND non-TR D2M*

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Out of 395 AxSpA patients included in this analysis, 355 (89.9%) were classified as non-D2M and 40 (10.1%) as D2M, among whom 22 (5.6%) patients met criteria for TR disease. There was no significant difference regarding age, gender, disease duration and proportion of radiographic disease among the three groups (Table 1). However, compared to non-D2M patients, TR patients, as well as non-TR D2M patients, exhibited significantly higher BASDAI, ASDAS, BASFI, Global and Pain VAS ($p< 0.001$ for all), as well as a higher number of comorbidities ($p=0.004$). However, depression was more frequent in the non-TR D2M group only ($p=0.002$). Particularly TR patients had significantly more syndesmophytes, more frequent hip involvement, and were more often overweight and current smokers. Finally, in our cohort all TR patients were HLA B27 positive, compared to 57% of non-TR D2M and 78% of non-D2M patients ($p=0.026$).

Conclusion: Treatment-refractory AxSpA represents a subgroup of D2M patients with severe disease, characterized by persistent inflammation, functional impairment, more advanced structural damage, despite extensive use of advanced therapies, and multiple comorbidities. Early identification and implementation of tailored multidisciplinary care is needed to improve outcomes in this population.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The aim of this study was to compare the effectiveness of switching from a first-line TNFi to upadacitinib (UPA), an oral JAKi, versus cycling to another TNFi or switching from a TNFi to an IL-17 inhibitor (IL-17i) on tender and swollen joint involvement in patients with PsA.

Methods: Data were drawn from the Adelphi Real World Spondylarthritis (SpA) V and VI Disease Specific Programmes™, cross-sectional surveys administered to physicians (rheumatologists, dermatologists, and internal medicine specialists) and their consulting patients in routine clinical practice in Germany, France, Italy, Spain, the United Kingdom, and the United States (SpA VI only), with respective data collection periods from March 2021 to November 2021 for SpA V and from June 2023 to June 2024 for SpA VI. Adult patients with PsA who switched treatment from a TNFi in the first line of advanced therapy to another advanced therapy were stratified by the second-line therapy of interest: TNFi to UPA, TNFi to TNFi, or TNFi to IL-17i. The outcome of physician-reported assessment of both TJC ≤ 1 and SJC ≤ 1 was evaluated ≥ 3 months from treatment switch. Patient demographics and clinical characteristics were balanced using inverse-probability-weighted regression adjustment (IPWRA).The covariates balanced within the IPWRA were age, sex, Charlson Comorbidity Index (CCI), and severity at initiation of second-line therapy as reported by their physician for the weighting and regression adjustment stage, and additionally second-line treatment duration was used for the regression adjustment stage. The regression analyses were conducted separately for comparisons between TNFi to UPA and TNFi to TNFi as well as between TNFi to UPA and TNFi to IL-17i.

Results: Of the 320 patients included in the analysis who switched from a first-line TNFi, 101 switched to UPA, 96 switched to a second TNFi, and 123 switched to an IL-17i. Patient demographics are presented in **Table 1**. The most commonly used first-line TNFi in each group was adalimumab. The most commonly used second-line therapy in the TNFi to TNFi group was

Table 1: Patient Demographics and Characteristics

Parameter	TNFi to UPA N = 101	TNFi to TNFi N = 96	TNFi to IL-17i N = 123
Age, mean (SD)	45.9 (10.1)	51.1 (13.7)	48.4 (10.4)
Sex, n (%)			
Male	48 (48)	47 (49)	60 (49)
Female	53 (52)	49 (51)	63 (51)
Charlson Comorbidity Index, mean (SD)	0.1 (0.5)	0.1 (0.5)	0.2 (0.7)
Time since PsA diagnosis, years, mean (SD)	5.8 (3.7) n = 100	8.3 (7.1) n = 90	7.0 (5.4) n = 110
TNFi received as first-line, n (%)			
Adalimumab	85 (84)	61 (64)	95 (77)
Etanercept	8 (8)	22 (23)	18 (15)
Infliximab	2 (2)	8 (8)	3 (2)
Certolizumab-pegol	3 (3)	2 (2)	5 (4)
Golimumab	3 (3)	3 (3)	2 (2)
Advanced therapy received as second-line, n (%)			
Adalimumab	-	58 (60)	-
Etanercept	-	9 (9)	-
Infliximab	-	9 (9)	-
Certolizumab-Pegol	-	9 (9)	-
Golimumab	-	11 (11)	-
Secukinumab	-	-	76 (62)
Ixekizumab	-	-	45 (37)
Bimekizumab	-	-	2 (2)
Upadacitinib	101 (100)	-	-
Concurrent csDMARD use, n (%)	12 (12)	23 (24)	30 (24)
Prior csDMARD use, n (%)	77 (76)	69 (72)	95 (77)
Duration of first line TNFi, years, mean (SD)	2.8 (2.7)	1.9 (2.0)	2.7 (2.6)
Duration of current advanced therapy, years, mean (SD)	0.9 (0.5)	2.6 (3.1)	2.1 (1.5)
Reasons for switch, n (%)			
Joint condition worsened	45 (45)	39 (41)	65 (53)
Skin condition worsened	24 (24)	13 (14)	56 (46)
Secondary lack of efficacy (loss of response after initial response)	38 (38)	13 (14)	41 (34)
Disease activity worsened	16 (16)	5 (5)	10 (8)
Formulary driven switch	1 (1)	22 (23)	1 (1)
Disease severity[a] at second-line treatment initiation, n (%)			
Mild	8 (8)	11 (11)	9 (7)
Moderate	57 (56)	56 (58)	83 (67)
Severe	36 (36)	29 (30)	31 (25)
TJC at second-line treatment initiation, mean (SD)	7.7 (7.8) n = 101	8.4 (8.8) n = 29	7.9 (9.3) n = 70
SJC at second-line treatment initiation, mean (SD)	5.0 (7.0) n = 101	5.6 (6.3) n = 29	4.6 (7.8) n = 70

[a]Disease severity assessed by physician's definition of mild, moderate, and severe when completing the survey.
csDMARD, conventional synthetic DMARD; IL-17i, IL-17 inhibitor; TNFi, TNF inhibitor; UPA, upadacitinib

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

adalimumab while secukinumab was the most used second-line therapy in the TNFi to IL-17i group. The most frequent reason for switching reported by the physician was a worsening of the joints. At the time of switch, most patients had a physician-reported assessment of moderate/severe disease severity (TNFi to UPA: 92%; TNFi to TNFi: 89%; TNFi to IL-17i: 93%). After adjustment via IPWRA, significantly more patients in the TNFi to UPA group had physician-reported assessment of both TJC and SJC ≤ 1 at the time of data collection compared with patients in the TNFi to TNFi group (94% vs. 76%; $P = .0342$) and the TNFi to IL-17i group (91% vs. 72%; $P = .0123$) (**Figure 1**).

Conclusion: In this real-world study, a higher proportion of patients who switched from their first TNFi advanced therapy to UPA as their second-line advanced therapy had both TJC ≤ 1 AND SJC ≤1 than cycling to a second TNFi or switching to an IL-17i. The results demonstrate that switching to UPA after a TNFi may benefit patients with PsA.

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A.

Previous analyses of phase (Ph)2b/3 safety data (data cut-off: July 2023) demonstrated that BKZ was generally well tolerated by patients (pts) with axial spondyloarthritis (axSpA; exposure: 2,513.8 patient-years [PY]) and psoriatic arthritis (PsA; exposure: 3,655.9 PY) longer-term over ∼2 years.[1] Here, we present updated safety analyses from these studies, including another year of BKZ exposure from the ongoing Ph3 open-label extensions (OLEs).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Safety data are reported for two pools, each comprising one Ph2b and two Ph3 studies and their OLEs, in pts with axSpA (non-radiographic and radiographic) and PsA, respectively (**Figure**).[1]

Exposure-adjusted incidence rates (EAIR)/100 PY and n (%) are reported for treatment-emergent adverse events (TEAEs; classified using MedDRA v19.0) among pts who received ≥1 dose of subcutaneous BKZ 160 mg every four weeks (wks; Q4W) in any treatment period. Data are reported to the data-cuts of September 2024 (axSpA) or August 2024 (PsA) in the ongoing BE MOVING and BE VITAL OLEs (corresponding with ≥156 wks of total Ph3 study participation; **Figure**).

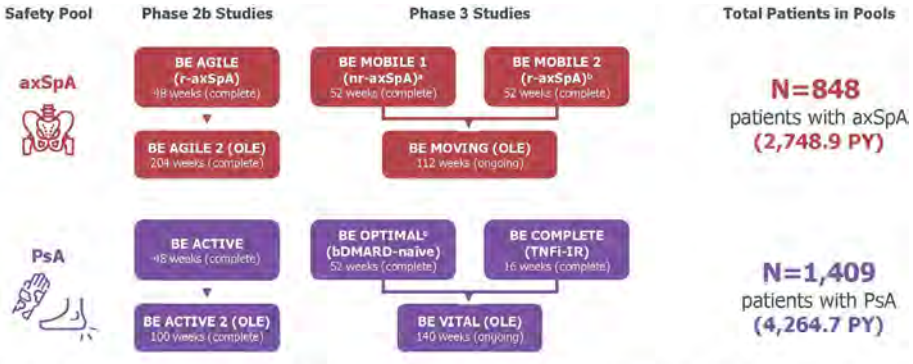
Results: The axSpA safety pool included 848 pts (2,748.9 PY); the PsA safety pool included 1,409 pts (4,264.7 PY; **Figure**).

Comparison of safety data with previous analyses did not indicate an increase in EAIRs of the majority of TEAEs; some TEAEs demonstrated an EAIR decrease with longer BKZ exposure, including *Candida* infections.[1] The 3 most frequently reported TEAEs in pts with axSpA and PsA (by preferred term) were corona virus infection, nasopharyngitis, and upper respiratory tract infection (**Table**).

Safety topics of interest are reported in the **Table**. Serious infections occurred at an EAIR/100 PY of 1.4 in pts with axSpA and 1.2 in PsA. The EAIR/100 PY of fungal infections was 8.1 in axSpA and 7.1 in PsA. Most fungal infections were muco-cutaneous and mild/moderate in severity; oral candidiasis was the most common fungal infection. Permanent BKZ discontinuation due to oral candidiasis was infrequent (axSpA: 0.2/100 PY; PsA: 0.3/100 PY). No systemic fungal infections were reported.

No cases of active tuberculosis, histoplasmosis, coccidioidomycosis or blastomycosis were reported in any study.

The EAIR/100 PY of hepatic events was 4.9 in axSpA and 4.6 in PsA; most were transient liver enzyme abnormalities (**Table**; no confirmed cases of Hy's law). For adjudicated definite/probable IBD, the EAIR/100 PY was 0.7 in axSpA and 0.2 in PsA. The uveitis EAIR/100 PY was 1.2 in axSpA and 0.1 in PsA.



Data from the September 2024 (axSpA) and August 2024 (PsA) data-cuts shown; including all patients who received ≥1 dose of BKZ 160 mg Q4W in the phase 2b/3 studies. Duration of overall treatment period shown; BKZ treatment duration by data-cut varied between patients, depending on study duration and initial randomization in the feeder studies. [a] Patients with nr-axSpA met Assessment of SpondyloArthritis international Society (ASAS) classification criteria. Patients with radiographic sacroiliitis were excluded; [b] Patients with r-axSpA met modified New York criteria and fulfilled ASAS classification criteria; [c] BE OPTIMAL also included an adalimumab treatment arm. Data from patients treated with adalimumab were not included in the PsA safety pool prior to switching to BKZ, but were included following the switch. ASAS: Assessment of SpondyloArthritis international Society; axSpA: axial spondyloarthritis; bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; nr-axSpA: non-radiographic axSpA; OLE: open-label extension; PsA: psoriatic arthritis; PY: patient-year; Q4W: every 4 weeks; r-axSpA: radiographic axSpA; TNFi-IR: tumor necrosis factor inhibitor inadequate response.

BE AGILE: NCT02963506; BE AGILE 2: NCT03355573; BE MOBILE 1: NCT03928704; BE MOBILE 2: NCT03928743; BE MOVING: NCT04436640; BE ACTIVE: NCT02969525; BE ACTIVE 2: NCT03347110; BE OPTIMAL: NCT03895203; BE COMPLETE: NCT03896581; BE VITAL: NCT04009499.

Figure. The two safety pools (axSpA, PsA) of patients treated with BKZ 160 mg Q4W across six phase 2b/3 studies and their open-label extensions

Data from the September 2024 (axSpA) and August 2024 (PsA) data-cuts shown; including all patients who received ≥1 dose of BKZ 160 mg Q4W. [a] Per investigator assessment; [b] Serious TEAEs met one or more of the following criteria: death, life-threatening event, significant or persistent disability/incapacity, congenital anomaly/birth defect, important medical event that may jeopardize the patient and may require medical/surgical intervention to prevent one of the previous mentioned outcomes, or initial inpatient hospitalization/prolongation of hospitalization; [c] No deaths were considered drug-related by the investigator in any study. No deaths reported in additional year of follow-up (Since July 2023); [d] TEAEs occurring in ≥6% of patients in both the axSpA and PsA patient pools; [e] Includes events described as drug-related hepatic disorders, excluding liver neoplasms; [f] Elevated liver enzymes include the following preferred terms reported as adverse events: increased/abnormal levels of ALT, AST, blood bilirubin, gamma-glutamyltransferase, hepatic enzyme, liver function test, total bile acids or transaminases; [g] axSpA: n=847; PsA: n=1,407; [h] Neutropenia includes additional preferred terms identified based on UCB-defined search criteria; [i] All patients had a history of psychiatric disorders or ongoing traumatic and stressful circumstances; [j] Crohn's disease: axSpA, n=10 (1.2%); PsA, n=2 (0.1%); ulcerative colitis: axSpA, n=6 (0.7%); PsA, n=2 (0.1%); unclassified: axSpA, n=5 (0.6%); PsA, n=5 (0.4%); [k] axSpA, n=15; PsA, n=13; [l] axSpA, n=833; PsA, n=1,396; [m] Includes the preferred terms autoimmune uveitis, iridocyclitis, iritis, and uveitis; [n] axSpA, n=130; PsA, n=21; [o] axSpA, n=718; PsA, n=1,388.

ALT: alanine transaminase; AST: aspartate aminotransferase; axSpA: axial spondyloarthritis; BKZ: bimekizumab; EAIR: exposure-adjusted incidence rate; IBD: inflammatory bowel disease; MACE: major adverse cardiovascular event; NEC: not elsewhere classified; NMSC: non-melanoma skin cancer; PsA: psoriatic arthritis; PY: patient-years; Q4W: every four weeks; SIB: suicidal ideation or behavior; TEAE: treatment-emergent adverse event; ULN: upper limit of normal.

Rates of suicidal ideation/behavior were low, and no cases of completed suicide were reported (**Table**). Rates of other safety topics of interest (major adverse cardiovascular events, malignancies, neutropenia, administration/injection site reactions) are shown in the **Table**.

No additional deaths occurred since the previous data-cut (**Table**).

Conclusion: With an additional year of exposure, the long-term safety profile of BKZ in pts with axSpA and PsA remained consistent with prior analyses; no new safety signals or concerns were raised.[1]

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Sonelokimab (SLK), a novel Nanobody that binds to both IL-17A and IL-17F with similarly high affinity, is designed to target difficult-to-reach sites of inflammation due to its small size and albumin-binding domain. ARGO was a Phase 2 trial of SLK in active PsA, which met its primary endpoint of ACR50 vs. placebo at Week (W) 12 for SLK 60mg and 120mg (with induction [WI]). Here, we report W24 data in the ARGO trial from a subset of patients naive to bDMARDs (prior biologic use was a stratification factor). We also describe the design of the Phase 3 IZAR-1 trial, which will further evaluate SLK 60mg WI and SLK 60mg with no induction (NI) in this patient population.

Methods: ARGO (NCT05640245) was a 24-week, global, randomized, placebo-controlled, double-blind trial of adults with active PsA (TJC68 ≥3 and SJC66 ≥3). Three SLK doses were assessed: 60mg NI (Q4W), SLK 60mg WI, and SLK 120mg WI (induction doses at W0, 2, 4, and 6; Q4W from W8). In this exploratory analysis, we assessed outcomes at W24 in patients without prior bDMARD exposure treated with SLK 60mg with or without induction (IZAR-1 doses).

Results: Of the 207 patients enrolled in ARGO (**Table**), 171 patients (82.6%) were naive to bDMARDs. SLK 60mg resulted in clinical responses at W24 in patients naive to bDMARDs (SLK 60mg WI, n=34; SLK 60mg NI, n=33), including ACR50 (SLK 60mg WI: 61.8%; SLK 60mg NI: 63.6%), the higher threshold of ACR70 (SLK 60mg WI: 41.2%; SLK 60mg NI: 45.5%), and the composite endpoint of minimal disease activity ([MDA]; SLK 60mg WI: 58.8%; SLK 60mg NI: 48.5%). For patients naive to bDMARDs with skin involvement (SLK 60mg WI, n=22; SLK 60mg NI, n=28), treatment with SLK resulted in notable PASI 90 (SLK 60mg WI: 81.8%; SLK 60mg NI: 67.9%) and PASI 100 responses (SLK 60mg WI: 68.2%; SLK 60mg NI: 57.1%).

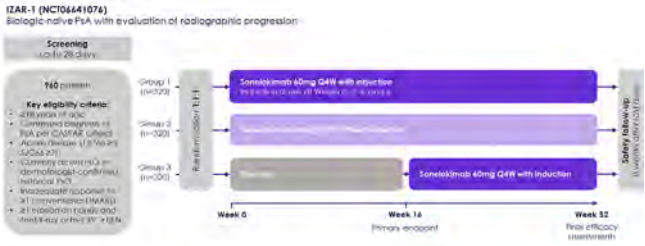
Table. Baseline characteristics from the ARGO trial

Table. Baseline characteristics from the ARGO trial

	All patients (N=207)	SLK 60mg Q4W NI (n=41)	SLK 60mg Q4W WI (n=41)
Age at screening, years, mean (SD)	48.6 (12.7)	50.3 (13.9)	47.5 (12.7)
Female, %	49.3	51.2	48.8
BMI [kg/m²], mean (SD)	29.0 (5.7)	29.6 (5.4)	27.7 (4.8)
Duration of PsA [years], mean (SD)	5.4 (5.8)	6.0 (5.7)	6.2 (7.4)
Naive to bDMARDs, n (%)	171 (82.6)	33 (80.5)	34 (82.9)
Concomitant non-biologic DMARD, %	74.4	82.9	68.3
Concomitant MTX, %	71.0	80.5	58.5
TJC68, mean (SD)	17.0 (12.4)	18.0 (12.2)	16.9 (14.1)
SJC66, mean (SD)	9.4 (7.1)	10.7 (8.2)	9.1 (7.1)
Affected BSA ≥3%, %	69.4	78.0	63.4
PASI [BSA ≥3%], mean (SD)	7.2 (6.6)	8.7 (5.7)	8.0 (9.7)
DAPSA score, mean (SD)	38.9 (18.9)	41.5 (20.5)	38.5 (19.6)

bDMARD, biologic disease-modifying anti-rheumatic drug; BMI, body mass index; BSA, body surface area; DAPSA, Disease Activity in Psoriatic Arthritis; DMARD, disease-modifying anti-rheumatic drug; MTX, metholrexate; NI, no induction; PsA, psoriatic arthritis; Q4W, every 4 weeks; SD, standard deviation; SJC66, 66 swollen joint count; SLK, sonelokimab; TJC68, 68 tender joint count; WI, with induction.

Figure. Study design



CASPAR, Classification Criteria for Psoriatic Arthritis; DMARD, disease-modifying anti-rheumatic drug; hs-CRP, high-sensitivity C-reactive protein; PsA, psoriatic arthritis; PsO, psoriasis; Q4W, every 4 weeks; SJC66, 66 swollen joint count; TJC68, 68 tender joint count; ULN, upper limit of normal.

Figure. Study design

SLK was well tolerated, with a safety profile consistent with IL-17 inhibition. Based on these findings, we have designed a 52-week, global, randomized, double-blind, PBO-controlled, Phase 3 trial in this patient population (IZAR-1; NCT06641076; **Figure**). An estimated 960 patients will be randomized 1:1:1 to receive SLK 60mg Q4W WI, SLK 60mg Q4W NI, or PBO (SLK 60mg WI from W16). Given the results from ARGO, this sample size should provide sufficient power to demonstrate a statistically significant difference for each SLK arm vs. PBO on the primary outcome of ACR50 at W16. Eligible participants will have a confirmed diagnosis of PsA (CASPAR criteria), active disease (TJC68 ≥3; SJC66 ≥3), currently active or dermatologist-confirmed historical psoriasis, inadequate response to ≥1 conventional DMARD, and ≥1 erosion on hands-and-feet X-ray or hs-CRP > the ULN. Key secondary outcomes (all vs. PBO at W16) include ACR20, PASI 90, and MDA; the PROs HAQ-DI and SF-36 Physical Component Summary; and radiographic progression (vdH-mTSS).

Conclusion: The Phase 2 ARGO study demonstrated high levels of clinical response with SLK, including in patients with active PsA naive to bDMARDs. The randomized Phase 3 IZAR-1 study will further assess outcomes with SLK in patients naive to bDMARDs and is actively recruiting, including at sites across the USA.

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Tildrakizumab (TIL) is an anti–IL-23 p19 monoclonal antibody approved for the treatment of adults with moderate-to-severe plaque psoriasis. In a Phase 2b trial in patients with active psoriatic arthritis (PsA; NCT02980692), TIL treatment significantly improved joint and skin symptoms and was well tolerated for up to 52 weeks. An open-label long-term extension (LTE) of that trial evaluated the safety of TIL through Week (W)208 of treatment in patients with active PsA.

Methods: Patients who completed treatment in the Phase 2b parent study, achieved ACR20 response at W52, and had sufficient clinical benefit per the investigator were eligible for the LTE. Patients continued to receive the same dose of TIL as in the parent study (200 mg every 4 weeks, 200 mg every 12 weeks [Q12W], or 100 mg Q12W) until parent study database lock (at least 52 weeks of treatment), after which all patients received TIL 100 mg Q12W through W208. Safety was assessed in all patients who entered the LTE and received ≥1 dose of TIL based on frequency and severity of adverse events (AEs); frequency of serious AEs (SAEs), AEs of special interest (AESIs), and AEs of clinical interest (AECIs); and presence of antidrug antibodies (ADAs) to TIL. Analyses were based on the treatment received.

Results: Of 303 patients from the parent study screened, 281 entered the LTE and received ≥1 dose of TIL, and 205 completed treatment through W208 (Table 1).

Any AEs, treatment-related AEs, SAEs, and treatment-related SAEs occurred in 79.7% (224/281), 19.6% (55/281), 14.2% (40/281), and 0.7% (2/281) of patients, respectively (Table 2). The most common treatment-related AEs were upper respiratory tract infection (3.2%) and nasopharyngitis (2.5%). A total of 6.0% (17/281) and 2.5% (7/281) of patients discontinued the study due to AEs and treatment-related AEs, respectively (Table 2), most due to infections and infestations. AESIs were reported in 4.6% (13/281) of patients and included infections and infestations (1.8%); cardiac disorders (1.1%; included 2 acute myocardial infarction events confirmed as major adverse cardiovascular events, not related to the study drug); malignancies (n = 2; 0.7%); respiratory, thoracic, and mediastinal disorders (n = 2; 0.7%); and vascular disorders (n = 1; 0.4%;

Aortic dissection	0	1 (4.5)	0	0	0	1 (0.4)
AECIs	0	0	0	0	1 (0.7)	1 (0.4)

Data are shown as n (%).

[a]Includes 1 patient each with gastritis, hyperbilirubinemia, nonalcoholic steatohepatitis, abdominal abscess, intestinal sepsis, pulmonary tuberculosis, septic shock, urinary tract infection, or arthritis.

[b]AESIs included severe infections, malignancies, confirmed major adverse cardiovascular events, and drug-related hypersensitivity reactions. Totals for the number of patients at the system organ class level may not align with the sum of patients with events at the preferred term level since a patient may report ≥2 different AESIs within the system organ class level.

AE, adverse event; AECI, adverse event of clinical interest; AESI, adverse event of special interest; COVID-19, coronavirus disease 2019; LTE, long-term extension; Q4W, once every 4 weeks; Q12W, once every 12 weeks; SAE, serious adverse event; TIL100, tildrakizumab 100 mg; TIL200, tildrakizumab 200 mg.

Table 3. Summary of ADA immunogenicity status and neutralizing antibodies in the LTE study

	TIL200 Q4W n = 5	TIL200 Q12W n = 22	TIL100 Q12W n = 49	TIL200 Q4W to TIL100 Q12W n = 54	TIL200 Q12W to TIL100 Q12W n = 151	Total N = 281
Evaluable patients						
Conclusive	2 (40.0)	11 (50.0)	48 (98.0)	53 (98.1)	150 (99.3)	264 (94.0)
Inconclusive[a]	2 (40.0)	4 (18.2)	0	1 (1.9)	1 (0.7)	8 (2.8)
Missing	1 (20.0)	7 (31.8)	1 (2.0)	0	0	9 (3.2)
Immunogenicity status						
Negative[b]	2 (40.0)	11 (50.0)	47 (95.9)	51 (94.4)	142 (94.0)	253 (90.0)
Non-treatment-emergent positive[c]	0	0	1 (2.0)	2 (3.7)	5 (3.3)	8 (2.8)
Treatment-emergent positive[d]	0	0	0	0	3 (2.0)	3 (1.1)
Neutralizing antibody, non–treatment-emergent						
Neutralizing negative	0	0	0	0	0	0
Neutralizing positive	0	0	0	0	2 (1.3)	2 (0.7)
Neutralizing antibody, treatment-emergent						
Neutralizing negative	0	0	0	0	0	0
Neutralizing positive	0	0	0	0	1 (0.7)	1 (0.4)

Data are shown as n (%).

[a]Patients who had negative pretreatment and post-dose samples and whose last post-dose sample had a tildrakizumab concentration at or above the drug tolerance limit for the ADA assay.

[b]Patients who had negative pretreatment and post-dose samples and whose last post-dose sample had a tildrakizumab concentration below the drug tolerance limit for the ADA assay.

[c]Patients who had a positive pretreatment sample and all negative post-dose samples or who had positive pretreatment and post-dose samples with a titer increase <2-fold post-dose.

[d]Patients who had a negative pretreatment sample and ≥1 positive post-dose sample (treatment-induced positive) or who had positive pretreatment and post-dose samples with a titer increase ≥2-fold post-dose (treatment-boosted positive).

ADA, antidrug antibody; LTE, long-term extension; Q4W, once every 4 weeks; Q12W, once every 12 weeks; TIL100, tildrakizumab 100 mg; TIL200, tildrakizumab 200 mg.

Table 2). Only 1 AECI (viral infection) occurred during the LTE. AEs leading to death were reported in 2 patients (1 aortic dissection and 1 metastatic adenocarcinoma), both deemed unrelated to the study drug (Table 2).

A total of 2.8% (8/281) and 1.1% (3/281) of patients were positive for non–treatment-emergent (TE) and TE ADAs, respectively; 0.7% (2/281) and 0.4% (1/281) had non–TE and TE neutralizing antibodies (nAbs; Table 3). Patients' TE ADA-positive or nAb-positive statuses were not associated with AEs of hypersensitivity or injection-site reactions, AESIs, or AECIs. The effects of ADAs and nAbs on TIL clearance could not be quantified due to the low number of ADA-positive patients.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The safety of TIL was maintained through W208 of treatment in patients with PsA, with no new safety signals. These data support continued development of TIL to treat patients with active PsA.

Abstract Number: 1457

Real-world Patient Trajectories in Psoriasis and Psoriatic Arthritis: a Retrospective Study

Philip J. Mease[1], Qi Wei[2], Lawrence Huang[3], Jason Hawkes[4], Clive Liu[5], Ying Wu[6], Tony Wang[7], Anthony Hager[8] and Jennifer Hadlock[3], [1]Department of Rheumatology, Providence-Swedish Medical Center and University of Washington, Seattle, WA, [2]Institute for Systems Biology, Seattle, WA, [3]Institute for Systems Biology, Seattle, [4]Oregon Medical Research Center, Portland, OR, [5]Bellevue Dermatology, Bellevue, [6]Bristol Myers Squibb, Princeton, NJ, [7]Bristol Meyers Squib, Princeton, NJ, [8]Bristol Myers Squibb, Seattle, WA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Real world data from community healthcare systems can provide insights into patient trajectories with psoriasis (PsO) and psoriatic arthritis (PsA): baseline characteristics, patterns of treatment, and transitions between PsO and PsA.

Methods: Patients with a new PsO or PsA diagnosis were identified from 51 hospitals and 1,085 clinics in Providence Health & Services, which serves urban centers and rural catchment areas across seven states in the Western US. The study period was Jan 1, 2011 to Aug 31, 2023. The PsO cohort index time t_0 was the first diagnosis of PsO without PsA, and the PsA t_0 was the first diagnosis of PsA. Baseline characteristics were determined by the most recent results during the year before t_0. Medication use was observed for 6 months after t_0. For the PsO cohort, we analyzed time-to-onset of PsA. For the PsA cohort, we analyzed time-to-augmentation and time-to-discontinuation for the first line of systemic immunomodulatory therapy (excluding steroids and NSAIDs). Time-to-event analyses were conducted using Aalen-Johansen survival estimators. Patients were right-censored at the end of their most recent encounter or at the end of the study period, whichever came first, and death considered as a competing outcome.

Area deprivation index, state > 5th decile	32513 (36.5)	9327 (40.4)

Data are n (%) or median (IQR). IMID = immune-mediated inflammatory disease. IQR = interquartile range. AI/AN, American Indian and Alaska Native. NHPI, Native Hawaiian and other Pacific Islander. NA = not applicable. For binary variables, p values are calculated by the Fisher's exact method; for categorical variables, p-values are calculated by the Chi-squared test of independence; for continuous variables, p-values are calculated by the Mann-Whitney U test. *Time of first diagnosis is defined as the first noted date of a patient's diagnosis or the first time they came to Providence for care. Total patients with Psoriasis diagnosis, excluding patients with pre-existing PsA diagnosis. Diagnoses in EHR may reflect initial misdiagnosis of rheumatoid arthritis prior to diagnosis of PsA.

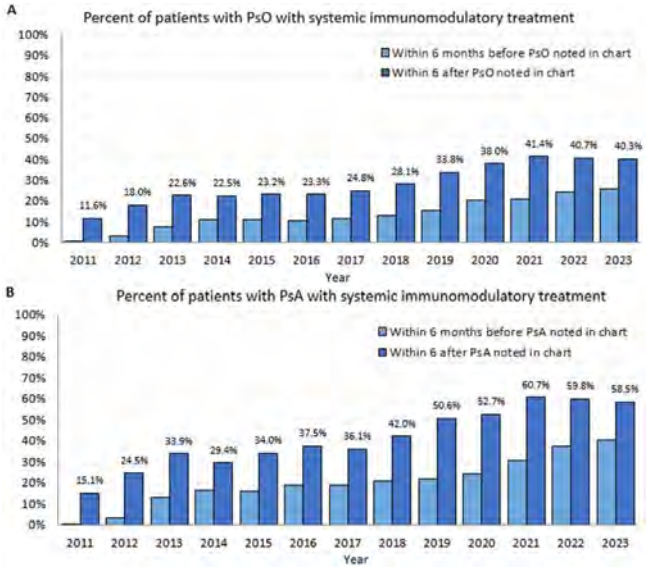

Figure 1. (A) Patients' systemic immunomodulatory treatment six months prior to the first diagnosis and six months after the first diagnosis. (A) Patients with Psoriasis condition and without pre-existing Psoriatic arthritis (PsA) condition (B) Patients with PsA condition. Systemic immunomodulatory treatment includes medications used for PsO, PsA, but not steroids or NSAIDs. Time of first diagnosis is defined as the first noted date of a patient's diagnosis within the healthcare system

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

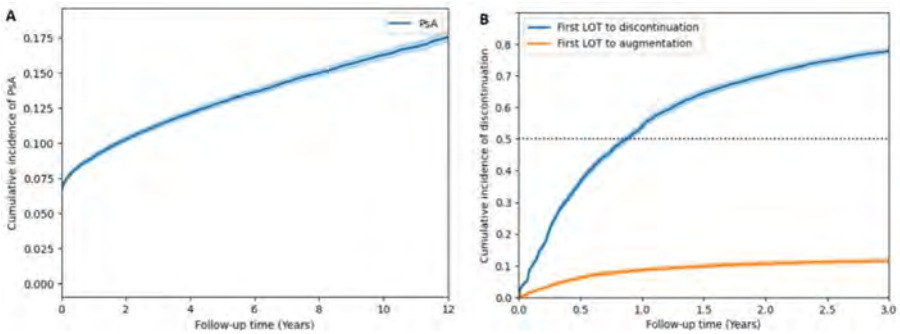

Figure 2: (A) Cumulative incidence of new Psoriatic Arthritis (PsA) diagnoses over time. The Y-axis represents the cumulative incidence (%) of patients newly diagnosed with PsA, while the X-axis shows follow-up time in years. (B) Time from first line systems immunomodulatory medication (other than steroids or NSAIDS) of patients with PsA diagnoses to discontinuation (blue) or augmentation (orange). The Y-axis represents the cumulative incidence (%), while the X-axis shows follow-up time in years.

Results: Of 96,533 patients with PsO, 7,558 (7.8%) had PsA at the time PsO was first reported. There were 88,975 patients with PsO without PsA (median age 54, 54.6% female) and 23,083 patients with PsA (median age 56, 59.1% female). See Table 1 for baseline characteristics. Within 6 months after t_0, patients use of systemic immunomodulatory medications included the following classes: steroid (PsO 16.7%, PsA 19.9%), antimetabolite (PsO 1.8%, PsA 11.6%), TNF-α inhibitor (PsO 1.5%, PsA 11.6%), calcineurin inhibitor (PsO 1.0%, PsA 0.5%), PDE4 inhibitor (PsO 0.8%, PsA 3.5%), IL-17 inhibitor (PsO 0.6%, PsA 3.3%), IL-23 inhibitors (PsO 0.6%, PsA 0.9%), IL-12/23 inhibitor (PsO 0.5%, PsA 1.2%), JAK inhibitor (PsO 0.1%, PsA 0.9%), and TYK2 inhibitor (PsO 0.0001%, PsA 0.0001%). The percentage of patients with systemic immunomodulatory medications within 6 months after t_0 (excluding steroids and NSAIDs) increased from 2011 (PsO 11.6%, PsA 15.1%) to 2023 (PsO 40.3%, PsA 58.5%). Time from PsO to PsA (Figure 1a) and time from the first PsA systemic immunomodulatory line of treatment to discontinuation or augmentation (Figure 1b) are shown below.

Conclusion: Data from a large community health system provides new insight into real world trajectories for patients with PsO and PsA. At the time of first reported PsO diagnosis, many patients have additional chronic medical conditions. The numbers of patients with PsA with systemic immunomodulatory treatment has increased since 2011 but remains lower than reported in studies conducted in academic centers, consistent with the 2016 MAPP survey.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients (pts) in PsA clinical trials often have greater joint involvement than in the clinical setting due to trial inclusion criteria,[1] thus it is important to assess treatment efficacy in pts with varying degrees of joint involvement. We investigated the efficacy of bimekizumab (BKZ), a selective inhibitor of interleukin (IL)-17F in addition to IL-17A, in subgroups of pts with varying joint involvement at baseline (BL), using data pooled from two phase 3 studies.

Methods: Post hoc analysis assessed subcutaneous BKZ 160 mg every 4 weeks (wks; Q4W) in pts with PsA and varying BL joint involvement. Pts were grouped by BL swollen joint count (SJC); thresholds defined based on quartile boundaries at BL (SJC ≤5 / 6–≤7 / 8–≤12 / >12). Due to small pt numbers with 3/4 SJC at BL, pts with 5 SJC were included in the first quartile; pt numbers in each quartile therefore vary.

Table. Baseline demographics and disease characteristics, reported by baseline joint involvement

	Joint involvement							
	SJC ≤5		SJC 6–≤7		SJC 8–≤12		SJC >12	
Mean (SD) unless otherwise specified	PBO n=139	BKZ 160 mg Q4W n=231	PBO n=71	BKZ 160 mg Q4W n=139	PBO n=81	BKZ 160 mg Q4W n=176	PBO n=100	BKZ 160 mg Q4W n=152
Age, years	49.6 (13.2)	47.9 (13.2)	49.8 (12.0)	49.6 (12.8)	49.3 (11.1)	49.5 (11.6)	49.4 (12.0)	50.2 (12.1)
Sex, male, n (%)	65 (46.8)	112 (48.5)	34 (44.7)	54 (38.8)	43 (43.4)	82 (46.6)	45 (45.0)	83 (54.6)

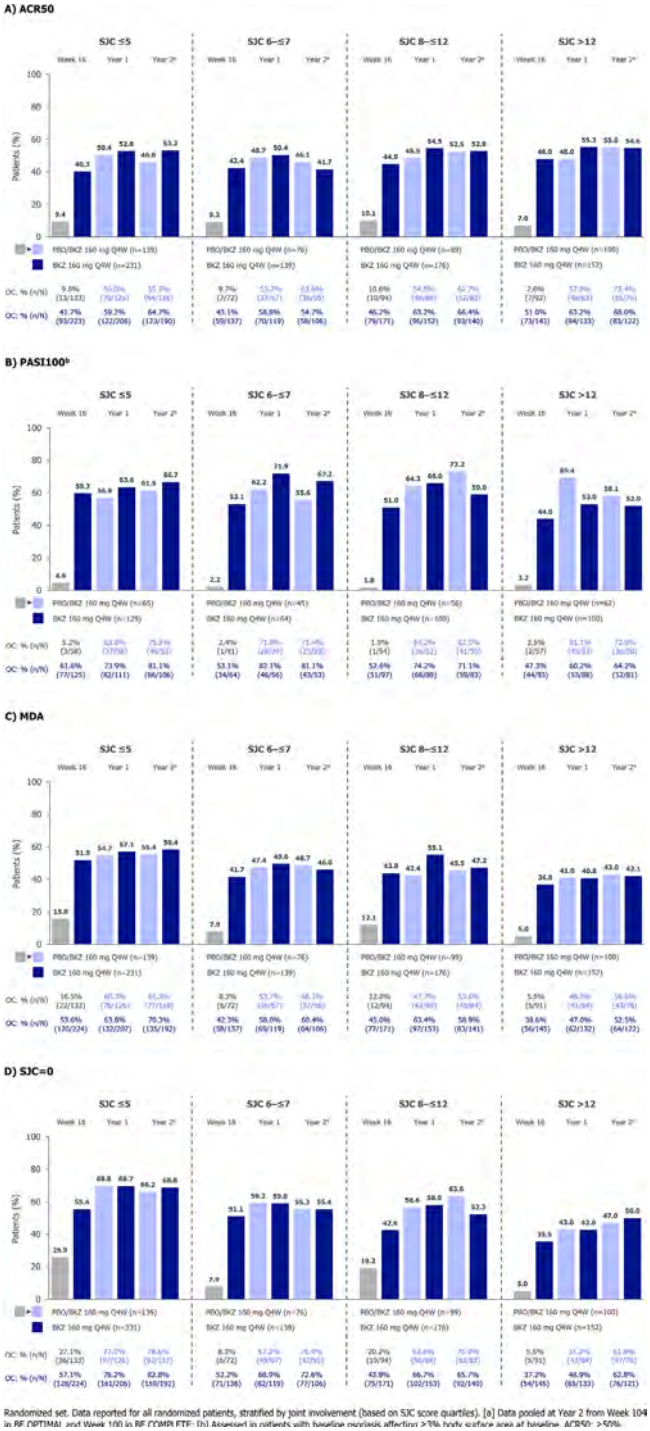

Figure 1. (A) ACR50, (B) PASI100, (C) MDA, and (D) SJC=0 responders at Week 16, Year 1, and Year 2, reported by baseline joint involvement (NRI, OC)

Pts were pooled from the BE OPTIMAL (NCT03895203; biologic DMARD [bDMARD]-naïve) and BE COMPLETE (NCT03896581; TNF inhibitor inadequate response/intolerance [TNFi-IR]) trials. As trials were different sizes (BE OPTIMAL 431 BKZ, 281 PBO; BE COMPLETE 267 BKZ, 133 PBO), proportions of bDMARD-naïve and TNFi-IR pts are not equal per quartile. Inclusion criteria for each trial included ≥3 tender and swollen joints. Both had a 16-wk double-blind, placebo (PBO)-controlled period. Pts completing Wk 52 of BE OPTIMAL or Wk 16 of BE COMPLETE could enter BE VITAL (NCT04009499; open-label extension), in which all pts received BKZ. BE OPTIMAL included a reference arm (adalimumab 40 mg Q2W); data not reported due to small pt numbers in SJC quartiles.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

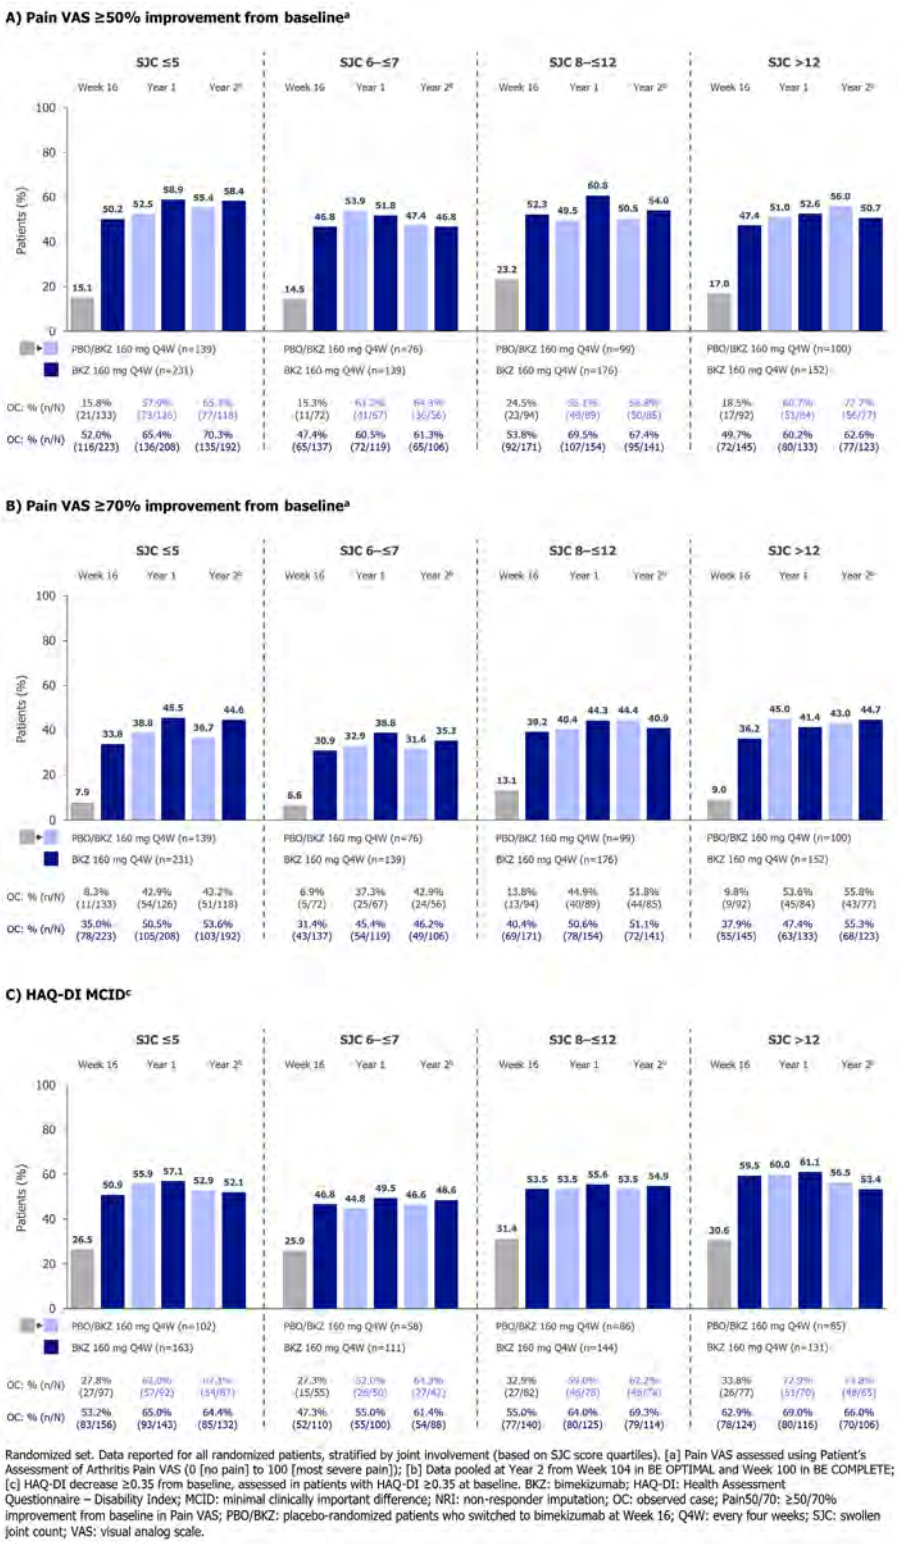

Figure 2. (A) Pain50, (B) Pain70, and (C) HAQ-DI MCID responders at Week 16, Year 1, and Year 2, reported by baseline joint involvement (NRI, OC)

Outcomes reported: ACR ≥50% improvement, Psoriasis Area and Severity Index 100% improvement, minimal disease activity, SJC=0, Pain visual analog scale ≥50/70% improvement from BL, Health Assessment Questionnaire – Disability Index minimal clinically important difference (≥0.35 decrease from BL in pts with BL score ≥0.35). Data are pooled across

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

both trials (non-responder imputation; observed case). Data are reported by randomization group at Wk 16, Year 1 (Wk 52), and Year 2 (pooled Wk 104/100 from BE OPTIMAL/BE COMPLETE).

Results: At BL, 370 pts had SJC ≤5, 215 had 6–≤7, 275 had 8–≤12, and 252 had >12. Demographic and disease characteristics by BL SJC are presented in the **Table**.

At Wk 16, BKZ-treated pts demonstrated numerically greater improvements in joint, skin, composite, and patient-reported outcomes vs PBO, across pts with varying BL joint involvement. For all domains assessed, improvements were sustained to 2 years in BKZ-randomized pts, with robust efficacy across pts with varying BL joint involvement (**Figure 1–2**). For pts who switched from PBO to BKZ at Wk 16, improvements in efficacy similar to BKZ-randomized pts with varying BL joint involvement were reported to Year 1 and sustained to Year 2.

Conclusion: In pts with PsA and varying BL joint involvement, BKZ treatment demonstrated greater improvements vs PBO across disease domains at Wk 16, and improvements were sustained to 2 years. Robust efficacy was observed across all groups of pts with varying BL joint involvement, reflecting the broader range of pts seen in clinical practice.

Background/Purpose: PsA is a chronic inflammatory disease characterized by joint pain, swelling and stiffness, and is often accompanied by cutaneous changes linked to psoriasis. Patients receiving treatment with an IL-17 inhibitor, such as secukinumab (SEC), reported higher incidence of *Candida* and other fungal infections. The objective of this post hoc analysis is to describe the incidence, severity, seriousness, and type of fungal infections, including *Candida*, among patients with PsA treated with SEC.

Methods: This post hoc analysis included patients with active PsA from a pooled population of 9 phase 3 clinical trials who received SEC 150 mg, SEC 300 mg, or placebo (PBO). Following the PBO-controlled period, patients randomized to PBO were switched to SEC 150 mg or SEC 300 mg while patients randomized at baseline to receive either dose of SEC continued the same dose. Baseline demographic and clinical characteristics are reported in patients with or without ≥1 fungal infection adverse event during the entire treatment period. Incidence of fungal infections, including *Candida*, are reported for the PBO-controlled period and through the entire treatment period. Characteristics of infections including the specific types (defined by MedDRA preferred term), severity grades, and infections resulting in treatment discontinuation are reported through the entire treatment period.

Results: Overall, 2416 and 932 patients with active PsA receiving SEC or PBO, respectively, were included. A total of 167 (6.9%) patients receiving SEC reported ≥1 fungal infection through the entire treatment period, and most (62.3%) were female. Female patients comprised 51.8% of the entire study population and the mean age was 48.6 years. During the PBO-controlled period, rates of total fungal infections were infrequent in each treatment group (exposure adjusted incidence rate [EAIR] per 100 patient years [95% CI], SEC 150 mg: 3.97 [2.17-6.66], SEC 300 mg: 10.04 [6.04-15.67], PBO: 4.45 [2.37-7.61]). EAIRs of *Candida* infections were also infrequent in patients receiving either SEC 150 mg (2.54 [1.16-4.83]), SEC 300 mg (5.78 [2.89-10.34]), or PBO (2.04 [0.75-4.45], **Table 1**). Through the entire treatment period, the rates of total fungal infections (SEC 150 mg: 3.86 [3.05-4.81], SEC 300 mg: 4.68 [3.75-5.77] and *Candida* infections (SEC 150 mg: 1.86 [1.33-2.55], SEC 300 mg: 2.18 [1.57-2.95]) did not increase. The majority of fungal infections, including *Candida*, in patients receiving any SEC in the entire treatment period were mild or moderate (99.6%). One severe fungal infection (0.04%) was reported in the SEC 150 mg group (-**Figure 1**). The vast majority (83.1% of total fungal infections and 89.7% of *Candida* infections) were fully resolved before the end of the treatment period (**Figure 2**), and 2 (0.8%) infections resulted in treatment discontinuation.

Table 1. Fungal Infections, Including *Candida*, During the PBO-Controlled Period in Patients With PsA Receiving Secukinumab

Infection type, EAIR (95% CI)[a,b]	SEC 150 mg (n=1128)	SEC 300 mg (n=656)	PBO (n=932)

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Work impairment is a key issue in PsA. Biologic treatments can improve work status in patients (pts) with PsA; however, there is lack of comparative real-world data for different modes of action, e.g. IL-23 and IL-17 inhibitors (i). The current analysis aimed to assess PsA pt-reported outcomes (PRO), specifically work productivity, activity impairment, and disease impact after 6 months of treatment with guselkumab (GUS) and IL-17i.

Methods: PsABIOnd (NCT05049798) is a global (20 countries) observational study in PsA pts starting GUS or IL-17i as 1st-to-4th line of biologic therapy per standard of care.[1] Here, the full population of the PsABIOnd study was analyzed over the first 6 months of follow-up. Work productivity (overall work productivity loss, absenteeism, presenteeism) and activity impairment were assessed via the Work Productivity and Activity Impairment Questionnaire (WPAI; 0-100).[2] Pt-reported disease impact was assessed using the PsA Impact of Disease-12 (PsAID-12; 0-10),[3] including the mean total score and proportions of pts achieving minimal clinically important improvement (MCII; improvement by ≥1.4; among pts with BL PsAID-12 score ≥1.4). All analyses were performed according to initial treatment group allocation and treatment comparison was based on 95% confidence intervals (CI).

Results: 1134 pts were analyzed; 555 and 579 received GUS or IL-17i, respectively, as their initial treatment. Mean age (53.2/53.5 yrs), sex (60.4%/59.2% female), and prior exposure to a targeted drug (63.4%/62.3%) were comparable for GUS/IL-17i. Mean overall baseline work productivity loss (42.3%/44.5% for GUS/IL17i groups), absenteeism (14.3%/12.9%), presenteeism (39.2%/42.1%), activity impairment (48.5%/50.6%), and mean baseline PsAID-12 total score (5.1/5.1) were also similar between groups.

At the 6-month visit, comparable improvements were observed in all WPAI outcomes with GUS and IL-17i. Mean (95% CI) improvements in GUS/IL-17i were: overall work productivity loss (-13.1 [-16.5, -9.7]/-13.8 [-17.5, -10.1]%), absenteeism (-6.4 [-10.4, -2.4]/-2.5 [-5.1, 0.2]%), presenteeism (-12.5 [-15.7, -9.3]/-14.0 [-17.5, -10.5]%), activity impairment (-13.1 [-15.4, -10.8]/-15.7 [-18.2, -13.1]%; **Fig 1**). Mean PsAID-12 total scores also improved significantly (-1.6 [-1.7, -1.4]/-1.8 [-2.0, -1.6]) reaching levels (3.5/3.3) indicative of symptom impact below the pt acceptable symptom state threshold (≤ 4.0) in both groups (**Fig 2**). Rates of pts achieving PsAID-12 MCII at 6 months were also comparable (54.7%/55.9%).

Conclusion: By 6 months of treatment in real-world, improvements in work productivity and ability to perform daily activities were observed with both GUS and IL-17i which were paralleled with clinically meaningful improvements in pt-reported multi-domain disease impact. Based on overlapping CIs, improvements in PROs were comparable between the two modes of

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is often associated with persistent pain despite effective anti-inflammatory treatment, substantially impacting patients' quality of life. Digital health applications (DiGAs) provide an innovative approach to address multidimensional aspects of chronic pain through psychological and behavioral strategies. Our objective was to assess the impact of a DiGA utilizing the acceptance and commitment therapy (ACT) on disease outcomes, including the West Haven-Yale Multidimensional Pain Inventory (MPI), in axSpA patients experiencing chronic back pain despite stable pharmacological therapy.

Values are presented as mean (standard deviation), unless otherwise indicated; ASAS: Assessment of Spondyloarthritis International Society; ASDAS: Ankylosing Spondylitis Disease Activity Score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Functional Index; BASMI: Bath Ankylosing Spondylitis Metrology Index; CRP: C-reactive protein; FIQ: Fibromyalgia Impact Questionnaire; HADS: Hospital Anxiety and Depression Scale; MPI (D): Multidimensional Pain Inventory; NRS: Numerical rating scale; NSAID: Nonsteroidal anti-inflammatory drug; PAM 13: Patient Activation Measure-13; SF-36: Short Form 36; PCS: Physical component summary (PCS); MCS: Mental component summary

Methods: This unblinded, monocentric, randomized controlled trial (1:1) compared an intervention group receiving the ACT-app with a standard of care (SOC) group. The ACT app provided behavioral therapy in seven interactive lessons. Patients were followed for 12 weeks. The primary outcome was MPI pain-related life interference; secondary outcomes included pain severity, affective distress and other patient reported outcomes (PRO). The Patient Global Impression of Change (PGIC) was used to evaluate patients' subjective perception of overall change during the study. Acceptance of the DiGA was assessed

Figure 1: Change of clinical characteristics stratified by group

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

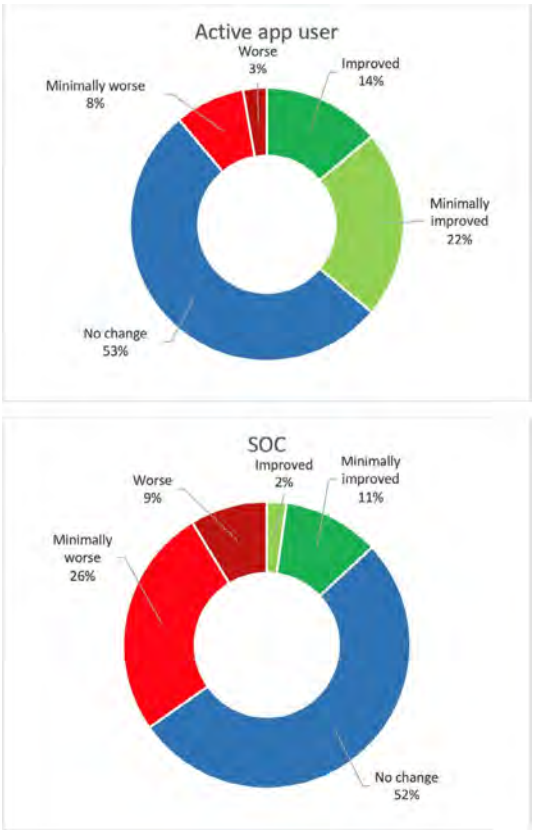

Figure 2: Patient Global Impression of Change (PGIC) Categories: Comparison Between Active App Users and Standard of care (SOC) Group

using the Net promoter score (NRS 0-10). Linear models estimating the effect of the ACT-app on the change of MPI pain-related life interference (model 1) and affective distress (model 2), with adjustments made for their respective baseline values, were calculated.

Results: A total of 136 patients were randomized to the intervention (n=73) with ACT-app and SOC group (n=63) without ACT-app (table 1). Among intervention patients, 44 actively used ACT-app, while 29 either did not receive the app code by their health insurance company or did not use the ACT-app at all. At week 12, all lessons in the ACT-app were fully completed by 19 (43%) patients in the intervention group. Baseline characteristics, including MPI scores, were comparable between groups (table 1). Active app users showed a significant reduction in pain-related interference ($p< 0.05$) as well as in other outcomes (figure 1). The improvements in pain-related life interference (model1: -0.36, 95% CI: -0.73 to 0.01) and affective distress related to the disease (model 2: -0.4, 95% CI: -0.84,0.003) were greater compared to SOC patients. Overall acceptance was moderate (Net Promoter Score 5.8 (4.3)).

Conclusion: The ACT-app demonstrated a meaningful reduction in pain-related interference, supporting that the use of DIGAs might become a supplementary tool in managing pain for axSpA patients. However, a substantial number of patients experienced challenges to use the app actively.

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Secukinumab has demonstrated long-lasting efficacy and a favorable safety profile across multiple clinical trials and domains of psoriatic disease. Real-world data provides additional valuable information on the long-term outcomes of secukinumab in routine clinical practice. Secukinumab has shown high retention rates and sustained effectiveness in patients with psoriatic arthritis (PsA) and radiographic axial spondyloarthritis (r-axSPA) during 5 years of follow-up in

Table 1: Demographics and baseline characteristics

Characteristics*	PsA (N = 522)
Age (years)	52.5 ± 12.0
Male, n (%)	234 (44.8)
Weight (kg)	83.6 ± 17.6
Body mass index (kg/m²)	28.7 ± 5.5
Caucasian race, n (%)	491 (94.1)
Time since diagnosis (years)	8.6 ± 7.4
Smoking status, n (%)	
Current	113 (21.6)
Former	89 (17.0)
Never	260 (49.8)
Previous biologic exposure prior to start of secukinumab, n (%)	
No biologics pre-treatment	164 (31.4)
1 biologics pre-treatment	147 (28.2)
2 biologics pre-treatments	88 (16.9)
3 or more biologics pre-treatments	123 (23.6)

*mean ± SD otherwise indicated. N, number of patients in populations; n, number of patients with non-missing data; PsA, psoriatic arthritis; SD, standard deviation

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Kaplan-Meier estimates of the retention rate of secukinumab by biologic-experienced vs biologic-naïve in PsA cohort

Figure 2. MDA response (components of MDA criteria)

the SERENA study. This post hoc analysis assesses minimal disease activity (MDA) components and retention rates in biologic-naïve and biologic-experienced patients during the study period.

Methods: SERENA (CAIN457A3403) was a non-interventional, prospective real-world study conducted across 19 countries in patients with moderate to severe chronic plaque-type psoriasis, active PsA, or r-axSpA, who had received secukinumab for ≥16 weeks before enrollment. The different components within the MDA assessment were evaluated for patients achieving the following criteria: tender joint count (TJC ≤1), swollen joint count (SJC ≤1), Psoriasis Area and Surface Index (PASI ≤1) or body surface area (BSA ≤3), patient pain visual analogue scale (VAS ≤15 mm), Health Assessment Questionnaire Disability Index (HAQ-DI ≤0.5), and tender entheseal points (TEP ≤1) from years 1 to 5. Secukinumab retention rate was derived from Kaplan-Meier estimates for the proportion of patients who had been treated with secukinumab from years 1 to 5.

Results: Overall, 522 patients with PsA were included in the analysis. The mean age at inclusion was 52.5 years, 44.8% male. The mean ± SD BMI was 28.7 ± 5.5 kg/m^2 and mean time since diagnosis was 8.6 ± 7.4 years (**Table 1**). Before inclusion in the study, the patients had been receiving secukinumab treatment for a mean duration of 1 year, and 68.6% had previous biologic exposure. Secukinumab retention rates were numerically higher in the biologic-naïve subgroup compared with the biologic-experienced subgroup, from years 2.5 onwards (**Figure 1**). The percentage of patients reaching the threshold of the different components within the MDA assessment are shown in **Figure 2**. Since the patient's global assessment (≤20) was not collected, it was not possible to report the overall MDA. There were no new safety signals in this subanalysis of patients with PsA.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this real-world data analysis, secukinumab demonstrated sustained clinical effectiveness and a favorable safety profile in patients with PsA over 5 years of observation. Retention rates remained high throughout the observation time, with no statistically significant differences observed in biologic naïve or pre-treated patients. Importantly, secukinumab demonstrated sustained long-term remission across all six collected components of the MDA criteria. These results reinforce the long-term value of secukinumab in managing multiple PsA domains in routine clinical practice.

Abstract Number: 1463

Effective Prevention of Psoriatic Arthritis with Secukinumab: A 5-Year Observation from the SERENA Study

Uta Kiltz[1], Petros Sfikakis[2], Andreas Bounas[3], Nicola Gullick[4], Eric LESPESSAILLES[5], Jan Brandt-Juergens[6], Rasho Rashkov[7], Cynthia Vizcaya[8], Andreas Clemens[8], Weibin Bao[9] and Karl Gaffney[10], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany, [2]NKUA - SCHOOL OF MEDICINE, Athens, Greece, [3]'OLYMPION', General Clinic of Patra, Patra, Greece, [4]Rheumatology Department, University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK, Coventry, United Kingdom, [5]University Hospital of Orléans, Orleans, France, [6]Rheumatologische Schwerpunktpraxis, Berlin, Germany, [7]Clinic of Rheumatology, University Hospital St. Ivan Rilski, Sofia, Bulgaria, [8]Novartis Pharma AG, Basel, Switzerland, [9]Novartis Pharmaceuticals Corporation, Hanover, NJ, [10]Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Secukinumab, an IL-17A inhibitor, has well-established effectiveness in the treatment of psoriasis (PsO) and psoriatic arthritis (PsA) in both long-term clinical trials and the real world.[1,2] There is an intense discussion if biologics can prevent the development of PsA in patients with psoriasis without PsA with nail involvement (higher risk patient group). SERENA is a large, longitudinal, observational study conducted at 438 sites across Europe in adult patients with moderate to severe chronic plaque PsO, active PsA and radiographic axial spondyloarthritis.[2] The observations will be put into perspective to historical evidence regarding patients with PsO without PsA not previously treated with biologics[3]. Here we evaluate the 5-year effectiveness of secukinumab in prevention of PsA.

Table 1. Effectiveness of secukinumab in patients with PsO without PsA and with nail involvement at inclusion

Endpoints	Study population	Year 1	Year 2	Year 3	Year 4	≥Year 5
PASI 100 n/M (%)	292	62/221 (28.1)	56/208 (26.9)	49/174 (28.2)	42/131 (32.1)	47/122 (38.5)
PASI 90 n/M (%)	292	119/221 (53.8)	113/208 (54.3)	95/174 (54.6)	76/131 (58.0)	77/122 (63.1)
PGA 0/1 response, n/M (%)	292	75/104 (72.1)	71/94 (75.5)	60/78 (76.9)	48/67 (71.6)	41/52 (78.8)

M, number of patients under evaluation; n, number of responders; N, number of patients in the study population; PASI Psoriasis Area and Severity Index, PGA, Physician's Global Assessment; PsA, psoriatic arthritis

Methods: Patients received secukinumab treatment for ≥16 weeks before enrolment into the study. In the subgroup of patients with PsO without PsA and nail involvement at the study entry, we analysed the incidence of PsA from inclusion into the study to the 5-year follow up. We describe the outcomes as exposure adjusted incidence rates (EAIR) of developing PsA during the 5-year follow-up, in terms of per 100 patient-years. Descriptive statistics of effectiveness assessments were based on observed data.

Results: Overall, 292 patients with active PsO with nail involvement without PsA were included in the analysis (mean age at study enrolment, 49.2 years; male, 79.8%; mean body mass index, 29.3 kg/m^2; mean time since diagnosis, 17.8 years). 28.8% had previous biologic exposure before the start of secukinumab. After 5 years of study enrolment and a total exposure of 1022 patient-years, most patients (287/292 patients; 98.3%) did not develop PsA. This translates into a yearly, exposure adjusted incidence rate (EAIR) of 0.49 (95% CI: 0.16,1.14). Secukinumab treatment resulted in a sustained control over skin changes as assessed by Psoriasis Area and Severity Index (PASI) and Physician's Global Assessment (PGA) 0/1 response, with 39% of patients achieving skin clearance (PASI 100) after 5 years (**Table 1**). Approximately 63% of patients achieved PASI 90 after 5 years (**Table 1**).

Conclusion: Previously, an 8-year prospective observational study in patients with PsO (including 35% of patients with nail involvement) without PsA reported a yearly incidence rate of PsA of 2.7 per 100 patients not treated with a biologic[3]. SERENA is one of the largest real-world studies in Europe observing the effect of secukinumab over 5 years. Long-term secukinumab treatment in patients with PsO with nail involvement without PsA resulted in an ~82% reduction of the annual incidence rate of PsA in comparison to historic non-biologic treated patients. These results suggest that secukinumab may be effective in preventing PsA in patients with PsO. Secukinumab-treated patients also achieved sustained long-term control over skin changes.

Incidence of Major Adverse Cardiovascular Events (MACE) in Psoriasis, Psoriatic Arthritis and Axial Spondyloarthritis Patients With and Without Cardiovascular Risk Factors Treated With Secukinumab: Five-Year Safety Data from the Real-World SERENA Study

Uta Kiltz[1], Petros Sfikakis[2], Andreas Bounas[3], Nicola Gullick[4], Eric LESPESSAILLES[5], Jan Brandt-Juergens[6], Rasho Rashkov[7], Cynthia Vizcaya[8], Andreas Clemens[8], Lara Gómez[9], Kim Hoyt[10], Weibin Bao[11] and Karl Gaffney[12], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany, [2]NKUA - SCHOOL OF MEDICINE, Athens, Greece, [3]'OLYMPION', General Clinic of Patra, Patra, Greece, [4]Rheumatology Department, University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK, Coventry, United Kingdom, [5]University Hospital of Orléans, Orleans, France, [6]Rheumatologische Schwerpunktpraxis, Berlin, Germany, [7]Clinic of Rheumatology, University Hospital St. Ivan Rilski, Sofia, Bulgaria, [8]Novartis Pharma AG, Basel, Switzerland, [9]Novartis Farmaceutica, Madrid, Spain, [10]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [11]Novartis Pharmaceuticals Corporation, Hanover, NJ, [12]Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with psoriasis (PsO), psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA) are at increased risk of major adverse cardiovascular events (MACE) due to systemic inflammation and cardiometabolic burden. Secukinumab, a fully human interleukin (IL)-17A inhibitor, has demonstrated long-term efficacy and safety across multiple indications. We assessed the 5-year incidence of MACE and baseline cardiovascular (CV) risk factors in patients with and without CV risk factors who were treated with secukinumab in the real-world SERENA study.

Methods: SERENA (CAIN457A3403) is a non-interventional, prospective real-world study conducted across 19 countries in patients with moderate to severe chronic PsO, PsA, or radiographic axSpA (r-axSpA), who received secukinumab for ≥16 weeks before enrollment. MACE were defined using MedDRA v26.1 (including myocardial infarction, stroke, and CV

death). Exposure-adjusted incidence rates (EAIRs) were calculated per 100 patient-years (PY). Descriptive comparisons of CV risk factors (age ≥60 years, BMI ≥30 kg/m^2, disease duration ≥15 years, and diabetes) were performed between patients with and without MACE. No formal statistical comparisons were made.

Results: Among 2927 patients (PsO: 1842; PsA: 579; r-axSpA: 506), 35 MACE were reported during 9679 PY: 24 in PsO, 7 in PsA, and 4 in r-axSpA. EAIRs were 0.39 (95% CI: 0.25 - 0.58), 0.38 (0.15 - 0.78), and 0.23 (0.06 - 0.60) per 100 PY, respectively; equivalent to 3.9, 3.8, and 2.3 events per 1000 PY. These rates are lower than those reported in biologic-naïve psoriatic disease cohorts (14.5–16.4/1000 PY),[1,2] as well as in patients with and without prior biologic experience: 7.4/1000 PY in PsA and 6.0/1000 PY in axSpA[3]. Among patients who experienced MACE, 42.9% were ≥60 years old, 31.4% were obese, 34.3% had long-standing disease (≥15 years), and 17.1% had diabetes vs 9.3% in non-MACE patients. Most events occurred in individuals with traditional CV risk factors, however there was no meaningful difference in baseline characteristics compared to patients who did not experience MACE (**Table 1**). No multivariable analysis was conducted due to the low event count.

Conclusion: These results support the favorable long-term CV safety profile of secukinumab in patients with PsO, PsA, and axSpA. Over five years of treatment in a real-world setting, MACE were infrequent, and incidence rates remained low and stable across indications, including patients with baseline CV risk. The lower observed incidence than that reported in biologic-naïve cohorts,[1-3] is in line with the hypothesis that IL-17A inhibition with secukinumab may help reduce the incidence of MACE in these populations.

SESSION INFORMATION

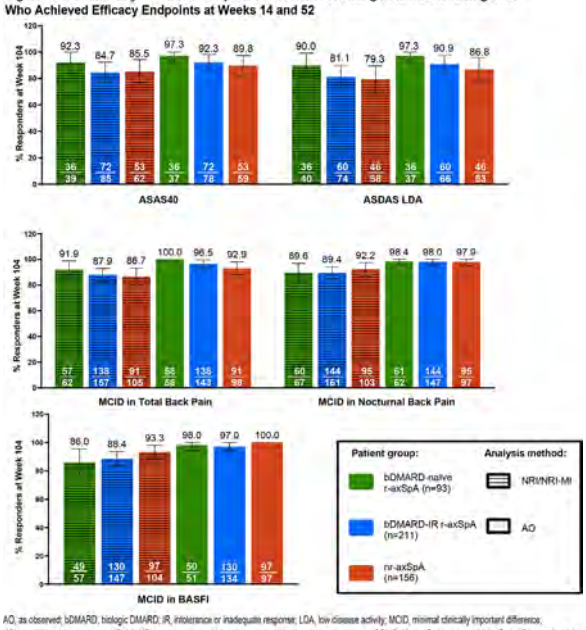
Session Date: Monday, October 27, 2025
Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Treatment with the oral JAK inhibitor upadacitinib (UPA) has shown efficacy and safety in patients with active axial spondyloarthritis (axSpA), including both radiographic (r-axSpA, historically known as ankylosing spondylitis [AS]) and non-radiographic (nr-axSpA). This therapeutic benefit was observed among patients who are naïve to biologic DMARDs (bDMARD-naïve) as well as those with an intolerance or inadequate response to biologic DMARDs (bDMARD-IR). Sustainability of response was previously demonstrated through week 52 among patients who achieved clinical responses at week 14.[1] This post hoc analysis evaluated the long-term sustainability of clinical outcomes through 2 years (104 weeks) in UPA-treated patients with axSpA from the SELECT-AXIS 1 and SELECT-AXIS 2 clinical trials.

Methods: Data from SELECT-AXIS 1 (bDMARD-naïve r-axSpA) and SELECT-AXIS 2 (two studies: bDMARD-IR r-axSpA and nr-axSpA which included a population with 33% bDMARD-IR and 67% bDMARD-naïve) were assessed in this post hoc analysis. Sustained treatment response at week 104 was evaluated in patients receiving UPA 15 mg once daily who achieved responses at both weeks 14 and 52. Endpoints included ASAS40 response, ASDAS low disease activity (LDA; score < 2.1), and achievement of a minimal clinically important difference (MCID) in total and nocturnal back pain (≥ 1.0 decrease) and in BASFI (≥ 0.6 decrease).[2] Data were analyzed using nonresponder imputation (NRI), NRI with multiple imputation (NRI-MI) for COVID-19 missing data, and as observed (AO). Sankey diagrams were used to illustrate ASDAS LDA achievement through week 104 using AO and NRI (with AO-NRI as appropriate) analyses.

Results: A total of 460 patients were included in this analysis (bDMARD-naïve r-axSpA, N = 93; bDMARD-IR r-axSpA, N = 211; nr-axSpA, N = 156). Among patients who achieved ASAS40 at weeks 14 and 52, most sustained this response at

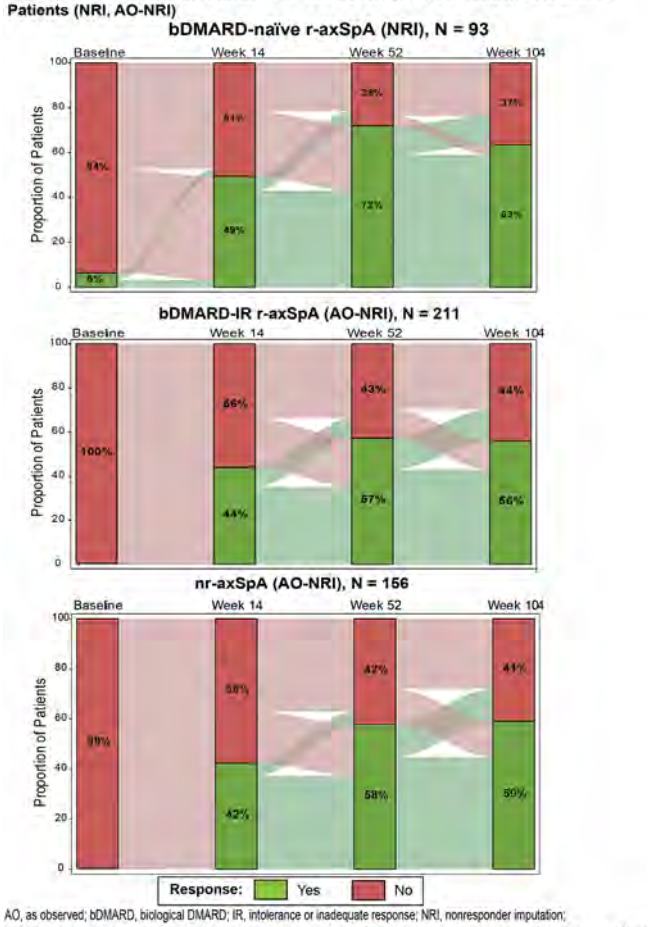
Figure 1. Sustainability of Clinical Response at Week 104 Among Patients Receiving UPA Who Achieved Efficacy Endpoints at Weeks 14 and 52



AO, as observed; bDMARD, biologic DMARD; IR, intolerance or inadequate response; LDA, low disease activity; MCID, minimal clinically important difference; NRI, nonresponder imputation; NRI-MI, NRI incorporating multiple imputations to handle missing data due to COVID-19; r-axSpA, radiographic axSpA; UPA, upadacitinib.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2: Achievement of ASDAS Low Disease Activity Over Time in UPA-treated Patients (NRI, AO-NRI)



AO, as observed; bDMARD, biological DMARD; IR, intolerance or inadequate response; NRI, nonresponder imputation; NRI-MI, NRI incorporating multiple imputation to handle missing data due to COVID-19; r-axSpA, radiographic axSpA; UPA, upadacitinib. AO-NRI was utilized in bDMARD-IR AS and nr-axSpA to ensure consistent categorization as responses would vary with NRI-MI.

week 104 (bDMARD-naïve r-axSpA: NRI, 92.3%; AO, 97.3%; bDMARD-IR r-axSpA: NRI-MI, 84.7%; AO, 92.3%; nr-axSpA: NRI-MI, 85.5%; AO, 89.8%) (**Fig 1**). Most UPA-treated patients who achieved ASDAS LDA at weeks 14 and 52 sustained that response at week 104 (bDMARD-naïve r-axSpA: NRI, 90.0%; AO, 97.3%; bDMARD-IR r-axSpA: NRI-MI, 81.1%; AO, 90.9%; nr-axSpA: NRI-MI, 79.3%; AO, 86.8%). Similar maintenance of response was observed for achievement of MCID in total back pain (NRI: range, 86.7% to 91.9%; AO: range, 92.9% to 100.0%), nocturnal back pain (NRI-MI: range, 89.4% to 92.2%; AO: range, 97.9% to 98.4%), and BASFI (NRI-MI: range, 86.0% to 93.3%; AO: range, 97.0% to 100.0%). In a longitudinal analysis, the long-term sustainability of ASDAS LDA was further examined over time (**Fig 2 & 3**), demonstrating an increased proportion of patients achieving ASDAS LDA from baseline to weeks 14, 52, and 104.

Conclusion: Patients treated with UPA who showed response at weeks 14 and 52 continued to maintain those responses in disease activity (ASAS40 and ASDAS LDA), total back pain, nocturnal back pain, and physical function at week 104. These findings highlight the consistent and long-term efficacy of UPA across the full spectrum of axSpA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1434–1466) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Spinal inflammation and structural progression are key features of radiographic axial spondyloarthritis (r-axSpA).[1] Canada-Denmark (CANDEN) scoring enables anatomical-based assessments of MRI inflammatory and structural lesions by spinal compartment.[2,3]

Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has shown sustained efficacy and safety to 2 years in patients (pts) with r-axSpA in the phase 3 study BE MOBILE 2 and its open-label extension (OLE), and to 5 years in a phase 2b study.[4,5]

Here, from BE MOBILE 2 and its OLE, we present the first 2-year evaluation of the effects of a biologic treatment (i.e., BKZ) on spinal MRI inflammatory and structural lesions in pts with r-axSpA using CANDEN scoring.

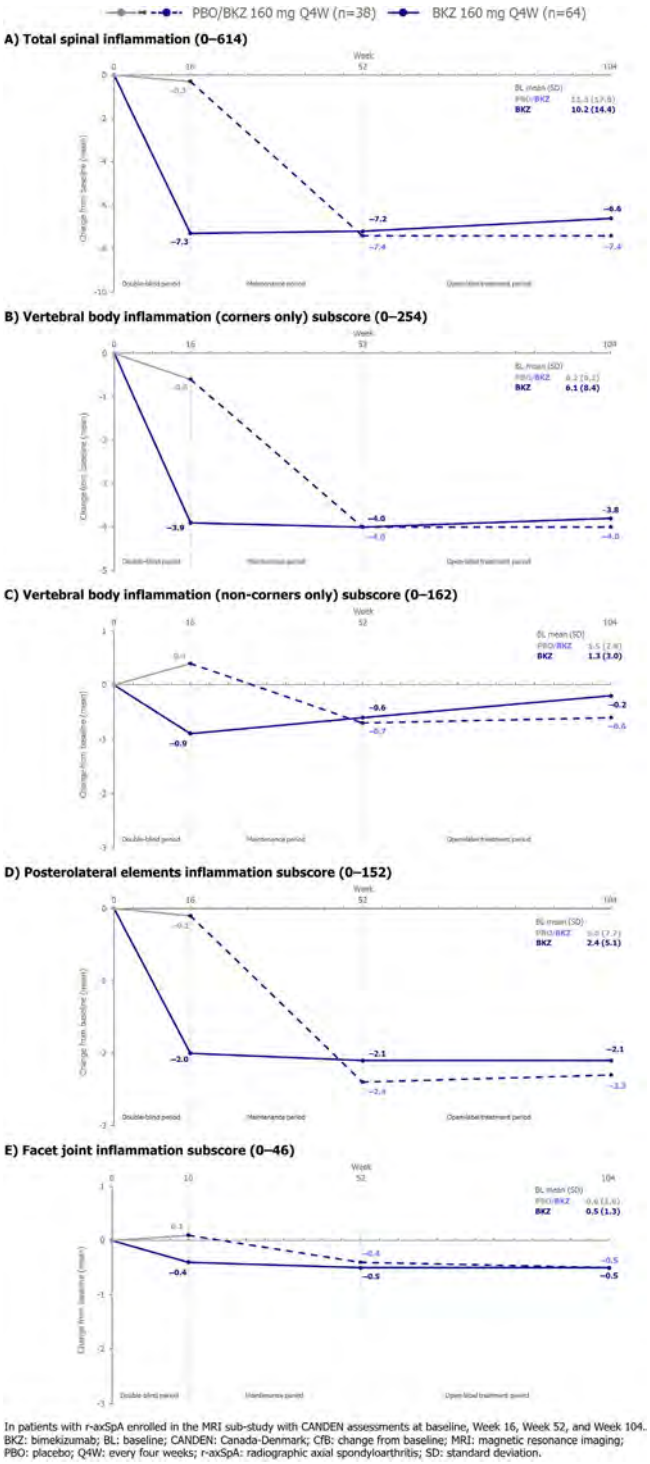
Methods: In BE MOBILE 2 (NCT03928743), pts with r-axSpA were randomized to subcutaneous BKZ 160 mg every 4 weeks (wks) or placebo (PBO); from Wk 16, all received BKZ. At Wk 52, eligible pts could enroll in the OLE (BE MOVING; NCT04436640).[4]

Post hoc CANDEN scoring assessments were conducted in pts enrolled in the MRI sub-study who had evaluable spinal MRIs at all four timepoints: baseline, Wk 16, 52, and 104. All readers were blinded to timepoint. We report mean change from baseline (CfB) at Wk 16, 52, and 104 in total spinal inflammation score and subscores for inflammation in vertebral bodies (corners and non-corners), posterolateral elements, and facet joints, and total spinal structural lesions scores (fat, erosions, new bone formation). All data use observed case.

Results: 140/332 (42.2%) pts in BE MOBILE 2 had MRIs eligible for CANDEN scoring. 102 pts had CANDEN scores at baseline, Wk 16, 52, and 104 (PBO/BKZ: n=38; BKZ: n=64). Baseline characteristics of these pts were largely comparable between treatment arms and with the overall population.

A greater reduction from baseline in total spinal inflammation was seen at Wk 16 with BKZ vs PBO. After switching to BKZ at Wk 16, PBO-randomized pts had an improvement from baseline comparable to BKZ-randomized patients at Wk 52, both of which were largely sustained at Wk 104 (**Figure 1A**). This was also observed for vertebral body (corners only) and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



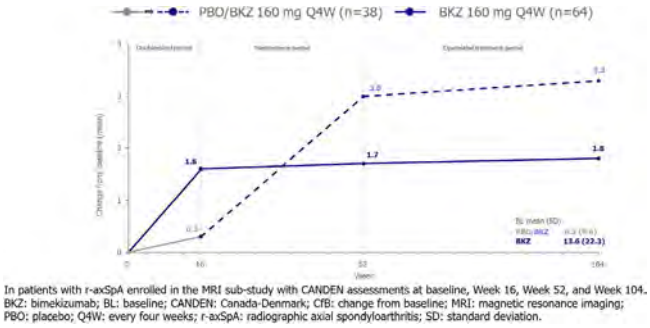
In patients with r-axSpA enrolled in the MRI sub-study with CANDEN assessments at baseline, Week 16, Week 52, and Week 104.
BKZ: bimekizumab; BL: baseline; CANDEN: Canada-Denmark; CfB: change from baseline; MRI: magnetic resonance imaging; PBO: placebo; Q4W: every four weeks; r-axSpA: radiographic axial spondyloarthritis; SD: standard deviation.

Figure 1. Change from baseline in CANDEN total inflammation score and subscores to Week 104 (observed case)

posterolateral elements inflammation (**Figure 1B, 1D**). Data for vertebral body (non-corners only) and facet joint inflammation are shown in **Figure 1C, 1E**.

At Wk 16, a greater increase from baseline in fat lesions was seen with BKZ vs PBO. BKZ-randomized pts had minimal change in fat lesions from Wk 16 to Wk 104. After switching to BKZ, PBO-randomized pts had an increase in fat lesions at Wk 52 and then minimal change at Wk 104 (**Figure 2**). Minimal changes were observed in new bone formation and erosion to Wk 104.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



In patients with r-axSpA enrolled in the MRI sub-study with CANDEN assessments at baseline, Week 16, Week 52, and Week 104. BKZ: bimekizumab; BL: baseline; CANDEN: Canada-Denmark; CfB: change from baseline; MRI: magnetic resonance imaging; PBO: placebo; Q4W: every four weeks; r-axSpA: radiographic axial spondyloarthritis; SD: standard deviation.

Figure 2. Change from baseline in CANDEN total fat lesion score to Week 104 (observed case)

Conclusion: In pts with r-axSpA, comprehensive scoring of spinal inflammatory and structural lesions using CANDEN showed BKZ led to a rapid and sustained long-term reduction in individual components of spinal MRI inflammation, an initial increase in fat lesions with minimal subsequent change, and minimal changes in new bone formation and erosion over two years.

ACEi or ARB	152 (39.3)

SLE, systemic lupus erythematosus; GFR, glomerular filtration rate; SGLT2i, sodium-glucose cotransporter-2 inhibitor; GLP-1RA, glucagon-like peptide-1 receptor agonist; ACEi, angiotensin converting enzyme inhibitor; ARB, angiotensin receptor blocker

Background/Purpose: Lupus nephritis (LN) affects over half of patients with systemic lupus erythematosus (SLE) and is associated with an increased risk for adverse kidney outcomes. We sought to identify risk factors for chronic kidney disease (CKD) and end-stage kidney disease (ESKD) in patients with newly diagnosed LN.

Table 2: Risks of Chronic Kidney Disease Stage ≥3 and End-Stage Kidney Disease at 5 Years Among Patients with Newly Diagnosed, Biopsy-Proven Lupus Nephritis

LN, lupus nephritis; HCQ, hydroxychloroquine; ACEi, angiotensin converting enzyme inhibitor; ARB, angiotensin receptor blocker
[a]Hazard ratio adjusted for age, sex, race, baseline diabetes and hypertension, and prior treatment with an immunosuppressive medication
[b]Membranoproliferative lupus nephritis includes patients with any component of class III or class IV disease on kidney biopsy

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We identified an inception cohort of patients with biopsy-proven LN in the Mass General Brigham health system. We included patients with an index kidney biopsy between 2001-2024, excluding those with prior kidney transplant, and with available laboratory signs of LN prior to the index kidney biopsy. These included a spot or timed urine protein estimating ≥500mg/24 hr or microalbumin ≥300mg/24 hr, urinalysis with ≥2+ protein, or RBC casts. We assessed the effect of time between the first abnormal LN laboratory sign and kidney biopsy (>90 days versus ≤90 days), chronicity index score on kidney biopsy (>3 compared to ≤3), as well as the use of hydroxychloroquine (HCQ) and an ACEi or ARB in the 12 months prior to kidney biopsy, on subsequent kidney outcomes. Primary outcomes included new-onset CKD stage ≥3 and ESKD through 5 years following the first kidney biopsy. We used Cox proportional hazards regression, adjusting for age, sex, race and ethnicity, diagnoses of diabetes and hypertension, and prior SLE immunosuppressant use (including oral and biologic immunosuppressants but not glucocorticoids). We also performed subgroup analyses among patients with membranoproliferative LN (class III or IV +/- class II or V) as well as those with membranoproliferative LN who had not received treatment with an immunosuppressant prior to the kidney biopsy.

Results: There were 387 patients with newly diagnosed, biopsy-proven LN with a mean age of 38.9 years (SD 16.1); 83% were female, 43% were White, and 26% were Black **(Table 1)**. Two-thirds of patients had membranoproliferative LN and one-third had previously received treatment with an immunosuppressive agent. Among those with membranoproliferative LN, a chronicity index score >3 on the first kidney biopsy was associated with an increased risk of new-onset CKD stage ≥3 and ESKD (adjusted HR [aHR] 2.94 [95% CI 1.44-5.99] and 12.27 [95% CI 2.16-69.67], respectively **(Table 2)**. The risk increased further among those with membranoproliferative LN without prior immunosuppressant use (aHR 3.79 [95% CI 1.47-9.81] and 70.43 [95% CI 2.68-1852.16], respectively. The rates of CKD and ESKD were numerically higher with a longer time to kidney biopsy from the first LN laboratory sign. Treatment with HCQ at baseline was protective against new-onset ESKD in unadjusted HRs, but did not reach statistical significance in the adjusted models.

Conclusion: In this cohort of patients with newly diagnosed LN on kidney biopsy, a higher chronicity index score was associated with a substantially increased risk of new-onset CKD stage ≥3 and ESKD. A duration of more than 90 days to kidney biopsy from the first LN laboratory sign may also portend an increased risk of these adverse kidney outcomes though did not reach statistical significance. HCQ use may be protective. Our data is limited by a small sample size. These findings highlight risk factors associated with a worse prognosis among newly diagnosed patients with LN.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is the most significant driver of morbidity and mortality in patients with systemic lupus erythematosus (SLE). The ACR 2024 lupus nephritis treatment guidelines (PMID: 40127995) emphasize the importance of intensive induction of LN flares with initiation of dual and/or triple therapy. The guidelines also recommend prompt

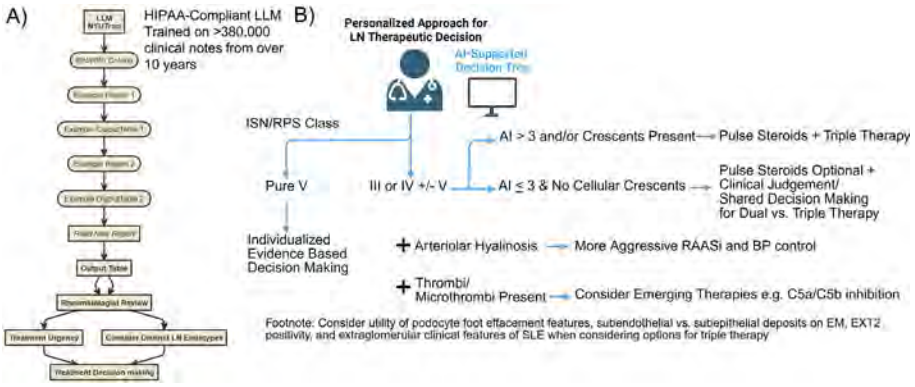

Figure 1. A) The organizational scheme for a HIPAA-compliant LLM is proposed as a clinical support tool for practicing rheumatologists. Our internal HIPAA-compliant LLM initially provides summary information regarding ISN/RPS LN classification criteria. Then, our additional prompt engineering includes two example input unstructured renal biopsy reports, with two paired ideal output organizational tables as well. Finally, a new LN biopsy report is introduced that the LLM reviews and summarizes. B) Proposed personalized approach for LN therapeutic decision utilizing AI-assisted rheumatologist review of renal biopsy reports. A clinical decision-making framework for rheumatologists includes stratifying patients by class (proliferative vs. pure class V vs. mixed classes), AI score, and the presence or absence of crescents, arteriolar hyalinosis, thrombi, and microthrombi. If AI >3 and/or crescents are present, pulse steroids and triple therapy should be strongly considered. However, if AI <3 and crescents are absent, dual therapy versus triple therapy, pulse steroids with or without cyclophosphamide can be optionally used, and these decisions should be guided by shared physician-patient decision-making. Additionally, arteriolar hyalinosis and thrombi/microthrombi may simultaneously prompt RAASi and complement-based therapies (e.g., C5a/C5b inhibitors), respectively.

pulse steroid therapy for both proliferative and pure membranous nephritis. However, these recommendations are conditional, and the necessity for the same treatment intensity for all LN, without regard for other features on biopsy (e.g. crescents, high activity index (AI)), is less certain. Recent data indicate that an AI of $\leq$3 predicts a more favorable prognosis, supporting the concept that a subset of patients can achieve sustained remission without pulse steroids (PMID: 39521057,40180257). Therefore, an evidence-based individualized treatment approach is essential for LN patients, prompting us to create a clinical decision-making support tool to stratify patients for treating providers.

Methods: We used a local HIPAA-compliant large language model (LLM), NYUTron, trained on 10 years of data from 387,144 patients (PMID: 37286606), currently used for clinical predictive modeling in our hospital system. This model organized renal biopsy reports into tabular data of AI, chronicity indices, crescents, sclerosis, thrombi, immunofluorescence, deposits, exostin2 staining, interstitial fibrosis, tubular atrophy, and arterial intimal fibrosis. Prompt engineering involved summarizing ISN/RPS criteria and ideal table examples (Fig 1A). We reviewed renal biopsies from 1/2024 to 3/2025 with ICD-10 SLE diagnoses, comparing results with LLM output to validate accuracy.

Results: 70 renal biopsies were included, with narrative reports generated by 10 renal pathologists (Arkana labs). Of these, four had limited specimens (< 10 glomeruli) or alternate pathology (e.g., focal segmental glomerular sclerosis, acute tubular injury, or lupus podocytopathy), all correctly identified by the LLM (100% accuracy). For ISN/RPS classifications, the LLM correctly assigned A (active), C (chronic), or A/C lesions in 65 of 66 biopsies (98.5% accuracy). The LLM demonstrated 100% accuracy in reporting microthrombi (6/70 biopsies) and cellular/fibrocellular crescents (23/70 biopsies) (Table 1). Arteriolar hyalinosis was accurately identified in 69 of 70 biopsies (98.6% accuracy). This LLM's retrospective renal biopsy summarization, validated by physician review, shows the feasibility of identifying relevant features in SLE renal biopsies to aid in individualized therapy plans (Fig 1B).

Conclusion: This study highlights our LLM's accuracy in analyzing LN renal biopsies, identifying key pathological features linked to poor prognosis. Summarizing these features can facilitate personalized therapy approaches through risk stratification, ultimately improving lupus nephritis treatment outcomes with further validation. We will focus next on fine-tuning our LLM model and integrating biopsy reports with unstructured rheumatologist notes and patient outcomes, aiming to deploy this model in a future prospective, single-arm trial.

Table 1. Clinical and pathological characteristics of the standardized cohort (N = 70). Summarizes our single-center patient cohort's clinical and pathological characteristics (N=70), including demographic data, lupus nephritis (LN) classification, activity and chronicity indices, and specific histological features. These features were all designated using our local LLM and validated by an independent physician review of each input renal biopsy report. *In one of the biopsies, a patient carrying a prior Class IV LN diagnosis underwent repeat biopsy to evaluate for recurrent lupus nephritis. They were noted to have sclerosing lupus nephritis, which one can argue classifies them as VI. Of note, our LLM noted on pathology report review remote active LN, with predominantly chronic features, and the histology of class IV disease, considered the case IV(C). **For another biopsy, where only mild arterial intimal fibrosis was noted upon physician review, our LLM still classified this case as mild arterial hyalinosis. Our model maintains a low threshold for highlighting any evidence of early arterial fibrotic disease, which may help prompt necessary aggressive blood pressure management in our patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: In systemic lupus erythematosus (SLE), differences have been observed between patients of different ages at onset. This study evaluates remission, low disease activity, and relapse in patients with SLE at different ages of onset.

Table 1. Demographic, clinical, auto-antibodies and treatment of studied patients. Data are expressed as number (percentage) or median (interquartile range). Statistical analysis: Chi-square test was used for nominal variables, and the Kruskal-Wallis test was used for numerical variables. APS: antiphospholipid syndrome, SAH: systemic arterial hypertension, AIHA: autoimmune hemolytic anemia, SLEDAI-2K: SLE disease activity index 2000, SDI: SLICC/ACR damage index, LLDAS: low level disease activity state, ACLF: acute on chronic liver failure. *Statistically significant.

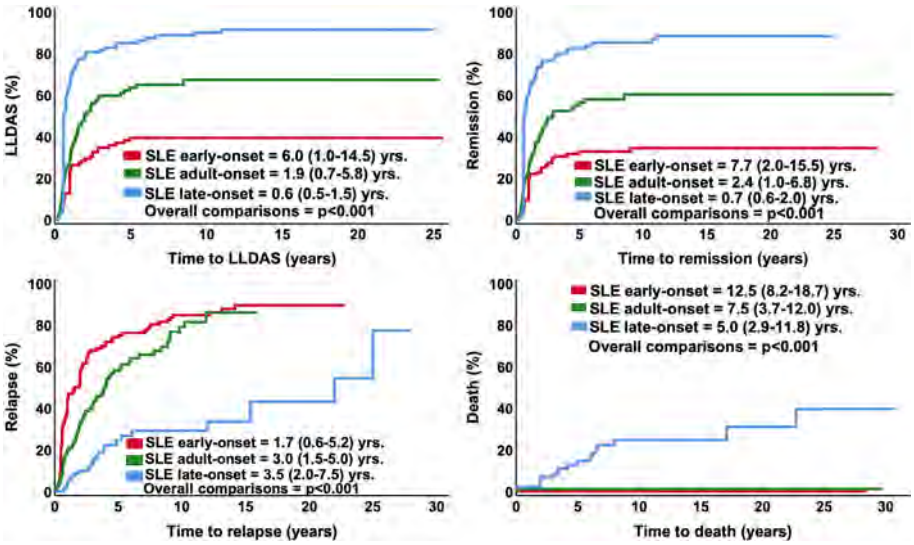

Figure 1. Survival analysis of the outcomes according to SLE groups (n=289). Statistical analysis: the log rank test was used to find differences in time to different outcomes comparing the age of onset of SLE groups. LLDAS: low level disease activity state.

Methods: Design: Retrospective cohort study. We included patients classified with SLE according to the EULAR/ACR 2019 criteria, divided into three groups based on age at onset: early-onset (SLEe < 18 years), adult-onset (SLEa 18–49 years), and late-onset (SLEl ≥50 years). We excluded patients with other autoimmune diseases, except for antiphospholipid syndrome or Sjögren's syndrome. Information was collected through medical record review to obtain demographic data, disease characteristics (disease activity assessed by SLEDAI-2K, accrual damage by SLICC/ACR-DI, autoantibodies, and treatment); and outcomes (remission defined according to DORIS; low disease activity defined according to LLDAS and relapse defined by SELENA-SLEDAI Flare Index). The analysis period began at the date of diagnosis and included all rheumatology follow-up visits until relapse, death, or the last recorded rheumatology visit before December 2024. Demographic and disease characteristics were recorded at onset and during the follow-up period. Outcomes were assessed during follow-up.

Results: We included 289 SLE patients: 96 in the SLEe, 96 in the SLEa and 97 in the SLEl group. A total 90.5% were women. At disease onset, patients in the SLEa group exhibited higher disease activity compared to the other groups. Neuropsychiatric manifestations were more frequent in the SLEe group, whereas mucocutaneous manifestations and lupus nephritis were more prevalent in the SLEa group (Table 1). SLEa group compared to SLEe and SLEl had more prevalence of positive anti-cardiolipin IgG (46.2% vs. 34.2% vs 14%, p< 0.001), IgM (54.9% vs. 50.6% vs. 20.9%, p< 0.001) and positive lupus anticoagulant (27.3% vs. 16.9% vs. 7.1%, p=0.002). In contrast, SLEe group showed a higher prevalence of positive anti-β2 glycoprotein I compared to SLEa and SLEl (IgG: 29.9% vs. 22.7% vs. 1.2%, p< 0.001; IgM: 38.2% vs. 21.3% vs. 9.3%, p< 0.001). Differences in treatment among the groups are summarized in Table 1. Remission and LLDAS were more frequently achieved in the SLEl group compared to the SLEe and SLEa groups. Relapses were more frequent in SLEe group compared to the other groups (Table 1). Moreover, severe relapses were more common in SLEe patients than in

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

those with SLEa or SLEl (63.5% vs. 42.7% vs. 14.4%, p< 0.001). Risk factors associated with relapse in studied patients included SLEe (HR 1.9, 95% CI, 1.4-2.8, p=0.008), constitutional manifestations at onset (HR 1.6, 95% CI, 1.2-2.2, p=0.048) and lupus nephritis during follow-up (HR 1.7, 95% CI, 1.2-2.4, p=0.024) (Table 2). Deaths occurred predominantly in SLEl group, with infections being the leading cause. Survival analysis of the outcomes is presented in Figure 1.

Conclusion: Patients with SLEe experienced more frequent relapses, while those with SLEl more often achieved remission and low disease activity. SLEe, constitutional manifestations at onset and lupus nephritis during follow-up were identified as risk factors for relapse.

Why Do Some Lupus Patients Skip Their Mycophenolate Mofetil? A Multi-Factorial Assessment of Patient Compliance

Nidaa Bukhari[1], **Ali Rizvi**[1], Jian sun[1], Zerai Manna[2], Paul Schaughency[3], Suraj Rajasimhan[4] and Sarfaraz Hasni[1], [1]National Institutes of Health, BETHESDA, MD, [2]NIH, Bethesda, MD, [3]NIAID, NIH, Bethesda, MD, [4]National Institutes of Health, Columbia, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Nonadherence to medication is a significant confounder in assessing treatment efficacy for systemic lupus erythematosus (SLE), with rates reported up to 75% depending on the measurement method. Mycophenolate mofetil (MMF) presents unique adherence challenges due to twice-daily dosing, large pill size, and gastrointestinal side effects. Measuring serum mycophenolic acid (MPA: active metabolite of MMF) levels have been used to gauge compliance. However, MPA levels are costly, unavailable during patient encounters, and only performed by a few labs. In this study, we aimed to determine the most reliable predictor of adherence to MMF in SLE patients using multiple modalities. Barriers to compliance were also explored.

Methods: Adult patients with SLE on stable MMF dosing for at least six weeks followed at the outpatient clinic under the NIH longitudinal cohort study, were included. Patients with significant renal dysfunction (eGFR < 30 mL/min/1.73m^2) or hypoalbuminemia (albumin < 3.5 g/dL) were excluded. Adherence was assessed using four methods: (1) Serum MPA trough levels were measured after an overnight fast and prior to the morning dose, with MPA < 1 mcg/mL considered nonadherent; (2) Pharmacy refill percentage was calculated as the proportion of MMF doses dispensed over the prescribed interval, with ≥80% considered adherent; (3) Patient self-assessment was quantified using modified Medication Adherence Self-Report Inventory (MASRI), with adherence defined as ≥80% by visual analog scale; and (4) Treating clinicians, blinded to MASRI scores and refill data, rated adherence using a 0–10 Likert scale. Patients were asked to provide reasons for non-compliance. Demographic and clinical data were collected via chart review and standardized survey. Comparisons between adherent and nonadherent groups were performed using t-tests and chi-square analyses, and correlations between adherence measures were assessed using Pearson coefficients.

	Post-graduate	0 (0.0)	3 (6.8)	
	Not disclosed	0 (0.0)	1 (2.3)	

Results: Of the 61 patients on stable MMF, 44 (72.1%) were classified as adherent based on MPA trough levels > 1mcg/ml. Pharmacy refill percentage was the only variable significantly associated with adherence: adherent patients had a higher mean refill percentage (0.89 ± 0.11) compared to nonadherent patients (0.66 ± 0.33; $p < 0.001$; r=0.47)(Table 1). Self-reported adherence (MASRI) trended higher in the adherent group (92.4 ± 14.2 vs. 83.2 ± 26.8; p=0.087. Physician compliance rating was similar in both groups (adherent mean (SD) 7.93(1.64) vs non-adherent 7.94(1.76) p=0.98). There was a trend toward higher adherence among married patients (56.8% vs. 29.4%, p=0.10). Age, BMI, number of

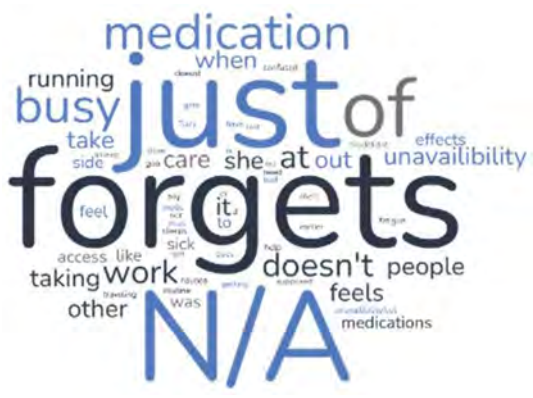

Figure 1. Word Cloud generated from patient responses. Reasons given for nonadherence

comorbidities, total number of medications, and MMF dosage were similar between groups. No significant differences were observed in ethnicity, sex, education, side effects, or MMF intake with food (Table 2). Forgetfulness and medication access were the most commonly identified barriers (Figure 1).

Conclusion: Only pharmacy refill percentage reliably predicted MMF adherence. Compliance can be improved by providing social support and using a reliable medication reminder system.

Prevalence and Clinical Outcomes of Hemophagocytic Lymphohistiocytosis in Systemic Lupus Erythematosus: A Multi-Institutional Cohort Study

Amir Daneshvar[1], Julia Wajsberg[1], Chelsea Guan[1], Keri Ann Pfeil[1], Elleson Harper[1], Lindsay Frumker[2], Meghan Gump[1] and Omer Pamuk[3], [1]University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH, [2]University hospitals Cleveland medical center, Highland Heights, OH, [3]University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multisystem involvement. A rare but life-threatening hyper-inflammatory hematological complication of SLE is hemophagocytic lymphohistiocytosis (HLH). This study aims to determine the prevalence of HLH among SLE patients and to compare clinical characteristics and outcomes between SLE patients with and without HLH.

Methods: In this study, we utilized data from the TriNetX global research network, which includes electronic medical records from 101 healthcare organizations. Our search in the TriNetX yielded 130,187 patients with SLE (ICD-10: M32), of which 448 patients had a diagnosis of HLH (ICD-10: D76.1) and 129,739 did not have an HLH diagnosis. Propensity score matching was performed using 59 demographic and clinical variables, yielding two well-balanced cohorts of 443 patients each. Variables studied included baseline patient demographics, clinical manifestations/comorbidities, and autoantibody profile. Outcomes analyzed included mortality, laboratory findings, and medication usage. Kaplan-Meier curve and log-rank test were used for survival analysis. Statistical significance was defined as a p-value of < 0.05.

Results: The prevalence of HLH among the general SLE population was 0.34%. Prior to propensity matching, higher rates of HLH were seen in males (26.1% vs 13.4%), African-American (35.3% vs 24.7%) and Asian populations (16.1% vs 7.5%) (all p-values $<$ 0.001). Clinical manifestations such as glomerular disease, anti-phospholipid syndrome, seizures & epilepsy, and pericarditis (all p-values < 0.001) as well as pleurisy ($p=0.008$) were seen more frequently in HLH patients before propensity matching (Table 1).

After matching, SLE patients with HLH were significantly more likely to have positive Ro/SSA (14.9% vs. 7.2%), RNP (11.3% vs. 4.3%) autoantibodies, low C3 complement (44.7% vs. 29.3%) and low C4 complement (30.5% vs. 20.1%) (all p values $<$ 0.001) (Table 2).

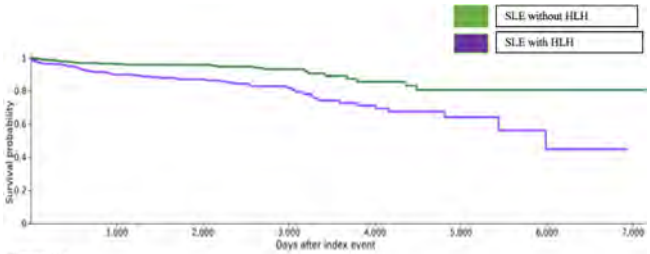

Figure 1A

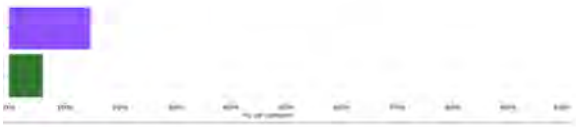

Figure 1B

Figure 1A: Survival Probability in Systemic Lupus Erythematosus Patients With and Without Hemophagocytic Lymphohistiocytosis Using Kaplan-Meier Survival Analysis Figure 1B: Mortality Rate Data in Systemic Lupus Erythematosus Patients With and Without Hemophagocytic Lymphohistiocytosis

Kaplan-Meier survival analysis revealed that HLH is a significantly poor prognostic factor in SLE patients , with diminished survival probability compared to patients without HLH (HR: 2.62, 95% CI: 1.67-4.1, p< 0.001). During the study period, 14.7% of patients with HLH died and 6.1% of patients without HLH died (RR: 2.41, 95% CI: 1.57-3.70) (Figure 1A & 1B).

Conclusion: HLH is an uncommon but clinically significant complication of SLE, associated with hypocomplementemia, distinct autoantibody patterns, and markedly increased mortality. These findings underscore the need for heightened clinical awareness and timely intervention in SLE patients presenting with features suggestive of HLH.

Characteristics and Predictors of LLDAS in Survivors of Early Active Lupus: Insights from a Decade-Long Cohort

Amirtha Gopalan[1], keerthi vardhan yerram[2], Mahesh Gaikwad[2] and Liza rajasekhar[3], [1]Nizams Institute of Medical Sciences, Hyderabad, Hyderabad, Telangana, India, [2]Nizams institute of medical sciences, hyderabad, Andhra Pradesh, India, [3]Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: LLDAS is a desirable state in lupus, with ongoing global reports on its durability and outcomes. The relationship between LLDAS, baseline characteristics, and drug efficacy is unknown. A university hospital's SLE registry (since 1998) describes the frequency, duration, and outcomes after achieving LLDAS in patients followed for ≥5 years.

Methods: Patients fulfilling the updated 1997 ACR or 2012 SLICC criteria with at least one follow-up clinic visit annually for a minimum of five years, were included. The registry records baseline disease characteristics, SLEDAI score, SLICC/ACR

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Immunosuppres medication use ever Cyclophosphamide Rituximab Mycophenolate	 184 (60) 19 (6.1) 80 (26)
Patients with HDAS before onset of LLDAS	266 (86)

Damage Index, serologies, and treatment in each clinic visit and is approved by the Institutional Ethics Committee. Records with missing data on clinical SLEDAI in more than 3 contiguous visits or deaths/ lost followup within 5 years and when the disease course could not be inferred by registry notes were excluded. HDAS before LLDAS was defined by either 1 BILAG A, 2 BILAG B, or clinical SLEDAI >6. LLDAS was scored if all five predefined criteria (Franklyn K et al) were fulfilled. LLDAS50 was recorded if at least half of the observation period was spent in LLDAS.

The study used non-parametric descriptive statistics for summarizing non-normally distributed data and generalized estimating equations (GEE) to identify predictors of LLDAS50. Group comparisons were performed using Mann-Whitney U tests and Chi-square tests as appropriate.

Aim - To characterize the attainment and maintenance of LLDAS over time in a cohort of SLE

Objectives

To determine frequency, predictor and time to flare following LLDAS

To identify the frequency and predictors of LLDAS50

Results: This study included a cohort of 307 (282 females) patients (Table 1) with 2679.6 patient-years of observation, averaging 3.15 ± 3.4 observations per patient per year. A large proportion (266 of 307, 86%) exhibited HDAS before achieving their first LLDAS.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. LLDAS ever; n (%)	253 (95.4)	41 (97.6)	0.30
Time to first LLDAS	2 (1-4.1)	1.17 (0.9-4)	0.2
Duration of first LLDAS	3.8 (1.9-6.1)	4.8 (2.4-7.7)	0.06
Median percentage of time spent in LLDAS	73.2 (48.5- 90.3)	86.1 (69.9 - 93.7)	**<0.001**
Flares after LLDAS_1 • 0 • 1 • 2 • >2 • Missing data	 118 (44) 70 (26) 45 (17) 9 (3.3) 17 (6.3)	 26 (63) 8 (19.5) 7 (17) 0 (0) 0 (0)	0.2
Median time to flare	2.84 (1.41-4.80)	3.67 (1.75-5.15)	0.34
% of LLDAS-50 achievers	195 (73.3)	32 (78)	0.65
Severe flares after LLDAS_1	106 (40)	7 (17)	0.008
Ever flare after steroid taper Yes No Missing data	 126 (47) 122 (45) 18 (6.7)	 12 (29) 24 (58.5) 3 (7.3)	**0.02**
Ever flare after IS taper Yes No Missing data	 112 (42) 129 (48) 24 (9)	 9 (22) 26 (63) 4 (9.7)	**0.04**

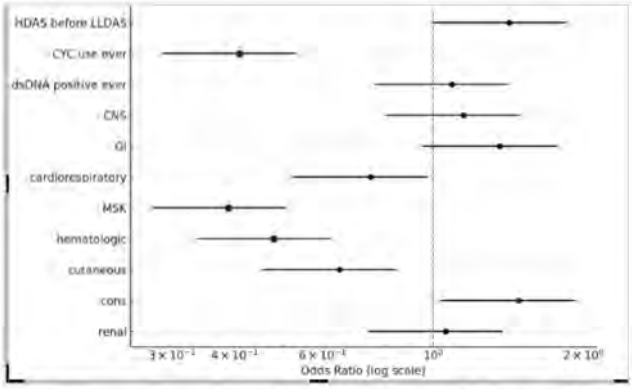

Figure 1 illustrates the predictors of failure to achieve LLDAS-50, derived from a multivariate Generalized Estimating Equation (GEE) model. The forest plot presents odds ratios (ORs) and 95% confidence intervals on a logarithmic scale, with the vertical dashed line representing the null value (OR = 1). Variables with ORs to the left of this line are associated with reduced odds of spending at least 50% of time in LLDAS. Black dots represent predictors included in the model, while red-circled black dots highlight statistically significant negative predictors ($p < 0.05$). Notably, cyclophosphamide use, hematologic involvement, and musculoskeletal involvement were significantly associated with lower likelihood of achieving LLDAS-50. Other clinical domains such as CNS, renal, and cardiorespiratory involvement, though included in the model, did not demonstrate statistically significant associations.

Figure 1: Predictors of LLDAS50

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

During the observation period 291 (94.7%) achieved LLDAS, 142 maintained it till last visit while 228 (78%) attained LLDAS50. Flares occurred in 154 patients (severe in 111). Median (IQR) time to flare was 2.89 (1.48, 4.95) years. Most (45%) flares occurred within 2 years of first attaining LLDAS. Differences in LLDAS characteristics in patients with and without prior HDAS is presented in Table 2.

GEE models showed that patients with hematologic or musculoskeletal involvement (OR and p value 0.48, 0.011; 0.39, 0.04 respectively) or cyclophosphamide use (OR 0.41, p 0.01) did not attain LLDAS50 (Figure 1).

At their last recorded visit, 194/291 (66%) patients were in LLDAS with one-third (102 of 307) off glucocorticoids. SDI was 0 in 43.4%, with some damage present in the others.

Limitations: This study does not include patients who died or were lost to follow-up within five years of first being seen at the hospital. Periods of non-compliance are not reliably captured.

Conclusion: In patients attending lupus clinic for more than five years, LLDAS is achieved by most early active lupus survivors but not often sustained. Patients with hematological and musculoskeletal involvement are less likely to achieve LLDAS50. High initial disease activity is associated with reduced time in LLDAS, earlier, more severe flares and flares after steroid/IS taper.

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Double-stranded DNA (dsDNA) antibodies are among the most specific biomarkers for systemic lupus erythematosus (SLE). They are associated with disease activity and are incorporated into widely accepted lupus activity indices. Additionally, dsDNA antibody titers have been linked to lupus nephritis, with improvements in titers serving as important predictors of renal response. However, serologic testing for these antibodies has limitations, as antibody positivity does not always correlate with clinical SLE. Several assays are available for detecting dsDNA antibodies in serum, including the ZEUS dsDNA enzyme-linked immunosorbent semi-quantitative assay, the Bio-Rad Anti-dsDNA semi-quantitative enzyme immunoassay, and the BioPlex 2200 multiplex flow immunoassay. This study aimed to evaluate and compare the diagnostic performance of these three assays to better elucidate their clinical utility in diagnosing SLE.

Methods: A total of 78 cross-sectional serum samples from patients seen at Vanderbilt University Medical Center between November 2024 and April 2025 were analyzed using the three dsDNA antibody assays. Among these, 36 patients had a diagnosis of SLE, of whom 26 had a SLE Disease Activity Index (SLEDAI) score greater than zero (excluding points for

dsDNA positivity). The remaining samples were from patients without SLE. Concordance rates between the assays were calculated, and the sensitivity and specificity of each assay, as well as combinations of assays, were assessed. Equivocal or indeterminate results were considered negative for the purposes of this analysis.

Results: The concordance rate between the Bio-Rad and BioPlex 2200 assays was 73.3%, between ZEUS and Bio-Rad was 67.6%, and between ZEUS and BioPlex 2200 was 78.5%. The Bio-Rad assay had the highest sensitivity at 75%, but the lowest specificity at 80.9%. The ZEUS and BioPlex 2200 assays demonstrated high specificity at 92.9% and 94.5%, respectively, though their sensitivity was lower at 52.9% and 46.7%. The sensitivity and specificity of a combination of these assays is depicted in Figure 1.

Conclusion: The performance of the three dsDNA antibody assays varied considerably. Concordance among the assays was suboptimal, and no single assay achieved both high sensitivity and specificity. These findings also indicate that using a combination of assays, for example through sequential testing, unfortunately does not significantly improve sensitivity or specificity of these tests. Ultimately, the results of this study suggest that existing assays, while useful adjuncts in assisting with the diagnosis of SLE, should continue to be interpreted with caution without corresponding clinical correlation given existing limitations in their diagnostic accuracy.

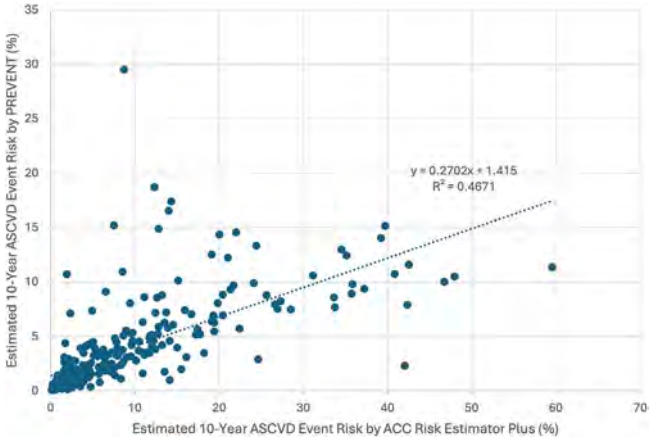

Figure 1. Pearson's Correlation Between Estimated 10-Year ASCVD Event Risk by PREVENT Calculator and Estimated 10-Year ASCVD Event Risk by ACC Risk Estimator Plus for the Lupus Erythematosus Cohort. The two calculators used to estimate the risk of a future atherosclerotic cardiovascular disease (ASCVD) event for individual patients within the primary prevention lupus erythematosus (LE) cohort with sufficient data in electronic medical records were the 10-year ASCVD event risk generated by the PREVENT Calculator (y-axis) versus the ACC ASCVD Risk Estimator Plus (x-axis). Two estimates of ASCVD event risk for each of the 278 eligible patients with LE. Each dot represents an individual patient.

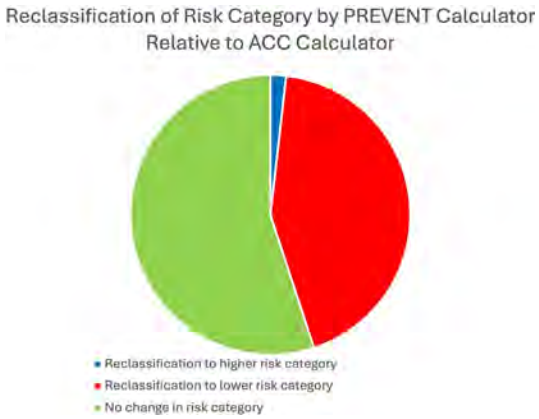

Figure 2. Distribution of Risk Category Change Using the PREVENT Calculator Compared to the ACC ASCVD Risk Estimator Plus (ACC) Calculator

Background/Purpose: Patients with lupus erythematosus (LE) are at an increased risk of clinical events from atherosclerotic cardiovascular disease (ASCVD), yet the accuracy of risk estimation tools in this population remains unclear. Here, we compared the new American Heart Association cardiovascular risk calculator, PREVENT, with the previous ACC ASCVD Risk Estimator Plus (ACC) in our longitudinal cohort of patients with cutaneous LE without (CLE-only) or with (CLE+SLE) concurrent systemic LE.

Methods: Utilizing our prospective longitudinal database of patients with LE, we conducted a retrospective chart review to estimate the risk of an ASCVD event in the next 10 years ("10-year ASCVD event risk") using both calculators, incorporating optional variables when available.

Results: A highly significant correlation was identified between the two calculators ($p< 10^{-15}$), but with considerable scatter (r^2=0.47) (Figure 1). The PREVENT calculator consistently generated far lower estimates of 10-year ASCVD event risk (median 2.33%, IQR 0.79%-5.16%) compared with the ACC calculator (median 4.65%, IQR 1.30%-11.98%; $p< 10^{-15}$ by the Wilcoxon signed-rank test), consistent with previous studies. Subtype analyses revealed significant differences between the two calculators for CLE-only patients and for CLE+SLE patients as well ($p< 10^{-15}$), although no significant difference was observed within PREVENT-generated scores between these two subgroups (p=0.11). Clinical management of ASCVD is

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. typically driven by risk category, and the PREVENT calculator reclassified 43.2% (120 out of 278) of the lupus patients to a lower category than was assigned by the ACC calculator (Figure 2).

Conclusion: Given an actual 10-year ASCVD event *rate* of 13.5% in this cohort (Zhao M et al. 2023), both calculators underestimated risk, with PREVENT underestimating more significantly. These findings highlight the need for caution when using PREVENT for LE patients. Overall, there is a need for better cardiovascular risk assessment and management for patients with lupus erythematosus.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at increased risk for herpes zoster (HZ) and its complications. Exposure to immunosuppressants (IS) at the time of the 2-dose recombinant zoster vaccine (RZV) may attenuate responses. We evaluated humoral immune responses to the RZV in a longitudinal SLE cohort, including individuals exposed and unexposed to IS.

Methods: Cohort participants meet ACR SLE criteria and have clinical data and biospecimens collected annually. We selected participants who received ≥1 RZV dose according to the provincial registry (2018-2024) and had available serum samples before vaccination plus at ≥1 time point after the first and/or second RZV dose. We determined serum anti-Varicella Zoster Virus glycoprotein E antibody (anti-gE Ab) concentrations using an enzyme-linked immunosorbent assay (ELISA, ReVacc Scientific, USA). We defined the humoral response threshold as a ≥4-fold increase in anti-gE Ab concentration compared to pre-vaccination titres. We determined the proportion of RZV recipients above the response threshold (RZV response rate), compared RZV responses according to IS exposure, and evaluated the persistence of humoral responses over time.

Time between RZV doses	2.6 (2-5)

*Unless indicated, participants could be on ≥1 SLE medication

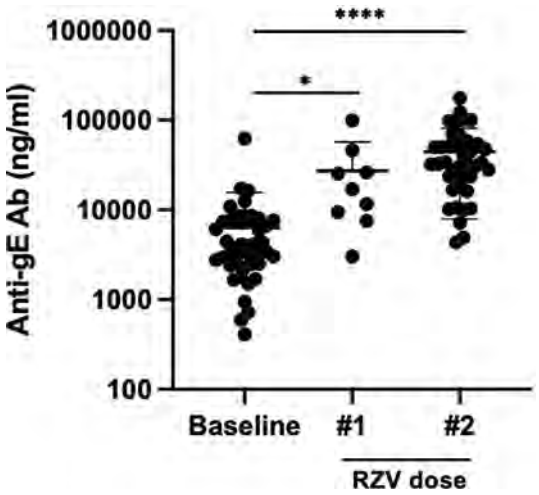

Figure 1. Anti-gE Ab concentrations (ng/mL) pre-vaccination, and after first and second RZV dose

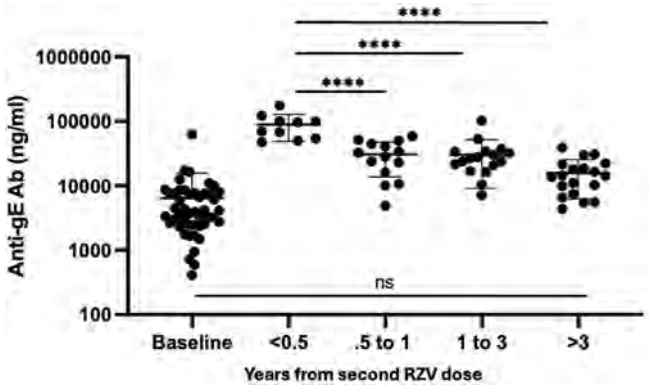

Figure 2. Anti-gE Ab concentrations (ng/mL) at baseline and over time after the 2-dose RZV

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We tested baseline and post-vaccine samples from 46 SLE cohort participants, 9 with samples collected after one RZV dose and 40 with samples collected after two doses (Table 1). All were seropositive for anti-gE Ab at baseline and 45/46 (98%) had an increase in anti-gE Ab concentrations following ≥1 RZV doses. The RZV response threshold was met in 5/9 (56%) at a median of 9 months (IQR 3-17) from the first RZV dose, and in 26/40 (65%) at a median of 11 months (IQR 6-21) from the second dose (mean ± SD anti-gE Ab concentration 27291 ± 29949 ng/ml post-first dose and 46471 ± 36933 ng/ml post-second dose, compared to 6341 ± 9270 ng/ml at baseline, Figure 1). Response rates to two doses were similar in those unexposed (15/22, 68%) and exposed to IS (11/18, 61%) at the time of vaccination, and in those who received 2 RZV doses ≤65 days apart (8/12, 67%) versus >65 days apart (18/28, 64%). Anti-gE Ab concentrations decreased according to time since vaccination (Figure 2), and in samples drawn ≥3 years post-vaccination, mean (±SD) anti-gE Ab concentration was not significantly different from baseline (15775 ± 9562 ng/ml versus 6417 ± 9184 ng/ml).

Conclusion: We detected a humoral response in most (68%) patients with SLE who received 2 doses of RZV, regardless of background treatment. However, increases in anti-gE Ab appear to return to baseline concentrations ≥3 years post vaccination.

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by widespread immune dysregulation and multi-organ involvement. Autoimmune hemolytic anemia (AIHA), marked by antibody-mediated red blood cell destruction, is a common hematological complication of SLE. The overlap of SLE and AIHA represents a distinct clinical phenotype with diagnostic challenges. This study examined the frequency of AIHA in SLE and its association with other clinical manifestations of SLE.

Methods: The systematic review and meta-analysis adhered to Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines and checklists. A comprehensive literature search was conducted using PubMed (1959–2025) with the keywords "systemic lupus erythematosus," "lupus," "hemolytic anemia," "autoimmune hemolytic anemia," "AIHA," and "hematologic manifestations. Studies reporting the frequency of AIHA in SLE patients were screened, and eligible articles were included to estimate AIHA prevalence and assess associations with other clinical features of SLE. A random effects model was used to pool AIHA frequency across SLE studies, with forest plots generated for composite estimates and corresponding 95% confidence intervals (CI). Study heterogeneity was assessed using the I^2 statistic. Correlation analyses were performed to evaluate associations between AIHA and specific SLE features.

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

Results: Fifty-six studies reported the frequency of AIHA in 25,549 SLE patients. The overall AIHA prevalence was 12.5% (95% CI: 10.3-15.1) using a random-effects model, selected due to substantial inter-study heterogeneity (I^2 = 96%). While most patients were female, gender-stratified AIHA analyses were limited by inconsistent reporting. Across the included studies, Pearson Correlation Analysis showed that AIHA frequency was significantly correlated with a positive Coombs test (r=0.96, p< 0.001), leukopenia (r=0.79, p< 0.001), lymphopenia (r=0.78, p< 0.001), thrombocytopenia (r=0.79, p< 0.001), lupus nephritis (LN) (r=0.62, p< 0.001), serositis (r=0.76, p< 0.001), neuropsychiatric SLE (NPSLE) (r=0.63, p< 0.001) and thrombosis (r=0.88, p< 0.001).

Conclusion: This study demonstrates that AIHA is present in approximately 1 in 8 patients with SLE (12.5%) and that it frequently co-occurs with Coombs positivity, cytopenias, thrombosis, serositis, LN, and NPSLE—all key markers of major organ involvement. These findings support AIHA as a hallmark hematologic manifestation of SLE, with potential utility as a marker of disease burden and prognostic significance. Further prospective studies are warranted to define the prognostic implications of AIHA and its possible role in SLE disease stratification, monitoring, and therapeutic decision-making in SLE.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: This study evaluates the contributions of large language models (LLMs) in clinical decision-making for atypical presentations of systemic lupus erythematosus (SLE). It focuses on the models' ability to assist with diagnosis, further investigations and treatment planning. Diagnostic and treatment recommendations from LLMs were compared with those of treating physicians and the relative strengths of each LLM were assessed. To our knowledge, this is the first study to assess LLMs in both diagnosis and management of atypical SLE. The LLMs used in the study are Claude 3 Opus, GPT-4o Mini and Gemini 2.0 Flash.

Methods: A PubMed search identified case reports published after April 2024, ensuring cases were not part of the LLMs' prior training data. Of 95 studies reviewed, 24 cases from 23 studies were included, involving atypical SLE presentations that did not meet established classification criteria. Exclusion criteria were prior SLE diagnosis, insufficient diagnostic information or unavailable full texts.

Clinical data including symptoms, laboratory, imaging findings and medical history were extracted, standardized and entered into LLMs for diagnosis, further investigations and treatment planning. Models operated without web access, relying entirely on internal knowledge. Antinuclear antibody (ANA) testing was prioritized for its high sensitivity and the timing and frequency of ANA requests were evaluated as indicators of SLE suspicion. The models' ability to identify SLE and its ranking in differential diagnoses were assessed. Initial and long-term treatment recommendations were compared with those of treating physicians.

Results: All LLMs successfully suggested SLE as a differential diagnosis in every case. While Gemini mostly ranked SLE first, Claude requested ANA more frequently but neither difference was significant. However, GPT prioritized ANA significantly earlier (p=0.011). Table 1 shows model comparisons.

Initial treatment was similar across models, suggesting corticosteroids as first-line therapy. Long-term treatment plans varied; Claude aligned most with treating physicians' long-term plans, while GPT often proposed guideline-consistent alternatives, such as mycophenolate mofetil (MMF) or hydroxychloroquine (HCQ).

In one case, all LLMs recommended HCQ despite the contraindication due to optic nerve atrophy, highlighting limitations in safety considerations. GPT and Gemini more frequently recalled rare differentials such as Aicardi-Goutières and Evans syndromes, whereas Claude more often assigned direct SLE diagnoses with fewer alternatives.

Table 1. Performance Comparison of LLMs in Diagnostic and Treatment Decisions for Atypical SLE Cases

	Claude	Gemini	GPT	p-value
SLE Diagnosis Mentioned	24 (100.0)	24 (100.0)	24 (100.0)	NA
Rank of the SLE Diagnosis	1.29 (0.55)	1.08 (0.28)	1.21 (0.41)	0.247
Request for ANA	23 (95.8)	21 (87.5)	22 (91.7)	0.580
Rank of ANA Request	4.88 (3.64)	3.21 (2.11)	2.55 (1.65)	**0.011**
Initial Treatment Aligning with Treating Physician	23 (95.8)	22 (91.7)	21 (87.5)	0.580
Long-Term Treatment Aligning with Treating Physician	13 (56.5)	13 (56.5)	10 (45.5)	0.684

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The lack of a non-SLE control group limited the assessment of false-positives and diagnostic specificity, raising concerns about potential overdiagnosis, particularly with GPT's early ANA prioritization.

Conclusion: LLMs effectively prioritized ANA testing, supporting early SLE consideration in complex cases. They showed strong diagnostic performance and appropriate initial treatment suggestions. However, variability in long-term management and limited safety considerations remain. The lack of a non-SLE control group limits specificity analysis and highlights the need for further research to improve clinical use.

Abstract Number: 1478

Construction and Validation of a Prediction Model of Cognitive Dysfunction in Patients with Systemic Lupus Erythematosus

Bin Zhou[1], QIn Huang[2], Pan Wang[3] and Qiguo Cui[4], [1]Nanfang Hospital, Guangzhou, Guangdong, China (People's Republic), [2]Nanfang Hospital, Guangzhou, China (People's Republic), [3]southern medical university Nanfang Hospital, Guangzhou, China (People's Republic), [4]Southern Medical Univercity Nanfang Hospital, guang zhou, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that affects multiple organs. Cognitive dysfunction (CD) is a common but often underestimated complication in SLE patients, seriously affecting their quality of life. The purpose of this study was to analyze the clinical data of SLE patients, screen effective predictors, and construct and validate a prediction model for the early identification of cognitive impairment in SLE patients.

Methods: The training cohort included 100 SLE patients. Baseline characteristics, clinical data, and laboratory and imaging data during hospitalization were screened using least absolute shrinkage and selection operator (LASSO) and logistic regression to construct a predictive risk score. The derived score represents an estimate of the risk of developing cognitive dysfunction in patients with SLE. A nomogram was constructed, and its accuracy and predictive performance were evaluated using the area under the receiver operating characteristic curve (AUC), calibration curves, and clinical decision curves. For the validation cohort, data were prospectively collected from 47 SLE patients.

Results: Six important predictors were screened out by LASSO regression: age, SDI, anxiety and depression, creatine kinase isoenzymes(CK-MB), triglycerides (TG), and anti-SSB antibodies, and a prediction model nomogram for SLE-CD was constructed. In the training cohort, the AUC of the model was 0.887 (critical value: 0.571, sensitivity: 0.821, specificity: 0.841, Youden index: 0.662). In the validation cohort, the AUC of the model was 0.877 (critical value: 0.526, sensitivity: 0.810, specificity: 0.846, Youden index: 0.656). The calibration curve showed that the predicted probability was highly consistent with the actual observed value, and the clinical decision curve suggested that the model had clinical application value within a wide range of thresholds.

Conclusion: The constructed SLE-CD prediction model showed good predictive efficacy in the training and validation cohorts and has potential clinical application value.

Abstract Number: 1479

Validation of Attention, Memory, and Frontal-Executive Abilities Screening Test (AMFAST) in Systemic Lupus Erythematosus (SLE), a prospective single-center study in The Bronx

Chen Chao[1], Garrett Thomas[2], Catherine O'Brien[2], Davina Chen[3], Sundus Mian[4], Tamar Rubinstein[5], Noa Schwartz[4] and Bryan Freilich[2], [1]Rheumatology Division, Department of Medicine, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, NY, [2]Department of Psychiatry, Montefiore Medical Center, Bronx, NY, [3]Division of Rheumatology, Department of Medicine, Montefiore Medical Center, New Rochelle, NY, [4]Division of Rheumatology, Department of Medicine, Montefiore Medical Center, New York, NY, [5]Albert Einstein College of Medicine, White Plains, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Up to 80% of Systemic Lupus Erythematosus (SLE) patients experience cognitive dysfunction (CD), which is a top distressing symptom affecting their quality of life.(1) This process is poorly understood and often a diagnostic challenge due to mild and nonspecific symptoms. The current gold-standard diagnostic tool, the comprehensive neuropsychological (CNP) testing, is time-consuming and requires specialized training. Other tests, such as the Automated Neuropsychological Assessment Metric (ANAM) or the Montreal Cognitive Assessment (MoCA), can be impractical in busy clinical settings or focus more on memory deficits that are less relevant than impairment in processing speed and executive function in young SLE patients. We propose using a novel tool, the Attention, Memory, and Frontal-Executive Abilities Screening Test (AMFAST), which is a 10-minute pen-and-paper test that has shown excellent sensitivity and specificity for neurologic pathologies within a large age range.(2) Our aim is to validate AMFAST as a bedside screening tool for detecting CD in adult SLE patients.

Methods: This IRB-approved longitudinal study assessed a cohort of 31 adult SLE patients from the Lupus Clinic at Montefiore Medical Center between 2023 and 2025. English-speaking patients with no pre-existing, non-SLE-related neurological conditions were recruited. Participants underwent AMFAST testing in the clinic, followed by a CNP battery evaluation administered by a blinded neuropsychologist within two weeks. Patients were then classified into two groups: those

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

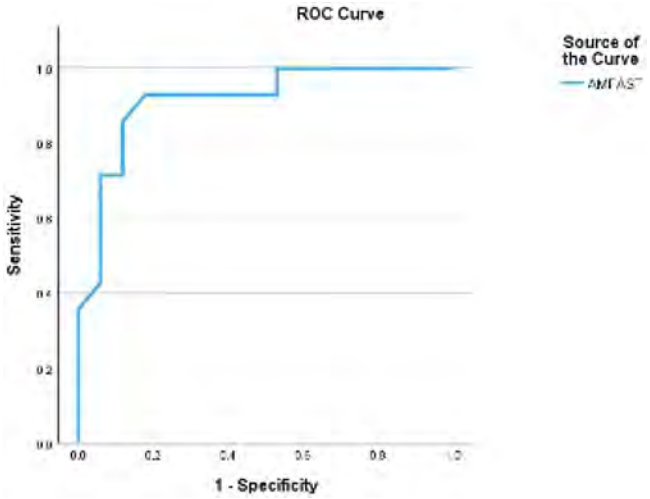

Figure 1: Receiver operating characteristic (ROC) of AMFAST test

Table 1: Baseline demographics

Characteristics	AMFAST population (n = 31)
Gender (n [%])	
Male	2 (6.5%)
Female	29 (93.5%)
Race & ethnicity (n [%])	
Black	19 (61.3%)
Asian	1 (3.2%)
Hispanic	11 (35.5%)
Education (mean [SD])	14.94 (2.66)

exhibiting CD, defined by scoring below one standard deviation (SD) on at least six of the 24 measures, and those without cognitive impairment (NCD).(3) A receiver operating characteristic (ROC) curve analysis was conducted to evaluate the correlation between AMFAST scores and CNP test battery performance.

Results: Participants had a mean age of 43 years (range 23-70) and were 93.5% female (Table 1). Based on the CNP battery tests, 14 out of 31 patients (45.2%) were classified as having CD. The mean score on the AMFAST test was 79.23 (SD = 18.1). ROC analysis demonstrated excellent diagnostic discrimination for the AMFAST test, with AUC of 0.92 (Figure 1). This indicates that AMFAST is highly effective in distinguishing between individuals with CD and NCD. AMFAST cutoff score of 83 had the best balance of sensitivity (93%) with specificity (82%), where overall, it was able to correctly classify 27 out of 31 cases (87.1%).(Table 2)

Conclusion: Our single-center findings confirm the robustness of AMFAST in screening SLE patients at risk of cognitive impairment. It is a simple bedside screening tool demonstrating promising results for identifying CD in SLE patients. The test's ease of administration with high sensitivity and specificity makes it an attractive clinical tool for early identification of CD, enabling timely intervention. Although our study provides valuable insights, further research is warranted.

Urinary Biomarkers Detect Proliferative Lupus Nephritis in SLE Patients with Subclinical Proteinuria.

CHEN-YU LEE[1], Rufei Lu[2], Carla Guthridge[2], Wade DeJager[3], Jennifer Barnas[4], Jennifer Anolik[5], H Michael Belmont[6], Judith James[2], Jill Buyon[7], Brad Rovin[8], Michelle Petri[9], Joel Guthridge[2], Andrea Fava[1] and the Accelerating Medicines Partnership: Autoimmune and Immune-Mediated Diseases Network and the Accelerating Medicines Partnership in RA/SLE Network, [1]Johns Hopkins University, Baltimore, MD, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City, [4]University of Rochester, Rochester, NY, [5]University of Rochester Medical Center, Rochester, NY, [6]NYU School of Medicine, New York, NY, [7]NYU Grossman School of Medicine, New York, NY, [8]The Ohio State University, Columbus, OH, [9]Johns Hopkins University School of Medicine, Timonium, MD

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Early treatment is critical to prevent irreversible kidney damage in lupus nephritis (LN). Current guidelines recommend kidney biopsy when the urine protein-to-creatinine ratio (UPCR) reaches ≥0.5 g/g. However, one-third of patients with UPCR between 0.25–0.5 g/g already harbor ISN Class III or IV ± V LN. While urinary biomarkers can detect active LN in patients with UPCR >0.5, their utility at lower proteinuria thresholds remains unclear. We analyzed candidate urinary biomarkers in SLE patients undergoing kidney biopsy at the initial onset of UPCR 0.25–0.49 g/g to identify molecular signatures of clinically underestimated LN that could support earlier diagnosis and treatment.

Methods: SLE patients with no history of LN, UPCR 0.250–0.49 g/g, and at least one additional LN risk factor (non-White race, low C3, low C4, anti-dsDNA positivity, or active urine sediment) were prospectively enrolled (KP1; n=21). For comparison, we analyzed a cohort of SLE patients with UPCR >0.5 undergoing clinically indicated kidney biopsy (AMP; n=282), and healthy controls (HC; n=31). Urine samples were collected near the time of biopsy, and 5,416 proteins were quantified using the Olink Explore HT platform. We focused on eight candidate biomarkers previously associated with histological activity, fibrosis, and future kidney function loss: IL16, CD163, CD206 (MRC1), PR3 (PRTN3), Galectin-1 (LGALS1), Tenascin-C (TNC), BAFF (TNFSF13B), and C9.

Results: In this interim analysis, 13 of 21 low proteinuria patients (62%) had biopsy-confirmed LN, including 3 (14%) with Class III and 5 (24%) with Class V (**Table 1**).

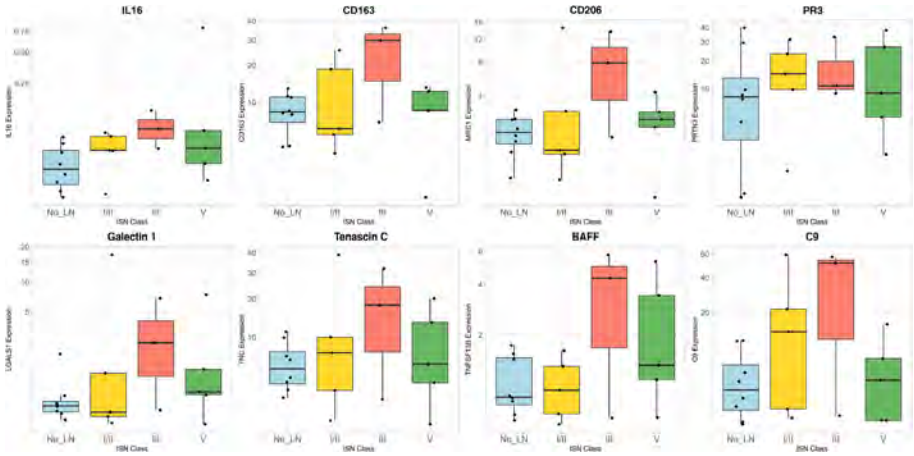

Figure 1. Urinary biomarkers of inflammation and fibrosis are elevated in early lupus nephritis across ISN classes. Boxplots display expression levels of inflammation-associated markers (IL16, CD163, CD206 [MRC1], PR3 [PRTN3], Galectin-1 [LGALS1], BAFF [TNFSF13B], and C9) and the myofibroblast marker Tenascin C [TNC] in early LN biopsies. Among the eight KP1 patients without histologic LN, six (75%) exhibited 20–30% foot process effacement, two (25%) showed glomerulosclerosis, five had atherosclerosis, and one had IgA nephropathy. Proteins are expressed as normalized protein expression (NPX) and normalized by plate controls.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

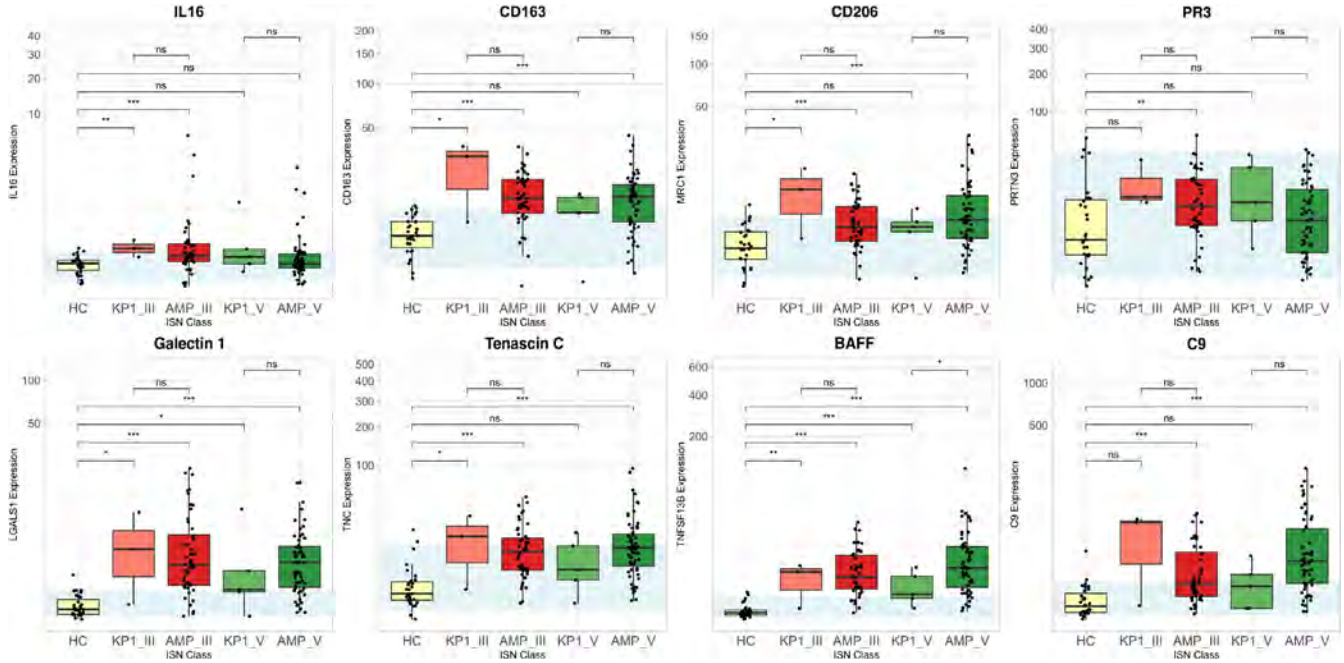

Figure 2. Urinary inflammatory and fibrotic protein expression is elevated in early and established proliferative and membranous lupus nephritis. Boxplots show expression levels of eight candidate biomarkers—IL16, CD163, CD206 (MRC1), PR3 (PRTN3), Galectin-1 (LGALS1), BAFF (TNFSF13B), C9, and Tenascin-C (TNC)—in urine samples from patients with low proteinuria LN (UPCR <0.5, KP1), high proteinuria LN (UPCR >= 0.5, AMP), and healthy controls (HC). KP1 Class III patients exhibited similar biomarker profiles to AMP Class III patients, suggesting early molecular activation despite subclinical proteinuria. Class V patients in both cohorts also showed enrichment of fibrotic markers (Tenascin-C). The blue shaded area represents the 5th to 95th percentile range of protein expression in HC. Statistical comparisons were performed using the Wilcoxon test. *p < 0.05; **p < 0.01; ***p < 0.001.

Compared to UPCR >0.5 SLE patients, low proteinuria patients had higher eGFR (but not statistically significant) and lower NIH activity and chronicity indices, suggesting earlier stages of inflammation and fibrosis.

Although the sample size limited statistical power, patients with Class III LN showed elevated levels of multiple candidate biomarkers—including CD163, CD206, IL16, Galectin-1, BAFF, C9, and Tenascin-C—compared to those with no LN (**Figure 1**).

All eight biomarkers were significantly enriched in low proteinuria Class III patients, mirroring the Class III profile in high proteinuria patients (**Figure 2**). This suggests that proliferative LN is already molecularly active at lower proteinuria levels, with signatures of M1/M2 macrophage activation (CD163, CD206), B cell stimulation (BAFF), complement activation (C9), and fibrotic remodeling (Tenascin C). Importantly, biomarker levels in KP1 Class III patients were comparable to those in AMP patients with UPCR >0.5, indicating that proteinuria alone underestimates the degree of renal inflammation. Notably, Class V patients in both KP1 and AMP cohorts showed elevated Tenascin-C, highlighting a pro-repair/fibrotic signature even in early membranous LN.

Conclusion: Urinary biomarkers may detect proliferative LN in SLE patients with subclinical proteinuria. These findings support the potential of biomarker-guided strategies to enable screening as well as earlier diagnosis and intervention in lupus nephritis. Ongoing analysis of the full 5,416-protein panel aims to elucidate early mechanisms of LN and identify novel targets for timely intervention.

Duffy Antigen Screening in Systemic Lupus Erythematosus Patients with Neutropenia: A Quality Improvement Initiative

Divya Sudireddy[1], Jason Yang[2], Huseyin Berk Degirmenci[3], Eva Petrow[2] and Michael York[4], [1]Boston Medical Center, Westborough, MA, [2]Boston Medical Center, Boston, MA, [3]Boston University Medical Center, Boston, MA, [4]Boston University, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Laboratory monitoring for patients with systemic lupus erythematosus (SLE) is essential for assessing disease activity and detecting treatment-related adverse effects, including cytopenias. Neutropenia in particular may result from immunosuppressive medications. In patients with chronic neutropenia, providers may discontinue immunosuppressive medications out of concern for drug-induced myelosuppression. However, individuals with Duffy null (Fy[a–b–]) red blood cell phenotype, more common among those of African ancestry, have lower baseline absolute neutrophil counts without increased infection risk. The neutropenia associated with Duffy null phenotype may be misattributed to medication-related toxicity leading to inappropriate discontinuation of effective immunosuppressive therapy. We aimed to assess the frequency of Duffy antigen screening in SLE patients with neutropenia at an urban safety-net hospital and implemented a quality improvement (QI) intervention to increase screening.

Table 1: Duffy Antigen Screening Outcomes in SLE Patients with Neutropenia

SLE patients with neutropenia = 62

Metric	Pre Intervention	Post Intervention	Total	Race
Number of Patients screened for Duffy antigen	6	9	15	12=African American 1= Asian 1=Caucasian 1=Other
Number of Patients with Duffy Null Phenotype	5	7	12	11=African American 1 = other

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: We used Epic's electronic health record (EHR) Slicer Dicer tool to identify patients with SLE and concurrent neutropenia at a single safety net hospital and reviewed the medical records to confirm presence of chronic neutropenia. We conducted an educational session for rheumatologists on the clinical relevance of the Duffy null phenotype and facilitated coordinated ordering of the test. We assessed whether a Duffy antigen screen had been performed and documented the results prior to and 2-months following the intervention.

Results: We identified 78 patients with SLE and leukopenia within the prior year, of whom 62 had neutropenia confirmed by medical record review. Prior to the intervention, 6 patients (9.7%) had undergone Duffy antigen testing, 5 of whom were Duffy null. Following the intervention, an additional 9 patients were screened over a 2-month period, increasing the post-intervention screening frequency to 14.5% (9/62). Among the 9 patients screened post-intervention, 7 had the Duffy null phenotype. Overall, 11 of the 12 patients identified as Duffy null were African American. (Table 1)

Conclusion: Our QI initiative led to a 4.8% absolute increase in Duffy antigen screening frequency in a 2-month post-intervention period. However, overall screening remained suboptimal. Given the higher prevalence of Duffy null phenotype in patients of African ancestry, which constitute a large percentage of SLE patients, recognizing this phenotype is important to prevent unnecessary medication changes that could compromise disease management. Future efforts to be considered include integrating electronic decision support tools, such as a Best Practice Advisory (BPA), to promote routine screening in SLE patients with chronic neutropenia. Our goal is to implement a more streamlined and automated process to ensure Duffy null antigen testing is routinely conducted.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Cognitive impairment (CI) in systemic lupus erythematosus (SLE) may be associated with different T cell subpopulations distribution and chronic pro-inflammatory state in which immunosenescence could be involved. This study investigates the distribution of T cell subpopulations and immunosenescent markers in SLE patients with CI.

Methods: We included women aged 18-50 years, classified with SLE according to the EULAR/ACR 2019 criteria. Women with other autoimmune diseases except antiphospholipid syndrome or Sjögren's syndrome, administration of any biologic drug < 6 months prior to study entry, clinical SLEDAI-2K >0, SDI ≥1, current prednisone >7.5 mg/day, education level ≤6 years, pregnancy or premature ovarian failure, active infection, malignant disease, history of other neuropsychiatric manifestations, other chronic comorbidities or major depressive disorder were excluded. We also include healthy women

Data are expressed as proportions (percentages) or medians (interquartile ranges). Statistical analysis: Chi-square or Fisher's exact tests were used for nominal variables, the Kruskal-Wallis test was used for numerical variables. CM: central memory, EM: effector memory, TEMRA: effector memory T cells re-expressing CD45RA. *Statistically significant.

(HC) paired for age ±5 years. We applied a neurocognitive battery, assessing eight cognitive domains: concentration, verbal memory, visuospatial memory, language, processing speed, motor speed, problem solving and executive function. CI was defined when a subject had scores ≥2 standard deviation below the mean of the normative data in at least one cognitive domain. According to the neurocognitive assessment patients were classified as: SLE with CI, SLE without CI and HC. The lymphocyte subpopulation profile for each patient was determined by flow cytometry. A CD4+/CD8+ ratio of < 1 (inverted ratio) was considered a marker of immunosenescence. The relative expression of the p16INK4a gene in CD3+ T lymphocytes was considered another marker of immunosenescence and was assessed through CD3+ cell purification from peripheral blood, RNA extraction, qPCR, and evaluation of relative expression (ddCT) normalized to the housekeeping gene GAPDH. Demographic and clinical data were also recorded.

Results: Fifteen patients in each group were included. The median age of patients studied was similar. SLE patients with CI had lower educational level than the SLE without CI and HC, and longer disease duration compared to SLE patients without CI. Disease activity and accrual damage was similar between the SLE groups (Table 1). In SLE patients with CI, the most frequently impaired cognitive domain was motor speed (73.3%), followed by visuospatial memory (33.3%), processing speed (13.3%), verbal memory (6.6%), language (6.6%), and problem solving (6.6%) (Figure 1). SLE patients with CI had significant lower levels of naive CD4+T cells and higher levels of CD8+ T cells compared to the other groups. The proportion of inverted CD4+/CD8+ ratio and relative expression of p16INK4a were greater in SLE with CI compared to SLE without CI and HC

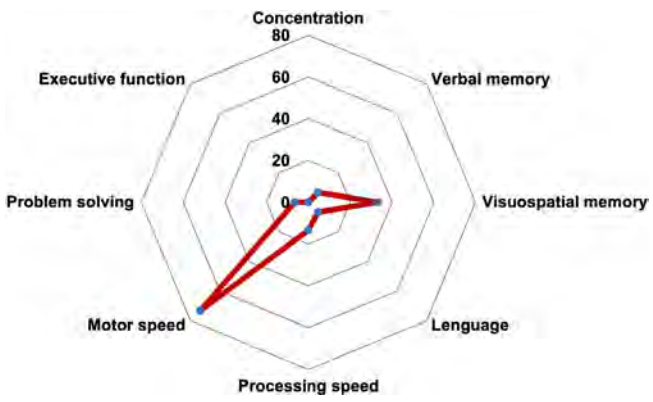

Figure 1. Impaired cognitive domains in SLE patients with CI. Data are expressed as percentages.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

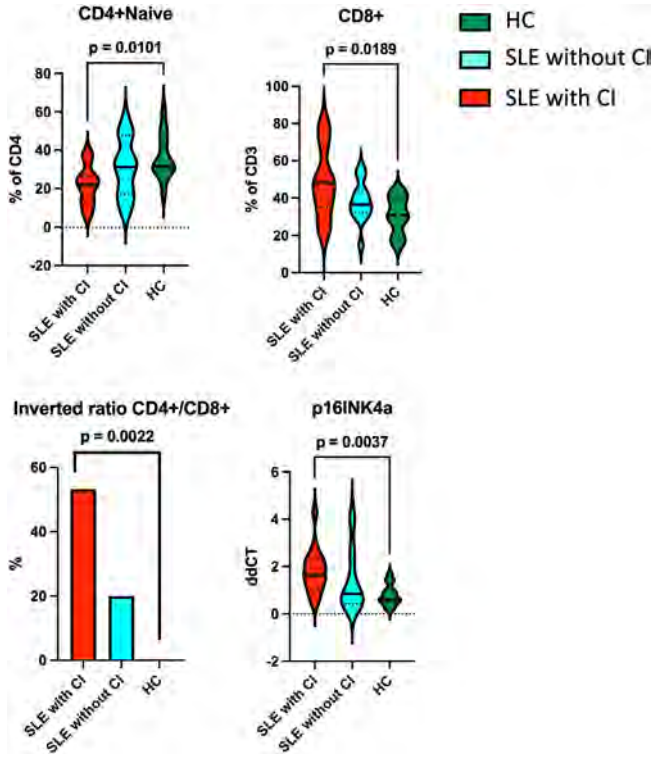

Figure 2. Statistical significant differences in subpopulations and senescent markers in T cells of studied patients. HC: healthy control, SLE: systemic lupus erythematosus, CI: cognitive impairment.

groups (53.3% vs. 20.0% vs. 0%, p=0.003 and 1.6 [1.0-2.3] ddCT vs. 0.8 [0.4-2.2] ddCT vs. 0.6 [0.5-1.0] ddCT, p=0.005, respectively) (Table 1, Figure 2).

Conclusion: In SLE with CI there were lower levels of naïve CD4+ T-cells, higher levels of CD8+ T cells and greater presence of immunosenescence markers compared to SLE without CI and HC. The study suggests the possibility that immunosenescence may play a role in CI in SLE.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease characterized by systemic inflammation and accelerated atherosclerosis, leading to increased cardiovascular (CV) risk. While CV disease typically affects older individuals, SLE patients may develop subclinical CV damage at a younger age due to chronic inflammation. Emerging echocardiographic techniques, including left ventricular ejection fraction (LVEF), global longitudinal strain (GLS) and pulmonary artery systolic pressure (PASP), enable early detection of CV dysfunction before clinical manifestations arise. This study aimed to evaluate subclinical CV alterations in young SLE patients compared to older healthy controls.

Methods: A cross-sectional study was conducted, enrolling patients aged ≤39 years who met the 2019 ACR/EULAR classification criteria for SLE, and a control group of healthy adults aged ≥40 years without rheumatic disease, recruited from a preventive cardio-rheumatology clinic. Individuals with a history of CV disease were excluded.

Table 2. Echocardiographic Parameters

Variable	Young SLE Patients n= 64	Older Healthy Controls n= 76	p-value
Left Ventricular Function			
LVEF, mean ± SD	59.04 ± 8.35	62.53 ± 5.17	**0.006**
GLS, mean ± SD	-18.99 ± 2.96	-20.84 ± 3.52	**0.010**
RWT, median (IQR)	0.293 (0.259 – 0.352)	0.342 (0.270 – 0.432)	**0.023**
LVMI, g/m², mean ± SD	66.38 ± 21.21	84.05 ± 29.18	**< .001**
E' wave, median (IQR)	0.16 (0.13 – 0.18)	0.12 (0.11 – 0.14)	**0.002**
E/e' ratio, mean ± SD	6.96 ± 2.47	8.47 ± 2.31	**< .001**
Deceleration Time, ms, median (IQR)	163 (149 – 187)	215 (187 – 255)	**< .001**
Right Ventricular Function			
TAPSE, mm, median (IQR)	21.00 (19.25 – 24.00)	18.00 (2.20 – 24.00)	**0.004**
PASP, mmHg, mean ± SD	24.03 ± 8.07	19.60 ± 8.18	**0.028**
S' velocity, cm/s, median (IQR)	13.00 (11.00 – 14.00)	12.00 (11.00 – 14.00)	0.305

Values are presented as mean ± SD or median (IQR), as appropriate. SD, Standard Deviation; IQR, Interquartile Range; SLE, Systemic Lupus Erythematosus; LVEF, Left Ventricular Ejection Fraction; GLS, Global Longitudinal Strain; RWT, Relative Wall Thickness; LVMI, Left Ventricular Mass Index; TAPSE, Tricuspid Annular Plane Systolic Excursion; PASP, Pulmonary Artery Systolic Pressure; S' velocity, Peak Systolic Velocity of the Tricuspid Annulus. Bold values indicate statistical significance at $p < 0.05$.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Demographic data, CV risk factors (hypertension, diabetes, dyslipidemia, and body mass index), and echocardiographic parameters were collected. All echocardiograms were performed by a single board-certified echocardiographer using standardized protocols, including B-mode, M-mode, spectral Doppler, color Doppler, and tissue Doppler imaging. Cardiac geometry, systolic and diastolic function were assessed and classified according to the 2016 ASE/EACVI guidelines. Data normality was evaluated using the Kolmogorov–Smirnov test. Between-group comparisons were conducted using Student's t-test, Chi-square test, or Mann–Whitney U test, as appropriate. A p-value of ≤0.05 was considered statistically significant.

Results: A total of 140 participants were included: 64 young SLE patients and 76 older healthy controls. Median age was 25.00 years in the SLE group and 55.00 years in controls ($p < 0.001$), with a higher proportion of women among SLE patients (90.62% vs. 64.47%; $p < 0.001$). SLE patients also had a lower body mass index ($p < 0.001$), and a lower prevalence of diabetes mellitus ($p < 0.001$), dyslipidemia ($p < 0.001$), and smoking ($p = 0.034$). HbA1c was also lower in SLE ($p = 0.012$), while erythrocyte sedimentation rate was higher ($p = 0.050$).

Echocardiography revealed reduced LVEF (59.04 vs. 62.53, $p = 0.006$) and impaired GLS **(–18.99 vs. –20.84**, $p = 0.010$) in SLE patients, while LVMI ($p < 0.001$) and RWT ($p = 0.023$) were higher in controls. Diastolic function assessment showed a higher E′ wave in SLE patients ($p = 0.002$), with lower E/e′ ratio ($p < 0.001$) and deceleration time ($p < 0.001$). TAPSE ($p = 0.004$) and PASP (**24.03 vs. 19.60 mmHg**, $p = 0.028$) were also higher in SLE.

Conclusion: Our findings indicate that young SLE patients may exhibit early echocardiographic alterations compared to older healthy individuals, including reduced myocardial strain, elevated pulmonary pressures, and impaired diastolic function. Notably, these differences were present despite a lower burden of traditional metabolic risk factors. These findings underscore subclinical CV impairment in young SLE patients and reinforce the need for routine CV monitoring in this population.

Abstract Number: 1484

Decoding the Impact of Systemic Lupus Erythematosus on Transcatheter Aortic Valve Implantation: A Nationwide population-based Study

Mariana Vanoye Tamez[1], **Freya Shah**[2], Neel Patel[3] and siddharth Agrawal[2], [1]New York Medical College / Landmark Medical Center, Providence, RI, [2]landmark medical center, Cumberland, RI, [3]University of Tennessee, Nashville

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with autoimmune connective tissue disease, such as Systemic Lupus Erythematosus (SLE), are at higher risk for developing aortic valve pathology. However, the impact of the presence of SLE on outcomes of Transcatheter aortic valve implantation (TAVI) has not been well described in the literature. We studied mortality, complications, readmission rates, and length of stay on a propensity-matched national cohort of SLE patients undergoing TAVI.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We queried the Nationwide readmission database from 2016-2020 using ICD 10 codes to extract the baseline population who underwent the TAVR procedure. Patients were identified and divided into two groups based on the presence of SLE. The Clinical outcomes were assessed at index admissions and readmissions using chi-square statistics, univariate and multivariate regression analysis using STATA v.17

Results: A total of 320,353 weighted index hospitalizations with TAVI were identified from 2016 to 2020. Out of which 1,348 patients had SLE while 319,005 patients did not. The mean age of the SLE group was 72.12 +/- 10.53 years while the non-SLE group was 79 +/- 8.53 years.

The non-SLE group had a statistically significant higher prevalence of hyperlipidemia (73.21% vs 69.74%, p:< 0.001); smoking (35.64% vs 30.06%, p:0.0116); and prior PCI (19.4% vs 13.23%, p:0.0007); prior CABG (15.88% vs 10.06; p:0.0003) compared to the SLE group. While the SLE group had a higher prevalence of pulmonary disease (25.28% vs 20.58%, p: 0.01); hypothyroidism (26.92% vs 18.6%, p< 0.0001); anemia (8.38% vs 5.15%, p:0.00014) and liver disease (2.71% vs 1.51%, p:0.0256).

There was no statistically significant difference in the crude and propensity-matched in-hospital outcomes including death, acute kidney injury, acute stroke, heart failure, myocardial infarction, use of mechanical circulatory support, post-procedural bleeding, cardiac tamponade, and Major adverse cardiac and cerebrovascular events (MACCE) among SLE and non-SLE groups. The multivariate regression analysis did not show statistically significant higher odds of SLE for the outcomes mentioned above.

The mean length of stay at index hospitalization in the SLE group was 5.63 +/- 8.44 days while the non-SLE group was 4.14 +/- 6.21 days. The SLE patients had higher rates of hospital readmission at 1 month (10.01% vs 9.31%) and 6 months (18.02% vs 13.05%).

Conclusion: In conclusion, SLE does not appear to be a risk factor for in-hospital mortality and the studied post-procedural complications in patients undergoing TAVI. However, patients with SLE who underwent TAVI were younger and differed significantly at baseline comorbidities, compared to patients without SLE. Patients with SLE had longer lengths of stay and higher readmission rates after TAVI.

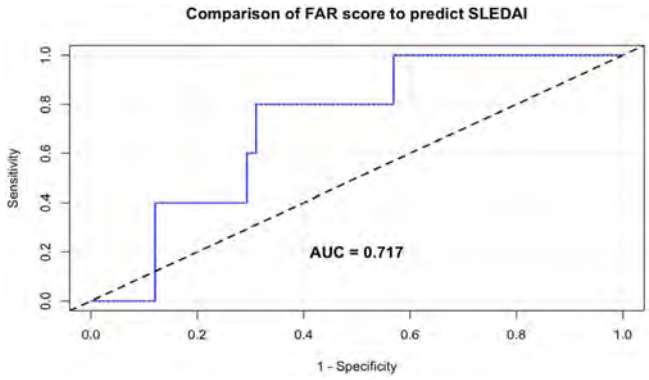

Fig 1: Comparison of FAR score to predict SLE disease activity.

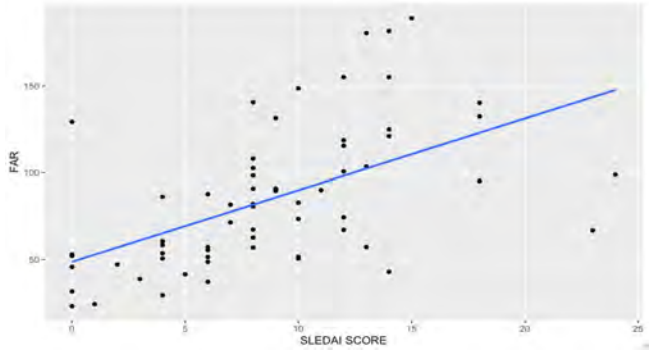

Fig 2: Scatter plot of SLEDAI Score and FAR Score in the study cohort.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic multisystem autoimmune condition presenting with unpredictable varying levels of severity. Thus, constant monitoring of disease activity is required. The fibrinogen-to-albumin ratio, is an emerging marker which can be used as a cost effective surrogate marker of disease activity in countries with limited resources.

Methods: In a cross-sectional observational study, 63 adult patients with SLE, were included in the study, conducted over a duration of one year, in the Department of Rheumatology, of a tertiary care centre. exclusion criterion included pregnancy, diabetes mellitus, active infections and presence of other autoimmune conditions. Clinical evaluation and laboratory assessments (including fibrinogen, albumin, ESR, CRP, complements, anti-dsDNA, UPCR, and 24-hour urine protein) were recorded. Disease activity was categorized using SLEDAI-2K as stable, mild, moderate, or severe. FAR was calculated, and its correlation with SLEDAI was assessed using Pearson's r. Receiver operating characteristic (ROC) analysis determined FAR's diagnostic accuracy in identifying severe disease.

Results: The cohort was predominantly female (95.2%), with a mean age of 32.2±8.9 years and mean disease duration of 4.9±4.1 years. The mean SLEDAI score was 8.7±5.4; FAR averaged 84.7±40.7. FAR exhibited a strong positive correlation with SLEDAI (r=0.645, $p< 0.001$). ROC analysis revealed an AUROC of 0.717 (p=0.028) for FAR in identifying severe disease. At a cut-off of ≥95.3, FAR predicted severe SLE with 80% sensitivity, 69% specificity, and an impressive 97.6% negative predictive value

Conclusion: Fibrinogen-to-albumin ratio demonstrates a strong correlation with SLE disease activity and offers moderate diagnostic accuracy in distinguishing severe flares. owing to its cost-effectiveness, it can be used a practical biomarker for SLE disease activity surveillance.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients (pts) with systemic lupus erythematosus (SLE) have a significantly increased risk of atherosclerotic cardiovascular disease (ASCVD). EULAR recommends a comprehensive assessment and management of cardiovascular risk (CVR), following general population guidelines (Drosos GC et al, Ann Rheum Dis 2022). Statin therapy plays a key role in reducing CVR and preventing ASCVD events (Yousef Yengej FA et al, Neth J Med 2017). This study aimed to determine the proportion of pts with SLE eligible for statin use for primary ASCVD prevention, based on American and European CVR guidelines.

Methods: This was an observational and cross-sectional study of GLADEL 2.0, a multi-ethnic Latin-American SLE cohort. Demographics, comorbidities, medications, disease activity, and laboratory data were analyzed. Statin eligibility was determined using the 2019 American College of Cardiology/American Heart Association (ACC/AHA) and the 2021 European Society of Cardiology (ESC) guidelines. CVR was assessed using the ASCVD risk calculator from the ACC/AHA, Systemic

Table 1. Baseline clinical characteristics, disease activity, damage index and treatments

	Total (N=1083)
Age, years, median (Q1, Q3)	35.4 (15.6, 77.5)
≥40 years, n (%)	394 (36.4)
Female, n (%)	970 (89.6)
Mestizo, n (%)	701 (64.7)
Obesity, n (%)	187 (18.5)
Disease duration, years, median (Q1, Q3)	5.6 (0.6, 61.6)
SLEDAI, median (Q1, Q3)	5 (0, 57)
SDI, median (Q1, Q3)	0 (0, 9)
HDL-c (mg/dL), median (Q1, Q3), n=504	49 (11, 102)
LDL-c (mg/dL), median (Q1, Q3), n=480	103 (28, 328)
Triglycerides (mg/dL), median (Q1, Q3), n= 557	124 (32, 619)
Diabetes, n (%)	45 (4.2)
Hypertension, n (%)	293 (27.2)
Dyslipidemia, n (%)	129 (12)
Active smoking, n (%)	54 (5.1)
Chronic kidney disease, n (%)	61 (5.6)
Acute myocardial infarction, n (%)	8 (0.7)
Statins, n (%)	155 (20.4)
Prednisone, n (%)	758 (72.5)
Hydroxychloroquine, n (%)	876 (84)

SLEDAI: Systemic Lupus Erythematosus Disease Activity Index, SDI: Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index

Table 2. Comparison of clinical characteristics based on their age group.

	< 40 years	≥ 40 years	*P* value
Obesity, n (%)	102 (15.8)	85 (23.3)	0.0031[2]
Disease duration, years, median (Q1, Q3)	4.1 (0.2 28.9)	9.9 (0.6, 61.6)	<0.0001[1]
SLEDAI, median (Q1, Q3)	6 (0, 57)	3 (0, 38)	<0.0001[1]
HDL-c, mg/dL, median (Q1, Q3), n=504	47 (11, 102)	52 (15, 100)	0.0003[1]
LDL-c, mg/dL, median (Q1, Q3), n=480	105.5 (37, 241)	101 (28, 328)	0.1404[1]
Triglycerides, mg/dL, median (Q1, Q3), n=557	123 (39, 619)	127 (32, 525)	0.4044[1]
Diabetes, n (%)	12 (1.7)	33 (8.4)	<.0001[2]
Active smoking, n (%)	30 (4.5)	24 (6.2)	0.0503[2]
Statins, n (%)	94 (19.8)	61 (21.3)	0.0510[2]
Prednisone, n (%)	525 (78.5)	233 (61.8)	<.0001[2]

SLEDAI: Systemic Lupus Erythematosus Disease Activity Index

[1]Kruskal-Wallis p-value; [2]Chi-Square p-value.

Coronary Risk Evaluation 2 (SCORE2), and Pan American Health Organization (PAHO) risk scores. Cohen's Kappa coefficient was used to determine inter-guideline agreement. Both guidelines only consider pts ≥40 years of age as candidates for CVR prevention with statins, due to eligibility dependence on CVR scores. Therefore, a comparative analysis was conducted between pts above and below this age threshold.

Results: Among 1083 pts in the GLADEL 2.0 SLE cohort, only 394 (36.4%) were older than 40 years of age; demographic characteristics are shown in Table 1. ACC/AHA could only be calculated for 164 pts, PAHO for 351 pts, and SCORE2 for 181 pts. Most of these pts were categorized as having a low CVR, regardless of the calculator used. A total of 15 pts were indicated to receive statin therapy based on European guidelines; among these, only 5 (33%) had a previous prescription for a statin. Among 50 pts eligible for statin therapy based on American guidelines, only 13 (26%) had been prescribed them. Inter-guideline agreement on statin eligibility was fair (Cohen's Kappa = 0.35; 95% CI: 0.15–0.55). Pts under 40 years of age were more obese and had higher disease activity compared with those older than 40 years of age (Table 2).

Conclusion: This study reveals a gap in the management of CVR among pts with SLE in the GLADEL 2.0 cohort, as only a small percentage are candidates for statin therapy, primarily due to the predominance of younger pts under age 40. Traditional CVR assessment tools fail to encompass this group, which is at an elevated risk for accelerated atherosclerosis. Among eligible pts, statin prescribing rates remain low, suggesting a missed opportunity in proactive cardiovascular prevention. The moderate agreement between differing guidelines highlights the inconsistency in risk assessment and management approaches for this population. There is a need for tailored strategies to comprehensively evaluate and address CVR in younger pts with chronic inflammatory conditions like SLE. Implementing more inclusive guidelines could enhance preventative measures and improve outcomes for pts at increased risk for ASCVD.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: To improve quality of life (QoL) in individuals with SLE, we developed the Whole Health Empowerment for Endotypes of Lupus (WHEEL) program—a 4-month, biweekly, virtual, SLE-specific peer support curriculum. Adapted from an existing evidenced-based group visit model and delivered by certified health coaches, WHEEL promotes self-care and engagement through education, goal setting, mindfulness, and group discussion (Fig 1). The current study conducted user testing to assess feasibility and acceptability. To optimize group dynamics and shared experience, participants were stratified into two Type 2 SLE endotypes: Intermittent (symptoms aligning with Type 1 activity) and Persistent (symptoms persisting despite Type 1 remission).

Methods: Adults with SLE (2012 SLICC or 2019 ACR/EULAR criteria) with ≥3 visits in an academic registry were screened for potential inclusion based on SLEDAI, Type 1 and Type 2 physician global assessments (PGA; 3-point visual analog scales), and the polysymptomatic distress (PSD) score. *High Type 1 SLE activity* was defined as clinical SLEDAI ≥4, SLEDAI ≥6, renal SLEDAI ≥4, or PGA ≥1. *High Type 2 SLE activity* was defined as Type 2 PGA ≥1 or PSD ≥8. Patients without high Type 2 SLE activity were not eligible.

User Testing Cohorts

- Persistent Type 2 SLE (SLE-P): High Type 1 SLE activity at < 30% and high Type 2 SLE activity at ≥50% of visits
- Intermittent Type 2 SLE (SLE-I): Fluctuating Type 2 SLE activity

User testing consisted of 8 group sessions, 2 individual health coach sessions, development of personal goals, and pre/post surveys. Feasibility and acceptability were assessed via accrual, attendance, attrition, satisfaction, and fidelity. Progress achieved on personal goals further informed feasibility. Whole Health Assessment and PROMIS surveys explored preliminary efficacy.

Results: We enrolled 5 women in each cohort (100% accrual). While race and ethnicity were similar between cohorts, the average age of the SLE-P cohort was 10 years older. Nine participants completed the program with 1 early withdrawal from SLE-P. Over 80% of all group sessions were attended, and 8 participants attended all but 1 group session. On average, participants set 3 personal goals. All participants made progress on at least 1 goal, and 7 of 9 participants achieved ≥1 personal goal.

Figure 1a. Aspects of the WHEEL program. 1b. Components of each WHEEL group session

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Anonymous feedback from User testing participants

"I liked being able to communicate with others who were on a similar journey and also learn through their goals. I enjoyed having a place to check in and talk about progress or setbacks. I also enjoyed learning about my condition"
"I liked the group aspect of the program in addition to the educational information provided about this disease I must learn to live with and manage."
"How all of it the educational parts, self-care, goals, and support from other women all works in tandem and produces a great program."
"This group was very beneficial, and I hope it continues for other patients. I never knew how much I needed this group until I started attending the sessions."
"Maybe a little longer. It seems to go by quickly."
"I like the activity at the end of each session week. It helps to keep me honest and accountable."

Table 2. Lupus Outcomes Pre and Post WHEEL intervention

	Intermittent		Persistent	
	Pre-WHEEL n=5	Post-WHEEL n=5	Pre-WHEEL n=5	Post-WHEEL n=4
	Median (IQR)	Median (IQR)	Median (IQR)	Median (IQR)
PROMIS Measures				
Pain Intensity	**59 (55-65)**	**52 (50-60)**	65 (60-72)	66 (62-71)
Pain Interference	**67 (62-68)**	**56 (56-65)**	67 (64-67)	64 (60-67)
Self-Efficacy: Medications	41 (36-41)	44 (39-46)	**48 (43-54)**	**53 (46-58)**
Self-Efficacy: Symptoms	44 (43-46)	44 (41-48)	43 (37-45)	45 (42-46)
Whole Health Assessment				
Movement and Exercise	30 (25-42)	56 (43-90)	47 (38-65)	63 (40-75)
Nutrition	50 (50-50)	70 (45-70)	55 (46-67)	70 (58-80)
Rest	20 (10-25)	50 (35-75)	32 (15-44)	33 (25-45)
Purpose and Meaning in Life	74 (70-75)	80 (54-90)	89 (54-100)	82 (44-98)
Stress	40 (29-60)	80 (47-80)	69 (34-100)	70 (34-95)
Physical environment	80 (70-100)	100 (83-100)	99 (74-100)	92 (77-100)
Relationships	80 (50-90)	80 (50-95)	90 (72-100)	100 (90-100)
Personal and Professional Goals	70 (50-80)	60 (56-86)	60 (48-80)	39 (23-66)
Lupus Medications	85 (75-90)	87 (84-90)	100 (98-100)	100 (96-100)
Trust in healthcare	94 (80-95)	94 (84-95)	100 (95-100)	99 (82-100)

Scoring: Scoring for PROMIS Pain Measures: High score = more pain. Scoring for PROMIS Self-Efficacy: High score = more self-efficacy. Whole Health Assessment scored 0-100 with higher score = better. Bolded scores indicate statistically significant improvements.

Program fidelity was high (98%). Participants reported excellent program satisfaction (96%) and provided overwhelmingly positive feedback (Table 1).

Post-WHEEL, PROMIS pain intensity and pain interference scores improved in SLE-I, while PROMIS medication self-efficacy improved in SLE-P (Table 2). Both cohorts reported gains in Whole Health nutrition and movement/activity; SLE-I additionally showed improvement in rest, purpose, stress, and environment, whereas SLE-P improved in relationships.

Conclusion: The WHEEL program was developed to improve quality of life in SLE. User testing demonstrated strong accrual, retention, acceptance, fidelity, and satisfaction. Participants progressed toward personal health goals and exhibited improvement across several outcome domains. Findings support the feasibility of a multi-modal, whole health approach for SLE and are informing adaptations of the WHEEL program.

Abstract Number: 1488

Limited Concordance Between anti-dsDNA Assays and Association with Lupus Nephritis

Jessica Dai[1], Peter Izmirly[2], Jill Buyon[3] and H Michael Belmont[4], [1]New York University Grossman School of Medicine, Tenafly, NJ, [2]New York University Grossman School of Medicine, New York, NY, [3]NYU Grossman School of Medicine, New York, NY, [4]NYU School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-dsDNA antibodies are a key diagnostic marker of systemic lupus erythematosus (SLE), often associated with active disease. Its presence is detected using various commercial assays including enzyme-linked immunosorbent assay (EIA), multiplexed flow immune assay (MFIA) and the Crithidia lucilae immunofluorescence assay (CLIFT), which differ in sensitivity, specificity and methodology. This variability complicates interpretation of anti-dsDNA results in relation to disease activity. Using a multiethnic, longitudinal SLE cohort, the analysis compares anti-dsDNA measurements by CLIFT, EIA and MFIA with disease activity.

Methods: Patients with SLE from Bellevue Hospital Center were included. All patients fulfilled SLE criteria by at least one method: American College of Rheumatology (ACR), Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) and/or 2019 ACR/European League Against Rheumatism (EULAR) classification criteria. A change in commercial anti-dsDNA antibody testing from enzyme immunoassay (EIA) to multiplex flow immunoassay (MFIA) on April 1, 2024, served as a natural point for analysis. Patients with anti-dsDNA results by EIA, CLIFT and MFIA within one year before and after this transition were identified. Titre and concordance or discordance among assays and association with ACR criteria lupus nephritis (LN) were analyzed.

Results: Of the 135 patients with SLE, 50% were Hispanic, 30% were Black, 17% were Asian, and 4% were unknown. Paired testing with EIA and CLIFT was performed in 103 patients, and MFIA and CLIFT in 104 patients. Comparison between CLIFT and EIA revealed that 57% of patients had consistently concordant results, 31% showed fluctuating concordance, and 12% were consistently discordant (Figure 1). Similarly, 60% of patients had concordant results between CLIFT and MFIA, 13% fluctuated, and 27% were consistently discordant. Following the transition from EIA to MFIA in April, 109 patients demonstrated concordant results between EIA and MFIA, while 26 had discordant findings. Among 68 patients with ACR criteria LN, 20 tested positive by EIA, 22 by MFIA and 29 by CLIFT. The specificity and sensitivity for detecting LN were 77% and 26% for EIA, 73% and 32% for MFIA, and 47% and 47% for CLIFT, respectively.

Conclusion: This cohort demonstrates that current anti-dsDNA antibody testing using CLIFT, in conjunction with EIA or MFIA shows limited concordance. Despite EIA and MFIA being similar immunoassays, 23% of patients exhibited discordant results following the laboratory decision to change assay. In our cohort, CLIFT had the lowest specificity for identifying patients with LN. Moreover, failing to identify anti-dsDNA antibody positive status by restricted method testing can have

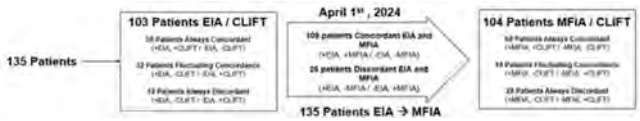

Figure 1. Flow diagram illustrating concordance and discordance of EIA and CLIFT or MFIA and CLIFT as well as the transition from EIA to MFIA immunoassays.

an impact on meeting SLE disease classification criteria and/or accurately determining disease activity. These findings suggest incorporating multiple dsDNA antibody assays may enhance the accuracy of SLE classification and ensure more reliable assessment of disease activity during routine monitoring.

Impact of Menopause on Long-Term Outcomes in Patients with Systemic Lupus Erythematosus

Lorena López, **José Bretón** and Luis Vilá, University of Puerto Rico Medical Sciences Campus, San Juan, PR

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Women of childbearing age are more prone to developing autoimmune diseases, suggesting a role for sex hormones, particularly estrogens, in regulating both cellular and humoral immunity. During menopause, estrogen levels decline significantly, which may affect the immune system and, in turn, influence clinical outcomes in systemic lupus

Table 1. SLE manifestations, disease activity, disease damage, lupus pharmacologic treatment, comorbidities, disease exacerbations, and hospitalizations (n=43).

	Pre-menopausal period	Post-menopausal period	p-value
SLE manifestations, %

erythematosus (SLE). However, the impact of menopause on patients with SLE has not been widely studied. Therefore, we aimed to assess the long-term outcomes of SLE patients after menopause.

Methods: A retrospective cohort study was conducted involving women with SLE, classified according to the 1997 revised American College of Rheumatology criteria, from a university-based center in Puerto Rico who had undergone menopause. The premenopausal and postmenopausal periods were compared in terms of SLE manifestations, disease activity (assessed using the Systemic Lupus Erythematosus Disease Activity Index), damage accrual (measured by the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index), incident comorbidities, disease exacerbations, and hospitalizations. Variables were evaluated annually before and after menopause. Paired analyses were used to compare outcomes between the premenopausal and postmenopausal periods.

Results: Out of 309 female patients, 80 were identified as postmenopausal. Thirty-seven were excluded due to hysterectomy prior to menopause, SLE diagnosis at or after menopause, or an unclear date of menopause. A total of 43 patients were included in the analysis. The mean (standard deviation [SD]) ages at SLE diagnosis, menopause, and last visit were 33.6 (9.1), 46.5 (5.6), and 57.2 (9.0) years, respectively. The mean (SD) durations of SLE before and after menopause were 13.7 (10.9) and 12.0 (6.5) years, respectively. Table 1 summarizes the data for the 43 postmenopausal women included in the analysis. Compared to the premenopausal period, the postmenopausal period was associated with significantly lower frequencies of malar rash, photosensitivity, neurologic involvement, anemia, leukopenia, lymphopenia, and thrombocytopenia. These patients also had significantly lower disease activity and reduced exposure to glucocorticoids and hydroxychloroquine compared to the premenopausal period. While the occurrence of arterial hypertension was more frequent in the premenopausal period, new-onset malignancy was more common in post menopause. No significant differences in damage accrual were observed between the two periods.

Conclusion: In this cohort of patients with SLE, the postmenopausal period was associated with a significant decrease in disease activity and clinical manifestations—particularly mucocutaneous, neurologic, and hematologic involvement—as well as reduced exposure to glucocorticoids and hydroxychloroquine. These findings suggest that the hormonal changes accompanying menopause may influence the long-term course of SLE.

*APS : antiphospholipid syndrome
*HCQ: Hydroxychloroquine
*SLEDAI-2K: Systemic Lupus Erythematosus Systemic Index 2000
**Organ damage measured by SLICC/ACR damage index

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that can affect multiple organs. Vitamin D levels have been associated with disease activity in SLE, and the neutrophil-to-lymphocyte ratio (NLR) has emerged as a potential marker of inflammation in autoimmune conditions, including SLE. However, the relationship between vitamin D and NLR in SLE patients remains unclear and requires further investigation.

Objective: To evaluate the association between serum vitamin D levels and the neutrophil-to-lymphocyte ratio (NLR) in patients with SLE.

Methods: We performed a cross-sectional study including 188 patients with systemic lupus erythematosus (SLE), recruited from a specialized outpatient clinic. All individuals met the 2019 EULAR/ACR classification criteria for SLE. Clinical and laboratory data were extracted from electronic medical records (SLEDAI-2K scores, comorbidities, current treatments, and serum 25-hydroxyvitamin D [25(OH)D] levels. The NLR was calculated using absolute counts from complete blood counts obtained on the same day. Data distribution was assessed using the Kolmogorov–Smirnov test. Group comparisons were performed using the Student's t-test or Mann–Whitney U test, as appropriate. The relationship between vitamin D levels and NLR was evaluated through Spearman's rank correlation and multivariable linear regression, adjusting for potential confounders. Statistical significance was set at $p < 0.05$. Analyses were conducted using STATA MP-Parallel Edition 17.0.

Results: The description of the main demographic, clinical, comorbidity, and analytical variables, along with their association with vitamin D levels (treated as a continuous variable), is presented in **Table 1**. Serum vitamin D levels were inversely correlated with NLR ($r = –0.195$; $p = 0.024$). Patients with organ damage had significantly lower vitamin D levels compared to those without (28.6 ± 10.2 vs. 33.3 ± 9.8 ng/mL; $p = 0.008$). A trend toward lower vitamin D levels was observed in patients with diabetes ($p = 0.048$). No significant differences were found regarding disease activity, sex, or other clinical manifestations. In the multivariable regression analysis, log-transformed vitamin D was significantly negatively associated with NLR (coef. -1.40, $p = 0.002$), indicating that higher vitamin D levels are linked to lower NLR. However, no significant associations were found between NLR and other variables sex, age, disease activity (SLEDAI2K), or organ damage (**Table 2**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2: Linear Regression Analysis of Factors Associated with Neutrophil-to-Lymphocyte Ratio in Systemic Lupus Erythematosus Patients

Variable	Coefficient (β)	Standard Error (SE)	t-value	p-value	95% Confidence Interval
Log(Vitamin D)	**-1.40**	**0.45**	**-3.11**	**0.002**	**(-2.29, -0.51)**
Sex (Male vs. Female)	-0.50	0.57	-0.87	0.39	(-1.63, 0.64)
Age (years)	-0.01	0.01	-0.86	0.39	(-0.04, 0.01)
SLEDAI-2K (Disease Activity)	0.09	0.07	1.38	0.17	(-0.04, 0.22)
Organ Damage	0.19	0.33	0.58	0.56	(-0.47, 0.85)

Conclusion: Vitamin D levels are inversely associated with the neutrophil-to-lymphocyte ratio in SLE patients, suggesting that vitamin D may play a role in immune modulation. Further research is necessary to explore the potential therapeutic effects of vitamin D in lupus management.

Composite definition of extrarenal SLE disease modification. Included: (i) a significant reduction in SLEDAI (>3 points), (ii) none severe flares, and (iii) ≤10 mg/day of prednisone for months 0-12 and ≤5 mg/day prednisone-equivalent for years 2-5. Values presented in bold represent significant differences of baseline descriptors between disease modification groups at the corresponding time point (p<0.05). The number of patients decreased at each time point due to either insufficient time in the cohort or loss of follow-up. Comparisons were performed using a Chi-squared test for qualitative variables or a non-parametric t-test for continuous variables. Abbreviations: IQR, interquartile range.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The concept of disease modification (DM) has been recently introduced to improve the long-term care of patients (pts) with SLE. DM is defined as 'the minimization of disease activity with the fewest treatment (tx)-associated toxicities and slowing/preventing organ damage progression.' To claim DM ultimately requires delayed or prevented progression of organ damage beyond 5 years. The concept of DM is valuable for assessing 'whether an intervention is on track for achieving DM at the 5-year mark,' based on interim evaluations during the first 5 years. Latin American pts with SLE are prone to poorer outcomes, which are associated with both disease severity and social determinants of health (SDH). This preliminary study evaluates the prevalence of extrarenal DM in Latin American pts with SLE and examines differences in SDH and tx between those who did and did not achieve extrarenal DM.

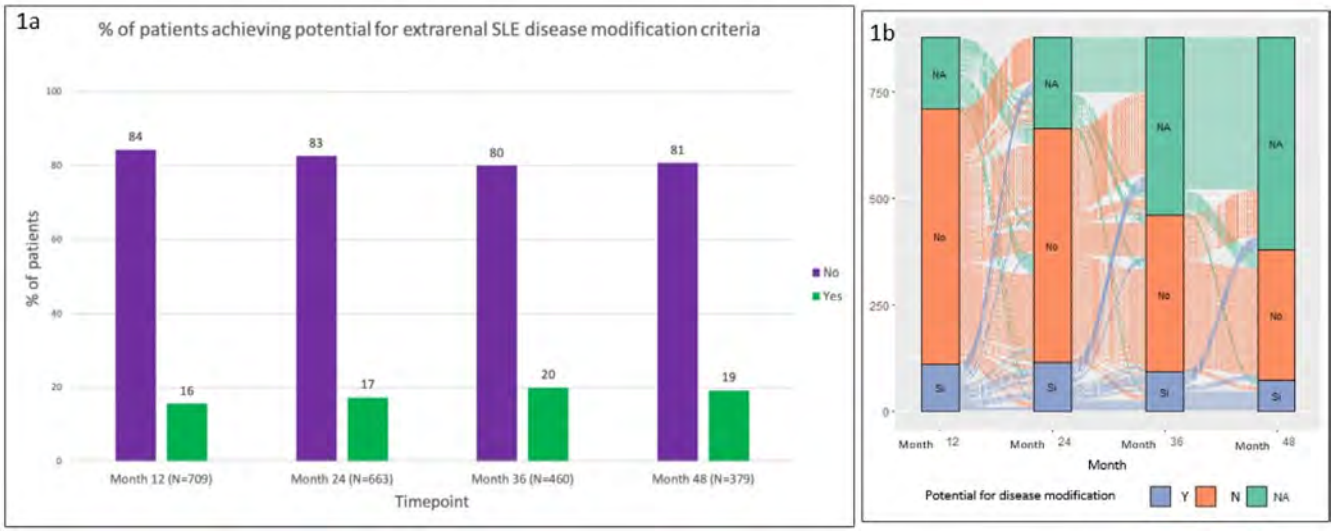

Figure 1. Percentage of patients achieving potential for extrarenal SLE disease modification (A) and disease modification trajectory (B)

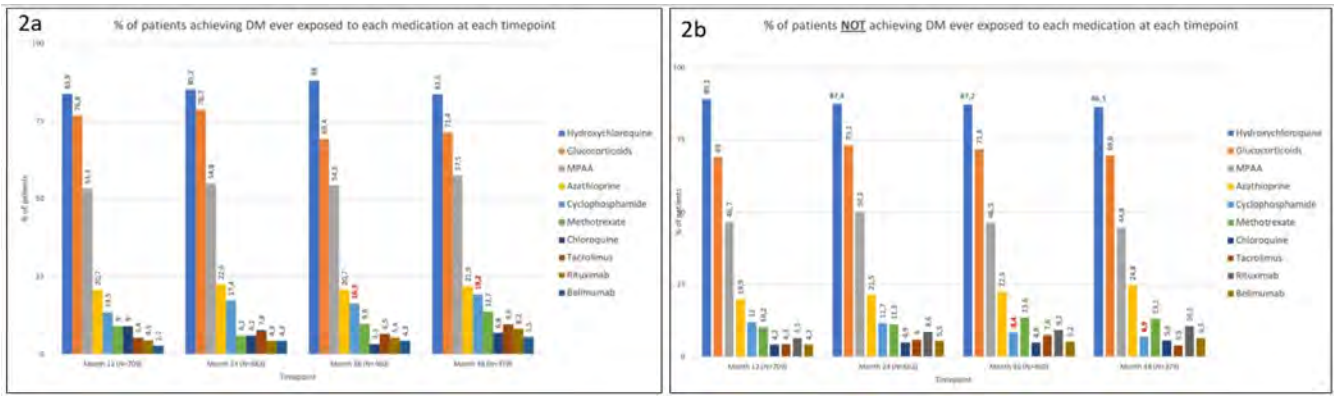

Figure 2. Medication exposure in patients who did (A) and (B) did not achieve DM

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: GLADEL 2.0 is a longitudinal cohort assessing the incidence and prevalence of SLE. Forty-three centers from 10 Latin-American countries enrolled pts ≥18 years of age who fulfilled the 1982/1997 ACR and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE. The composite definition of DM for extrarenal SLE included: (i) a significant reduction in SLE Disease Activity Index (SLEDAI; >3 points), (ii) no severe flares, and (iii) ≤10 mg/day of prednisone for months 0–12 and ≤5 mg/day prednisone-equivalent for years 2–5. Pts with complete data at baseline, 12, 24, 36, 48, and 60 months were analyzed. We compared baseline SDH and exposure to medications between pts who did and did not achieve DM criteria over time.

Results: Among 1083 pts who entered the GLADEL 2.0 cohort, 709 had the baseline data needed to fulfill DM criteria. Table 1 shows differences in demographic and SDH data by extrarenal DM achievement groups over time. Data from month 60 were not analyzed as data were available for only 64 pts. Although educational attainment varied between groups and genders at each time point, a higher proportion of pts achieved DM among men compared to women at the 36 and 48-month marks. Overall, the proportion of pts achieving DM criteria ranged between 16%–20% across time points (Fig 1a). Figure 1b shows DM trajectories during follow-up. Medication exposure is depicted in Fig 2. A higher number of pts achieving extrarenal DM at months 36 and 48 received cyclophosphamide.

Conclusion: In this preliminary investigation, up to 20% of Latin American pts with SLE achieved extrarenal DM. The study highlights critical disparities, indicating that pts with lower educational attainment and women were less likely to achieve DM. Our findings suggest that specific medication exposure plays a significant role in extrarenal DM achievement, particularly with medications like cyclophosphamide. These results underscore the importance of addressing SDH and tailoring tx strategies to improve outcomes for marginalized groups within this population. Continued research is essential to discern the independent contributions of SDH and different tx modalities on achieving extrarenal DM, ultimately aiming to enhance long-term care and pt quality of life.

Abstract Number: 1492

Prevalence and Risk Factors of Gynecologic Cancers in Female Patients with Systemic Lupus Erythematosus

Katherine Moseley[1], Dulaney Wilson[2], Emily Vara[1] and Diane Kamen[3], [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, [3]Medical University of South Carolina, Johns Island, SC

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic systemic autoimmune disorder that is nine times more prevalent in women. Patients with SLE are at an overall increased risk of cancer and may additionally have an increased risk of specific female reproductive cancers. This increase in cancer risk may be attributed to factors such as chronic inflammation, immunosuppression with decreased clearance of oncogenic viral infections, or treatment medication exposure. Our objective was to investigate if specific SLE clinical disease characteristics and sociodemographic factors are associated with gynecologic cancer in female patients with SLE.

Table 1. Baseline Demographic Characteristics and Cancer Prevalence for Female SLE Patients and Controls

Methods: We conducted a retrospective study utilizing our institutional ongoing longitudinal registry with a study population which included females ≥18 years of age, meeting classification criteria for SLE, and non-SLE population-matched female controls. Sociodemographic information and medical history were obtained from patient interviews and medical record information recorded in the registry. SLE disease damage was measured using SLICC Damage Index (SDI), modified for this study by excluding malignancy from the total score. Gynecologic cancers included any cancer of the female reproductive tract. Statistical analyses were Chi-squared test, Fisher's exact test, two-sided t-test, and ANOVA, as appropriate, with significance determined by p-values < 0.05.

Results: Table 1 shows baseline demographic characteristics of the study population, comparing patients with SLE (n=800) to controls (n=499). Overall malignancy prevalence was higher among patients (8.5%) compared to controls (3.6%, $p< 0.001$), including a higher prevalence of breast cancer and gynecologic cancer. Of the 800 included female SLE patients (**Table 2**), 68 (8.5%) had been diagnosed with cancer, 14 (20.6%) of which had gynecologic cancers. Older age at baseline, and history of nicotine use were associated with a significantly higher prevalence of cancer and gynecologic cancers. Although the patients with SLE were disproportionately Black (74.5%) compared to White (21.3%), patients with gynecologic cancer were more likely to be White (57.1%, $p< 0.001$). The modified SDI score was associated with gynecologic cancers ($p=0.04$), while SDI score >2 was associated with both overall cancer ($p=0.002$) and gynecologic cancers ($p=0.004$). No significant association was found with childhood onset of SLE, lupus nephritis, or exposure to specific SLE medications. While most of the studied serologic markers did not correlate with the presence of cancer, a positive association between the presence of antiphospholipid antibodies and gynecologic cancers was found ($p< 0.001$).

Conclusion: Our findings provide insight into which SLE disease characteristics may be associated with gynecologic cancers for our cohort of female patients with SLE. The primary SLE disease characteristic found to correlate with gynecologic cancers was a higher modified SDI, while no association was found with SLE treatment medications, although overall cancer numbers were low. These results support ongoing investigation into additional risk and preventative factors for gynecologic cancers in patients with SLE.

Abstract Number: 1493

Long-Term Outcomes in Systemic Lupus Erythematosus Patients Infected with SARS-CoV-2: Variant-Specific Analysis of Pre-Delta/Delta and Omicron Periods

Lilliana Serrano-Arroyo, César Rosado-Bloise and Luis Vilá, University of Puerto Rico Medical Sciences Campus, San Juan, PR

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The post-acute sequelae of SARS-CoV-2 infection may involve low-grade inflammation, immune dysregulation, and endothelial dysfunction. Therefore, it would not be surprising if SARS-CoV-2 negatively impacts the clinical outcomes of patients with autoimmune disorders such as systemic lupus erythematosus (SLE). Previously, we reported that COVID-19 did not significantly affect the short-term outcomes of patients with SLE during the Pre-Delta/Delta and Omicron waves. Therefore, we sought to evaluate the long-term outcomes in these patient groups.

Methods: We studied a cohort of adults (≥21 years) with SLE (per 1997 American College of Rheumatology classification criteria), from a single center in Puerto Rico. Patients with confirmed COVID-19 infection during the pre-Delta/Delta (March 2020–November 2021) and the Omicron periods (December 2021–December 2022) were compared. Participants were followed at 12- and 24-month post-infection to evaluate SLE flares, disease activity (measured by the Systemic Lupus Erythematosus Activity Index), damage accrual (based on the Systemic Lupus International Collaborating Clinics/American College

Table 1. Clinical Outcomes and pharmacologic treatment in SLE patients with COVID-19: Pre-Delta/Delta period at 12- and 24-months post-infection (n=18).

Cyclophosphamide	0.0	0.0	--	0.0	--

*Highest yearly score was used to calculate median. SLE: Systemic lupus erythematosus; SLEDAI: Systemic Lupus Erythematosus Disease Activity Index; SD: Standard deviation; SDI: Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index

of Rheumatology damage index [SDI]), and lupus pharmacologic treatment. Outcomes were compared between baseline and 12- and 24-follow-up periods for pre-Delta/Delta and Omicron groups using paired analyses.

Results: A total of 148 patients with SLE were studied: 18 from the pre-Delta/Delta period and 130 from the Omicron period. None of the patients died during the follow-up. Tables 1 and 2 present demographic characteristics, SLE flares, SLEDAI scores, SDI scores, and pharmacologic therapy at the time of SARS-CoV-2 infection (baseline), as well as at 12 and 24 months. A slight but statistically significant increase in SLEDAI scores was observed at 12 and 24 months in the Omicron group. Hydroxychloroquine exposure was significantly lower in this group at 24 months. No significant differences in other outcome measures or pharmacologic treatments were noted for the study groups at 12- and 24-months post–COVID-19.

Conclusion: In this cohort of SLE patients infected with SARS-CoV-2 during the pre-Delta/Delta and Omicron periods, long-term outcomes were favorable. Aside from a slight increase in disease activity and reduced hydroxychloroquine exposure in the Omicron group, there was no increase in lupus flares, damage accrual, or use of other immunosuppressive therapies in either group.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Young adulthood (18-30 years) is a life stage with many transitions. Young adults with Systemic Lupus Erythematosus must navigate this period while living with a devastating illness. Young adults with childhood-onset SLE (cSLE) have more time to adapt compared to adult-onset SLE (aSLE) patients. Thus, lived experiences of young adults with cSLE may differ from their aSLE counterparts. We aimed to compare the lived employment (school and work) experiences of young adults with cSLE and aSLE.

Methods: Participants were recruited from 3 rheumatology clinics in Canada for individual semi-structured, English language qualitative interviews. Participants completed a pre-interview questionnaire (socio-demographics, SLE history and work characteristics). Semi-structured interviews were conducted by video/phone, transcribed verbatim, double-coded and analyzed using thematic analysis. Divergence is defined as differences in articulating experiences under the same theme.

Results: 34 SLE patients: 16 (47%) cSLE, 18 (53%) aSLE, were interviewed. There were 25 females, 7 males, 2 non-binary. Median ages were 21 (cSLE) and 28 years (aSLE). 59% of cSLE and 76% of aSLE participants were working. Major organ involvements were present in 56% (similar in cSLE and aSLE and disease duration).

There were 4 main themes and 10 sub-themes. Diverging subthemes are highlighted below:

1) *Decreased productivity (subthemes: physical tasks and cognitive performance):* Both groups endorsed fatigue, cSLE group changed course to reduce fatigue while aSLE group tried to push through. cSLE group avoided flares by planning ahead but aSLE group dealt with flares as they occurred and were forced to change course. Though both groups report brain fog, cSLE group described attention problems but aSLE group memory problems.

2) *Interference with employment (subthemes: changing career path, losing/quitting job/ school, and medical encounters):* cSLE group planned their career by making different choices before entering the workplace but the aSLE group had to change their work.

3) *Social relations (subthemes: interference with social relations, and social support needs):* The cSLE group had to learn to prioritize their health over social activities but the aSLE group prioritized their health.

4) *Flexibility (subthemes: autonomy in different settings):* While both groups desired autonomy, the cSLE group was better able to access it compared to the aSLE group.

Conclusion: While young adults with cSLE and aSLE face similar challenges during employment, they also have different lived experiences. This may also reflect differences in age, life stage, and type of employment (school vs. work) between the 2 groups. Interventions targeting the challenges identified in young adulthood offer an opportunity for change with large potential future effects. Late cSLE teens and early post-diagnosis aSLE patients could be offered interventions to help them gain and sustain productive employment.

Abstract Number: 1495

Comparing the 0-10 Physician Global Assessment Scale to Categorical Disease Activity States among Pediatric Patients with SLE

Livie Timmerman[1], Melissa Mannion[2] and Emily Smitherman[2], [1]University of Alabama at Birmingham, Gardendale, AL, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The Physician Global Assessment (PGA) is used to measure disease activity on a 0–10 scale for many pediatric rheumatic conditions. However, the thresholds at which 0-10 PGA scores correspond to clinically defined categories (inactive, mild, moderate, severe), or a 0-3 scale as utilized in childhood lupus low disease activity state (cLLDAS), are not standardized. Understanding the relationship between 0–10 and 0–3 PGA may clarify if the 0–3 scale is necessary for cLLDAS or whether a transformed 0–10 scale could serve as an acceptable substitute. Our objective was to define 0-10 PGA score thresholds that correspond to clinician-assigned categorical disease activity levels using statistical modeling and predicted probabilities.

Methods: We analyzed electronic health record (EHR) data collected from a tertiary care pediatric rheumatology clinic between December 2021 and February 2023. We identified ambulatory visits for SLE using a clinician-documented structured field. Our EHR documentation included structured fields to collect: 1) 0-10 PGA (21 points with 0.5 increments), built as a drop-down menu; 2) a categorical "Disease Activity Assessment" with radio buttons for "Inactive", "Mild", "Moderate", and "Severe" arranged in a row, representing 0-3 PGA anchored values. We calculated descriptive statistics for PGA by clinician-assigned disease activity category. PGA was then evaluated as a continuous predictor of disease activity category using ordinal logistic regression. Predicted probabilities of each disease activity category were estimated using margins from the ordinal model. We then derived PGA thresholds and calculated the frequency of visits within each PGA category compared to clinician-assigned categories.

Results: We analyzed 190 visits < ![if !supportAnnotations] >[ES1]< ![endif] > < ![if !supportAnnotations] >[LT2]< ![endif] > < ![if !supportAnnotations] >[MM3]< ![endif] > for SLE with both 0-10 PGA and disease activity category completed (Figure 1). Clinician-assigned categories were Inactive for 50% of visits (PGA median 0, IQR 0-0), Mild 42% (1.0, 1-2), and Moderate 8% (3.75, 2.25-5). Each 1-point increase in PGA more than doubled the odds of being assigned to a higher disease activity category (OR = 2.08, 95% CI: 1.57–2.59, p < 0.001). Visits with PGA ≤0.5 had >80% probability of clinician-assigned

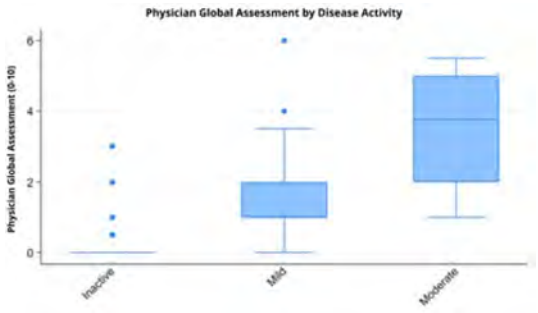

Figure 1. Distribution of 0-10 Physician Global Assessment Scores by Clinician-Assigned Disease Activity Assessment Category (inactive, mild, moderate) across 190 Pediatric Rheumatology Encounters for SLE.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Predicted Probability of Clinician-Assigned Disease Activity (PGA) Category by 0-10 Physical Global Assessment (PGA) Score

PGA	Pr(Inactive)	Pr(Mild)	Pr(Moderate)
0	83%	17%	<1%
1	38%	61%	<1%
2	7%	88%	5%
3	<1%	70%	29%
4	<0.1%	23%	77%
5-10	≈0%	<1%	≈99%

Table 2. Number of visits within each Physician Global Assessment (PGA) Threshold cross-tabulated with Clinician-Assigned Disease Activity Category

PGA Range	Inactive Category, n (%)	Mild Category, n (%)	Moderate Category, n (%)
0-0.5	90 (94%)	11 (14%)	0
1-3.5	6 (6%)	66 (83%)	7 (50%)
4-10	0 (0%)	3 (3%)	7 (50%)

inactive category, 1-3.5 had the highest probability of mild, and ≥5 had >95% probability of moderate (Table 1). PGA 0-0.5 identified 94% of the visits assigned inactive, 1-3.5 identified 83% of the visits assigned mild, and 4-10 identified 50% of the visits assigned moderate (Table 2),

Conclusion: In children with SLE, 0-10 PGA scores are strongly aligned with clinician-assigned disease activity categories, supporting transformation between the 2 scales. Using a 21-point 0-10 PGA scale, we propose that 0-10 PGA ≤3.5 corresponds to cLLDAS criteria and 0-10 PGA ≤0.5 corresponds to clinical remission criteria, suggesting a modification from strict mathematical transformation. Aligning the cLLDAS 0-3 PGA scale to 0-10 scale used in other pediatric rheumatic conditions is likely to increase reliability of collection in routine clinical practice.

Demyelinating Syndromes in Systemic Lupus Erythematosus: A 23-Year Retrospective Analysis of Clinical Features and Treatment Outcomes from a Tertiary Care Center

Manikandan Gopal[1], Ashish Jacob Mathew[2] and john mathew[3], [1]christian medical college, Vellore, India, [2]Christian Medical College, Vellore, Tamil Nadu, India, [3]Christian Medical college , Vellore , India, Vellore, Tamil Nadu, India

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) with acute myelitis or optic neuritis is rare and causes significant morbidity. Data on these conditions remain limited. This study aimed to evaluate the clinical profile and outcomes of patients presenting with demyelinating syndromes (transverse myelitis or optic neuritis) in SLE.

Methods: A retrospective chart review was conducted, identifying patients diagnosed with SLE and myelitis or optic neuritis at our center between 2000 and 2023. SLE was diagnosed using ACR-EULAR 2019 criteria. The Expanded Disability Status Scale (EDSS) was used to assess disability levels. Data were analyzed using descriptive statistics.

Table 1: Patient Demographics and Clinical Characteristics

Table 1: Patient Demographics and Clinical Characteristics

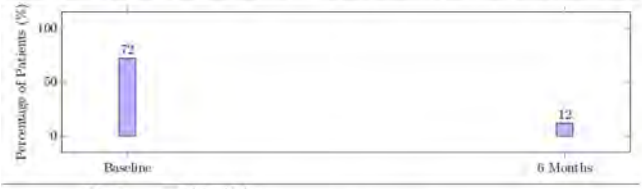
Characteristic	Value
Number of patients	25
Sex	100% (25/25) female
Age (years, mean ± SD)	27.04 ± 9.69
SLEDAI (mean ± SD)	17.72 ± 6.88
Demyelination as initial SLE manifestation	24% (6/25)
Time to nadir ≤ 24 hours	64% (16/25)
Motor deficit	88% (22/25)
Sensory level involvement	88% (22/25)
Urinary retention	72% (18/25)
Optic neuritis	16% (4/25)
Thoracic cord involvement (MRI)	88% (22/25)
Longitudinally extensive myelitis (MRI)	53% (13/25)
ANA positive	100% (25/25)
Low complements	76% (19/25)
Aquaporin-4 antibody positive	12% (3/25)

Table 2: Treatment and Outcomes

Table 1: Treatment and Outcomes

Treatment/Outcome	Value
Pulse methylprednisolone	92% (23/25)
Cyclophosphamide	68% (17/25)
Severe disability at baseline (EDSS > 5)	72% (18/25)
Severe disability at 6 months (EDSS > 5)	12% (3/25)
Relapse after treatment	12% (3/25)
Mortality (sepsis)	4% (1/25)
Optic atrophy within 1 year (optic neuritis patients)	0% (0/4)

Figure 1: Expanded Disability Status Scale (EDSS > 5) Score Distribution and Criteria



Score	Description
0.0	Normal neurological exam, no disability.
1.0–1.5	No disability, minimal signs in one or more functional systems.
2.0–2.5	Minimal disability in one or two functional systems.
3.0–3.5	Moderate disability in one functional system or mild disability in multiple systems, fully ambulatory.
4.0–4.5	Significant disability but ambulatory without aid, able to walk 300–500 meters.
5.0–5.5	Disability severe enough to impair daily activities, able to walk 100–200 meters without aid.
6.0	Requires unilateral assistance (cane/crutch) to walk about 100 meters.
6.5–7.5	Requires bilateral assistance or wheelchair for mobility.
8.0–9.5	Restricted to bed, with varying degrees of retained function.
10.0	Death due to disease.

Figure 1: EDSS (Expanded Disability Status Scale) Score at baseline and 6 month and EDSS Criteria

Results: A total of 25 female patients were identified with a mean age of 27.04 ± 9.69 years. The interval between SLE diagnosis and onset of demyelination varied widely, with 24% of patients presenting with demyelination as an initial manifestation. The mean SLEDAI was 17.72± 6.88. Sixteen patients (64%) reached the nadir of clinical presentation within 24 hours. Severe impairments included motor deficit (88%), sensory level involvement (88%), urinary retention (72%), and optic neuritis (16%). MRI was abnormal in all cases, with thoracic cord involvement in 88%, longitudinally extensive myelitis in 53%, and area postrema involvement in 8.3%. ANA was positive in all patients, 76% had low complements, and 12% tested positive for aquaporin-4 antibodies. Pulse methylprednisolone was administered to 92%; cyclophosphamide (68%) was the most used second-line therapy. At baseline, 72% had severe disability (EDSS > 5), which improved after six months,

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with only 12% retaining severe disability. Three patients relapsed after treatment and one patient succumbed to sepsis. No patients with optic neuritis developed optic atrophy within one year.

Conclusion: Demyelinating syndromes in SLE primarily affect young females and correlate with high disease activity. Early immunosuppressive therapy leads to improved outcomes , though some patients retain residual disability, underscoring the need for prompt intervention.

Acute Care Utilization in Patients with Antiphospholipid Syndrome And/or Systemic Lupus Erythematosus

Megan Barber[1], Fengjuan Yang[2], Leslie Skeith[2], Danielle Southern[3] and Ann Clarke[1], [1]Division of Rheumatology, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]University of Calgary, Calgary, Canada

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Little is known about acute care utilization in patients with APS and/or SLE. This study focuses on hospitalizations, intensive care unit (ICU) admissions and emergency department (ED) visits, in patients with APS and/or SLE, both one year prior to and after identification of positive aPLs or diagnosis with SLE, compared to a control population.

Methods: Patients from our observational aPL/APS and SLE registries were included. Patients had persistently positive aPL (medium positive [40-80 GPU] or high positive [>80 GPU] anticardiolipin or anti-beta-2 glycoprotein 1 or a positive lupus anticoagulant test, measured at least 12 weeks apart) and/or fulfilled ACR or SLICC SLE classification criteria. Patients diagnosed with APS clinically met revised Sapporo Criteria. The index date was defined as the date that persistently positive aPL were first identified or that SLE classification criteria were met. Acute care utilization one year prior to and after the index date was determined. Data were sourced from several provincial health-related databases in Alberta, Canada. Acute care utilization was compared to age, sex, and geographic matched controls, excluding individuals with testing for aPLs, ANA, ENA or anti dsDNA or those with any practitioner claim codes or ICD codes for SLE or APS. Controls were assigned the index date of their matched case. Descriptive statistics were used to summarize baseline demographics and acute care utilization. Conditional logistic regressions were applied to assess differences between cases and matched controls for binary outcomes, generalized linear mixed Poisson regression models for discrete count and Gamma regression models for continuous outcomes, accounting for matched pairs.

Table 1: Baseline characteristics at index date

Characteristics	APS	APS Control	SLE	SLE Control

	(Median, IQR)	4.00 (2.00-4.00)	2.00 (2.00-4.00)	0.0119*	2.00 (1.00-4.00)	1.00 (1.00-2.00)	<0.0001*

Note:
Availability of data is based on participants' active status in the Alberta Provincial Registry and availability of the Discharge Abstract Database (since April 1, 2002) and National Ambulatory Care Reporting System (since April 1, 2001) in Alberta.
*$P < 0.05$ indicates a statistically significant difference.
- Statistical Analyses were not performed due to the small sample size.

Results: 459 patients participated: 65 with APS (+/- SLE), and 440 with SLE (+/- aPL) (Table 1). There were 2,525 matched controls randomly selected. One year prior to the index date, patients with APS and/or SLE had significantly higher rates of hospitalizations compared to their respective control groups (all $p < 0.0001$) (24.0% in APS vs. 3.7% in controls, and 13.9% in SLE vs. 5.0% in controls). ED visits rates were also higher in APS (54.0% vs. 16.7%) and SLE (46.1% vs. 15.9%) groups.

One-year post-index date, healthcare utilization remained significantly higher in patients with APS and/or SLE. Hospitalization rates rose to 42.6% in APS and 33.0% in SLE, both significantly higher than their controls (4.7% and 4.9%, respectively; $p < 0.0001$). SLE patients also had longer hospital stays (5.75 (3.00-9.00) vs. 2.00 (1.00-3.00) median days, p = 0.0323) and more hospitalizations (1.00 (1.00 -2.00) vs. 1.00 (1.00 -1.00), p = 0.0012). ICU admissions rates were higher in SLE patients than controls (1.03% vs. 0.07%, $p = 0.0190$). ED visit rates remained elevated in APS (59.3% vs. 13.4%) and SLE (47.5% vs. 14.7%) groups, with significantly higher mean visit counts in both (p = 0.0119 for APS; p < 0.0001 for SLE) (Table 2).

Conclusion: Patients with APS and/or SLE have a higher rate of hospitalizations and ED presentations compared to a control population, both one year prior to and after the first identification of positive aPLs or diagnosis of SLE.

Abstract Number: 1498

Both Race and Socioeconomic Status Affect Mortality in SLE

Gursimran Kaur[1], Daniel Goldman[2], Andrea Fava[3], Laurence Magder[4] and **Michelle Petri**[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Timonium, MD, [3]Johns Hopkins University, Baltimore, MD, [4]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: A recent meta-analysis found an overall 2.87-fold increase in all-cause mortality in systemic lupus erythematosus (SLE) with cause-specific increases in renal disease, infections, cardiovascular disease, stroke and cancer. An increase in mortality due to lupus nephritis was found between 2015-2020. Yen et al examined SLE mortality in the United States from 1968 to 2013. Multiple logistic regression found sex (male), race (blacks) and region (the South) were associated with SLE mortality. We evaluated the role of different demographic variables on mortality outcomes in systemic lupus erythematosus (SLE) in a large single-center cohort.

Methods: Using data from the cohort and the National Death Index, we analyzed demographic and clinical information to discover links between demographic characteristics and mortality. Cox proportional hazards models were used to assess the independent effects of age, gender, race/ethnicity, education and socioeconomic status on mortality risk while controlling for disease activity and comorbidities. Given the strong non-linear relationship between age and mortality, all estimated associations with mortality are adjusted for age at diagnosis and age at diagnosis squared.

Table 1. Predictors of Mortality based on a Cox Proportional Hazard Model

Variable	Level	N of patients	Number (%) of deaths	Age-adjusted hazard ratios (95% CI)	P-value
All		3021	628 (21%)		
Sex	Female	2773	561 (20%)	1.00 (Ref. Group)	--
	Male	248	67 (27%)	**1.40 (1.090, 1.82)**	**0.0098**
Race	White	1575	301 (19%)	1.00 (Ref. Group)	--
	Black	1183	316 (27%)	**1.76 (1.50, 2.07)**	**<0.0001**
	Other	263	11 (4%)	**0.36 (0.20, 0.66)**	**0.0009**
Education	≥12 yrs	2619	484 (18%)	1.00 (Ref. Group)	--
	12 yrs	230	105 (46%)	**2.28 (1.93, 2.77)**	**<0.0001**
Household Income	>$40,000/yr	1530	182 (12%)	1.00 (Ref. Group)	--

Table 2. Multivariable Model of Predictors of Mortality

	Hazard Ratios (95%CI)	P-value
Male gender	1.57 (1.19, 2.07)	0.0014
Black race vs White	1.41 (1.17, 1.69)	0.0003
Other race vs. White	0.52 (0.29, 0.98)	0.042
Less than 12 years of Education	1.40 (1.11, 1.77)	0.0053
Household Income less than or equal to $40,000	1.73 (1.42, 2.11)	<0.0001
Decade of Diagnosis		
Pre 1990		
1990-2000	0.63 (0.51, 0.78)	<0.0001
2000-2010	0.53 (0.40, 0.70)	<0.0001
2010+	0.24 (0.12, 0.44)	<0.0001

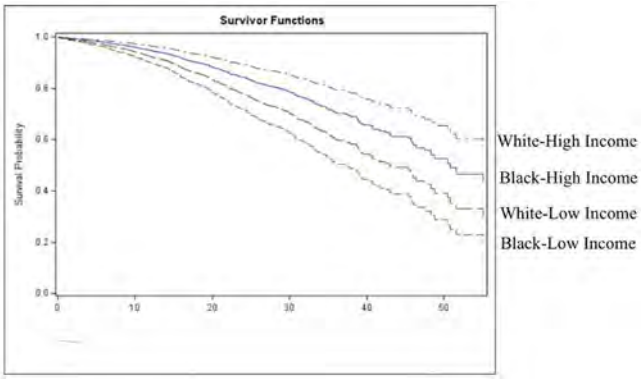

Figure 1. Estimated probability of survival by years since diagnosis by Race and Income

Results: Of the 3,021 patients included from the cohort, 628 deaths were recorded. They were 89% female, 34% had a household income of more than $40,000, and 82% had 12 years or more years of education. They were 48% White, 50% Black, 1% East Asian and 1% Other or mixed racial background. Male gender (p=0.0098), Black race vs White (p< 0.0001), less than 12 years of education (p< 0.0001), and household income of less than or equal to $40,000 (p< 0.0001) were associated with increased mortality in both univariate (Table 1) and multivariable (Table 2) models. Decreased mortality was observed for those diagnosed with lupus after 1990 (Table 1, Table 2). White race with high income had the lowest mortality, and black race with low income had the highest mortality (Figure 1).

Conclusion: Patel et al, in a meta-analysis, found that Blacks had higher mortality than Whites, but could not comment on socioeconomic factors. In the Eight Americas study, Falasinnu et al found that Blacks sharing the same social and geographic contexts as Whites had higher mortality, but SLE mortality did not vary between socially advantaged and disadvantaged Blacks. Our results, using individual patient data to measure socioeconomic status in 2 ways (household income and education) clearly contradict the Eight Americas study. Race and socioeconomic status both played a role in mortality risk in SLE, even in a single center of excellence (where access to care and medication were not issues). Our single center study was able to use actual individual patient household income and education, and not infer it from zip codes or county of residence. Black race with high income had better survival than white race with low income.

Abstract Number: 1499

Predictors of Proteinuria Flares in Biopsy Positive Lupus Nephritis

Michelle Petri[1], Andrea Fava[2], Daniel Goldman[1] and Laurence Magder[3], [1]Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Over 20% of lupus nephritis (LN) patients progress to end stage kidney disease. One of the most important predictors is renal flare.

Methods: The analysis is based on members of a longitudinal SLE cohort who had biopsy-proven lupus nephritis. The analysis includes all cohort visits that occurred after the positive biopsy. Two cohort visits, separated by less than 120 days in which the urine protein-creatinine ratio (UPCR) was measured, were referred to as a set of "paired visits". A proteinuria flare was defined as an increase in UPCR of 500 mg/gm or more in a pair of visits. We calculated the proportion of paired visits that exhibited a proteinuria flare in subgroups of paired visits defined by various patient characteristics. The association between patient characteristics and risk of a proteinuria flare was quantified using odds ratios from a logistic regression model fit with GEE to account for the fact that each patient contributed more than one set of paired visits. A multivariate equation to predict the risk of a proteinuria flare was developed using a forward-stepwise approach, considering each of the variables in Tables 1 in turn, and adding the variable that led to the greatest reduction in Quasi-likelihood Information Criterion (QIC).

Results: In 524 biopsy proven LN patients there were 776 proteinuria flares, with a mean $\pm$ SD of 1.48 $\pm$ 2.59 flares per patient. The patients were 88% female, 31% White, 51% Black, and 17% Other. Table 1 shows the univariate analysis of associates of proteinuria flare. African-American race, younger age, low C3 and lower household income predicted flares.

Table 1. Rates of proteinuria flares based on demographics

Variable	Level	N paired visits	Number (%) of proteinuria flares	Odds Ratio (95% CI)	P-value

	Yes	442	13 (3%)	0.29(0.17,0.51)	0.0000

All recent serologies (low C3, low C4 or high anti-dsDNA), higher SLEDAI, UPCR > 500 mg and higher serum creatinine all predicted proteinuria flare. Hydroxychloroquine use did not protect against proteinuria flare, but anti-hypertensive drug use did. NSAID use protected against proteinuria flare. Table 2 shows the final multivariate model. Higher serum creatinine, higher UPCR, younger age, African-American race, low C3, low C4 and anti-Ro predicted proteinuria flares. Protective factors included ACE-inhibitor/ARB use, age over 45, and NSAIDs.

Conclusion: Reduction of proteinuria flares is an essential goal to prevent progression to end-stage kidney disease, as each flare leads to additional loss of nephrons and podocytes. Our study could not address adherence to medication, a key factor in renal flare. We did find pathways that are essential: ACE-inhibitor/ARB use is protective. Treatments that normalize low C3 and low C4 would be hypothesized to also be key in preventing flares. One shocking finding was that NSAID use (which we counsel patients to avoid) was protective, even in the multiple variable model.

Table 3. Multivariate model to predict a proteinuria flare

Variable	Comparison	Odds Ratio (95% CI	P-value
Recent Serum Creatinine	0.8-1.2 vs <0.8	1.19 (0.94, 1.51)	0.15625
	1.2+ vs <0.8	2.27 (1.79, 2.87)	0.00000

Prognostic Impact of Thrombocytopenia on Morbidity and Mortality in Systemic Lupus Erythematosus: A Retrospective Single-Center Study

Milad Heydari-Kamjani[1], Amir Daneshvar[2], Dana Nachawati[2], Elleson Harper[2], Keri Ann Pfeil[2], Meghan Gump[2], Lindsay Frumker[3] and Omer Pamuk[1], [1]University Hospitals Cleveland Medical Center/ Case Western Reserve University, Cleveland, OH, [2]University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH, [3]University hospitals Cleveland medical center, Highland Heights, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune rheumatic disease with heterogeneous hematologic manifestations. Thrombocytopenia (TP) in SLE may be associated with major organ involvement and poor prognosis. Our study aimed to evaluate the frequency and prognostic significance of TP in a large, single-center SLE cohort.

Methods: We conducted a retrospective cross-sectional study using data from the SLE cohort at University Hospitals Cleveland Medical Center. Patients met 2019 EULAR/ACR classification criteria for SLE. Clinical, demographic, immunologic, and outcome variables were extracted to assess associations with a history of TP, defined as any documented platelet count $< 150 \times 10^9$/L. Chi-square (χ^2) tests were used to assess the relationship between TP and categorical variables, including clinical manifestations, laboratory markers, medication use, and mortality. To determine independent risk factors for TP in SLE patients, multivariate logistic regression analysis was performed. Parameters which were found significant in univariate analysis were utilized in logistic regression analysis. A two-sided p-value of < 0.05 is considered statistically significant. The study was IRB-approved.

Results: Among the 279 SLE patients, 105 (37.6%) had a history of TP. TP was significantly associated with several immunologic and clinical features. Patients with TP were more likely to have leukopenia (74.3% vs. 37.9%, $p < .001$), lymphopenia (83.8% vs. 36.8%, $p < .001$), low C3 (41.9% vs. 13.8%, $p < .001$), and low C4 (37.1% vs. 13.8%, $p < .001$). There was a non-statistical trend toward higher anti-dsDNA antibody positivity (57.7% vs. 46.5%, $p = .072$). TP was associated with major organ involvement including increased rates of lupus nephritis (41.0% vs. 18.4%, $p < .001$), ESRD (21.9% vs. 2.3%, $p < .001$), CNS involvement (17.1% vs. 9.2%, $p = .049$), cerebrovascular events (20.0% vs. 4.1%, $p < .001$), and thrombotic events (25.0% vs. 9.8%, $p < .001$). Additionally, in this cohort, they had an approximately 6.8-fold higher risk of mortality (7.5% vs. 1.1%, $p = 0.039$). Use of immunosuppressive therapies, including mycophenolate mofetil (48.6% vs. 26.4%, $p < .001$) and rituximab (11.4% vs. 3.5%, $p = .013$), was also significantly more common among patients with TP. In contrast,

Table 1: Baseline demographics and comorbid conditions in SLE with and without thrombocytopenia.

Variables	SLE without Thrombocytopenia (n = 174)	SLE with Thrombocytopenia (n = 105)	p-value
Gender			
Female	158 (90.8%)	94 (89.5%)	0.65
Race			0.51[1]
White	76 (43.7%)	42 (40%)	-
African American	86 (49.4%)	59 (56.2%)	-
Asian	5 (2.9%)	1 (1.0%)	-
Ethnicity			0.24[2]
Non-Hispanic ethnicity	170 (97.7%)	100 (95.2%)	-
Comorbidities			
Smoking	45 (25.6%)	33 (31.4%)	0.77
Hypertension	73 (42.4%)	55 (52.4%)	0.10
Diabetes mellitus	19 (11.0%)	19 (18.1%)	0.098
Coronary artery disease	11 (6.4%)	13 (12.4%)	0.086
Malignancy	15 (8.7%)	15 (14.3%)	0.14

[1] p-value from Pearson chi-square test comparing overall race distribution between groups.

[2] p-value from Pearson chi-square test comparing overall distribution of ethnicity categories across groups.

Table 2: Comparison of serologic markers in SLE patients with and without thrombocytopenia.

Variables	SLE without Thrombocytopenia (n = 174)	SLE with Thrombocytopenia (n = 105)	p-value
Leukopenia	66 (37.9%)	78 (74.3%)	**<.001**
Lymphopenia	64 (36.8%)	88 (83.8%)	**<.001**
Low C3	24 (13.8%)	44 (41.9%)	**<.001**
Low C4	24 (13.8%)	39 (37.1%)	**<.001**
dsDNA antibody	80 (46.5%)	60 (57.7%)	0.07
Anti-Sm antibody	37 (21.5%)	24 (23.1%)	0.76
Ro/SSA antibody	57 (33.1%)	35 (33.7%)	0.93
La/SSB antibody	19 (11.0%)	12 (11.5%)	0.90
Chromatin antibody	50 (28.9%)	39 (37.1%)	0.15
RNP antibody	59 (34.3%)	40 (38.5%)	0.48
Lupus anticoagulant	17 (13.4%)	18 (20.0%)	0.19

Table 3: Clinical manifestation of SLE patients with and without thrombocytopenia.

Variables	SLE without Thrombocytopenia (n = 174)	SLE with Thrombocytopenia (n = 105)	p-value
Malar rash	58 (33.3%)	35 (33.3%)	1
Discoid rash	12 (6.9%)	8 (7.6%)	0.821
Photosensitivity	31 (17.8%)	26 (24.8%)	0.163
Oral ulcers	25 (14.4%)	11 (10.5%)	0.348
Alopecia	29 (16.7%)	16 (15.2%)	0.753
Arthritis	129 (74.1%)	75 (71.4%)	0.621
Pleuritis	22 (12.6%)	19 (18.1%)	0.213
Pericarditis	16 (9.2%)	15 (14.3%)	0.19
Lupus nephritis	32 (18.4%)	43 (41.0%)	**<.001**
End-stage renal disease	4 (2.3%)	23 (21.9%)	**<.001**
CNS involvement	16 (9.2%)	18 (17.1%)	**0.049**
Cerebrovascular disease	7 (4.1%)	21 (20.0%)	**<.001**
Thrombosis	17 (9.8%)	26 (25.0%)	**<.001**
Mortality	1 (1.1%)	4 (7.5%)	**0.039**

there were no statistically significant differences between patients with and without TP in terms of gender, race, ethnicity, or comorbid conditions such as hypertension, diabetes mellitus, coronary artery disease, or malignancy. Multivariate logistic regression analysis showed that lymphopenia (OR: 7.6, 95%CI: 1.5-38.5, p=0.014) and the presence of cerebrovascular disease (OR: 37, 95%CI: 2.1-647.2, p=0.013) are independent factors associated with TP in our SLE cohort.

Conclusion: TP in SLE is significantly associated with leukopenia, lymphopenia, and decreased C3/C4. It is also linked to severe clinical manifestations, including lupus nephritis, ESRD, CNS and cerebrovascular events, thrombosis and increased mortality. Multivariate analysis confirmed that lymphopenia and cerebrovascular disease are independent predictors of TP. These findings support TP as a powerful prognostic marker in SLE.

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with heterogeneous hematologic manifestations. Thrombocytopenia (TP) in SLE may be associated with major organ involvement and poor prognosis. In this study, we aimed to evaluate the frequency and prognostic significance of TP in a large, multi-center, real-world SLE cohort.

Methods: We conducted a retrospective cohort study using the TriNetX Research Network, a de-identified, federated electronic health record database (accessed March 20, 2025). Adult patients (≥18 years) with SLE (ICD-10: M32.9) and TP (ICD-10: D69.6), with at least one follow-up encounter, were included. A 1:1 propensity score matching was performed using 41 variables including demographics, comorbidities, and medication exposures to balance baseline characteristics. Continuous and categorical variables were compared using t-tests and chi-squared tests ($\alpha = 0.05$).

Table 1: Baseline characteristics and comorbidities in patients with SLE with and without thrombocytopenia before and after propensity score matching.

Variables	Before Matching			After Matching		
	SLE-TP (n = 17,407)	SLE-non-TP (n = 118,640)	P-Value	SLE-TP (n = 17,097)	SLE-non-TP (n = 17,097)	P-Value

Complement C4	7,387 (42.4%)	40,243 (33.9%)	<0.001	7,158 (41.9%)	6,537 (38.2%)	**<0.001**
Medications						
Hydroxychloroquine	7,902 (45.4%)	50,272 (42.4%)	**<0.001**	7,714 (45.1%)	7,725 (45.2%)	0.905
Glucocorticoids	11,380 (65.4%)	62,482 (52.7%)	**<0.001**	11,079 (64.8%)	11,029 (64.5%)	0.572
Azathioprine	1,171 (6.7%)	5,625 (4.7%)	**<0.001**	1,130 (6.6%)	1,137 (6.7%)	0.879
Mycophenolate mofetil	2,384 (13.7%)	8,895 (7.5%)	**<0.001**	2,258 (13.2%)	2,337 (13.7%)	0.21
Cyclophosphamide	581 (3.3%)	1,486 (1.3%)	**<0.001**	507 (3.0%)	498 (2.9%)	0.773
Belimumab	175 (1.0%)	1,958 (1.7%)	**<0.001**	172 (1.0%)	157 (0.9%)	0.406
Rituximab	714 (4.1%)	1,137 (1.0%)	**<0.001**	592 (3.5%)	588 (3.4%)	0.906

Results: A total of 17,407 patients with SLE and TP (SLE-TP) and 118,640 without TP (SLE-non-TP) were identified, with SLE-TP comprising 14.7% of the cohort. Before matching, SLE-TP patients were more likely to be male and African American ($p < 0.001$) and had significantly higher frequencies of inflammatory arthritis, pleurisy, glomerular disease, antiphospholipid syndrome, seizure, and hemolytic anemia (all $p < 0.05$). Comorbidities including obesity, type 2 diabetes, and hypertension were also more common in the SLE-TP group (all $p < 0.001$)

After matching, African American patients were slightly less prevalent in the SLE-TP group compared to the SLE-non-TP group (29.3% vs. 30.7%, $p = 0.005$). SLE-TP patients had significantly higher rates of peripheral neuropathy ($p = 0.006$), La/SSB autoantibody ($p = 0.013$), low C3 ($p = 0.001$), and low C4 ($p < 0.001$) (Table 1 and Table 2). There was a trend toward higher obesity in the SLE-TP group ($p = 0.093$). Use of immunosuppressive medications was not significantly different between the matched groups (Table 2).

During the study period, 3,182 (18.6%) SLE-TP patients and 1,368 (8.0%) SLE-non-TP patients died (relative risk [RR]: 2.33; 95% CI: 2.19–2.47) (Figure 1A). Survival analysis showed significantly worse prognosis in the SLE-TP group (hazard ratio [HR]: 1.94; 95% CI: 1.83–2.07; $p < 0.001$) (Figure 1B), indicating that SLE patients who had thrombocytopenia exhibited a significantly lower survival probability compared to those without this condition.

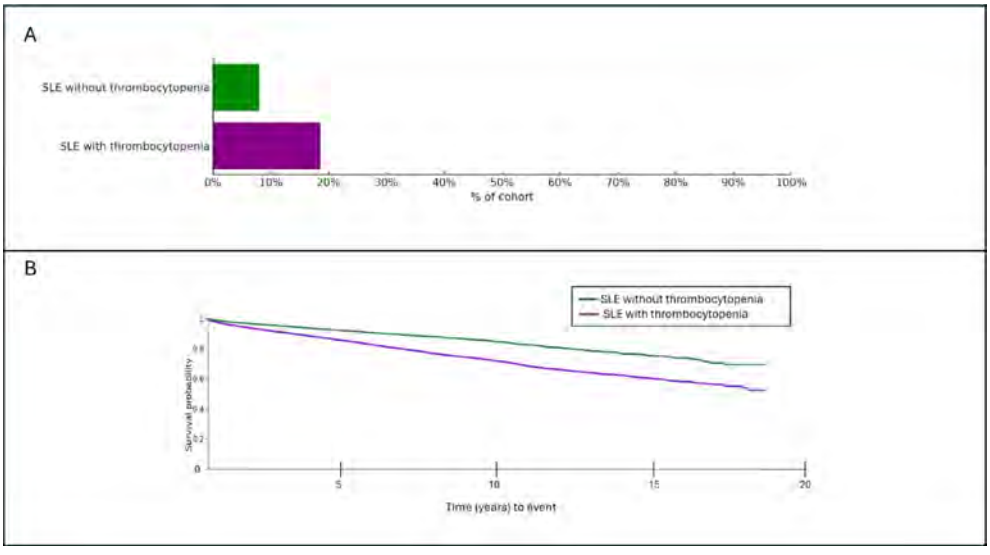

Figure 1: Impact of thrombocytopenia in SLE on mortality and survival in patients with and without thrombocytopenia.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The presence of La/SSB autoantibody, hypocomplementemia (low C3 and C4), and peripheral neuropathy are the immunological and clinical features most strongly associated with SLE-TP. More importantly, this group faces over a twofold increase in mortality with survival analysis confirming a significantly worse prognosis. These findings confirm thrombocytopenia as a powerful prognostic marker in SLE, indicating that low platelet counts are linked to substantially worse outcomes and nearly double the risk of death.

Prevalence and Associated Factors of Autoimmune Hepatitis and Primary Sclerosing Cholangitis in Systemic Lupus Erythematosus: A Systematic Review and Meta-Analysis

Bisma Shaikh[1], Sarfaraz Hasni[2] and **Omer Pamuk**[3], [1]Jinnah Sindh Medical University, Karachi, Pakistan, [2]NIH/NIAMS, Bethesda, MD, [3]University Hospitals Cleveland Medical Center/ Case Western Reserve University, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune, chronic disorder characterized by multisystem organ involvement. The hepatic involvement in SLE is categorized as a primary or secondary disease, which incorporates drug-induced liver injury, vascular disorders, alternative hepatic comorbidities, and concurrent autoimmune liver diseases (AILDs). The most prevalent AILDs include autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC), which may manifest alone or concurrently. The primary aim of this study is to perform a systematic review of the literature to determine the relationship between SLE and AILDs.

Methods: We searched the literature using PubMed and Cochrane Library up to 2024 for studies investigating the frequency of AIH, and PBC in patients with SLE and other connective tissue diseases (CTDs). Abstracts presented at international conferences and references of relevant articles have been also reviewed, without any restrictions, between 1959 and 2024. We used the terms 'systemic lupus erythematosus', 'lupus', 'autoimmune liver disease', 'autoimmune hepatitis',

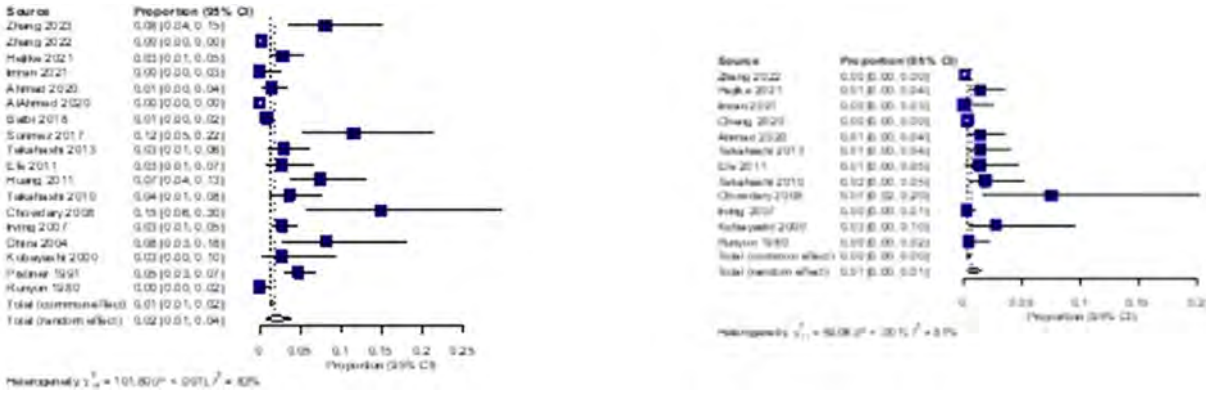

Figure 1A. The prevalence of AIH in patients with SLE. Figure 1B. The frequency of PBC in SLE group.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2A. The rate of SLE in patients with AIH. Figure 2B. The prevalence of SLE in patients with PBC.

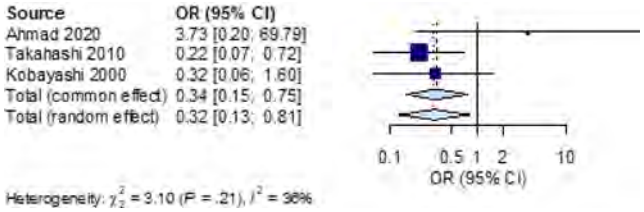

Figure 3. The comparison of the frequency of PBC in patients with SLE and other CTDs.

'primary sclerosing cholangitis', and 'primary biliary cirrhosis'. To detect the frequency of AIH and PSC in the SLE series, a random effect model was used. Forest plots were created to summarize composite data, generating frequencies, odd ratio (OR), and corresponding 95% CI for each subgroup. The I^2 statistic was utilized to evaluate heterogeneity between studies.

Results: Our literature search yielded 1745 articles. After reviewing the titles and abstracts, 254 articles merited full-text review. A total of 29 manuscripts met our eligibility criteria. The pooled cohorts included a total of 58,052 SLE and/or AIH/PBC patients. A random effects model was used to detect the prevalence of AIH/PSC in SLE patients. Eighteen eligible studies comprising 7,651 SLE patients evaluated the frequency of AIH in patients with SLE. The frequency of AIH was 1.88% (95%CI: 0.87-4.01) (Figure 1A). The frequency of PBC was analyzed in 12 studies including 12,538 patients with SLE. The prevalence of PBC was 0.67% (95%CI: 0.30-1.48)) (Figure 1B). Three studies that investigated the frequency of SLE in patients with AIH containing 17,358 patients were included in our analysis. The frequency of SLE was 5.12% (95%CI: 0.98-22.75) in patients with AIH (Figure 2A). Six studies provided data on SLE in patients with PBC (a total of 2,814 PBC patients). The frequency of SLE was found 3.17% (95%CI: 2.26-4.45) in patients with PBC (Figure 2B). Three studies-including 1161 SLE patients provided data comparing the frequency of AIH and PBC between SLE and other CTDs. SLE and other CTD groups showed similar frequencies of AIH (OR: 1.39, 95%CI: 0.31-6.23, p >0.05). The frequency of PBC was found to be lower in SLE than in other CTD groups (OR: 0.32, 95%CI: 0.13-0.81, p= 0.0003) (Figure 3).

Conclusion: Our study showed autoimmune liver diseases such as AIH and PBC are more common in SLE than in the general population. Pooled data revealed that SLE is also relatively common in AIH and PBC. Patients with AIH and PBC need to be screened for concomitant SLE.

Abstract Number: 1503

Lupus Disease Activity Adversely Affects the Quality of Life but not Intimate Relationship and Sexual Function in Indian Female Lupus Patients

Ranjan Gupta, Nilanchali Singh, Nisha Jawaliya, Rudra Prosad Goswami, Soniya Dhiman and Parul baisoya, All India Institute of Medical Sciences, New Delhi, Delhi, India

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) disease activity can affect the normal functioning of the patients. This functioning in various domains can be assessed using quality of life (QoL) tools like Lupus QoL which is a disease specific QoL tool. Similarly, sexual function can be measured by tools like Female Sexual Function Index (FSFI) which is not an SLE specific instrument. We aimed to assess the impact of lupus disease activity on QoL and sexual function of female SLE patients from India.

Methods: We recruited 160 SLE (all females; Mean (±SD) age 28.75 (±8.07) years) patients satisfying ACR/EULAR 2019 classification criteria. A formal disease activity assessment was done using SLEDAI. Lupus QoL instrument in Hindi was used to assess the QoL. Briefly, a transformed domain wise score was calculated based on the responses in each of the 8 domains and a cumulative score for the instrument was calculated by adding the individual transformed domain scores and dividing it by the number of contributory domains. Sexual function in these ladies was assessed using the FSFI instrument (Hindi Version) and a domain wise score calculated in 6 domains. For FSFI, patients were divided into 2 groups based on having sexual intercourse within the last month: Sexually active (SA) and sexually inactive (SI). Age matched healthy ladies were recruited as healthy controls (HC) for comparison of FSFI scores in SA and SI groups. Continuous variables were expressed as Mean (±SD). Unpaired t-test was used to compare the scores and Spearman's correlation coefficient was used to express correlation. A p-value< 0.05 was considered significant.

Results: Mean SLEDAI for all the patients was 4.88 (±3.22). Lupus QoL had worst scores in Fatigue domain and best in the physical health domain. (Table) In Lupus QoL, physical health, pain, planning, burden to others, emotional health, fatigue and the total QoL scores showed a modest negative correlation with SLEDAI. (Table 1)

A total of 89 patients out of 160 (55.62%) and 35 (45.45%) ladies among the HC (n=77), reported having a sexual intercourse within the past 1 month. The scores in all domains of FSFI were compared for these. A total of 146 out of 160 patients (91%) and 75 out of 77 HC (97%) had an FSFI score < 26.55 putting them at risk for developing sexual dysfunction (p >0.05).

Table 1. Domain wise and total scores for Lupus Quality of Life tool for lupus patients and their correlation with disease activity (SLEDAI)

Lupus QoL domains	All Patients	Spearman's Correlation coefficient w.r.t SLEDAI	p-value
Physical Health	67.39 (±27.46)	-0.25	**0.002**
Pain Score	65.082 (±29.95)	-0.26	**0.001**
Planning Score	67.31 (±29.21)	-0.19	**0.019**
Intimate Relationship	64.58 (±29.79)	-0.16	0.08
Burden to Others	57.943 (±31.92)	-0.25	**0.001**
Emotional Health	57.89 (±29.64)	-0.25	**0.002**
Body Image	57.44 (±30.26)	-0.10	0.23
Fatigue Score	57.13 (±27.56)	-0.19	**0.015**
Total Score	**61.76 (±24.19)**	**-0.26**	**0.001**

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Comparison of the domain wise and total Female Sexual Function Index mean (±SD) scores among patients and healthy females

	Patients (n=160)		Healthy Controls (n=77)	
	Sexually Active	Sexually Inactive	Sexually Active	Sexually Inact
FSFI Domains				
Desire	4.04 (±1.16)	3.43 (±0.99)	3.77 (±1.17)	5.6 (±0.74)
Arousal	3.52 (±1.12)		3.16 (±1.13)	
Lubrication	4.17 (±0.72)		3.8 (±0.88)	
Orgasm	3.57 (±0.93)		3.48 (±0.94)	
Satisfaction	2.46 (±1.44)		2.45 (±1.61)	
Pain	4.71 (±1.23)*		4.02 (±1.37)	
Total Score	**22.49 (±3.99)***		**20.71 (±4.38)**	

*Significant when compared to healthy controls

For SI patients and HC, the scores only in the desire domain were compared which were not different. However, among the SA patients, scores in the pain domain and total FSFI scores were significantly better ($p < 0.05$ for both) as compared to HC. (Table 2) Neither any of the individual domains nor the total FSFI score correlated with SLEDAI.

Conclusion: The QoL in Indian SLE patients is the worst in the fatigue domain and best in the physical health domain. Except the intimate relationship and the body image scores in the QoL, all the scores and the total QoL score is adversely affected by disease activity. Sexual function in Indian female SLE patients is better than age matched HC even though 91% patients are at risk of developing sexual dysfunction. Absence of correlation of SLEDAI with the FSFI scores & intimate relationship domain of the QoL suggests that disease activity does not affect sexual function in these patients.

Abstract Number: 1504

High prevalence of clonal hematopoiesis of indeterminate potential (CHIP) somatic mutations in a cohort of 1,073 SLE participants

Richard Oppong[1], Joanne Nititham[2], Ashira Blazer[3], Manuel Ugarte-Gil[4], Jinoos Yazdany[5], Maria Dall'Era[6], Alexander Bick[7], Lindsey Criswell[2] and Cristina Lanata[8], [1]National Institutes of Health, Bethesda, MD, [2]NIH/NHGRI, Bethesda, MD, [3]University of Maryland Baltimore, Baltimore, Maryland, [4]Grupo Peruano de Estudio de Enfermedades Autoinmunes Sistémicas, Universidad Científica del Sur, Lima, Peru; Hospital Guillermo Almenara Irigoyen, EsSalud, Lima, Peru, Lima, Peru, [5]UCSF, San Francisco, CA, [6]Division of Rheumatology, University of California, San Francisco, CA, [7]Vanderbilt University, Nashville, TN, [8]NIH/NHGRI, Bethesda

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Clonal hematopoiesis of indeterminate potential (CHIP) is characterized by the presence of somatic mutations in hematopoietic stem cells that lead to the expansion of a genetically distinct blood cell clone. CHIP is associated with increasing age, chronic inflammatory states and an elevated risk of cardiovascular events. The prevalence of CHIP mutations in healthy individuals is ~**10%** among those over age 65. In this study, we aimed to investigate the prevalence and mutational landscape of CHIP, as well as its association with clinical outcomes, in a large, multi-ethnic cohort of individuals with SLE.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We analyzed 1,073 individuals with SLE across four cohorts for CHIP using a hybrid capture–based targeted sequencing panel encompassing 22 canonical CHIP-associated genes, sequenced at high depth. Raw reads were aligned and processed following GATK Best Practices. Somatic mutation calling and filtering was done by GATK Mutect2 and annotated via ANNOVAR. Rigorous filters were applied to exclude potential germline mutations and artifacts. Variants were classified as exonic or deleterious mutations (defined by CADD Phred score >20). Statistical models evaluated associations between CHIP mutation status and SLE ACR classification criteria, and cardiovascular outcomes, adjusting for age, sex, disease duration, cohort and race/ethnicity.

Results: The mean age of participants was 44.7 (SD 14.4), with a disease duration of 13.2 years (SD 9.8). Exonic CHIP mutations were identified in 47% of participants, with 31% harboring deleterious CHIP mutations. The most frequently mutated genes were *SETBP1* (16.3% exonic, 14% deleterious) and *DNMT3A* (11.4% exonic, 15.2% deleterious). The burden of deleterious CHIP mutations increased by 25.9% per decade of life ($p = 0.002$), and both age at diagnosis and disease duration were significantly associated with the presence of exonic ($p = 0.003$, $p = 0.011$) and deleterious mutations ($p = 0.008$, $p = 0.019$). While overall CHIP mutation status was not significantly associated with the ACR classification criteria or cardiovascular outcomes, gene-specific associations emerged. For instance, mutations in *IDH1* and *IDH2* were associated with hematologic involvement ($p = 0.004$ and $p = 0.015$, respectively), while mutations in *KRAS* and *MPL* were associated with a history of stroke ($p = 0.008$ and $p = 0.02$, respectively). Additionally, *SETBP1, DNMT3A, ASXL1, KIT*, and *IDH2* showed gene-phenotype associations with renal and immunologic manifestations.

Conclusion: SLE may influence the prevalence of CHIP mutations relative to the general population, as both disease duration and age at diagnosis are important risk factors. While global CHIP status was not associated with ACR criteria, specific associations have been observed between CHIP and adverse clinical outcomes including stroke, renal and hematologic involvement. These findings highlight the need for longitudinal studies to investigate the causal role of CHIP mutations for these outcomes in SLE.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Understanding the discordance between patient- and physician-reported disease assessment scores is essential for incorporating patient-reported outcomes into disease activity measures and identifying gaps between physician and patient perception of disease activity. Our objective is to identify factors associated with discordance between Patient Global Assessment (PtGA) and Physician Global Assessment (PGA) scores in a large multicenter SLE cohort.

Methods: The Lupus Clinical Trials Consortium (LCTC) is a prospective cohort of SLE patients from U.S. and Canadian centers. Data were collected during biannual routine visits. Discordance was defined as PtGA minus PGA, with positive discordance indicating higher scoring of disease activity by the patient as compared to their physician. Multivariable linear mixed effects regression evaluated associations between discordance and patient characteristics. Multivariable mixed effects logistic regression was performed to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for the association between positive discordance and patient characteristics. All statistical analyses were performed in RStudio, with a significance level set at 0.05.

Results: The study included 1,349 SLE patients. Patients who met 4 of 11 ACR criteria for SLE and had baseline PtGA and PGA scores available were included. Mean age at diagnosis was 29.3 (±12.4) years, with an average disease duration of 12 years. The cohort was 48% White and 37% Black. Mean PGA and PtGA scores were 0.72 and 0.92, respectively (range 0 to 3); 60% of patients rated their disease as more severe than their physician. Black patients had 0.09 lower discordance than White patients (95% CI [-0.17, 0.00], p=0.043). College-educated patients had 0.11 lower discordance than those without a degree (95% CI [-0.19, -0.04], p=0.002). Current smokers showed 0.16 higher discordance than never-smokers (95% CI [0.04, 0.28], p=0.01). Patients needing help with daily activities had nearly double the odds of positive discordance (OR=1.96, 95% CI [1.36, 2.83], p< 0.001). Government insurance was associated with increased odds of positive discordance (OR=1.55, 95% CI [1.01, 2.38], p=0.044). Each point increase in SELENA SLEDAI score was linked to a 15% decrease in odds of positive discordance (OR=0.85, 95% CI [0.82, 0.89], p< 0.001). Patients with arthritis, renal disease, or neurologic disorder had 41% (OR=0.59, 95% CI [0.38, 0.91], p=0.018), 35% (OR=0.65, 95% CI [0.47, 0.90], p=0.01), and 38% (OR=0.62, 95% CI [0.40, 0.97], p=0.037) lower odds, respectively, of rating disease activity higher than physicians. No association was found between discordance and medication adherence, hospitalizations, or disability.

Conclusion: In this large SLE cohort, most patients rated their disease as more severe than their physicians. Functional limitations and governmental insurance were key predictors of higher patient-rated disease activity. In contrast, disease activity measured by SLEDAI and certain organ manifestations were linked to lower odds of positive discordance.

Perspectives on Clinical Trial Participation for Novel Advanced Therapies: A Focus Group Study in Systemic Lupus Erythematosus (SLE)

Olivia A. Stein[1], Jennifer Lee[1], Evelyne Vinet[2], Arielle Mendel[3], Christian Pineau[4], Leanne Mielczarek[5] and **Sasha Bernatsky**[2], [1]Research Institute of the McGill University Health Centre, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [3]McGill University Health Centre, Montreal, Canada, [4]McGill University, Montréal, QC, Canada, [5]Lupus Canada, Newmarket, Canada

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Our objective is to identify barriers and facilitators perceived by people with systemic lupus erythematosus (SLE) regarding participation in clinical trials for novel/advanced agents, such as cellular therapies.

Methods: Adults from our SLE research cohort were invited to participate in 1-hour virtual focus groups concerning their perspectives on clinical trials for novel/advanced SLE therapies. Sessions, facilitated by trained moderators using standardized questions, were recorded and transcribed. An inductive thematic analysis approach was used to code the data and generate themes/sub-themes.

Results: Nineteen patients participated in four focus groups (two in English, two in French). The mean age (range) was 50.0 (21-77) years and mean disease duration was 21.4 years. Most (90%) of participants were female and 79% (15/19) were White, with the remainder being Black, Asian, and Hispanic. Six major themes emerged: two barriers and four facilitators to trial participation. The first barrier was time and logistical constraints, such as employment and travel. The second was risk aversion, including subthemes of concerns of SLE flare, drug side effects and early-phase trials. Facilitators included receiving clear, detailed clinical trial information. Disease instability was another driver, making patients increasingly willing to accept elevated health risks, time commitment and/or logistical challenges. Desire to support the lupus community was also an important factor. Finally, access in clinical trials to mental health counsellors, peer support, and close medical follow-up were strong facilitators of participation.

Conclusion: We identified potential barriers and facilitators/driving factors for SLE patients regarding clinical trial participation, which are particularly relevant for novel/advanced agents like cellular therapies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Since SLE is associated with significant morbidity and healthcare burden, estimates of SLE incidence are needed to inform research and public health initiatives, including rheumatology workforce planning. SLE incidence estimates may be affected by health care access or care-seeking behaviour (which may have been altered during COVID-19 pandemic years i.e. 2020-2022) and/or by changing environmental factors (e.g. viral triggers, climate change). Our objective is to estimate annual SLE incidence rates over time, using real-world US data.

Methods: Using the Merative™ MarketScan® Commercial (+/-Medicare Supplemental) databases, we identified adults (18+) with $\geq$ 2 years of continuous enrollment and no SLE diagnoses during those 2 years between Jan. 2016-Dec. 2022. Among these, a 20% random sample was selected for analysis. Time zero was the first qualifying date for cohort entry. Incident SLE was defined by International Classification of Diseases diagnostic codes, based on ≥2 physician visits ≥8 weeks apart within two years and/or ≥1 hospitalization. Individuals were followed from time zero until the earliest of SLE diagnosis, health plan disenrollment, or end of follow-up. Annual SLE incidence rates were calculated with 95% confidence intervals (CI). We report incidence overall and stratified by sex, and female-specific rates were further stratified according to whether person-time was contributed during reproductive age (age younger than 52). We assessed age (continuous) and sex in a multivariate hazard regression predicting SLE onset, controlling for calendar year.

Table 1: Annual SLE incidence by 10,000 person-years with 95% CI, US MarketScan, 2016-2022*

Table 1: Annual SLE incidence by 10,000 person-years with 95% CI, US MarketScan, 2016-2022*

	Years

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: We analyzed 4.6 million individuals followed an average of 2.8 years (standard deviation, SD 2.2); 52.6% were female, and mean age at time zero was 43.1 years (SD 14.8). During this period, 1,593 new SLE cases (89.2% female) were identified across 12.9 million person-years (12.3 events per 100,000 person-years). There was no clear difference in incidence comparing 2020-2022 (12.6 events per 100,000 person-years) versus 2016-2019 (12.2 events per 100,000 person-years). In any given calendar year, the incidence was (as expected) much greater among females than males (Table 1). Overall, women had a higher incidence during reproductive years (23.3 events per 100,000 person-years; 95% CI 21.9-24.9) versus later (16.8 events per 100,000 person-years; 95% CI 15.3-18.5). In multivariate models, hazard ratios (HR) for female sex was 7.47 (95% CI 6.38-8.75) and for age (continuous),1.00 (95% CI 1.00, 1.01).

Conclusion: These clinically relevant real-world data suggest SLE incidence in the US is holding steady, during the period 2016-2022. Potential limitations of our analyses include selection bias (all individuals had private insurance), short average follow-up time period, and possible outcome misclassification, including the possibility that some prevalent SLE cases were mis-characterized as incident. Additional/ongoing analyses will consider other important factors, such as urban-versus-rural residence, race/ethnicity, and environmental exposures over a longer time period.

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by systemic inflammation, autoantibody production, and multiorgan involvement. Although genetic, hormonal, and environmental factors are known contributors to disease development, the role of obesity – a growing epidemic in the United States – remains underexplored in SLE. Evidence suggests that adipose tissue in obese individuals secretes inflammatory mediators, which may influence immune function and disease activity. Our published study showed that a high-fat diet accelerates lupus development and autoimmunity in MRL/lpr lupus-prone mice. Here, we examined immune cell profiles (especially T cell

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

subsets), clinical manifestations, and laboratory parameters in non-obese, overweight, and obese SLE patients to explore the immunometabolic link between obesity and lupus pathogenesis.

Methods: Peripheral blood specimens were collected from 56 consented SLE patients: 15 (27%) non-obese (BMI ≤ 25kg/m2), 12 (21%) overweight (BMI 25-30kg/m2), and 29 (52%) obese (BMI ≥ 30 kg/m2). Multiparameter flow cytometry and serial gating were used to examine immune cell populations in patients' blood. Clinical data including demographic information, body mass index (BMI), SLE disease activity (SLEDAI), titers of anti-dsDNA antibody, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and complement (C3, C4) levels were extracted from Epic electronic medical record system. Statistical significance and correlation among groups were determined by Student's t-test and Chi-squared test. Two-tailed $p < 0.05$ was considered significant.

Results: SLE patients included in this study were 96.4% female, 71.4% African American, 21.4% Caucasian American, 3.6% Asian, and 3.6% Hispanic/Latino. Obese and overweight lupus patients had a significantly higher CRP ($p < 0.01$) compared to the non-obese patients. The percentage of patients with severe lupus (SLEDAI > 6) was significantly higher in the obese (21.7%) and overweight (8.3%) groups than the non-obese group (0%). In addition, a higher percentage of lupus with skin lesions was found in the obese (27.3%) and overweight (17.9%) groups than the non-obese group (0%). Flow cytometry results revealed a significantly higher frequency of circulating CD4+ T helper cells (especially CCR4+CCR6- Th2 cells and CD4+ICOS+ T follicular helper cells) in obese and overweight lupus patients, compared to non-obese lupus patients ($p < 0.05$, $p < 0.01$, respectively). Interestingly, these increased frequencies of circulating Th2 ($r=0.8910$) and Tfh helper cells ($r=0.5902$) in obese SLE patients were significantly correlated to SLEDAI level ($p < 0.05$), whereas the increased levels of complement levels (C3 and C4) in obese SLE patients were closely correlated to patients' BMI levels ($p < 0.05$).

Conclusion: Our results showed that obese and overweight lupus patients had an altered Th2 and Tfh cell profile and dysfunctional clinical features with worse outcomes. The increased level of complement is due to obesity, not autoimmunity. Further mechanism studies may provide insight into lupus pathogenesis and treatment strategies for obese SLE patients.

Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Past reports have shown that serositis is a risk factor for organ damage in patients with SLE. However, the distinct clinical features of newly onset SLE with serositis remain unclear. This study aims to elucidate specific clinical features of SLE with serositis at initial onset compared to those without.

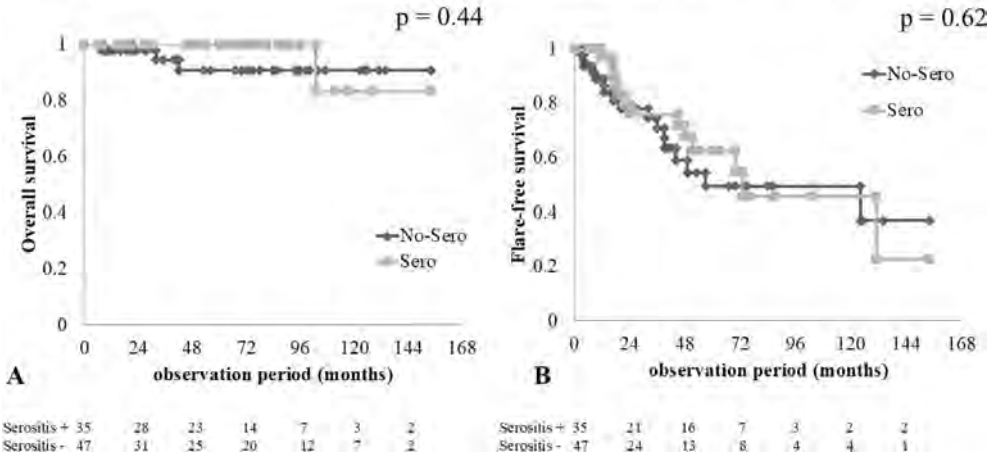
Clinical features of newly-onset SLE patients with serositis compared to those without

Methods: This study is a retrospective inception cohort design. Newly diagnosed patients with SLE treated in the Department of Rheumatology at Fukushima Medical University Hospital between 2011 and 2023 were included. Patients who followed up for over 6 months were selected for this study. Those with newly onset SLE with serositis, which includes pericarditis, pleuritis, and peritonitis, were classified as the serositis group. Clinical features, including age, sex, disease duration, SLE symptoms, laboratory data, disease activity, organ damage, and treatment, were compared with those without serositis (no-serositis group). Cumulative overall survival and flare-free survival were also compared between the two groups using Kaplan-Meier analysis.

Results: Among 95 patients with newly onset SLE treated in our department, 82 patients were included. The mean age was 36.5 years, and 75 patients were female (91.8%). The mean observation period was 61.9 months, and the mean SLEDAI score was 18.4. Among the 82 patients, 35 (42.7%) had serositis at the initial disease onset. The comparison of clinical characteristics between the serositis group (35 patients) and no-serositis group (47 patients) is shown in Figure 1. General characteristics were similar between the two groups, except for higher SLEDAI scores and lower complement levels in the serositis group. The serositis group showed a significantly increased number of flares with serositis compared to no-serositis group. Additionally, the SDI scores at the end of follow-up were significantly higher in the serositis group. In terms of therapy,

Figure 2 Kaplan-Meier analyses between Serositis group and No-serositis group



Kaplan-Meier analyses between newly-onset SLE with serositis group and those without (no-serositis group)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

significantly higher PSL doses and increased frequencies of mPSL pulse therapy were observed in the serositis group. Kaplan-Meier analysis revealed similar cumulative overall and flare-free survival rates between the two groups (Figure 2). We further analyzed the risk factors for organ damage accrual (SDI of 1 or more) in patients with newly onset SLE. Logistic regression analysis indicated that age and serositis were independent risk factors for damage accrual (odds ratio: age 1.05, 95%CI 1.01-1.09; serositis 2.74, 95%CI 1.01-7.40, respectively, $p< 0.05$).

Conclusion: Newly onset SLE with serositis may demonstrate higher organ damage accrual compared to that without serositis. More frequent flare-ups of serositis/enteritis may occur in newly onset SLE with serositis.

Biomarker landscape for neuropsychiatric involvement in patient with systemic lupus erythematosus

Sitian Zang[1], Ranran Yao[2] and Zhanguo Li[3], [1]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China (People's Republic), [2]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China (People's Republic), [3]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China, Beijing, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multifactorial autoimmune disease result in substantial organs or systems damage or even fatal. The estimated number of global patients with SLE was up to 4 million, and the annually newly diagnosed number was 0.37 million. Neuropsychiatric damage, comprising the overwhelming majority of the manifestations, are lethal.

Methods: A comprehensive search strategy on the associations between biomarkers and organ or system involvement was developed and implemented across multiple databases, including Embase, PubMed and Web of Science, from inception to 1 June, 2023. Additionally, reference lists of key reviews, meta-analyses, and primary studies were hand-searched to identify potential articles not captured in the initial database queries to maximize the inclusion of relevant studies. We pooled effect estimates by DerSimonian-Laird random-effects model when $I2 > 50\%$ or p value for Q less than 0.1, and performed sensitivity analyses by sequentially omitting one study at a time to assess the impact of each individual study on the pooled effect estimates. Otherwise, we use the fixed effects model.

Results: Of the 24,279 citations identified, 5,056 full-text was screened, and 229 publications was included in the studies, involving 42464 patients with lupus, of them, 8550 patients with neuropsychiatric involvement, spanning 38 countries and territories. There are 39 blood and seven CSF biomarkers uniquely associated with the risk of neuropsychiatric involvement in patients with SLE, and mean difference between patients with versus without neuropsychiatric involvement in SLE of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Effect size of biomarkers in patients with VS without neuropsychiatric involvement. A-B, blood biomarkers. C-D, cerebrospinal fluid biomarkers.

11 blood and 11 cerebrospinal fluid (CSF) biomarkers are statistically significant. Anti-neuronal abs (odd ratio [OR] 14.31, 95% confidence interval (CI) 4.41 to 46.45) in CSF are associated with the risk of neuropsychiatric involvement in patients with SLE, and the quality of evidence is moderate because of consistency, low risk of bias and large effect. Besides, anti-neuronal abs (OR 6.1, 95%CI 1.65 to 22.59) in blood are associated with the risk of neuropsychiatric involvement. The blood and CSF level of anti-neuronal abs in patients with versus without neuropsychiatric involvement are significantly higher. Anti-N-methyl-D-aspartate receptor subtype NR2a/2b antibody (anti-NR2 antibody) in blood are associated with the risk of neuropsychiatric involvement in patients with SLE (OR 4.6, 95%CI 1.70 to 12.47), the blood level of Anti-NR2 IgG (mean difference [MD] 7.6, 95%CI 0.84 to 14.36 U/ml) and anti-NR2A (MD 0.07, 0.05 to 0.08 OD), CSF Anti-NR2 IgG (MD 16.62, 95%CI 8.83 to 24.41 U/ml) in patients with versus without neuropsychiatric involvement are significantly higher. Blood low CSF α-Klotho have excellent diagnostic accuracy for predicting neuropsychiatric involvement in patients with SLE, and the sensitivity, specificity, and AUC is 82.3%, 96.0%, and 0.94, respectively.

Conclusion: Multiple biomarkers have diagnostic value for neuropsychiatric involvement in patients with SLE, which may be used in clinical diagnosis in the future to reduce the disease burden caused by neuropsychiatric involvement.

Mental Health and Medical Burden: The Impact of Depression on Length of Stay in Lupus Patients

Sophia Chang Stauffer[1], Huan Chang[2], Parth Desai[3], Elaine Adams[4], William Galanter[5] and Axi Patel[6], [1]Mount Sinai Hospital, Sinai Urban Health Institute and Univ.of Illinois @ Chicago, Dept Medicine, Div. Endocrinology, Chicago, IL, [2]University of Illinois at Chicago, Div Rheumatology and Jesse Brown VA Medical Center, Chicago, IL, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]Jesse Brown VA Medical Center, Chicago, IL, [5]University of Illinois at Chicago, Division of General Internal Medicine, Chicago, IL, [6]University of Illinois at Chicago, Div Rheumatology, Chicago, IL

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Depression is more common in patients with systemic lupus erythematosus (SLE) than in the general population. Individuals with SLE and a mental health condition have higher rates of healthcare use than those without mental health conditions, but the effect of SLE and depression on hospitalization has not been studied. In this pilot study we assess the impact of co-morbid depression on in-hospital mortality, length of hospital stay (LOS), and hospital charges in patients admitted for SLE.

Methods: We utilized the 2022 National Inpatient Sample (NIS) to identify adult hospitalizations with a primary diagnosis of SLE, further categorizing patients into those with coexisting depression (SLE+DEP) and those without (SLE only) based on ICD-10 codes across secondary diagnoses. Survey weights were applied to generate national estimates. We conducted 1:3 propensity score matching (PSM) using a nearest-neighbor algorithm with a caliper of 0.1, adjusting for demographic and clinical covariates. Balance diagnostics confirmed improved covariate balance post-matching. Outcomes assessed included length of stay (LOS), and in-hospital mortality.

Results: Of an estimated 8,180 weighted SLE hospitalizations, 110 had coexisting depression diagnoses. Patients in the SLE+DEP group were predominantly female (90.9%) and older (mean age 46.7 ± 16.8 years) compared with the SLE-only group (88.0% female; mean age 38.9 ± 15.2 years). Mean LOS was longer among SLE+DEP patients (9.0 vs. 7.2 days), though not statistically significant in unadjusted models. Mean total hospital charges were lower in the SLE+DEP group ($70,478 vs. $99,755), with no observed in-hospital mortality among the depressed cohort versus 0.87% among the non-depressed cohort.

Conclusion: Currently there is no standard of care for mental health monitoring and treatment for SLE patients. Our data suggest that hospitalized patients with diagnoses of SLE and depression have significantly longer lengths of stay than those with a diagnosis of SLE only. Our data also suggest a trend between longer stays and lower cost. Our data were limited by the information available in the dataset, which does not include intensity of care. Additionally, our pilot study includes only 1 year of data and the cohorts differed in mean age. Nevertheless, our study reveals intriguing findings that could have

Table 1. Baseline Characteristics

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: With the introduction of anifrolumab to clinical practice, there is a growing interest in identifying factors associated with IFN activity in patients with SLE. An association between IFN gene signature and anti-U1-RNP antibody positivity has been reported. However, data from Asians are scarce. In this study, we investigated serological parameters associated with the IFN gene signature in patients with SLE, as well as its association with disease activity.

Methods: We utilized transcriptome data from 130 Japanese patients diagnosed with SLE from the ImmuNexUT database. IFN score was defined as the average normalized expression levels of *IFI27*, *IFI44*, *IFI44L*, and *RSAD2*. The associations between clinical parameters and the IFN score were assessed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

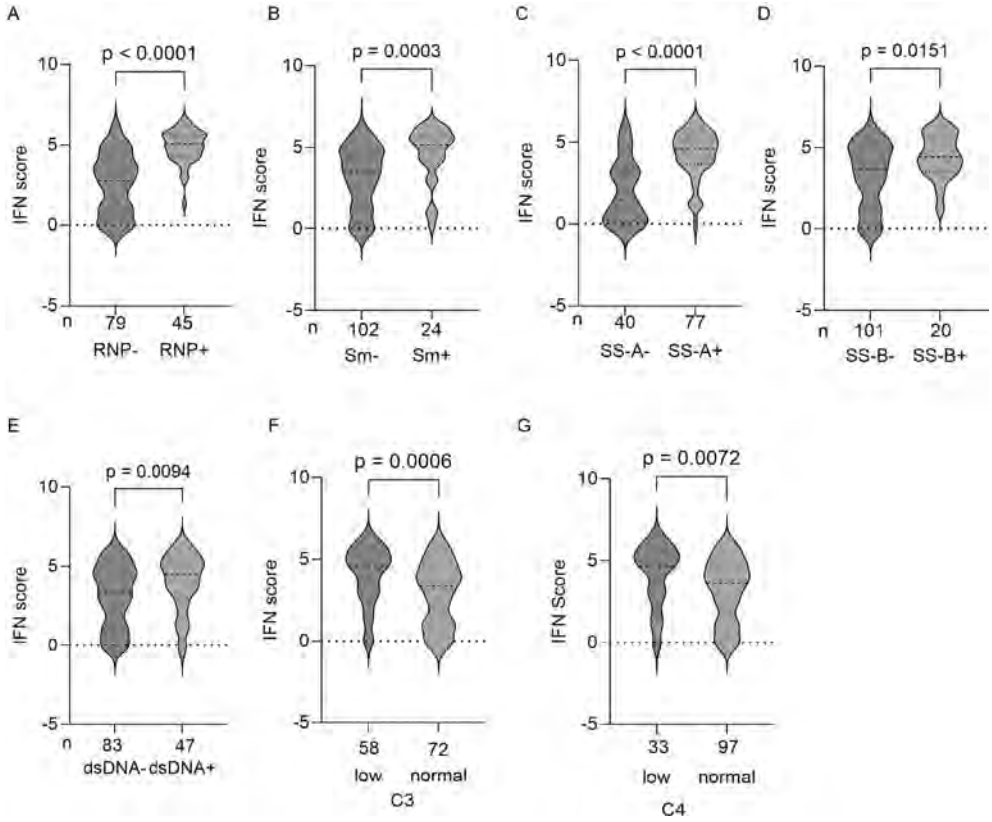

Figure 1: IFN Score and Serological Characteristics (A–E) IFN scores according to the anti-U1-RNP (A), anti-Sm (B), anti-SS-A (C), anti-SS-B (D), and anti-dsDNA (E) antibody statuses. (F and G) IFN scores according to C3 (F) and C4 (G) levels.

Results: The IFN scores showed a bimodal distribution; therefore, the patients were divided into two groups according to a cutoff score of 1.6. Of the 130 patients, 31 and 99 were classified into the low and high IFN groups, respectively. Clinical characteristics of patients in each group are shown in Table 1. Notably, disease activity was higher in the high IFN than the low IFN group (median [IQR] SLEDAI-2K score: 5 [2–9] vs. 2 [0–2], $p < 0.0001$). The IFN score was higher in patients positive for anti-U1-RNP antibodies (median [IQR]: 5.0 [4.3–5.4] vs. 2.8 [0.9–4.1]), anti-Sm antibodies (median [IQR]: 3.5 [1.4–4.7] vs. 5.1 [4.0–5.6]), anti-SSA antibodies (median [IQR]: 4.6 [3.7–5.3] vs. 1.4 [0.2–3.4]), anti-SSB antibodies (median [IQR]: 4.4 [3.5–5.6] vs. 3.7 [1.4–5.0]), and anti-dsDNA antibodies (median [IQR]: 4.5 [3.0–5.4] vs. 3.3 [1.2–4.7]) compared with patients negative for these autoantibodies (Figure 1A–E). Classification and regression tree analysis indicated anti-U1-RNP antibody positivity as the most important serological predictor of the IFN score (Figure 2A). Even among patients who are

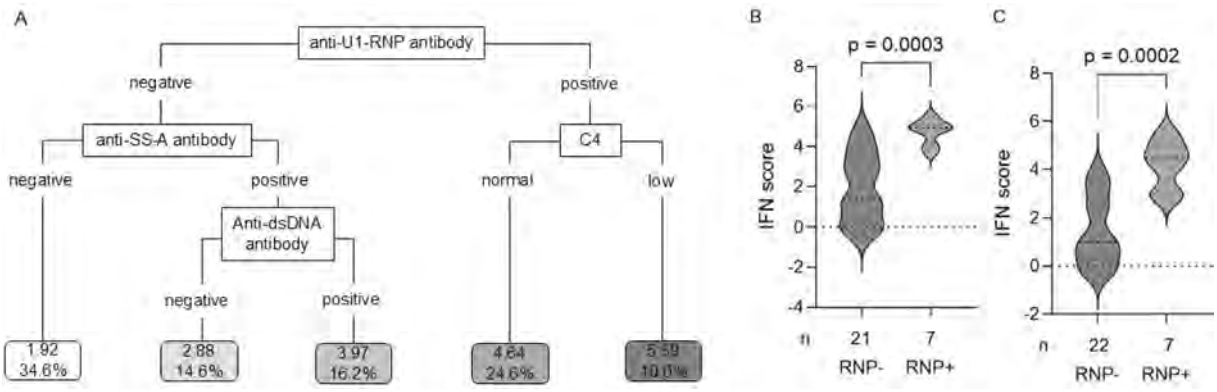

Figure 2: The IFN score and anti-U1-RNP Antibody Status (A) Classification and regression tree analysis of serological factors associated with the IFN score. The numbers in the boxes indicate the average IFN score in each group and the percentage of patients in that group. (B, C) IFN scores in serologically active, clinically quiescent patients (B) and inactive patients (C) according to anti-U1-RNP antibody status.

Table 1: Clinical Characteristics of Patients in the Low and High IFN Groups

Table 1. Clinical characteristics of patients in the low and high IFN groups

	Low IFN (n=31)	High IFN (n=99)	
Age, years, mean ± SD	48.2 ± 12.1	45.8 ± 13.1	n.s.
Sex (female), n (%)	29 (93.5%)	91 (91.9%)	n.s.
Disease duration, years, median (IQR)	12 (5-20)	14 (3-18)	n.s.
SLEDAI-2K score, median (IQR)	2 (0-2)	5 (2-9)	$p<0.0001$
Treatment			
Glucocorticoids, n (%)	28 (90.3%)	81 (81.8%)	n.s.
PSL (mg), median (IQR)	5 (4–5)	5 (3–7.5)	n.s.
PSL ≥ 10 mg	2 (6.5%)	11 (11.1%)	n.s.
HCQ, n (%)	14 (45.2%)	46 (46.5%)	n.s.
Tacrolimus, n (%)	10 (32.3%)	17 (17.2%)	n.s.
CyA, n (%)	1 (3.2%)	11 (11.1%)	n.s.
MMF, n (%)	9 (29.0%)	21 (21.2%)	n.s.
Azathioprine, n (%)	2 (6.5%)	10 (10.1%)	n.s.
Symptoms during the entire disease course			
Lupus nephritis, n (%)	20 (64.5%)	59 (60.0%)	n.s.
Arthritis, n (%)	23 (74.2%)	70 (70.7%)	n.s.
Mucocutaneous, n (%)	19 (61.3%)	77 (73.7%)	n.s.
Leukopenia, n (%)	25 (80.6%)	86 (86.9%)	n.s.
Thrombocytopenia, n (%)	8 (25.8%)	29 (29.3%)	n.s.
Active symptoms			
Lupus nephritis, n (%)	1 (3.2%)	28 (28.3%)	$p=0.0035$
Arthritis, n (%)	3 (9.7%)	20 (20.2%)	n.s.
Mucocutaneous, n (%)	2 (6.5%)	36 (36.4%)	$p=0.0014$
Leukopenia, n (%)	0 (0.0%)	9 (9.1%)	n.s.
Thrombocytopenia, n (%)	0 (0.0%)	7 (7.1%)	n.s.

SD: standard deviation; IQR: interquartile range; PSL: prednisolone (for patients taking glucocorticoids other than PSL, the equivalent doses were calculated); HCQ: hydroxychloroquine; CyA: cyclosporin A; MMF: mycophenolate mofetil.

serologically active clinically quiescent (SACQ) and among patients who were both serologically and clinically inactive, the IFN score was higher in anti-U1-RNP antibody positive patients compared to negative patients (median [IQR]: 4.7 [4.1–5.1] vs. 1.4 [0.2–5.0], p = 0.0003 for SACQ, Figure 2B; median [IQR]: 4.5 [3.0–5.1] vs. 1.0 [0.3–2.6], p = 0.0002 for inactive, Figure 2C). Among SACQ patient and inactive patients, all patients positive for anti-U1-RNP antibodies belonged to the high IFN group while less than half of the patients negative for anti-U1-RNP antibodies belonged to the high IFN group (8/8 (100%) vs 10/21 (47.2%), p=0.03 for SACQ and 7/7 (100%) vs 8/22 (27.6%), p=0.01).

Conclusion: Autoantibody profiles, especially anti-U1-RNP antibodies, are useful for predicting IFN scores. Anti-U1-RNP antibody-positive patients have high IFN scores irrespective of disease activity.

Abstract Number: 1513

Race, Renal Failure, and Risk: A five-to-ten year retrospective cohort study of Racial differences in outcomes of patients with dialysis-dependent Lupus nephritis

Ufuoma Mamoh[1], Queeneth Edwards[2], Chukwuemelie Okeke[3], Justin Riley Lam[4], Soziema Salia[5] and Christhopher Haas[6], [1]Medstar Health Georgetown University Internal Medicine Residency Program, Baltimore, MD, [2]Georgia Southern University, Statesboro, GA, [3]Maimonides Medical Center, Brooklyn, NY, [4]Albert Einstein Medical Center, Philadelphia, PA, [5]MedStar Health Georgetown University (Baltimore) Internal Medicine Program, Baltimore, MD, [6]MedStar Health Georgetown University (Baltimore) Internal Medicine Program, Baltimore

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that disproportionately affects racial and ethnic minority populations, particularly Black/African American and Hispanic/Latino individuals. In 50% of patients with SLE, Lupus nephritis typically develops within 5 years of diagnosis. These patients have an increased risk of developing ESRD. This study evaluates the racial disparities in clinical outcomes of adults diagnosed with SLE and dialysis-dependent ESRD over 20 years, between Black/African American and Hispanic/Latino populations.

Methods: This retrospective cohort study utilized TriNetX Global Collaborative Network data, encompassing over 144 healthcare organizations. Adults (age >18 years) with a diagnosis of systemic lupus erythematosus (SLE), end-stage renal disease (ESRD), and who were on dialysis within the past 20 years were included in the study. We classified two

Table 1. Demographic Comparison of Blacks and Hispanics – Pre- and Post-Propensity Score Matching

Characteristic	Blacks (Pre-Match, N=2,101)	Hispanics (Pre-Match, N=1,007)	Blacks (Post-Match, N=965)	Hispanics (Post-Match, N=965)
Age (Years)	53.0 ± 15.5	50.3 ± 15.9	50.0 ±15.2	50.4 ± 15.9
Age at Index	46.0 ± 15.6	43.2 ± 16.0	42.9 ± 15.1	43.2 ± 15.9

Table 2. Clinical Outcomes after Propensity Matching

Outcome	Blacks	Hispanics	Statistical Test Risk Difference:	Hazard Ratio (95% CI)	Odds Ratio (95% CI)
All-cause Mortality	446 / 2683 (16.6%)	271 / 2669 (10.2%)	0.065 (0.047,0.0830)	1.700 (1.462,1.977)	1.764 (1.501-2.074)
MI (Ischemic Heart Disease)	442 / 2092 (20.2%)	375/2081 (18.2%)	0.022 (-0.002,0.045)	1.194 (1.039,1.372)	1.150 (0.985-1.342)
Stroke	157 /2514 (6.2%)	112 /2557 (4.4%)	0.019 (0.006,0.031)	1.486 (1.166–1.894)	1.454 (1.134-1.865)

cohorts: Cohort A (Black or African American, n=7491), and Cohort B (Hispanic/Latino, n=2723). Exclusion criteria included patients younger than 18 or diagnosed more than 20 years ago. Propensity score matching was applied to balance demographics, diagnoses, and medications. The outcomes measured were all-cause mortality, myocardial ischemia (MI), and stroke.

Results: After matching, each cohort included 2690 patients. The average age was 50 years in both Cohorts. Both cohorts were predominantly female (79.3% and 77.5%). Blacks had a significantly higher odds of all-cause mortality than Hispanic patients [16.6% vs 10.2%; OR 1.764; 95% (CI = 1.501,2.074)]. There was a higher odds of stroke in black patients compared to Hispanic patients [6.2% vs 4.4% OR 1.454; 95% (CI = 1.134, 1.865)]. There was no significant difference in the odds of MI [OR 1.150, 95% (CI = 0.985, 1.342)].

Conclusion: These findings suggest the racial disparities in clinical outcomes in patients with dialysis-dependent ESRD secondary to lupus nephritis. Black patients had higher odds of all-cause mortality and stroke compared to their Hispanic counterparts, despite comparable baseline characteristics. Posulated reasons include differences in quality and access to healthcare and health-promoting resources, differences in healthcare utilization patterns, differences in comorbid disease patterns, and underlying epigenetic patterns. These results highlight the need for tailored interventions and equitable healthcare delivery to mitigate outcome disparities and further investigations to determine the underlying processes causing these differences in results

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) exhibits profound clinical and pathogenic heterogeneity, complicating diagnosis and treatment. Identifying subtype-specific biomarkers might intrinsically link to organ involvement.

Methods: Patients with SLE were classified into five subgroups, including renal, hematologic, mucocutaneous, neuropsychiatric, and cardiopulmonary subtypes. Serum antigens were captured by purified IgG from a cohort consisting of 10 SLE patients per subgroup, together with sex- and age-matched 10 rheumatoid arthritis (RA), 10 Sjogren's syndrome (pSS), 10 anti-synthetase syndrome (ASS) patients and 10 healthy controls. Affinity Chromatography-purified autoantigens were set to liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis and machine learning to identify pathogenic molecules in different groups of SLE patients. The significantly upregulated and downregulated proteins with fold change > 2 ($p < 0.05$) were selected.

Results: We identified 39, 32, 36, 13 and 12 differentially expressed (DE) autoantigens in renal, hematological, mucocutaneous, neuropsychiatric, and cardiopulmonary subtypes, respectively. Based on the newly identified autoantigens, including CH60, FABPS, CREG1, ODO2, and TRY3, diagnostic prediction models were further constructed for SLE subtypes with renal, hematological, mucocutaneous, neuropsychiatric, and cardiopulmonary involvement. The average accuracy and AUC of the 5 groups were 92%/0.96, 93%/1.00, 95%/1.00, 89%/0.98, and 84%/0.99, respectively. The predominant autoantigens were enriched in distinct molecular pathways correlating with the clinical manifestations. Signal pathways were analyzed among these DE autoantigens.

Conclusion: These findings reveal SLE subtype-specific immune signatures, offering novel biomarkers for clinical stratification and potential targeted therapeutics.

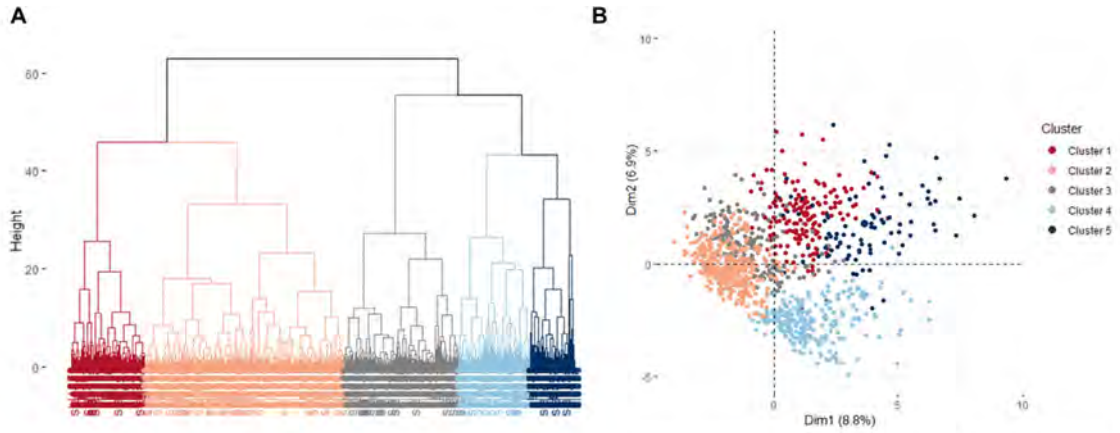

Figure 1. Hierarchical clustering tree and cluster reduction factor maps of systemic lupus erythematosus (SLE). (A) Five SLE clusters were defined by hierarchical cluster analysis. (B) Factor maps of each cluster, colored by cluster affiliation.

Hierarchical clustering tree and cluster reduction factor maps of systemic lupus erythematosus (SLE)

Background/Purpose: To refine clinical subtypes of systemic lupus erythematosus (SLE) using unsupervised machine learning, and to elucidate the molecular basis of disease heterogeneity through integrated immune, proteomic, and transcriptomic profiling.

Methods: We enrolled 1,065 SLE patients hospitalized at Peking University People's Hospital between 2012–2024. Unsupervised hierarchical clustering was applied to integrated clinical and laboratory variables. Peripheral blood lymphocyte subsets were assessed to characterize immunologic divergence across clusters. One-year prospective follow-up was conducted to evaluate therapeutic responses. Multi-omics profiling—including serum proteomics (LC-MS/MS) and transcriptomics (bulk RNA-seq) of peripheral blood mononuclear cells—was performed in subtype-stratified patients and age-/sex-matched healthy controls. Differential expression and enrichment analyses were used to define cluster-specific molecular signatures.

Results: Unsupervised machine learning identified SLE subtypes: Cluster 1 exhibited nephritis, high disease activity, and anti-Sm positivity; Cluster 2 had skin/mucosal involvement with low inflammation; Cluster 3 was defined by neuropsychiatric manifestations and anti-U1RNP/SSA positivity; Cluster 4 featured anemia, leukopenia, and thrombocytopenia (85.9%), with Coombs positivity and antiphospholipid antibody enrichment; Cluster 5 involved serosal/vascular complications with older age and elevated LDH. Immune cell profiling revealed distinct T, B, and NK subset distributions. Rituximab was most effective in Cluster 5 ($\beta = 0.286$, $p < 0.001$), while cyclophosphamide benefited Cluster 3 ($\beta = 0.284$, $p < 0.001$). Cluster 2 showed the highest LLDAS (46.4%) and steroid tapering; Cluster 4 had the highest SLEDAI < 4 rate (84.1%). In addition, multi-omics analyses identified key cluster-enriched molecules: APOA4 and LAMC1 in Cluster 1; CXCL7 and CCL18 in Cluster 2 ; S100A7 and ACTN4 in Cluster 3 ; IGHG1 and SERPINA1 in Cluster 4; THBS1 and LOX in Cluster 5. Transcriptomics revealed shared upregulation of interferon-inducible genes (e.g., IFI44, IFITM1) and cluster-specific cytokines (e.g., WNT5B, KRT5, BDNF), highlighting distinct pathogenic pathways that parallel clinical phenotypes.

Conclusion: Machine learning–guided subtyping uncovers clinically and molecularly distinct SLE subgroups. These findings support biologically informed stratification and might lay the groundwork for precision therapy in SLE.

The Benefits of SGLT2i on GFR Slope and Proteinuria in SLE Depend on Subgroups of Diabetes Mellitus and Baseline eGFR

Jennifer Lee[1], Andrea Fava[2], Daniel Goldman[3], Laurence Magder[4] and **Michelle Petri**[3], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Timonium, MD, [4]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1467–1516) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) affects over 50% of SLE patients. Twenty percent of LN patients develop end-stage renal disease (ESRD) within 10 years. The 2021 CREDENCE trial and subsequent studies in the general population demonstrated that sodium-glucose co-transporter 2 inhibitors (SGLT2i) were shown to slow the progression of chronic kidney disease in type 2 diabetes patients. However, experience in SLE is limited. We investigated changes in eGFR and proteinuria in SLE patients following SGLT2i initiation.

Methods: We studied 109 SLE patients longitudinally (86% female; 32% White, 60% African-American, 9% Other, 32% with diabetes, 60% with eGFR< 60, and 58% with UPCR< 0.50 gm) who started taking SGLT2i and had at least one clinical visit within three years before and/or after treatment initiation. eGFR was calculated using the 2021 CKD-EPI creatinine equation, and proteinuria was assessed using the urine protein-creatinine ratio (UPCR**)**. Longitudinal mixed effects regression models with random slopes and intercepts were used to estimate changes in eGFR and UPCR before and after SGLT2i initiation. Models included terms for immediate level change and slope change starting 30 days after SGLT2i initiation, assuming linear trends in eGFR or UPCR. Subgroup analyses were done for diabetes mellitus status and baseline kidney function (eGFR < 60 vs. ≥60 mL/min/1.73m^2).

Results: In the cohort, the mean annual decline in eGFR before SGLT2i initiation was -2.0 (P=0.0002). The immediate change in eGFR post SGLT2i showed a decline of -1.4 (P=0.17). The eGFR slope post SGLT2i improved by 0.43 (P=0.63, Table 1). The initial decline followed by improvement in GFR slope were similar to the results of the CREDENCE trial, but did not reach statistical significance.

The improvement in eGFR slope was greater in those with diabetes and in those with eGFR < 60 (Table 2). This same benefit was shown in those with UPCR < 0.50g at SGLT2i initiation (Table 2, p=0.036) and also in those with UPCR < 0.30g at SGLT2i initiation (p=0.043).

Table 1. Estimated impact of SGLT2 on eGFR and mean Urine Protein-Creatinine ratio.

Subgroup	*Outcome*	*Effect*	*Estimate (95% CI)*	*P-value*
All (n=109)	eGFR	Annual decline before SGLT2i	-2.0 (-3.1, -1.0)	0.0002
		Immediate change	-1.4 (-3.5, 0.6)	0.17
		Change in slope after SGLT2i	0.43 (-1.3, 2.2)	0.63
	UPCR	Annual increase before SGLT2i	0.10 (-0.01, 0.20)	0.074
		Immediate change	-0.14 (-0.30, 0.02)	0.083

		Immediate change	-0.7 (-3.6, 2.3)	0.65
		Change in slope after SGLT2i	**2.7 (0.1, 5.3)**	**0.043**

Next we looked at the effect of SGLT2i on UPCR. There was a significant reduction in the UPCR after starting SGLT2i in all SLE patients (Table 1). Contrary to the eGFR effects, the benefit was statistically significant in those without diabetes (Table 2, p< 0.001) and with baseline eGFR >60 (Table 2, p< 0.001).

Conclusion: In this analysis, SGLT2i use did not significantly reduce eGFR decline (although the results were in the correct direction), but had a significant improvement on proteinuria. This differs from the 2022 Phase I/II trial in SLE by Wang et al, which found the opposite to be true. Our subgroup effects are fascinating and go in opposite directions. The benefit of SGLT2i on GFR slope is seen in those WITH and GFR < 60 (neither were significant). In particular, protection of GFR slope was seen in those with LOW levels of UPCR, such as < 0.50 g and < 0.30 g. The benefit of SGLT2i on proteinuria is seen in the all patient analysis (p=0.0001) and in those without diabetes (p< 0.001) and eGFR > 60 (p< 0.0001). Both GFR protection and reduction in proteinuria are desirable goals in SLE, but our study found that GFR protection was not statistically significant in the all patient analysis, whereas proteinuria reduction was.

Abstract Number: 1517

The Chinese Experience with Telitacicept in Lupus Nephritis Management: 51-Patient Cohort Analysis on Therapeutic Outcomes and Safety Parameters

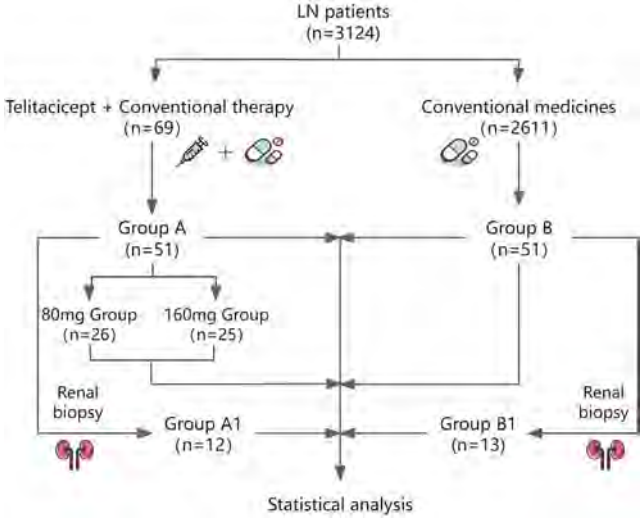
Aijing Liu[1], Fei Chang[2] and Qiuhong Xu[1], [1]Department of Rheumatology and Immunology, The Second Hospital of Hebei Medical University, Shijiazhuang, China (People's Republic), [2]Department of Rheumatology and Immunology, The Second Hospital of Hebei Medical University, Shijiazhuang, Hebei, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN), affects 30%-50% of systemic lupus erythematosus (SLE) patients, a major contributor to SLE-related mortality. Telitacicept, an innovative recombinant fusion protein, disrupts the interaction between BLyS/APRIL and their receptors, thereby effectively curbing B lymphocyte proliferation and maturation. While both Phase I and Phase II clinical trials have substantiated Telitacicept's efficacy in ameliorating SLE progression, its therapeutic potential in LN remains underexplored, with limited data on efficacy and safety. To evaluate the real-world efficacy and safety of Telitacicept in LN patients at a single center, we aim to furnish evidence for B-cell-targeted therapeutic strategies in LN management.

Methods: A total of 51 LN patients treated with Telitacicept combined therapy (Group A) and 51 matched controls receiving conventional therapy (Group B) in the Second Hospital of Hebei Medical University from March 2021 to January 2024 were enrolled in the retrospective study. Clinical data, including laboratory results, disease activity, renal response rates, and adverse events (AEs) were collected at 4, 12, 24, and 52 weeks. Further, LN patients confirmed by renal biopsy were divided into Group A1 (n=12) and Group B1 (n=13), and clinical data were compared and analyzed based on different pathological types. Additionally, Group A patients were stratified by telitacicept dosage (160mg and 80mg) and compared with Group B.



Flow chart of the study

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Comparisons of renal indexes in LN patients with Telitacicept group and conventional therapy group. (24h urinary total protein, serum albumin, eGFR and serum creatinine in LN patients of Group A and Group B) **P<0.01.

Results: 1. Compared to Group B, Group A showed substantial improvement in serum albumin from week 4 to week 24 and reduced 24-hour urine protein at week 24 (P< 0.05). The systemic lupus erythematosus responder index 4 and complete renal response (CRR) rate in Group A were 71.88% and 87.5%, respectively, significantly higher than those in Group B (P=0.030 and P=0.050). At weeks 12 and 24, complement 3 (C3), C4, and immunoglobulins (Ig) in Group A improved notably, with faster IgG reduction (P< 0.05). Anti-dsDNA antibodies decreased at week 52 (P< 0.05). From week 4 to week 52, glucocorticoid (GC) use was considerably lower in Group A (P< 0.05).

2. Compared to Group B1, type IV LN patients in Group A1 showed improved C3, C4 and reduced GC use at 24 week (P< 0.05). Type V LN patients had lower GC use and increased C3 at week 52 (P=0.037). CRR rates were 91.67% (A1) vs. 76.92% (B1) (P=0.315). The partial RR rates were 8.33% and 23.08%, where type IV accounted for 100% and 66.67%, respectively, with no statistical analysis due to small sample size.

3. 160 mg of Telitacicept reduced IgG more effectively than 80mg group at week 24 (P=0.025).

4. AE rates were 23.5% (Group A) and 19.6% (Group B) (P=0.350) respectively, with infections being the most common. No severe AEs were reported in Telitacicept group.

Conclusion: Compared to conventional therapy, Telitacicept combined therapy remarkably reduces proteinuria, improves immunological markers, enhances CRR, and effectively reduces GC use in LN patients. The 160mg dose is more effective in reducing IgG. Telitacicept is safe, with no severe AEs reported.

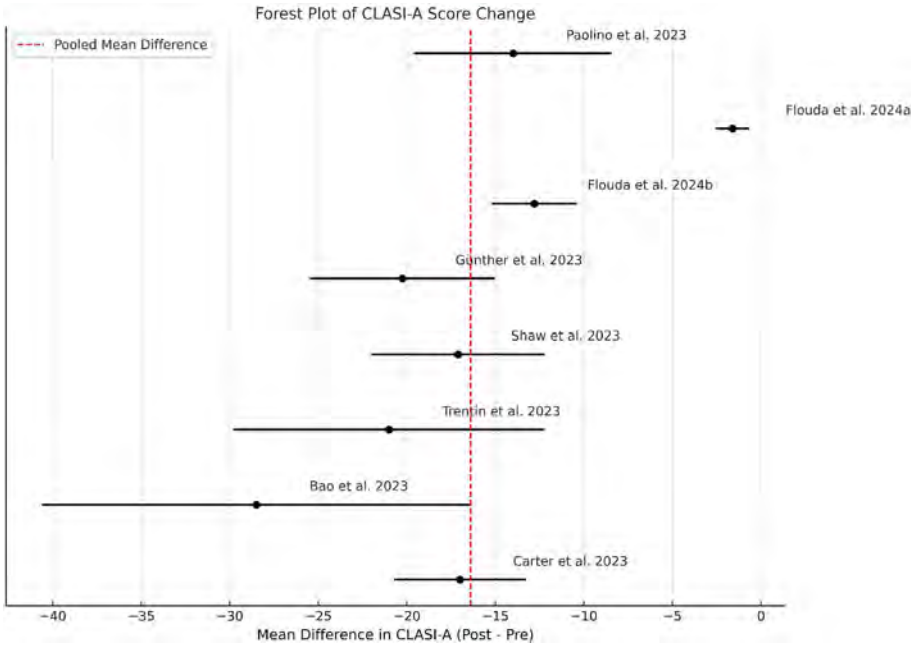
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Anifrolumab, a monoclonal antibody targeting the type I interferon receptor, demonstrated clinical efficacy in systemic lupus erythematosus in the pivotal TULIP-2 trial[1]. However, its role in discoid lupus erythematosus (DLE) remains less well defined. Emerging case-based studies indicate potential benefit in refractory DLE[2]. This review aims to evaluate the clinical role of anifrolumab in DLE using a focused literature review and meta-analysis.

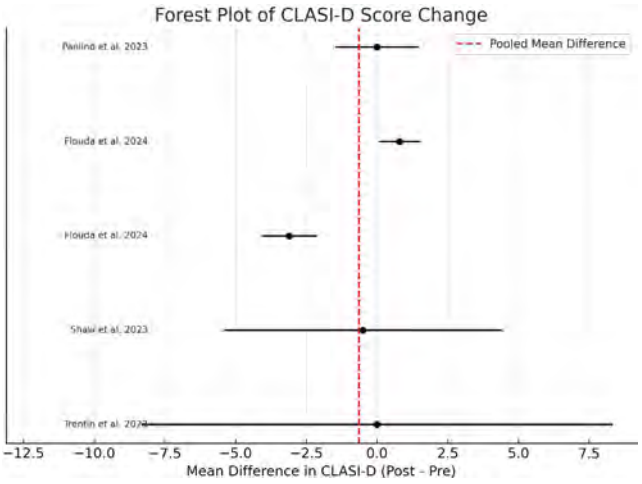
Methods: To evaluate the clinical role of anifrolumab in DLE, we conducted a comprehensive literature search of MEDLINE and EMBASE for studies published between January 2015 and April 2025. We prioritized studies that reported Cutaneous Lupus Erythematosus Disease Area and Severity Index – Activity (CLASI-A) and – Damage (CLASI-D) scores to ensure a standardized assessment of treatment response. We included 8 studies (n = 36) for CLASI-A and 5 studies (n = 25) for CLASI-D. A random-effects meta-analysis using the DerSimonian-Laird method was applied. In studies lacking reported variability, we estimated standard deviations as 25% of the mean, consistent with methods used in prior meta-analyses of small clinical samples. All patients had received hydroxychloroquine and at least one prior immunosuppressive therapy.

Results: The meta-analysis demonstrated a significant reduction in CLASI-A scores among 36 patients with available data, with a pooled mean difference of –16.41 (95% CI: –19.72 to –13.10; $p < 0.001$; $I^2 = 97.9\%$), indicating meaningful improvement in disease activity. For CLASI-D, assessed in 25 patients, the pooled mean difference was –0.63 (95% CI: –2.33 to 1.06; $p = 0.465$; $I^2 = 78.2\%$), suggesting no statistically significant change in cutaneous damage. Among the 89 patients included across all studies, only 36 had CLASI-A scores and 25 had CLASI-D scores reported. Most patients also exhibited features of systemic lupus, including arthritis, serologic abnormalities, or other systemic involvement. Although the remaining cases lacked formal CLASI documentation, most were described as having improvement in their skin disease based on physician assessment or clinical descriptors. Average CLASI-A scores dropped from approximately 14.7 at baseline to 2.0 after treatment, while CLASI-D decreased from 4.9 to 3.0. No hospitalizations or deaths were reported. Six patients developed mucocutaneous herpes simplex virus (HSV) or varicella-zoster virus (VZV) infections, including one case of herpes zoster



Forest Plot of CLASI-A Score Change

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Forest Plot of CLASI-D Score Change

oticus. Among 22 patients with corticosteroid data, the average prednisone dose was reduced from 13.75 mg/day to 2.5 mg/day following anifrolumab treatment.

Conclusion: Anifrolumab appears effective and well tolerated in DLE, particularly in reducing disease activity and corticosteroid burden. Its impact on reversing cutaneous damage is limited. These findings support its role as a targeted therapy for DLE. While promising, the results are based on a small sample size and retrospective data, underscoring the need for validation in larger, prospective studies.

	Cenerimod ex-4 mg N=85	Placebo N=86
Number of subjects with at least one event (%)	54 (63.5)	43 (50.0)
Number of subjects without event [a] (%)	30 (35.3)	43 (50.0)
Kaplan-Meier estimate (days)		
Median (95% CI)	304 (217, 354)	334 (272, NE)
Treatment effect		
Hazard-ratio versus Placebo [b] (95% CI)	1.431 (0.958, 2.139)	

NE = Value not estimated.
[a] Censored at the date of the last non-missing mSLEDAI-2K assessment.
[b] Cox proportional hazard model adjusted for stratification factors (oral corticosteroids dose and mSLEDAI-2K)

4-month sustained response in mSLEDAI-2K of Cenerimod ex-4 mg group as compared to the placebo

Background/Purpose: Cenerimod is a highly selective $S1P_1$ receptor modulator which is undergoing trials for potential therapeutic benefits in autoimmune disease, including Systemic Lupus Erythematous (SLE). The Phase 2b CARE study (NCT03742037) evaluated the efficacy and safety of cenerimod at doses 0.5, 1, 2, and 4 mg in moderate to severe SLE patients. Patients in the 0.5, 1, 2 mg, and placebo arms continued the study drug for an additional 6 months. Patients assigned to cenerimod 4 mg arm were randomly assigned (1:1) to either cenerimod 2 mg or placebo for another 6 months, designated herein as cenerimod Ex-4 mg group. All patients who had received cenerimod 4 mg for the first 6 months were included in the analysis irrespective of their treatment assignment in the next 6 months to either 2 mg or placebo. Safety outcomes were monitored for 12 months.

This post-hoc analysis was performed to assess sustained responses in mSLEDAI-2K (defined as a decrease of ≥4 points from baseline for 4 consecutive monthly assessments) vs placebo over a period of 12 months.

Methods: The treatment effect was estimated for each treatment group vs placebo using a Cox proportional hazards model stratified by baseline oral corticosteroid and mSLEDAI-2K. Hazard ratios and 95% confidence interval were derived from the model. The analysis was performed over the 12-month period and the initial randomization was used as the basis for group allocation.

Results: 427 patients were randomized, 85 patients each in the 0.5, 1, and 4 mg arms and 86 patients each in the 2 mg and placebo arms. Median age was 42 years (range 18–72), 406 (95%) were female, and 337 (79%) White.

A sustained response in mSLEDAI-2K score was observed in 63.5% of the patients in the cenerimod Ex-4mg group as compared to 50.0% of those in the placebo group. The median time is the time by when the event has occurred in 50% of the study subjects. The median time to the first confirmation of a 4-month sustained response in mSLEDAI-2K was estimated at 304 days in cenerimod Ex-4mg group vs 334 days in placebo group. The hazard ratio was estimated at 1.43 in cenerimod Ex-4mg group, suggesting that this group has a 43% greater chance of experiencing a 4-month sustained response in mSLEDAI-2K as compared to the placebo group (Figure 1).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This analysis showed that over a period of 12 months, patients in the cenerimod Ex-4 mg group were 1.43 times more likely to achieve a 4-month sustained response than those receiving placebo.

The ongoing confirmatory Phase 3 program OPUS (NCT05648500 and NCT05672576) will further evaluate the safety and efficacy of 4 mg cenerimod in adults with SLE.

Hematologic			
Drug-induced thrombocytopenia	1	Grade 3	10 d
Drug-induced neutropenia	1	Grade 1	6 mo
Other			
Scleritis	1	Grade 1	6 mo
Exacerbation of eczema	1	Grade 1	2 mo
Atypical squamous cells of undetermined significance+HPV	1	N/A	24 mo

Abbreviations: AE, adverse event; URI, upper respiratory infection; UTI, urinary tract infection; HPV, human papillomavirus; ASCUS, which stands for atypical squamous cells of undetermined significance; mo, months; wk, weeks; d, days

Methods: We conducted a retrospective single-center study of 26 LN patients (pts) who received at least 1g of OBI between 2015 and 2025. Clinical and laboratory data were collected to assess longitudinal changes in serum creatinine, eGFR, urine protein-to-creatinine ratio (UPCR), and B cells. A mixed-effects model was used to analyze changes in eGFR and UPCR over 48 months. Three pts with progressive renal decline either initiated hemodialysis or were lost to follow-up. B cell reconstitution kinetics, LN flare rates, and adverse events (AE) were analyzed.

Renal responses were classified as complete, partial, or no response. Complete (CR) and partial remission (PR) were defined as follows: CR: UPCR < 0.5 and eGFR ≥85% of baseline; PR: ≥50% reduction in UPCR from baseline, UPCR < 1 (or < 3 if baseline was ≥3), and eGFR ≥85% of baseline.

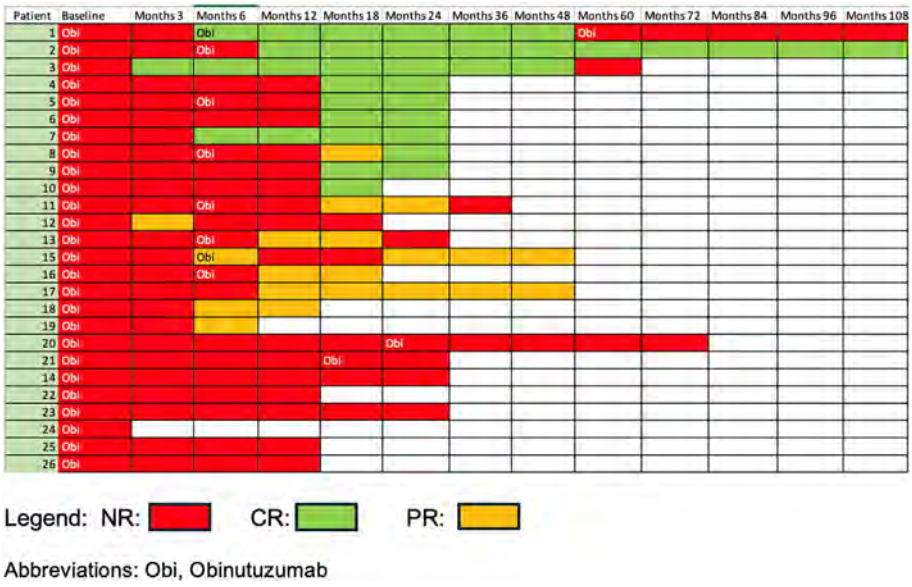

Fig 1. Longitudinal Treatment Responses in Patients Receiving Obinutuzumab Between 2015 and 2025

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Of 26 pts who received OBI, 25 with adequate follow-up were analyzed (Table 1). UPCR levels decreased significantly over time ($p < 0.001$). There was no statistically significant difference in eGFR across time points.

By 24 months, CR was achieved in 10 pts (40%), PR in 8 (32%), and NR in 7 pts (28%) (Fig. 1). Most CR and PR responses occurred between 6-18 months. Of 6 pts who flared, 2 CR pts flared 5 years after receipt of OBI, and 4 PR pts flared within 1 year. Nine pts in the CR and PR groups were able to discontinue steroids. Among the 7 pts who previously received rituximab, 3 did not respond to OBI.

Across response groups, baseline UPCR values were similar: CR: 4.5; PR: 5.5; NR: 4.7 ($p = 0.78$). Pts achieving CR had a significantly higher baseline mean eGFR compared to NR (102 vs 58 mL/min/1.73 m^2; $p = 0.014$). The mean difference in baseline eGFR between PR (80) and NR (58) was not significant ($p = 0.32$). Over 24 months, 50% of CR pts demonstrated stable or improved eGFR (mean change: +36%), and 50% had a decrease in eGFR (mean change: –7%). In the PR group, 83% of pts had stable or improved eGFR (mean change: +19%), and 17% had a decrease. When combined (CR + PR), 62% of pts had stable or improved eGFR (mean change +31%), while 38% had a decline in eGFR (mean change -6%).

No significant association was found between baseline LN class and response outcome.

Peripheral B cell counts decreased from a median of 48 cells/μL (IQR 12–121) at baseline to 3 cells/μL (IQR 1–39) at ~6 months. Reconstitution began by 12 months (median 14, IQR 0–55) and continued through 24 months (median 41, IQR 5–87). Of 12 pts with B cell data through 24 months, a total of 8, 11, and 12 repleted (>10 cells/ μL) at 12, 18, and 24 months, respectively.

AEs occurred in 18 pts, mostly mild or moderate. Infections and infusion-related reactions were the most common, with most events occurring within 6 months (Table 2).

Conclusion: Despite inadequate responses to prior therapies, two-thirds of our cohort achieved CR or PR. AEs were generally mild. These findings support the potential role of OBI as a long-term therapeutic option in LN.

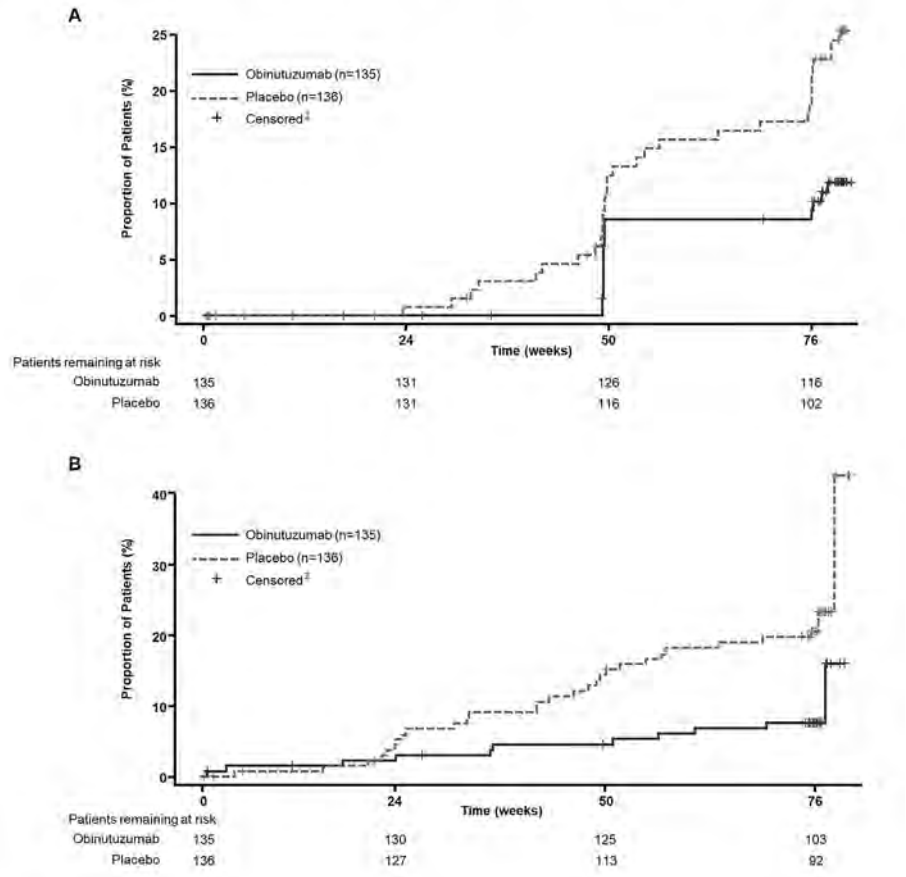
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is the most common, severe, organ-threatening manifestation of systemic lupus erythematosus (SLE). The randomized, double-blind, placebo-controlled, Phase III REGENCY trial (NCT04221477) demonstrated superiority of obinutuzumab over placebo for achievement of complete renal response at Week 76 when added to standard therapy (mycophenolate mofetil plus glucocorticoids) in patients with active LN. This study assessed the effects of obinutuzumab on time to LN flare, time to an unfavorable kidney outcome and annualized estimated glomerular filtration rate (eGFR) slope during the REGENCY trial.

Figure 1: Time to A) Lupus Nephritis Flare* from Week 24 through Week 76 and B) an Unfavorable Kidney Outcome†



eGFR, estimated glomerular filtration rate; LN, lupus nephritis; UPCR, urine protein-to-creatinine ratio.

*LN flare from Week 24, diagnosed if one of the following conditions occurred: eGFR decrease >20% compared with Week 24 in patients with UPCR >1 g/g and/or cellular casts; UPCR increase (A) to >1 g/g if Week 24 UPCR was <0.2 g/g, (B) to >2 g/g if Week 24 UPCR was 0.2-1 g/g or (C) to double if Week 24 UPCR was >1 g/g; receipt of rescue therapy, except for corticosteroid-only rescue. †Time to unfavourable kidney outcome, assessed from baseline to Week 76, was defined as the first of the following events: death, doubling of serum creatinine or treatment failure. ‡Patients who experienced early study withdrawal before experiencing the event were censored at the time of the study withdrawal. Patients who completed a 76-week treatment period and did not experience the event were censored at the upper limit of the Week 76 visit window in the LN flare group and censored at Week 76 in the unfavourable kidney outcome.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. eGFR Slope From Week 12 to Week 76

eGFR (mL/min/1.73m²/year)	Obinutuzumab n=135	Placebo n=136
Estimated eGFR slope (SE)	−0.71 (1.46)	−4.39 (1.46)
95% CI	−3.55 to 2.14	−7.24 to 1.54
Difference in eGFR slope (SE)	3.68 (2.06)	
95% CI	−0.35 to 7.72	
P value	0.073	

The eGFR slope was analyzed using a mixed effect model with random intercept and random slope. The difference in eGFR slope shows annualized difference.

eGFR, estimated glomerular filtration rate; SE, standard error.

Methods: In the REGENCY study, all patients met the ACR classification criteria for SLE and had biopsy-proven proliferative LN. In this pre-specified analysis of REGENCY, time to LN flare was assessed between Weeks 24 and 76 by Cox regression. The composite outcome of death, doubling of serum creatinine or treatment failure was defined as an unfavorable kidney outcome. Time to an unfavorable kidney outcome from baseline to Week 76 was also assessed by Cox regression after stratifying for race and region. Finally, linear mixed-effects modelling was used to assess eGFR slope between Weeks 12 and 76. These analyses were not controlled for type I error.

Results: Between Weeks 24 and 76, the proportion of patients with LN flare was lower in the obinutuzumab arm (11.1%) compared with the placebo arm (23.5%), with a hazard ratio of 0.44 (95% CI, 0.24 to 0.82; *P*=0.0074) (**Figure 1A**). The proportion of patients with unfavorable kidney outcomes in the obinutuzumab arm (8.10%) was also lower compared with the placebo arm (21.30%), with a hazard ratio of 0.37 (95% CI, 0.18 to 0.75; *P*=0.0039) (**Figure 1B**). Numerical attenuation of eGFR decline from Week 12 to Week 76 was observed in the obinutuzumab arm with the annualized eGFR slope calculated as –0.71 (SE=1.454) compared with –4.39 (SE=1.454) in the placebo arm, with a difference in eGFR slope of 3.68 (SE=2.055; *P*=0.0732), favoring patients treated with obinutuzumab (**Table 1**).

Conclusion: This pre-specified exploratory analysis of the REGENCY trial demonstrated that obinutuzumab significantly reduced the occurrence of LN flares and unfavorable kidney outcomes and attenuated the annualized decline in kidney function compared with placebo-treated patients. Together with the significantly higher proportion of patients achieving a complete renal response in the obinutuzumab arm, these findings suggest that obinutuzumab affords long-term kidney survival benefits compared with standard therapy.

Abstract Number: 1522

Outcomes of Continuing Hydroxychloroquine following Renal Transplant in Patients with Lupus Nephritis: A retrospective Cohort Study using the TrinetX database

Carlos Pena[1], Irene Tan[2], Rafal Ali[3], Arthur Lau[4], Shahrzad Abdollahi[5], Fabian Rodriguez Quinonez[6] and Marianne Meshreky[7], [1]Jefferson Einstein Philadelphia, Wynnewood, PA, [2]Einstein Healthcare Network Philadelphia - Jefferson Health, Bala Cynwyd, PA, [3]Jefferson Einstein Philadelphia, Lansdale, PA, [4]Jefferson Einstein Hospital, Maple Glen, PA, [5]Jefferson Einstein Hospital, Philadelphia, PA, [6]Einstein Medical Center Philadelphia, Philadelphia, PA, [7]St. Mary's Hospital, Philadelphia

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Evidence of kidney disease occurs in up to one half of patients with SLE, and approximately 10% of the patients with lupus nephritis (LN) will go on to develop end stage renal disease (ESKD). Kidney transplantation is a safe and effective treatment for ESKD secondary to LN; and is associated with improved patient survival. of ESKD has been described as associated with a decrease in extrarenal manifestations of SLE following kidney transplantation when patients are placed on anti-rejection immunosuppressive therapy. Hydroxychloroquine (HCQ) has often been described as a medication with significant benefits and improving overall survival in patients with SLE regardless of their disease activity. With this in mind, we sought to explore outcomes of continuing HCQ following renal transplant in patients with LN.

Methods: In this retrospective, observational cohort study, we explore various outcomes in patients with SLE and kidney transplant status receiving hydroxychloroquine following transplant compared to those with SLE and kidney transplant status who did not receive HCQ following transplant.

We utilized the TrinetX database, which includes electronic health records from over 80 different global healthcare organizations. We created two groups: the first cohort included patients with SLE, kidney transplant status and HCQ (2855 patients), and the second cohort included patients SLE, kidney transplant status not on HCQ (4627 patients). The outcomes investigated were cerebral infarction, MACE risk, deceased, and ESKD (occurring within 3 years after transplant and receiving HCQ vs not receiving it "index event"), using International Classification of Diseases, Tenth Revision (ICD-10) codes. We excluded patients with these outcomes prior to undergoing kidney transplant and/or starting the medication.

Results: After propensity score matching, it was noted that between the cohorts, there was no difference between each group for developing cerebral infarction (2.757% vs 2.709 %), with a risk ratio of 1.018, p-value of 0.919 with a 95% CI (0.726,1.426). There was a reduced risk in all-cause mortality in the first (HCQ) cohort (3.271% vs 5.452%), with a risk ratio of 0.6, p-value of 0.0002 with a 95% CI (0.458,0.786). For MACE risk, there was no difference between groups (5.075% vs 4.588%), with a risk ratio of 1.106, p-value of 0.4366 with a 95% CI (0.858, 1.426). Lastly, the HCQ cohort had increased risk of developing ESKD following kidney transplant (40.015% vs 16.918%) with a risk ratio of 1.49, p-value < 0.0001 with a 95% CI (1.323, 1.678).

Conclusion: In SLE patients status post kidney transplantation, hydroxychloroquine (HCQ) use was associated with a significantly reduced risk of all-cause mortality, suggesting a potential survival benefit. However, HCQ use was also linked to a substantially increased risk of progression to end-stage kidney disease. No significant differences were observed in the risk of cerebral infarction or major adverse cardiovascular events (MACE). These findings suggest a complex and context-

Genetic architecture and translational insights for SLE progression from preclinical stages

Lida Wang[1], havell Markus[1], Laura Carrel[1], Nancy Olsen[2], Galen Foulke[3] and **Dajiang Liu**[1], [1]Penn State College of Medicine, Hershey, PA, [2]Penn State University/Milton S Hershey, Hershey, PA, [3]Penn State Health, Hershey, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE), have a preclinical phase where individuals display a subset of symptoms, but do not meet the full diagnostic criteria. Identifying genetic variants influencing the progression from preclinical stage is crucial, since autoimmunity can quickly cause irreversible organ damage. Biobanks with electronic health records are valuable for studying disease progression but can be underpowered due to limited number of diseases cases. We previously developed genetic prediction scores (GPS, Wang, Markus et al, Nature Communications, 2025) that can predict the progression of SLE from preclinical stages. Compared to conventional genetic risk scores calculated from SLE case-control

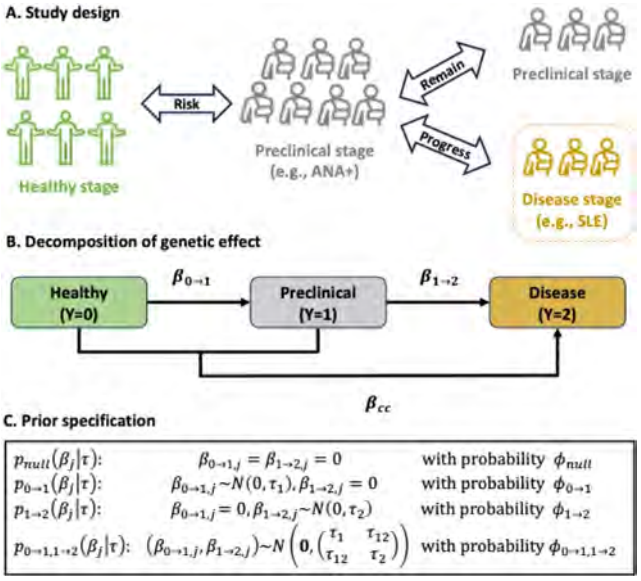

Fig 1. Study design and the key model for the method to detect genetic associations with progression phenotype. Panel A: each SLE patients will undergo a preclinical stage. Panel B. We will decompose the genetic effects into effects influencing healthy to preclinical progressions and the effects influencing preclinical to SLE progressions.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

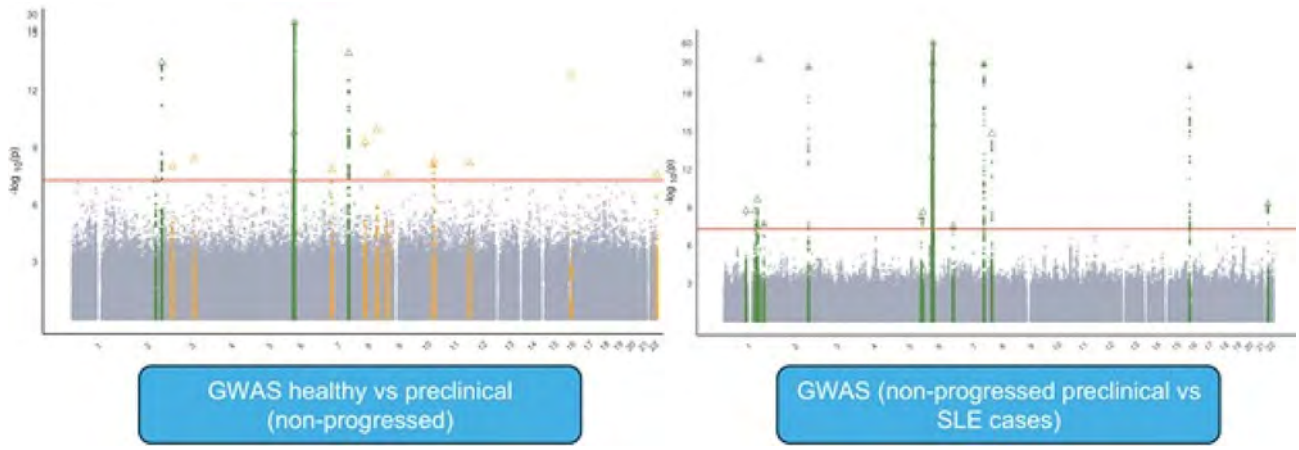

Fig 2. GWAS identifies distinct loci influencing different stages of SLE progression. Left panel: GWAS hits influencing healthy to preclinical stage progressions. Right panel: GWAS hits influencing preclinical to SLE progressions. Green color shows loci identified previously from case-control studies and yellow color shows loci unique to SLE progression traits.

studies, the GPS method increases the accuracy of risk prediction by ~20%-1000%. Despite the progress, individual variants associated with SLE progressions remain elusive. More powerful methods are needed to understand the etiology of preclinical SLE.

Methods: Almost SLE cases will undergo a preclinical stage with positive antinuclear antibody. Leveraging this insight, we can break the genetic effects influencing healthy → SLE transition into the effects influencing healthy → preclinical and that influencing preclinical → SLE transition, leading a novel Bayesian model to detect genetic association with progression (GAP). GAP borrows strength from the large sample sizes of SLE case-control studies and improves power of GWAS for progression phenotypes (Fig 1). We also developed a novel drug repurposing pipeline that leverages GAP results to identify compounds capable of slowing down the preclinical → SLE progression by reversing the expression levels of causal genes in disease-relevant cell types including B cells.

Results: We apply GAP to identify genetic associations with preclinical → SLE progressions, integrating BioVU biobank (749 SLE cases, 2,784 preclinical individuals, 46,174 controls) and case-control GWAS summary statistics from six different studies (14,355 cases and 505,956 controls). We identified 4 and 17 novel loci for control → preclinical and preclinical → SLE progressions (Fig 2). Intriguingly, two causal variants in *IRF5* are colocalized with eQTLs from different genes, emphasizing the importance of resolving phenotype heterogeneities due to different disease stages. Leveraging our drug-repurposing pipeline, we identify several novel drugs, leukotriene receptor antagonist (montelukast) and TNF-α inhibitors (pentoxifylline and lenalidomide). We also confirmed the effectiveness of hydroxychloroquine for slowing down SLE progression, a drug that is frequently prescribed but lacking solid scientific support.

Conclusion: Our results reveal distinct genetic architecture of healthy → preclinical and preclinical → SLE progressions. The novel genes and putative drugs we identify will inform clinical studies and accelerate the therapeutic development for slowing the progression of SLE from preclinical stages.

Abstract Number: 1524

Hydroxychloroquine Reduces Autoantibody Levels in Persons at Risk for Systemic Lupus Erythematosus

David Karp[1], Prithvi Raj[1], Changsong Zhu[1], Dajiang Liu[2], Duanping Liao[2] and Nancy Olsen[3], [1]UT Southwestern Medical Center, Dallas, TX, [2]Penn State College of Medicine, Hershey, PA, [3]Penn State University/Milton S Hershey, Hershey, PA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The Study of Antimalarials in Incomplete Lupus Erythematosus (SMILE, NCT03030118) was a double-blind, randomized, placebo-controlled study of hydroxychloroquine (HCQ) to prevent the development of lupus in people at risk. Participants had an ANA of ≥1:80 and one or two but not three 2012 SLICC criteria for the classification of SLE. They were randomized to either 400 mg/d of HCQ (200 mg for participants under 40kg) or matching placebo (PBO). They were followed for up to 24 months for the development of new SLICC criteria. 187 individuals were enrolled in the trial. Biospecimens were collected every three months for mechanistic studies. The objective of this study was to assess the effect of HCQ on the level of antibodies to a panel of 120 potential autoantigens.

Methods: Serum was collected from SMILE participants at baseline and every three months for a total of 24 months or until they met SLICC classification criteria for SLE. IgG and IgM antibodies to 120 antigens previously demonstrated in patients with SLE and other autoimmune diseases were quantified by fluorescence intensity on antigen microarrays. Signal intensity was normalized to total IgG or IgM for each sample and log_2transformed for analysis. Levels of individual autoantibodies were compared at baseline and at the last study visit and significance determined using a paired t-test. Nominal p values were corrected for multiple comparisons by Benjamini-Hochberg at a False-Discovery Rate of 0.05.

Results: 152 of the 187 SMILE participants had informative pairs of serum samples. These included 46 individuals who got HCQ and 50 who got PBO and did not develop new SLICC criteria over 24 months (“Non-Progressors”, NP); 16 individuals who got HCQ and 16 who got PBO who developed a second SLICC criterion in addition to the ANA (“Progressors”, PR); 12 individuals who got HCQ and 12 who got PBO who developed criteria for classification of lupus (“Developed SLE”, DS).The Progressors and Developed SLE individuals were combined (PRDS) for comparison to the NP.

In the group of participants who received HCQ, 93 of 120 antibodies levels were significantly lower at the end of the study compared to 6 of 120 antibodies in the group that received PBO ($p = 2.2x10^{-6}$, Fisher’s exact test). Table 1 shows the results by treatment group and study outcome. No IgG antibody levels were significantly increased at the end of the study and no IgM antibody levels were significantly affected by hydroxychloroquine in the SMILE study.

Table 1: Effect of Hydroxychloroquine on Autoantibody Levels

	Participant Outcome			
	Non-Progressors		Progressors and Developed SLE	
Treatment[1]	N[2]	Median % decrease (range)[3]	N	Median (range)
HCQ	62	13.4 (8.8-46.4)	73	19.4 (9.6-52.7)
PBO	5	17.7 (13.9-37.5)	1	18.5

[1]HCQ: Hydroxychloroquine; PBO: Placebo.
[2]Number of antibodies with lower mean levels at the end of the study having a corrected p value < 0.05; 42 antibodies were in common between outcomes such that there were 93 total in the HCQ treatment group.
[3]Percentage decrease from first visit to end of study

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2: Mean Decreases in Autoantibody levels for Select Antigens in Individuals Receiving Hydroxychloroquine

Antigen	Non-Progressors	Progressors and Developed SLE
Glomerular Basement Membrane	NS	28.5%, p = 0.004
Genomic DNA	40.1%, p = 0.004[1]	52.6%, p = 0.003
Histone 2B	46.4%, p = 0.02	21.0%, p = 0.03
Nucleolin	NS	32.8%, p = 0.003
Nucleosome	NS	23.6%, p = 0.006
Thyroglobulin	23.1%, p = 0.003	30.8%, p = 0.009
Thyroid Peroxidase	12.7%, p = 0.004	19.4%, p = 0.015
U1-RNP-C	NS	22.3%, p = 0.01

[1]p values corrected for multiple comparisons by Benjamin-Hochberg.

The median decrease in autoantibody level was 13.4% for the NP participants and 19.4% for the PRDS participants. The maximum decreases were 46.4% for the NP participants and 52.7% for the PRDS participants. Decreases in mean autoantibody levels in response to hydroxychloroquine varied. The mean decreases in antibody titers for select antigens are shown in Table 2.

Conclusion: In a cohort of individuals at risk for the development of systemic lupus erythematosus, treatment with hydroxychloroquine resulted in significant decreases in autoantibody levels measured against a diverse panel of antigens. This feature of treatment with hydroxychloroquine may be a factor in the clinical efficacy of this agent.

Rituximab super-responders: characteristics of patients with more than 3 years response to a single cycle of treatment

Md Yuzaiful Md Yusof[1], Junaid Patel[2], Paul Emery[3] and **Ed Vital**[3], [1]University of Leeds, Leeds, United Kingdom, [2]University of Leeds, Leeds, [3]University of Leeds, Leeds, England, United Kingdom

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Emerging therapies such as CD19 CAR-T-cells have been reported to induce deeper B-cell depletion and thereby drug-free remission up to 18 months. With rituximab, we showed that efficacy is related to depth of depletion and rate of repopulation, which are highly variable, and related to FCGR genotype[1]. We have observed "RTX-super-responders" with sustained remission after one cycle of RTX. The objectives of this study were to assess a) incidence of RTX-super-response, b) factors associated with sustained remission.

Methods: We conducted an observational study of RTX-treated SLE patients in a single centre over 20 years with on-demand retreatment . Usual practice was to continue concomitant immunosuppressants but taper glucocorticoids. Univariable and multivariable logistic regression analyses were performed to identify factors associated with RTX long-response, with $p < 0.1$ associated with the deviance used for inclusion into the model.

Relapse-free survival after first cycle of rituximab

	Median (IQR) SLEDAI-2K				Median (IQR) Plasmablast (x10^9/L)		
	Baseline	6-Month	2-Year	3-Year	Baseline	6-Month	3-year
RTX-Super Responder on IS (n=15)	9 (6-13)	1 (0-2)	1 (0-2)	1 (0-2)	0.0048 (0.0035-0.0092)	<0.0001 (0.0000-0.0001)	0.0023 (0.0007-0.0051)
IS-Free RTX Super-Responder (n=8)	10 (8-14)	3 (2-4)	2 (1-3)	2 (0-2)	0.0062 (0.0020-0.0110)	0.0002 (0.0000-0.0003)	0.0007 (0.0003-0.0012)

IS = oral immunosuppressant

Disease activity and plasmablast repopulation

Results: Of 149 first-cycle-RTX-treated patients, 114 were included in the study [excluded due to non-response in Cycle 1=17; received fixed retreatment at 6-9 months=15; deaths within the first 3 years=2; and discontinued RTX due to psoriasis=1]. Based on survival curve, we defined super-responders as >3 years. This occurred in 23/114 patients (20%) with median (IQR) duration of response 263 (212,423) weeks.

At baseline, RTX-super-responders had: mean (SD) age 35 (14) years, 20/23 (87%) female, ancestry European=9/23 (39%); South Asian=6/23 (26%), Chinese/SE Asian=2/23 (9%); African=5/23 (22%); and Mixed=1/23 (4%], concurrent APS 6/23 (26%), disease duration 2.8 (1,5) years, median (IQR) SLEDAI-2K 11 (7-15), and median (IQR) numeric BILAG score 21 (13-25). Sustained suppression of plasmablasts was observed at 3 years: median (IQR) 0.0008 (0.0002-0.0045). 8/23 RTX-super-responders (34.8%) were either not prescribed immunosuppressants or withdrew them during follow up (drug free remission).

In multivariable analysis of all 114 patients, RTX-super-response was associated with non-European ancestry (OR 4.6, 95% CI 1.6-12.7)) and concurrent APS, (3.2, 0.99-10.35). Longer disease duration (0.89,0.80-0.99 per year) was associated with lower odds of RTX-super-response. No other factors (age, sex, anti-dsDNA+, low C3/C4, number of antibodies, concomitant immunosuppressant, disease activity score, and active BILAG A/B in 5 most frequent domains) were predictive.

Conclusion: Sustained drug-free remission is not confined to patients who have received CAR-T CD19. 1 in 5 RTX-treated patients had >3 years response to their first cycle, and 1 in 12 had sustained, immunosuppressant-free remission. RTX-super-responders have patient characteristics denoting disease severity (early disease, non-European ancestry and APS), and marked suppression of plasmablast repopulation. This suggests that sustained drug-free remission is a feature of the overall immune environment rather than the modality of B cell killing. Future work will include more detailed biomarker evaluation of this cohort.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite guidelines for SLE emphasizing the importance of tapering corticosteroids (CS), detailed recommendations on how to taper are limited. The purpose of this modified Delphi consensus exercise is to develop consensus-based guidance for tapering CS in patients with SLE, including specific tapering regimens.

Methods: *Delphi Rounds*

Following a literature and guideline review, candidate statements were grouped into three topics:

1) CS-tapering regimens in lupus: general considerations

2) Managing flares and patients with high risk of flare during CS tapering

3) Managing CS-associated toxicity and CS withdrawal symptoms

Open-ended and multiple-choice questions were also included, and example CS-tapering regimens for different disease severities were proposed. Results were obtained over two rounds of online surveys, with Round 1 results supporting the development of Round 2. In Round 2, respondents were asked to vote for which regimens they deemed acceptable for use in clinical practice and could vote for multiple regimens per patient scenario.

Respondents
Snowball sampling was used to identify a global interdisciplinary group of experts to participate in the Delphi rounds.

Defining consensus

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1: Summary of recommended CS-tapering regimens. *Respondents could choose multiple schemes that they considered acceptable; †CS-tapering regimen is the reduced-dose regimen from the KDIGO 2024 guidelines for lupus nephritis; ‡respondents voted that the regimen for active lupus nephritis could also be used in severe non-renal SLE as per Table 2. CS, corticosteroid; IV, intravenous; KDIGO, Kidney Disease: Improving Global Outcomes

Patient characteristics	Timing	CS dose		Respondents who agreed regimens are acceptable in clinical practice (%)
Mild SLE **(CS initiation and tapering)**	Week 1 2 3 4	Oral prednisone equivalent (mg/day) 10–15 5–10 2.5–5 0 if lupus is controlled		87.2
Moderate SLE **(CS initiation and tapering)**	Optional day 1–3	**With or without*** IV methylprednisolone pulses 0.125–0.5 g/day (for up to 3 days)		Regimen with or without IV pulses: 93.6 Regimen with IV pulses: 59.6 Regimen without IV pulses: 67.0
	Week 1 2 3 4 5 6 7 8 9 10 11 12 13 14 >15	Oral prednisone equivalent (mg/day) 20–30 20–25 15–20 15–20 10–15 10–15 5–10 5–10 2.5–7.5 2.5–7.5 0–5 0–5 0–2.5 0–2.5 0 if lupus is controlled		
Patients with severe non-renal SLE or active lupus nephritis†‡ **(CS initiation and tapering)**	Day 1–3	IV methylprednisolone pulses 0.25–0.5 g/day up to 3 days as initial treatment		74.5
	Week 0–2 3–4 5–6 7–8 9–10 11–12 13–14 15–16 17–18 19–20 21–24 >25	Oral prednisone equivalent (mg/day) 0.5–0.6 mg/kg (up to 40) 0.3–0.4 mg/kg 15 10 7.5 5 2.5 2.5 2.5 2.5 2.5 <2.5		
Patients on long-term, low-dose CS treatment	Faster regimen: Week 1–2 3–4 5–6 7–8 9–10 11–12	Oral prednisone equivalent (mg/day) where 1 mg tablets **are** available 5 4 3 2 1 0	Oral prednisone equivalent (mg/day) where 1 mg tablets **are not** available 5 5 and 2.5 on alternating days 2.5 2.5 2.5 and 0 on alternating days 0	62.8
	Slower regimen: Month 1 2 3 4 5 6	Oral prednisone equivalent (mg/day) if 1 mg tablets **are** available 5 4 3 2 1 0	Oral prednisone equivalent (mg/day) if 1 mg tablets **are not** available 5 5 and 2.5 on alternating days 2.5 2.5 2.5 and 0 on alternating days 0	67.0

In Round 1, respondents were asked to rate their agreement with the candidate statements using a nine-point Likert scale, with a rating of 1–3 indicating disagreement, 4–6 indicating neutrality, and 7–9 indicating agreement. Consensus was defined as ≥70% of respondents voting either ≤3 (disagreement) or ≥7 (agreement). In Round 2, respondents were presented with the mean ratings from Round 1, their own Round 1 ratings, and the opportunity to revise their rating.

Results: Of the 124 respondents invited, 101 (81%) completed Round 1 and, of these, 94 (93%) completed Round 2. Respondents who completed both rounds were from 30 countries and comprised 79 rheumatologists, 11 nephrologists, three dermatologists, and one internist. Of the eight example

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2: Consensus received on final CS-tapering voting statements. CS, corticosteroid; dsDNA, double-stranded DNA; IV, intravenous

Topic 1: CS-tapering regimens in lupus: general considerations	Consensus (%)
When initiating treatment in a patient with mild disease, IV methylprednisolone pulses should be used	Disagreement (84.0)
When initiating treatment in a patient with moderate disease, IV methylprednisolone pulses could be used	Agreement (71.3)
When initiating treatment in a patient with severe disease, IV methylprednisolone pulses should be used	Agreement (93.6)
In non-renal SLE, CS tapering should only be initiated as soon as clinical manifestations significantly improve, rather than having a pre-planned tapering regimen	Agreement (84.0)
In non-renal SLE, whenever CS are initiated, there should be a tapering scheme	Agreement (76.6)
In moderate and severe disease, CS tapering should be initiated after initiation of an adequate immunosuppressant or biologic	Agreement (88.3)
In mild disease, CS tapering should be initiated after initiation of an adequate immunosuppressant or biologic	No consensus
Long-term prednisone maintenance should be avoided (tapering of CS to 0 mg should always be attempted)	Agreement (77.7)
Long-term prednisone could be used to control disease activity at the lowest effective dose if other options have had a lack of response	Agreement (86.2)
CS dose should be titrated to the lowest possible dosage (comment: the lowest possible dose does not need to be a multiple of 5 mg/day, eg 3 or 4 mg/day could also be used, if available)	Agreement (93.6)
In patients for whom complete CS withdrawal is not possible, physicians should aim for a target dosage of ≤2.5 mg/day when the patient is in remission	Agreement (83.0)
In patients for whom complete CS withdrawal is not possible, physicians should aim for a target dosage as low as possible, but not exceeding 5 mg/day, when the patient is in a state of low disease activity	Agreement (95.1)
Antimalarials are recommended for all patients, unless contraindicated	Agreement (98.9)
Immunosuppressants or biologics should be used to increase the likelihood of success during CS tapering	Agreement (97.9)
Immunosuppressants or biologics should be optimized if previous CS-tapering attempts have failed	Agreement (100.0)
In patients who have already attempted CS tapering, but the treatment plan has failed, standard of care should be re-evaluated and biologics should be considered	Agreement (95.7)
Adrenal insufficiency should be tested for when initiating CS tapering in stable patients on long-term low-dose CS	No consensus
Plasma cortisol levels (circadian rhythm) should be measured throughout a CS-tapering regimen	Disagreement (86.2)
Clinicians should engage in shared decision-making	Agreement (96.8)
Shared decision-making should be documented	Agreement (88.3)
The same CS-tapering regimen(s) that can be used for patients with severe active lupus nephritis can also be used for patients with severe non-renal SLE disease activity or severe flares	Agreement (88.3)
CS tapering should be slower for patients who have already attempted CS tapering, but the treatment plan has failed	Agreement (87.2)
Topic 2: Managing flares and patients with a high risk of flare during CS tapering	
The slower CS-tapering regimen (the 6-month regimen for patients on long-term low-dose CS) is acceptable for a patient with high anti-dsDNA antibodies and/or low complement	Agreement (86.2)
One or more standard-of-care drugs other than CS should be added for patients with overt/undisputed persistent very active serology (eg high titer of anti-dsDNA or low complement)	Agreement (84.0)
IV methylprednisolone pulses may be used to control flares during CS tapering in patients with severe disease	Agreement (88.3)
If a flare occurs during tapering in patients with mild or moderate disease, CS dose should be increased according to the activity and severity of the flare and tapering resumed once disease control is established	Agreement (90.4)
If a moderate or severe flare occurs, a new CS induction regimen adapted to the severity of flare may be required (comment: this can potentially include IV methylprednisolone)	Agreement (94.7)
Topic 3: Managing CS-associated toxicity and withdrawal symptoms	
Patients on long-term CS treatment should be educated about adrenal insufficiency during CS tapering	Agreement (90.4)
Patients should be educated on how to manage CS during periods of acute illness/stress	Agreement (95.7)
In patients at high risk of CS-associated toxicities, a faster tapering schedule should be recommended	Agreement (86.2)
In patients that have previously experienced CS-associated toxicities, a faster tapering schedule should be recommended	Agreement (93.6)
In patients at high risk of CS-associated toxicities, a CS-sparing regimen should be recommended from the beginning of treatment	Agreement (93.6)
CS tapering may need to be extremely rapid in patients with serous CS-related maculopathy to prevent blindness	Agreement (91.5)

CS-tapering regimens presented, three achieved ≥70% agreement that they would be acceptable to use in clinical practice (regimens for mild SLE, moderate SLE, and lupus nephritis or severe SLE). The regimens that received the highest agreement in Round 2 for each patient scenario are presented in Table 1. Consensus for either agreement or disagreement was achieved in 31/33 statements in Round 2 (Table 2).

Conclusion: This consensus-based guidance will support physicians in choosing a CS-tapering approach for patients with SLE across different clinical scenarios. The next step is to obtain the patient perspective on these results to ensure that patient preferences are considered when initiating CS tapering, followed by dissemination into routine practice.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: About a half of the patients with systemic lupus erythematosus (SLE) can present lupus nephritis (LN) throughout the course of their disease, representing one of the most severe manifestations of SLE. Patients with LN could develop end-stage kidney disease which carry an important burden of morbidity and mortality. In order to improve the quality of care of patients with LN, several medical associations have developed clinical practice guidelines (CPG) and recommendations. However, the quality of care of these patients might be impacted by the quality of the CPG. To evaluate the quality of LN CPG, we aimed to critically appraise and compare the LN CPG from the main international medical associations.

Table 1. Comparison of the methodological quality of lupus nephritis guidelines across six domains of the AGREE II tool.

Domain	GLADEL	EULAR/ERA	EULAR	KDIGO	APLAR	ACR	p-value
1. Scope and purpose	6.2 (1)	6.3 (1)	5.7 (2.1)	7 (0)	5.5 (2.3)	7 (0)	0.346
2. Stakeholder involvement	5.3 (1)	4.5 (2.9)	6 (0.9)	4.7 (2.3)	4.3 (2)	6.7 (0.5)	0.190
3. Rigor of development	5.3 (1.9)	4.9 (2.1)	6.7 (0.7)	6.6 (0.7)	5.6 (1.2)	5.3 (1.9)	**0.005**
4. Clarity of presentation	7 (0)	7 (0)	7 (0)	7 (0)	6 (1.3)	7 (0)	0.215
5. Applicability	4.1 (1.4)	3.5 (1.9)	3.3 (1.5)	5.3 (1.8)	4.1 (2.2)	4 (2.4)	0.344
6. Editorial independence	7 (0)	6.8 (0.5)	7 (0)	7 (0)	5.5 (3)	5.3 (1.7)	0.339
Overall judgement	5 (1.4)	5.5 (0.7)	5 (1.4)	6 (0)	5.5 (0.7)	6 (0)	0.595
Final score	5.8 (1.1)	5.5 (1.4)	5.9 (1.4)	6.3 (1)	5.2 (0.8)	5.9 (1.2)	-

Numbers represents mean (SD).

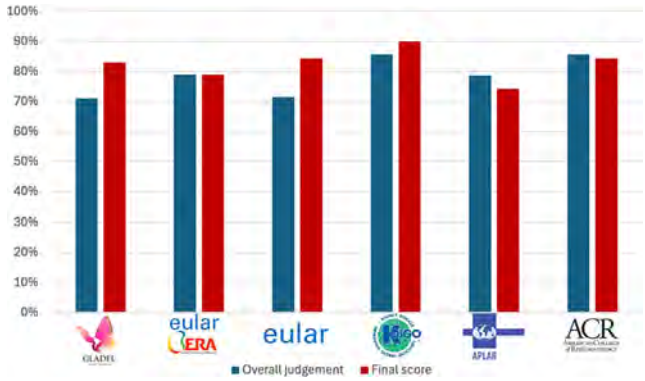

Figure 1. Overall judgement and final scores of AGREE II instrument across six clinical practice guidelines for LN.

Methods: We included globally representative CPG published in the last ten years that focused on LN or SLE including recommendations for renal involvement. We used the Appraisal of Guidelines for Research and Evaluation (AGREE II) instrument. It comprised of 23 items organized into 6 quality domains: 1) Scope and purpose; 2) Stakeholder involvement; 3) Rigor of development; 4) Clarity of presentation; 5) Applicability; and 6) Editorial independence. It also includes two final overall assessment items that requires to make overall judgements of the practice guideline while considering how the 23 items were rated. Two appraisers review each CPG and any supplementals. The average score for each item was considered to calculate the final scores by domain. The results are presented for each CPG. Guidelines scores were compared overall and by domain. Descriptive statistical analysis was performed. ANOVA test was employed to evaluate the differences between the six domains of the AGREE instrument. A p-value < 0.05 was considered statistically significant.

Results: We included six CPGs that evaluated SLE and/or LN, published between 2018 and 2025. The oldest CPG appraised was GLADEL (2018), and the newest was ACR (2025). Four CPGs were developed by rheumatology associations (GLADEL, EULAR, APLAR, ACR), one by a nephrology association (KDIGO), and one was a collaboration of both rheumatology and nephrology (EULAR/ERA). Most CPGs involved both rheumatologists and nephrologists, except for KDIGO (only nephrologists) and GLADEL (only rheumatologists). Four out of the six CPGs took into consideration the patient's preferences in the making of their recommendations (EULAR, APLAR, GLADEL, ACR). The CPG with the highest final score was KDIGO (6.3/7 points), and the lowest was APLAR (5.2/7 points). The domain with the lowest score across all CPGs was domain five (Applicability), with a mean of 4/7 points. On the contrary, domain four (Clarity of Presentation) was the highest graded (6.8/7 points) (**Figure 1**). When comparing scores of each domain between the six CPGs, only the domain 3 (Rigor of development) showed a significant difference ($F= 5.120$, $p= 0.005$) (**Table 1**).

Conclusion: The findings highlight areas for improvement in guideline development, particularly in making recommendations more applicable to diverse patient populations.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic multisystem autoimmune disease associated with increased morbidity and mortality, particularly due to cardiovascular complications. Atherosclerotic cardiovascular disease (ASCVD) has emerged as one of the leading causes of death in young patients with SLE. This elevated cardiovascular risk cannot be fully explained by traditional risk factors alone, suggesting that disease-specific mechanisms, including chronic inflammation, immune dysregulation, and treatment-related factors, play a pivotal role. We aimed to evaluate the impact of prednisone in patients with SLE on lipid profile and the risk of subclinical atherosclerosis.

Methods: A cross-sectional, comparative, and analytical case-control study was conducted. Eighty patients, older than 18 years, who met the classification criteria for SLE according to ACR/EULAR 2019 criteria guidelines were enrolled.Carotid ultrasound was accomplished in 34 patients, and the presence of plaque was recorded, defined as wall thickening greater than 50%, or a focal region with a measurement greater than 1.5 mm that protrudes into the lumen. CIMT was also

Table 1 Demographic data

Left Plaque, n (%)	0 (0%)	1 (10%)	0.116
Bilateral Plaques, n (%)	0 (0%)	1 (10%)	0.116

CIMT, Carotid Intima-Media Thickness; SD, Standard Deviation; p25, Percentile 25; p75, Percentil 75.

registered. The descriptive analysis was done with frequencies (%), mean (± SD), median (q25-q75), and comparisons with Chi square and Student's T, accordingly. We considered $p < 0.05$ as statistically significant. Statistical analysis was performed using SPSS version 25 (IBM, New York, USA).

Results: In this cohort study of patients with SLE, those receiving prednisone were significantly younger (35.32 ± 11.67 vs. 42.6 ± 15.63 years, $p = 0.045$) and more frequently treated with DMARDs (39 [60%] vs 1 [6.66%] $p < 0.001$), while hydroxychloroquine/chloroquine use was higher in the non-prednisone group ($p = 0.018$). There were no significant differences in traditional cardiovascular risk factors like obesity, diabetes, hypertension, or smoking. Despite the known adverse metabolic effects of corticosteroids, patients not on prednisone had significantly higher levels of VLDL ($p = 0.049$), LDL cholesterol ($p = 0.004$), and fasting glucose ($p = 0.007$), suggesting a paradoxical trend toward a worse metabolic profile in those without steroids (Table 1). In a subset of 34 patients who underwent carotid ultrasound, right carotid intima-media thickness (CIMT) was also significantly greater in the non-prednisone group (0.43 ± 0.069 vs 0.52 ± 0.17 $p = 0.046$), indicating more subclinical atherosclerosis (table 2).

Conclusion: This study suggests that in patients with SLE, prednisone use despite its known metabolic side effects, was paradoxically associated with a more favorable lipid and glucose profile, as well as lower carotid intima-media thickness, compared to those not on prednisone. There were no significant differences in traditional cardiovascular risk factors or carotid plaque presence. These findings indicate that the anti-inflammatory effects of prednisone may, in certain contexts, mitigate metabolic and vascular risks, potentially reducing subclinical atherosclerosis. However, further longitudinal studies are needed to better understand its long-term cardiovascular impact in SLE.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: BMS-986353 (CC-97540; CD19 NEX-T) is a CD19-directed chimeric antigen receptor (CAR) T cell therapy that expresses the same CAR as lisocabtagene maraleucel (liso-cel); it is manufactured via the NEX-T™ process to reduce manufacturing time and optimize phenotypic attributes. In Breakfree-1 trial (NCT05869955), BMS-986353 showed promising initial safety and efficacy in pts with severe refractory SLE.[1] Here, we report updated data on BMS-986353 in the SLE cohort.

Methods: This phase 1, multicenter trial assesses safety and efficacy of BMS-986353 in pts with severe, treatment-resistant autoimmune diseases. Inclusion criteria required active disease (BILAG A score) and an inadequate response to ≥ 2 immunosuppressants and steroids. After lymphodepletion, a single BMS-986353 infusion was administered at 2 dose levels (DLs) to optimize risk–benefit in SLE: DL1, 10×10^6; DL2, 25×10^6 CAR+ T cells. All pts were weaned off lupus-directed therapies by day 29 post-infusion. Primary endpoint was safety.

Results: As of March 17, 2025, 26 pts with SLE were enrolled; 19 were treated with BMS-986353 (DL1, n=13; DL2, n=6), with 17 (DL1, n=11) evaluable for efficacy. Median age: 30.0 (18–49) years. Median follow-up (range): 181.0 (7–488) days. Four and 15 pts had BILAG A cardiorespiratory and BILAG A renal involvement, respectively, and had refractory disease despite multiple prior therapies (median [range]: 7.0 [4–11]).

Lower frequency and grade (gr) of adverse events were observed in DL1 vs DL2. Gr 3/4 neutropenia occurred in 46.2% (DL1) versus 83.3% (DL2); all events resolved. There were no gr 3/4 thrombocytopenia or prolonged cytopenias at either DL. Low gr cytokine release syndrome (CRS) occurred in 61.5% at DL1 (**Table**) versus 100% at DL2; no gr ≥3 CRS events

	DL1 (n = 13)	
	CRS	ICANS
Any grade, n (%)		
Grade 1	7 (53.8)	0
Grade 2	1 (7.7)	0
Grade 3	0	0
Grade 4–5	0	0
Median onset (range), days	7.5 (2–11)	0
Median duration[a] (range), days	2.0 (1–5)	0
Treatments, n (%)		
Tocilizumab	4 (30.8)	–
Steroids	3 (23.1)	0

[a]Multiple events occurring within 7 days from each other are considered as 1 episode. CRS, cytokine release syndrome; DL, dose level; ICANS, immune effector cell-associated neurotoxicity syndrome.

CRS and ICANS at Part B expansion dose.

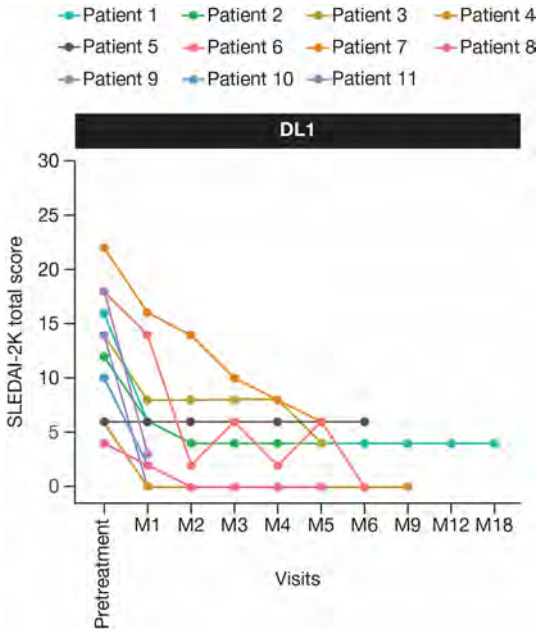

Figure 1. Total SLEDAI-2K score following BMS-986353 treatment in the SLE efficacy-evaluable population at DL1. DL, dose level; M, month; SLE, systemic lupus erythematosus; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000.

were observed at either DL. Immune effector cell-associated neurotoxicity syndrome (ICANS) was not observed at DL1; 2 gr 3 ICANS events occurred at DL2. All CRS and ICANS were brief and reversible. DL1 was selected for expansion in Part B based on the improved safety profile at DL1 in Part A.

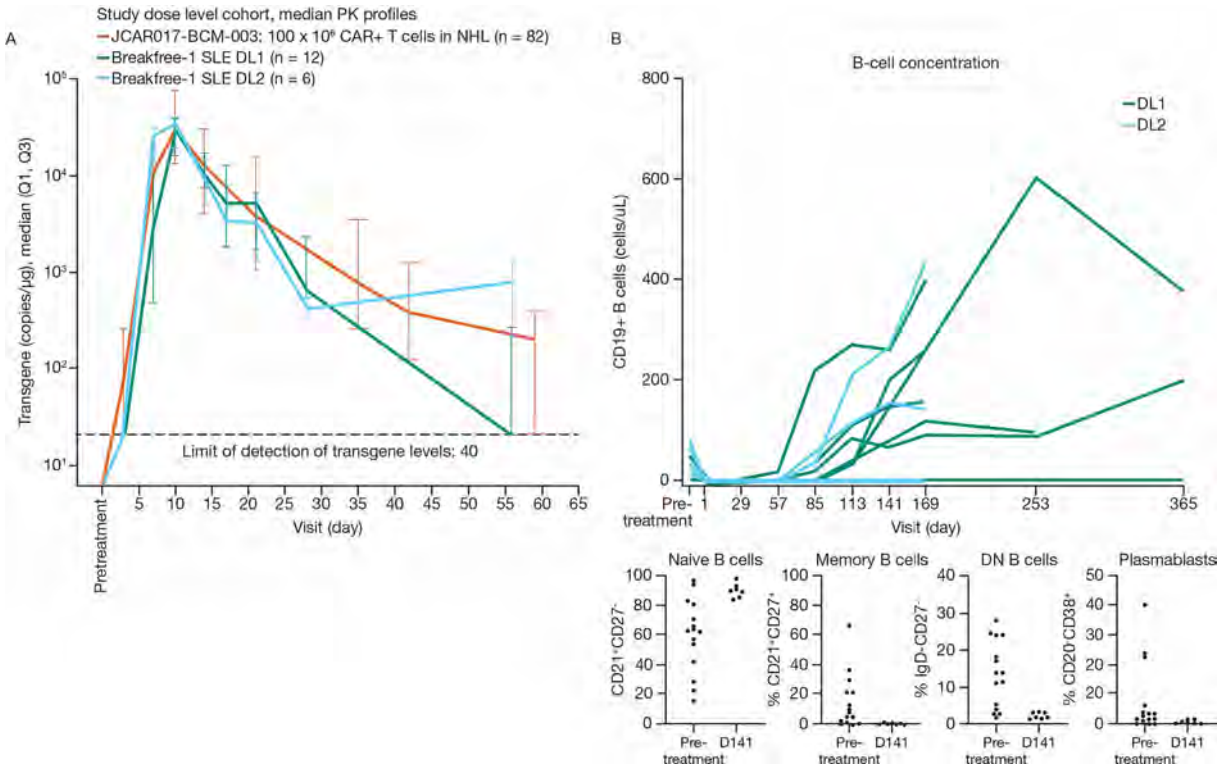

Figure 2. Median transgene PK profiles (A) and peripheral B cell concentration and phenotype (B) following BMS-986353 treatment in the SLE population. PK were analyzed using droplet PCR and pharmacodynamics were evaluated via flow cytometry. DL, dose level; DN, double negative; PCR, polymerase chain reaction; PK, pharmacokinetics; SLE, systemic lupus erythematosus.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

After BMS-986353 administration, most evaluable pts experienced a substantial improvement in disease activity as assessed by a significant reduction in SLEDAI-2000K (2K) and Physician's Global Assessment (PGA) scores; with 6 months of follow-up, DL1 pts had a median 9 point reduction in SLEDAI-2K score (**Fig 1**) and a 90% improvement in PGA. No clinically meaningful differences in efficacy outcomes were observed between DLs.

Double-stranded DNA and serum complement (C3 or C4) had significant titer reduction or normalized over time for pts with abnormal values at screening. All pts showed robust CAR T cell expansion compared with liso-cel and complete peripheral blood B-cell depletion at both DLs with primarily naive repopulating B cells (**Fig 2**).

Conclusion: These data show a manageable safety profile and preliminary clinical benefit of BMS-986353 for pts with severe, treatment-resistant SLE, suggesting BMS-986353 may be a potential therapeutic option.

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Effective, non-invasive disease activity and treatment response assessments are needed for patients with systemic lupus erythematosus (SLE), especially if associated with kidney disease, i.e. lupus nephritis (LN). The treatment goal of LN is to achieve complete renal remission (CRR). Proteinuria of >0.5 g/day can prompt a kidney biopsy to diagnose LN. The Renal Activity Index for Lupus (RAIL) measures the degree of kidney inflammation. The RAIL-score is calculated from the creatinine-adjusted RAIL biomarkers (neutrophil gelatinase-associated lipocalin [NGAL], kidney injury

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Urine samples collected from 69 SLE adult patients with and without LN were studied longitudinally at enrollment into the GLADEL cohort (T0), at 6 months (T1) and 12 months (T2). Absolute scores and changes in RAIL-scores over time were assessed for presence of CRR status (proteinuria of < 0.5 g/day) by logistical regression models. The Youden Index optimal cut-points on the receiver operating characteristic (ROC) curves were calculated.

Results: For 186 visits from 51 (74%; 91% female) patients with LN and 18 (26%) patients without LN diagnosis, patient characteristics and disease courses are shown in **Table 1**. RAIL-scores were correlated with renal-SLEDAI (r=0.46; p< 0.0001) and proteinuria (r=0.37; p=0.002). Considering all visits (CRR present/absent=146/40), mean (SD) RAIL-scores with CRR-status were 1.17 (1.53) lower than without CRR (p=0.023; area under the ROC curve =0.73), as shown in **Figure 1**, RAIL scores of no more than 3.4 identified CRR-status with 78% specificity (Positive Predictive Value [PPV]=0.77, sensitivity=62). Patients who newly achieved CRR-status at the next visit had a mean (SD) RAIL-score decrease of 1.0 (1.524) since the last visit (Percentage Variance Value [PVV]=82%, p=0.0024) and a further decrease of ≥0.57 of achieving CRR at the next visit.

Conclusion: RAIL-scores are significantly lower with CRR-status in LN and decreases of 1.0 between visits >0.57 or larger may predict future CRR achievement.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: An integrated post hoc analysis of five Phase 3 trials in adults with SLE showed greater benefit of belimumab (BEL) than placebo (PBO), plus standard therapy (ST), in attaining Definition of Remission In SLE (DORIS) and Lupus Low Disease Activity State (LLDAS).[1] As these trials were conducted before glucocorticoid (GC) tapering recommendations were introduced,[2] tapering was not mandated, resulting in prolonged GC courses in a large proportion of patients (pts), impacting attainability of DORIS and LLDAS.[1] Assessed here was attainment of DORIS and LLDAS in these trials using definitions excluding the GC requirement (non-GC-DORIS and non-GC-LLDAS).

Methods: This post hoc analysis pooled data for adults with active SLE from five trials (BLISS-76 [GSK Study 110751; NCT00410384], BLISS-52 [110752; NCT00424476], North East Asia [113750; NCT01345253], BLISS-SC [112341; NCT01484496], EMBRACE [115471; NCT01632241]) receiving BEL (10 mg/kg/month IV or 200 mg/week [wk] subcutaneous) or PBO, plus ST. Non-GC-DORIS and non-GC-LLDAS (defined in Figure 1) attainment rates were calculated and compared between BEL and PBO using modified Poisson regression adjusted for trial variance in all pts and

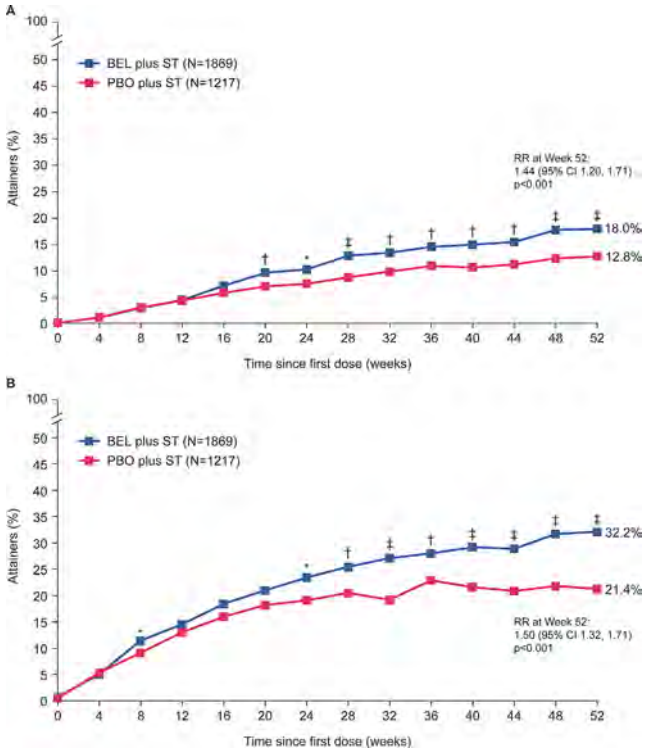

Figure 1. Attainment of (A) non-GC-DORIS and (B) non-GC-LLDAS up to Wk 52 in the overall population. *p<0.05; †p<0.01; ‡p<0.001. Non-GC-DORIS: clinical SLEDAI=0 (irrespective of serological activity), PGA <0.5. Non-GC-LLDAS: SLEDAI-2K ≤4 with no activity in major organ systems (renal, central nervous system, cardiopulmonary, vasculitis, fever), no hemolytic anemia or gastrointestinal activity, and no new features of SLE disease activity (using SLEDAI-2K) compared with the previous assessment, PGA ≤1. PGA, Physician's Global assessment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

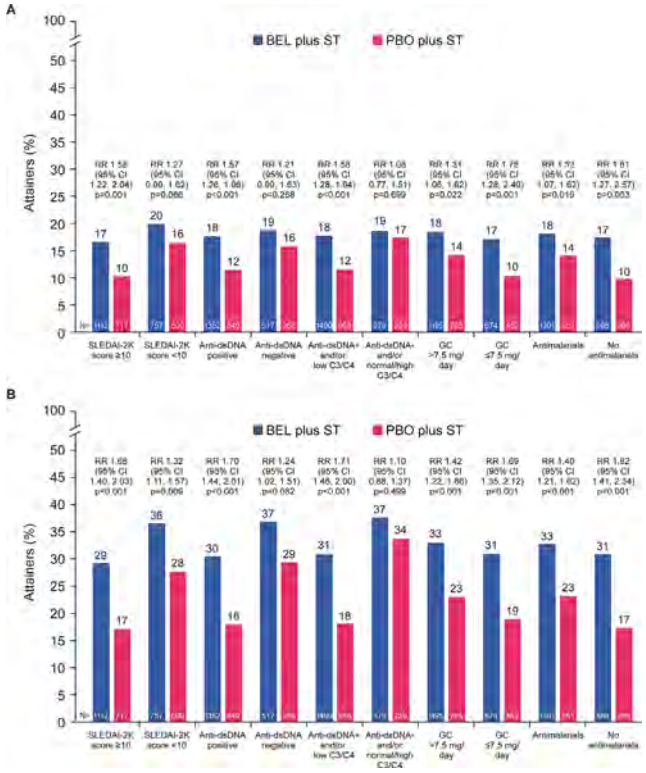

Figure 2. Attainment of (A) non-GC-DORIS and (B) non-GC-LLDAS at Wk 52 in pt subgroups defined by baseline characteristics. C, complement component.

subgroups based on baseline/pt characteristics (SLEDAI-2K score, anti-dsDNA positivity, complement levels, GC dose, antimalarial use, race).

Results: Included were 1869 BEL and 1217 PBO pts. At Wk 52, non-GC-DORIS and non-GC-LLDAS attainment rates were higher with BEL versus PBO (**Figure 1**). Significance maintained to Wk 52 was reached by Wk 20 for non-GC-DORIS and Wk 24 for non-GC-LLDAS. At Wk 52, significantly greater proportions of BEL versus PBO pts were in non-GC-DORIS and non-GC-LLDAS across most subgroups (**Figure 2**); for baseline SLEDAI-2K score ≥10, maintained from as early as Wk 16 (non-GC-DORIS remission: risk ratio, RR [95% CI]: 1.95 [1.20, 3.16], p=0.009; non-GC-LLDAS: 1.54 [1.17, 2.02], p=0.003).

At Wk 52, non-GC-DORIS and non-GC-LLDAS attainment rates were higher with BEL versus PBO for Asian (BEL n=698, PBO n=405; non-GC-DORIS: RR [95% CI]: 1.60 [1.13, 2.27], p=0.013; non-GC-LLDAS: 1.59 [1.25, 2.02], p=0.001) and White pts (n=596, n=436; 1.66 [1.23, 2.25], p=0.002; 1.76 [1.42, 2.19], p< 0.001); numerical differences were seen for pts of Black African ancestry (n=403, n=229; 1.13 [0.76, 1.69], p=0.577; 1.14 [0.86, 1.51]; p=0.438) and Indigenous American pts (n=172, n=147; 1.17 [0.80, 1.71], p=0.496; 1.35 [1.00, 1.82], p=0.117).

Conclusion: When analyzing data from past trials, it is key to consider context, timing, and effects of confounding factors. GC taper was not mandated in the BEL trial protocols and was not part of the assessment of BEL benefit. In this analysis, BEL was associated with higher attainment of both DORIS and LLDAS versus PBO in all pts and most subgroups. Attainment rates were ~2-fold higher than reported with full DORIS and LLDAS definitions.[1] This analysis corroborates benefits of BEL over PBO, plus ST, in inducing remission and low disease activity in pts with SLE.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: SLE is characterized by B cell activation, autoantibody production and autoreactivity. Recently, CAR-T therapy has emerged as a promising strategy to deplete autoreactive B cells and induce sustained remission. CTA313 is a CD19/BCMA dual-targeted "off-the-shelf" universal CAR-T product with T cell receptor and human leukocyte antigen class knockout, as well as ANSWER^{TM} inhibitory molecule overexpression to resist host immune rejection - leading

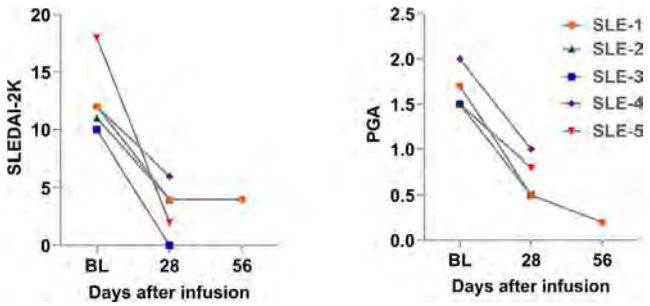

Figure 1. SLEDAI-2K score and PGA

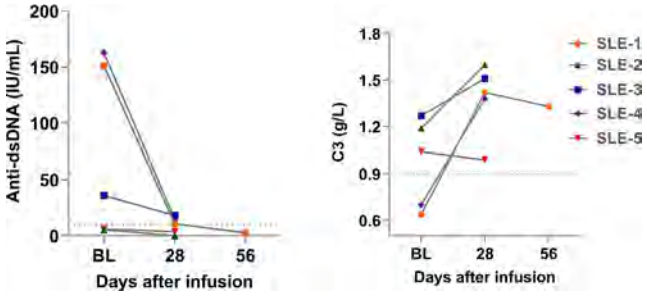

Figure 2. Anti-dsDNA antibodies and complement C3

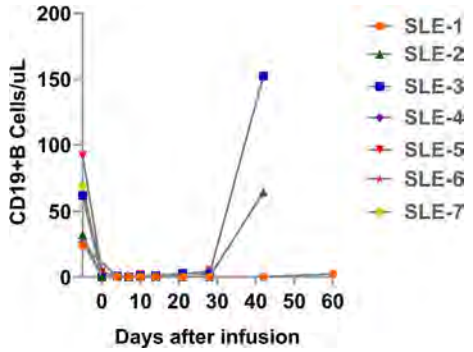

Figure 3. B cells

to increased expansion and persistence in the context of standard dose lymphodepletion. The study aims to evaluate the safety, efficacy and cellular kinetics of CTA313 in patients with active SLE.

Methods: Patients received a single administration of CTA313 treatment at 2 dose levels (DLs): DL1 as 3×10^6 CAR+ T cells/kg, DL2 as 6×10^6 CAR+ T cells/kg following lymphodepletion with cyclophosphamide (300 mg/m^2, day -5 to -3) and fludarabine (30 mg/m^2, day -5 to -3). Cellular kinetics are measured by quantitative PCR and flow cytometry; pharmacodynamics assessments include quantification of B cells, complement (C3/C4), and autoantibodies. Clinical activity assessments include disease activity scores (SLEDAI-2K), Physician's Global Assessment (PGA) and renal outcome measures.

Results: As of April 30, 2025, seven patients with active SLE received CTA313 at two doses, DL1 (n=3), DL2 (n=4). Six (86%) patients were female, median age 43 (22-50) years, median disease duration 6 (1.3-13.0) years, and 2 patients had lupus nephritis. All patients had been previously treated with steroids and immunosuppressive drugs, including hydroxychloroquine (n=7), tacrolimus (n=7), mycophenolate mofetil (n=4), cyclosporine A (n=2), thalidomide (n=2), and methotrexate (n=1), and one patient received belimumab.

To date, treatment has been well tolerated with only Grade 1 cytokine release syndrome (CRS) observed in four of seven patients; no neurotoxicity, GvHD or infections were reported. Hypogammaglobulinemia, which did not require intravenous immunoglobulin treatment, was a common adverse event.

With 5 patients reaching initial disease assessment, preliminary efficacy indicated reductions in SLEDAI-2K and PGA. All 5 patients achieved SRI-4 response, and 4 of 5 patients achieved Lupus Low Disease Activity State (LLDAS). Importantly, three patients discontinued all immunosuppressive agents, including glucocorticoids, achieving drug-free remission. Autoantibodies levels declined, accompanied with increasing level of C3. Meanwhile, 24-hour proteinuria significantly decreased in 2 patients with lupus nephritis. PK analysis revealed median peak expansion (C_{max}) of 286,265 copies/ug DNA by qPCR at Day 7-10. Complete B cell depletion was observed by Day 4-7 post-infusion. To date, B cell recovery was observed in 3 patients, with median B cell aplasia of 42 days. In patients who achieved anti-dsDNA antibody eradication, the antibody remained undetectable despite B cell reconstitution.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: Preliminary data from this trial suggest favorable safety, CAR T cell expansion, B cell depletion and promising clinical activity of CTA313 in active SLE. Ongoing follow up and dose escalation in additional patients will provide insights into long term safety and efficacy.

Belimumab Is Associated with Early Improvement in Disease Activity Measures Among Patients with Systemic Lupus Erythematosus in the US

Yan Chen[1], Maral DerSarkissian[1], Shumin Rui[1], Justin Clark[1], Daniel Moldaver[2], **Jeffrey J. Ellis**[3], Karen Worley[3] and Aarat M Patel[4], [1]Analysis Group, Los Angeles, CA, [2]GSK, Global Real-World Evidence & Health Outcomes Research, Toronto, ON, Canada, [3]GSK, Global Real-World Evidence & Health Outcomes Research, Collegeville, PA, [4]GSK, US Medical Affairs, Durham, NC

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Belimumab (BEL), a B-cell modulator mAb that selectively inhibits soluble B-lymphocyte stimulator and reduces autoreactive B cells that drive lupus disease activity, is approved for SLE and LN in adults and children.[1] While early response to BEL has been demonstrated to occur within weeks for several key clinical endpoints,[2] robust real-world evidence is limited regarding the characteristics of patients who experience early improvement in SLE disease activity measures (DAM). To address this knowledge gap, we identified key predictors of early improvement in SLE DAM among patients with SLE in the US.

Methods: This retrospective, longitudinal cohort study (GSK Study 222157) used electronic health record data from the Specialty Networks rheumatology practice database. Eligible patients were aged ≥18 years, diagnosed with SLE, initiated either subcutaneous or intravenous BEL (9/1/2011–12/25/2024; defined index), and had ≥12 months of pre-index (defined the baseline period) and ≥2 months of post-index clinical activity. For the analysis of each SLE DAM, patients had ≥1 record of disease activity with a nonzero value in baseline and ≥1 record of the same DAM within 2 months post-index. Early improvement in each DAM was evaluated within 2 months post-index and defined as presence of ≥1 observation that was less than the mean baseline score (at the patient level) minus its minimal important difference (0.5×standard deviation of baseline DAM) or value of 0. Predictors of early improvement for patient pain index (PPI), Health Assessment Questionnaire Disability Index (HAQ-DI), swollen joint count (SJC), and tender joint count (TJC) were assessed separately and in ≥1 of these measures on aggregate using a least absolute shrinkage and selection operator (LASSO) regression model. Predictors assessed at baseline included age, sex, race, year of index, baseline DAM, SLE disease severity, organ damage, Quan-Charlson Comorbidity Index (QCCI), and comorbidities.

Results: Overall, 684 patients were included, 54.7% (n=374) of whom experienced early (within 2 months) improvement in ≥1 DAM on aggregate. Early improvement in PPI, HAQ-DI, SJC, and TJC was experienced by 41.2%, 32.5%, 48.7%, and 38.8% of patients, respectively (**Table 1**). Demographics and clinical characteristics of patients with improvement in ≥1 DAM versus those without improvement are summarized in **Table 2**. LASSO identified male sex (vs female) (odds ratio [OR; 95% confidence interval (CI)]: 2.25 [1.03, 5.29]), minority race (vs White) (OR [95% CI]: 1.77 [1.21, 2.60]), and baseline

moderate/severe SLE (vs mild) (OR [95% CI]: 1.50 [1.08, 2.10]) as predictors of early improvement in ≥1 SLE DAM on aggregate (**Table 3**).

Conclusion: Greater than half of patients with SLE initiating BEL experienced early (within 2 months) improvement in burdensome dimensions of disease activity (e.g. pain and joint involvement), demonstrating the rapid therapeutic effect of BEL. Moderate/severe SLE and non-White race were predictive of early improvement, suggesting a potentially greater treatment benefit of BEL in these subgroups.

Rapid Oral Glucocorticoid Discontinuation or Dose Reduction Among US Patients with SLE Receiving Belimumab in a Real-World Setting

Yan Chen[1], Maral DerSarkissian[1], Shumin Rui[1], Justin Clark[1], Daniel Moldaver[2], **Jeffrey J. Ellis**[3], Karen Worley[3] and Aarat M Patel[4], [1]Analysis Group, Los Angeles, CA, [2]GSK, Global Real-World Evidence & Health Outcomes Research, Toronto, ON, Canada, [3]GSK, Global Real-World Evidence & Health Outcomes Research, Collegeville, PA, [4]GSK, US Medical Affairs, Durham, NC

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Belimumab (BEL), a B-cell modulator mAb that selectively inhibits soluble B-lymphocyte stimulator and reduces autoreactive B cells that drive lupus disease activity, is approved for SLE and LN in adults and children.[1] Prolonged oral glucocorticoid (OGC) use can lead to organ damage, and OGC reduction is an important treatment goal in SLE. BEL has been shown to reduce OGC use in the real world; however, limited evidence exists regarding the characteristics of patients who are able to reduce OGC use with BEL. We studied OGC reduction or discontinuation within 6 months of BEL initiation in patients with SLE in US clinical practice and aimed to identify patient characteristics that may support prediction of early OGC dose reduction or discontinuation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Hematologic disorders	1.34 (0.84, 2.13)
Hypertension	0.55 (0.24, 1.13)

Methods: This retrospective, longitudinal cohort study (GSK Study 222157) used health record data from the Specialty Networks rheumatology practice database. Eligible patients were aged ≥18 years, diagnosed with SLE, initiated either subcutaneous (SC) or intravenous (IV) BEL (9/1/2011–4/25/2024; defined index), had ≥12 months of pre-index (defined as baseline period) and ≥10 months of post-index clinical activity, ≥1 OGC prescription with dose information (in prednisone-equivalent units), and no OGC discontinuation during baseline. To ensure sufficient exposure, within 3 months of index prescription, SC BEL initiators were required to have ≥1 SC or ≥1 IV BEL record while IV BEL initiators were required to have ≥1 SC or ≥2 IV BEL records. OGC dose reduction by ≥50% or discontinuation (≥120 consecutive days without OGC supply) within 6 months was defined as "early" if it occurred within the first quartile of the time from index to either event calculated across all patients, using a data-driven approach. Predictors of early OGC dose reduction or discontinuation were identified using a least absolute shrinkage and selection operator (LASSO) logistic regression model. Candidate predictors included age, sex, race, year of index, SLE disease severity, organ damage, Quan-Charlson Comorbidity Index, and comorbidities.

Results: Among 541 patients included in the study, approximately half (50.8%, n=275) achieved ≥50% OGC dose reduction or discontinuation within 6 months of initiating BEL. Median time to ≥50% dose reduction or discontinuation was 177 days and 25% (n=136) of patients achieved this outcome in < 2 months (57 days). Patients with early (i.e. within 57 days) OGC reduction or discontinuation were slightly older than those without (50.3 vs 48.3 years), a greater proportion had

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

moderate (74.3% vs 66.9%) or severe (3.7% vs 2.2%) SLE, but the same proportion (9.6%) had evidence of baseline organ damage (**Table 1**). LASSO regression identified moderate/severe SLE at baseline (vs mild) (odds ratio [95% confidence interval]: 1.64 [1.04, 2.65]) as a predictor of early OGC dose reduction or discontinuation (**Table 2**).

Conclusion: Among patients initiating BEL treatment for SLE, half achieved OGC discontinuation or dose reduction by ≥50% within 6 months. This outcome was achieved by 25% of patients within 2 months of BEL initiation, with this earlier benefit more likely in patients who had moderate/severe SLE.

Abstract Number: 1535

INB-619 - A Novel Gamma-Delta (γδ) T cell Engager to Target B cells in Autoimmune Diseases

Lei Ding, Yanjie Li, Mariska ter Haak, Sadhak Sengupta, Kate Rochlin and **Lawrence Lamb**, IN8bio, Inc., New York, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: T cell engagers (TCEs) redirect T cells to bind target cells by linking T cells with target-associated antigens expressed on cells responsible for disease pathology. Most TCEs to-date target alpha-beta (αβ) T cells, binding both an antigen such as CD20 on the cell of interest and CD3 on the T cell. This approach is complex, requiring CD3 detuning due to the risks of T cell exhaustion and severe, potentially life-threatening complications such as cytokine release syndrome (CRS). Gamma delta (γδ) T cells offer a promising alternative due to their innate MHC-independent cell killing and low production of CRS-associated cytokines. INB-619, a novel pan-γδ TCE that exhibits specific targeting of CD19+ B cells, including those from SLE patients with active disease. INB-619 induces potent cytotoxicity and drives robust activation and expansion of Vδ1and Vδ2 T cells. These unique properties potentially solve the challenge of current B cell depleting TCE's, where dysfunctional immune cells, tissue-resident B cells and potential toxicities may limit the depth of B cell depletion. These findings position INB-619 as a promising therapeutic candidate for autoimmune indications.

Methods: INB-619 binding and activation specificity were confirmed by co-incubation of a 1:1 ratio of NALM-6 ALL (CD19+) or CD19- cell lines with expanded γδ T cells at increasing concentrations of INB-619. PBMC from healthy donors (n=2) and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

from subjects with active SLE (n=3) were exposed at DAY 0 to 5nM of INB-619 and assessed over 10 days for lymphocyte phenotype, expression of cell surface activation/ degranulation markers, and secreted cytokines (N = 3).

Results: INB-619 bound specifically to CD19+ NALM-6 and to γδ T cells and induced specific and dose-dependent γδ T cell cytotoxicity and upregulation of CD107a, PD-1, and CD69 at EC50 values from 26 to 51 pM but showed no specific activity against a CD19- cell line. Complete depletion of B cells from healthy and SLE donor PBMC were shown over a 10-day incubation period. In all cases, γδ T cells showed robust expansion of both CD27+CD45RA+ and CD27+/-CD45RA- populations reflecting the Vδ1 and Vδ2 populations, respectively. INB-619-expanded PBMC also exhibited a favorable cytokine release profile, with no detectable or minimal release of cytokines associated with CRS such as IL-4, IL-6, IL-10, and IL-17α. Concentrations of IgG1 and IgM in the coculture supernatants of all three SLE donors significantly decreased in TCE treatment groups concurrent with B cell depletion, with a correlation between the level of B cell depletion and γδ T expansion.

Conclusion: INB-619 is a novel CD19-targeting γδ TCE that expands both major γδ T cell subtypes sufficiently to eliminate a large population of B cells in vitro. The combined expansion and activation of tissue-resident Vδ1 and circulating Vδ2 populations, with the favorable cytokine pattern evidenced here, suggests that INB-619 could provide deep B cell depletion with a clinically relevant improvement in safety over current methods.

Abstract Number: 1536

Evaluating Systemic Lupus Erythematosus Remission Among Patients Initiating Belimumab in a Real-World Setting in the USA

Aarat M Patel[1], Renee L. Gennarelli[2], Temitope Bello[2], Ali Bonakdar[2] and Karen Worley[3], [1]GSK, US Medical Affairs, Durham, NC, [2]Cencora, Real-World Evidence, Conshohocken, PA, [3]GSK, Global Real-World Evidence & Health Outcomes Research, Collegeville, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The Definition Of Remission In SLE (DORIS) criteria were developed to provide alignment on defining remission in patients with SLE.[1,2] Belimumab (BEL) treatment increases the proportion of patients with SLE in DORIS remission.[3] Several real-world studies have evaluated DORIS remission in BEL-treated patients with SLE[4,5,6]; however, data are limited for patients in the USA.

Methods: This retrospective, observational cohort study (GSK Study 222161) assessed remission among adult patients with SLE receiving BEL in a real-world setting in the USA using the OM1 PremiOM SLE dataset (OM1, Inc, Boston, MA, USA). Study period: Jan 1, 2013, to May 31, 2024. Eligible patients had ≥1 BEL pharmacy/medical encounter during the identification period (Jan 1, 2014, [index: first BEL receipt during identification period] to Oct 31, 2023). Primary objective: determine the proportion of patients achieving SLE remission (DORIS definition by proxy: SLEDAI score=0 [no disease activity]; Physician's Global Assessment [PGA] < 2; prednisone equivalent dose ≤5 mg/day) at 28, 48, and 52 weeks (wks) post–BEL initiation. Secondary objectives included: describe SLEDAI scores and PGA before BEL and 28, 48, and 52 wks post–

BEL initiation. Two censoring approaches assessed estimate robustness (last available score: earlier of (1) latest available SLEDAI or PGA score in follow-up period and (2) end of follow-up; end of follow-up: earlier of 52 wks post-index, last activity date, or date of data cutoff). Analyses were descriptive.

Table 2. Proportion of patients achieving real-world SLE remission (per DORIS proxy), no disease activity (per SLEDAI), and PGA-based threshold for remission. *The two censoring approaches were utilized to assess the robustness of estimates: the last available score which was the earlier of latest available PGA or SLEDAI score in the follow-up period (not carried forward) and end of follow-up, and the end of follow-up which was the earlier of 52 weeks post-index, last activity date or date of data cutoff; †the proportion of patients achieving SLE remission (per DORIS proxy) at 28, 48, and 52 weeks after initiating therapy with belimumab defined as SLEDAI score=0, PGA score <2, and prednisone-equivalent dose ≤5 mg/day; ‡the proportion of patients with no disease activity (per SLEDAI; SLEDAI=0); §the proportion of patients with at least one PGA score meeting the predefined threshold for remission (<2). CI, confidence interval.

	Point estimate (95% CI)		
Censoring approach*	**28 weeks**	**48 weeks**	**52 weeks**
Proportion of patients achieving real-world SLE remission (per DORIS proxy)†			
Last available score censoring approach	7.7% (4.7, 10.7)	25.9% (18.8, 32.4)	28.3% (19.8, 35.9)
End of follow-up censoring approach	5.0% (2.9, 7.1)	13.0% (9.5, 16.3)	13.8% (10.3, 17.2)
Proportion of patients achieving no disease activity (per SLEDAI)‡			
Last available score censoring approach	21.3% (16.8, 25.6)	40.7% (33.3, 47.3)	45.8% (36.6, 53.7)
End of follow-up censoring approach	18.6% (14.7, 22.3)	28.1% (23.5, 32.4)	29.5% (24.8, 33.9)
Proportion of patients achieving PGA-based remission threshold§			
Last available score censoring approach	45.9% (40.4, 51.0)	60.6% (54.2, 66.1)	68.5% (58.2, 76.3)
End of follow-up censoring approach	43.7% (38.6, 48.4)	54.6% (49.4, 59.3)	56.3% (51.1, 60.9)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Overall, 398 patients were included (Table 1). Estimates were sensitive to censoring approach (Table 2). By last available score, point estimates for the proportion of patients achieving SLE remission (per DORIS proxy) increased from 7.7% at 28 wks to 25.9% at 48 wks and 28.3% at 52 wks post–BEL initiation. The proportion of patients achieving no disease activity (SLEDAI=0) within 28 wks was 21.3%, increasing to 45.8% within 52 wks post–BEL initiation. The proportion of patients achieving PGA-based remission thresholds increased from 45.9% at 28 wks to 68.5% at 52 wks. By end of follow-up approach, the proportion of patients achieving SLE remission increased from 5.0% at 28 wks to 13.0% at 48 wks and 13.8% at 52 wks post–BEL initiation. Point estimates for the proportion of patients achieving no disease activity were 18.6% within 28 wks post–BEL initiation increasing to 29.5% within 52 wks. The proportion of patients achieving PGA-based remission thresholds was 43.7% at 28 wks and 56.3% at 52 wks.

Conclusion: This study demonstrates the achievement of real-world remission targets for patients with SLE initiating BEL in the USA, with DORIS remission criteria being reached within 28 wks for about 5–8% of patients, and within 52 weeks for 14–28% of patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: CD19-targeting chimeric antigen receptor (CAR) T-cell therapy has revolutionized treatment strategies for severe B-cell driven autoimmune diseases (AID) like Systemic Lupus erythematosus (SLE), Systemic Sclerosis (SSc) or Idiopathic Inflammatory Myositis (IIM). Cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS) and hematotoxicity are the most common and best described side effects, but little is known about AID-specific adverse events (1,2).

Purpose of our study was to describe a new form of toxicity – Local Immune effector cell-Associated Toxicity Syndrome (LICATS), related to the treatment of patients with autoimmune disease (AID) with CD19-targeting chimeric antigen receptor (CAR) T-cells.

Methods: AID patients receiving CD19-CAR T-cell therapy in Erlangen and Duesseldorf with a follow-up of at least 30 days were assessed for organ-specific LICATS occurring after CAR T-cell infusion. Observed reactions were documented according to localization, time, duration and graded for severity (grade 1: spontaneous resolution; grade 2: glucocorticoid use; grade 3: glucocorticoid use plus prolonged hospital stay; grade 4: intensive care treatment). No systemic events, such as fever, chills, nausea, fatigue, diffuse pain/hypersensitivity or hemodynamic changes were classified as LICATS to

Demographics, Incidence and organ involvement of LICATS.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

separate it from CRS. Furthermore, per definition, LICATS were time-limited events that spontaneously regressed or stopped after a short course of glucocorticoid treatment in order to distinguish it from recurrence of AID.

Results: Between March 2021 and October 2024, 39 patients with AID were treated with CD19-CAR T-cells (20 systemic lupus erythematosus, SLE; 13 systemic sclerosis, SSc; 6 idiopathic inflammatory myositis, IIM). 25 patients (64.1%) were females. Median age was 36 years [22;43.5]. 54 local reactions, which we termed "Local Immune effector Cell-Associated Toxicity Syndrome" (LICATS) were recorded, affecting overall 30 patients (76.9%) with median (IQR) time of onset of 14 [5;21] days and a median duration of 11 [5;14] days. LICATS exclusively occurred during the B-cell aplasia phase and only involved organs previously affected by the respective AID. Most frequent affected organs were the skin (N=19, 35.2%) and the kidneys (N=12, 22.2%). Most LICATS were mild (grade 1: 35, grade 2: 16). Only three LICATS were grade 3. All LICATS resolved without sequelae.

Conclusion: LICATS is a new form of toxicity in CD19-CAR T-cell treated patients with AID, most likely based on the cleansing of immune cells from the affected organs. It is self-limited, organ-specific and usually mild in its intensity.

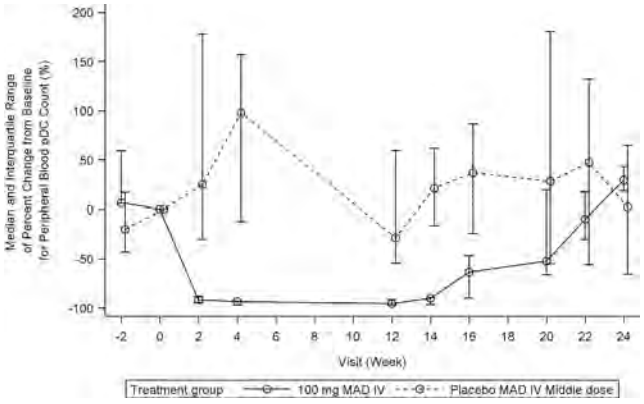

Figure 1: Median and interquartile range of percent change from baseline for peripheral blood pDC count (%) in 100 mg/body IV

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Plasmacytoid dendritic cells (pDCs) are known to be the main source of type 1 interferon (IFN), which is the cause of various autoimmune diseases. The increased accumulation of pDCs in tissues is associated with inflammation and damage in Lupus. KK4277 is a monoclonal antibody targeting pDCs with its unique dual mode of action that directly depletes pDCs by enhanced Antibody-Dependent-Cellular-Cytotoxicity activity and independently inhibits type 1 IFN production from pDCs.

Methods: This was a first-in-human study that consisted of a randomized, placebo-controlled, double-blind, single-dose ascending study in Japanese and non-Asian healthy men (Part 1) and a multicenter, randomized, placebo-controlled, double-blind, multiple-dose ascending study in SLE or Cutaneous Lupus Erythematosus (CLE) Asian patients with active skin lesions (Part 2) (NCT05411016). In Part 1, healthy adult men were enrolled in eight cohorts for intravenous (IV) administration, 0.005 to 150 mg/body and four cohorts for subcutaneous (SC) administration, 100 to 300 mg/body (n=8 for each cohort). In Part 2, SLE or CLE patients who had active skin lesions without any disease severity requirements were enrolled in 5 mg/body cohort. The patients with CLE Disease Area and Severity Index Activity (CLASI-A) score of ≥8 were enrolled in 100 mg/body cohort. Participants received KK4277 or placebo intravenously with their standard of care every 2 weeks for 6 doses, followed by safety observation until Week 24. pDC and myxovirus resistance protein A (MxA) in skin were measured in addition to pDC and type 1 IFN signature in blood. CLASI-A score was assessed by investigators through the study. Another cohort of SC multiple administrations was undergoing at the time of data cut-off, and the data is not included.

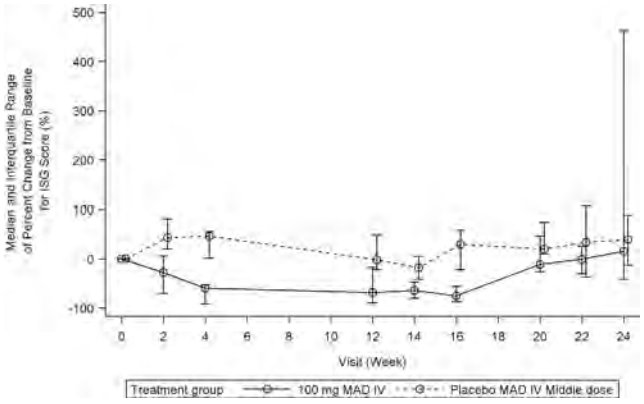

Figure 2: Median and interquartile range of percent change from baseline for Type 1 IFN signature (%) in 100 mg/body IV

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In Part 1, 97 subjects were enrolled. No serious or severe adverse event (AE) occurred. The tolerability of up to 150 mg/body IV and 300 mg/body SC was confirmed. More than a 90% reduction in blood pDCs was observed at 5 mg/body or higher doses, and the duration of the reduction increased in a dose-dependent manner. In part 2, 21 subjects were enrolled and received the study treatment. In 100 mg/body IV (KK4277: 8, Placebo: 4), more than a 90% reduction in blood pDCs was observed in the KK4277 group after the first administration and maintained until Week 14 (Figure 1). The median change in type 1 IFN signature was -69% in the KK4277 group and -2% in the placebo group at Week 12 (Figure 2). Three and two skin samples were provided in the KK4277 and placebo group, respectively, and a great reduction of pDC and MxA was obtained in all KK4277-treated individuals. Whereas the median change of CLASI-A score at Week 12 was not clearly different between the groups (KK4277: -62%, placebo: -56%), numerically huge improvements were observed in several subjects in the KK4277 group, including severe patients. No serious or severe AE was observed. The proportion of AE incidences was similar between the groups (KK4277: 63%, placebo: 75%).

Conclusion: Multiple doses of 100 mg/body IV were tolerable. KK4277 greatly depleted pDC in blood and skin and reduced type I IFN. A proof of pharmacological action was obtained. An additional study is expected for further evaluation in Lupus.

Background/Purpose: Type I interferon (IFN) signaling is central to systemic lupus erythematosus (SLE) pathogenesis, and anifrolumab, a monoclonal antibody targeting the IFN-α receptor (IFNAR), has emerged as a promising therapy. This systematic review evaluates the impact of baseline IFN signature on anifrolumab's efficacy and safety and synthesizes its overall clinical profile in SLE.

Methods: A comprehensive systematic review was conducted in accordance with PRISMA guidelines. We analyzed data from four randomized controlled trials (RCTs, n = 1,271 patients) comparing anifrolumab (150–1,000 mg) to placebo. Primary outcomes included SLE Responder Index-4 (SRI-4), BILAG-Based Composite Lupus Assessment (BICLA), and IFN signature-stratified efficacy/safety. Secondary outcomes assessed pooled efficacy and adverse events. Risk of bias was assessed using the Cochrane Risk of Bias 2.0 tool across five domains. Two reviewers independently evaluated the studies, and discrepancies were resolved by consensus.

Results: Patients with high baseline IFN signatures (measured via 4- or 21-gene assays) demonstrated superior clinical responses. In phase 3 trials, anifrolumab 300 mg achieved significantly higher BICLA response rates versus placebo (47.8% vs. 31.3%, *p* < 0.001), particularly in high IFN subgroups. SRI-4 responses were 36.1% (anifrolumab) vs. 40.2% (placebo) in TULIP-1 (*p* = 0.03), with enhanced efficacy in IFN-high patients. In lupus nephritis, an intensified anifrolumab regimen (900 mg induction) reduced urine protein-creatinine ratio (UPCR) in 84.3% vs. 73.5% placebo. However, IFN-high patients faced elevated infection risks (e.g., herpes zoster: 10/45 vs. 8/49 placebo). Pooled analysis revealed anifrolumab increased SRI-4 likelihood (RR = 1.4, 95% CI: 1.1–1.8) but raised serious infections (13.9% vs. 16.3% placebo). Upper respiratory infections (15–30%) and infusion reactions (10–15%) were common. Most included RCTs showed low risk of bias.

Conclusion: Anifrolumab is efficacious in SLE, with maximal benefit in IFN-high patients, though this subgroup requires vigilant monitoring for infections. These findings underscore the IFN signature's role as a predictive biomarker and highlight the need for personalized risk-benefit assessment in SLE management.

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with multi-organ involvements and recurrent relapses. The objectives of treatment include ensuring long-term patient survival, preventing disease relapses and organ damage. Belimumab(BEL) is a humanized monoclonal antibody that targets B-Cell Activating Factor of the TNF Family(BAFF) and has been approved as the first antibody to treat SLE. Tofacitinib(TOFA) functions as an inhibitor of Janus kinase (JAK). Previous study demonstrated the safety and efficacy of TOFA in treating mucocutaneous involvement and

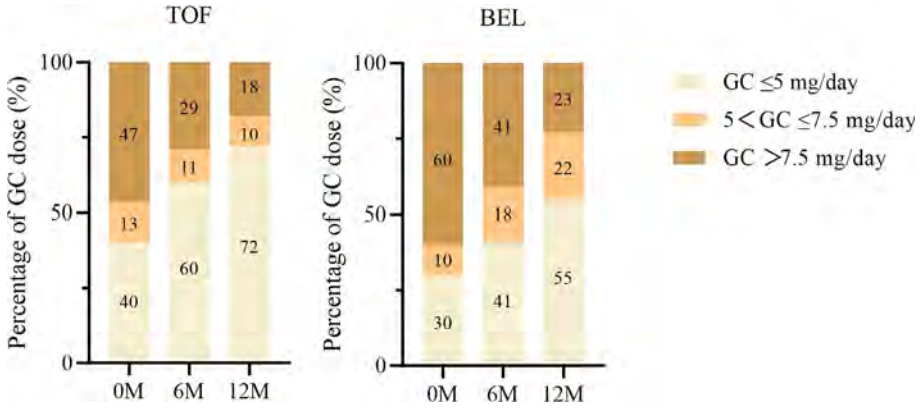

Fig.3. Change of GC dosage(prednisone equivalent) regarding the effectiveness of TOF versus BEL

arthritis in lupus. TOFA showed the potential efficacy to faster reach BICLA (BILAG-based Composite Lupus Assessment) response than belimumab in patients with mild to moderate SLE. However, the long-term effect of TOFA versus BEL in maintenance therapy of SLE remains unknown.We conducted this study to compare efficacy and safety of TOFA and BEL in maintenance therapy of SLE.

Methods: We conducted a real-world, multicenter, retrospective cohort study based on the Chinese SLE Treatment and Research Registry (CSTAR). Maintenance therapy was defined as treatment after achieving a clinical Systemic Lupus Erythematosus Disease Activity Index (cSLEDAI) score of zero. A total of 51 patients treated with TOF and 102 patients treated with BEL were enrolled through propensity score matching. The primary endpoint was the 12-month disease relapse rate, as defined by the Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI Flare Index (SFI).

Results: No statistically significant difference in relapse rates were observed between the TOF group and the BEL group within 6 and 12 months (19.61% vs. 18.63%, $p > 0.999$; 25.49% vs. 29.41%, $p = 0.704$). Subgroup analysis of the serologically active clinical quiescence (SACQ) patients also showed no significant difference between two groups (6 months: 21.43% vs. 17.74%, $p = 0.773$; 12 months: 25% vs. 30.65%, $p=0.626$). A gradual decline in C3 levels in the TOF group, while the BEL group showed a physiological increase over time. C4 levels increased within the first 6 months but gradually returned to baseline by 12 months in both groups. The glucocorticoid dosage curves for both groups exhibited a descending trend. Four patients in the TOF group and one patient in the BEL group reported adverse events during the one-year follow-up.

Conclusion: Tofacitinib demonstrated potentially comparable effects to belimumab in the maintenance treatment of SLE, both drugs can aid in tappering off glucocorticoid.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite the evolution of various flare definitions and their inclusion in SLE clinical trials, moderate flares tend to be underestimated in trials owing to their evaluation based on a single time interval as opposed to multiple intervals. Dapirolizumab pegol (DZP) is a novel CD40L inhibitor with broad modulatory effects on SLE immunopathology;[1,2] it consists of a polyethylene glycol (PEG)-conjugated antigen-binding fragment (Fab'), which lacks an Fc domain. In the phase 3 PHOENYCS GO trial (NCT04294667) of DZP in SLE, the primary endpoint, BILAG-based Composite Lupus Assessment (BICLA) response at Week (Wk) 48, was met.[3] Additionally, through Wk 48, a lower proportion of patients (pts) receiving DZP plus standard of care (DZP+SOC) vs placebo (PBO)+SOC had BILAG 2004 severe flares (11.6% vs 23.4%; nominal p=0.0257).[3] We report moderate flare outcomes from PHOENYCS GO and explore alternative definitions to more accurately estimate their frequency.

Methods: PHOENYCS GO was a 48-wk, randomized, double-blind, PBO-controlled trial. Pts were randomized 2:1 to intravenous DZP 24 mg/kg+SOC or PBO+SOC every 4 wks. Pre-specified analyses defined a BILAG 2004 severe flare as ≥1 BILAG 2004 Grade A due to a new/worse individual item(s), and a BILAG 2004 moderate flare as ≥2 BILAG 2004 Grade Bs due to new/worse individual items in different organ systems at the same visit. Post hoc analyses included two alternative definitions of BILAG 2004 moderate flares that allowed for ≥2 BILAG 2004 Grade Bs due to new/worse individual items in different organ systems to occur across either: (1) up to 2 consecutive visits and (2) up to 3 consecutive visits, all visits 4 wks apart (**Figure 1**).

Table. Baseline demographics and disease characteristics

	DZP+SOC n=208	PBO+SOC n=107
Age, years, mean (SD)	43.5 (12.3)	41.5 (12.4)
Female, n (%)	193 (92.8)	100 (93.5)
Time since first diagnosis of SLE, years, mean (SD)	10.1 (7.9)	9.8 (8.5)
SLEDAI-2K, mean (SD)	10.7 (3.5)	11.2 (3.4)
SLEDAI-2K ≥10, n (%)	140 (67.3)	79 (73.8)
BILAG 2004 total score, mean (SD)	18.4 (4.0)	18.7 (4.4)
Concomitant SLE medications at baseline, n (%)	208 (100.0)	107 (100.0)
Antimalarials	166 (79.8)	91 (85.0)
Systemic glucocorticoids	171 (82.2)	87 (81.3)
Immunosuppressants	129 (62.0)	70 (65.4)
Systemic glucocorticoid dose >7.5 mg/day, n (%)	105 (50.5)	51 (47.7)
Glucocorticoid dose, mg/day, mean (SD)	7.9 (5.9)	9.6 (8.1)

Full analysis set.
BILAG: British Isles Lupus Assessment Group; DZP: dapirolizumab pegol; PBO: placebo; SD: standard deviation; SLE: systemic lupus erythematosus; SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index-2K; SOC: standard of care.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Pre-specified and alternative definitions of BILAG 2004 moderate flares

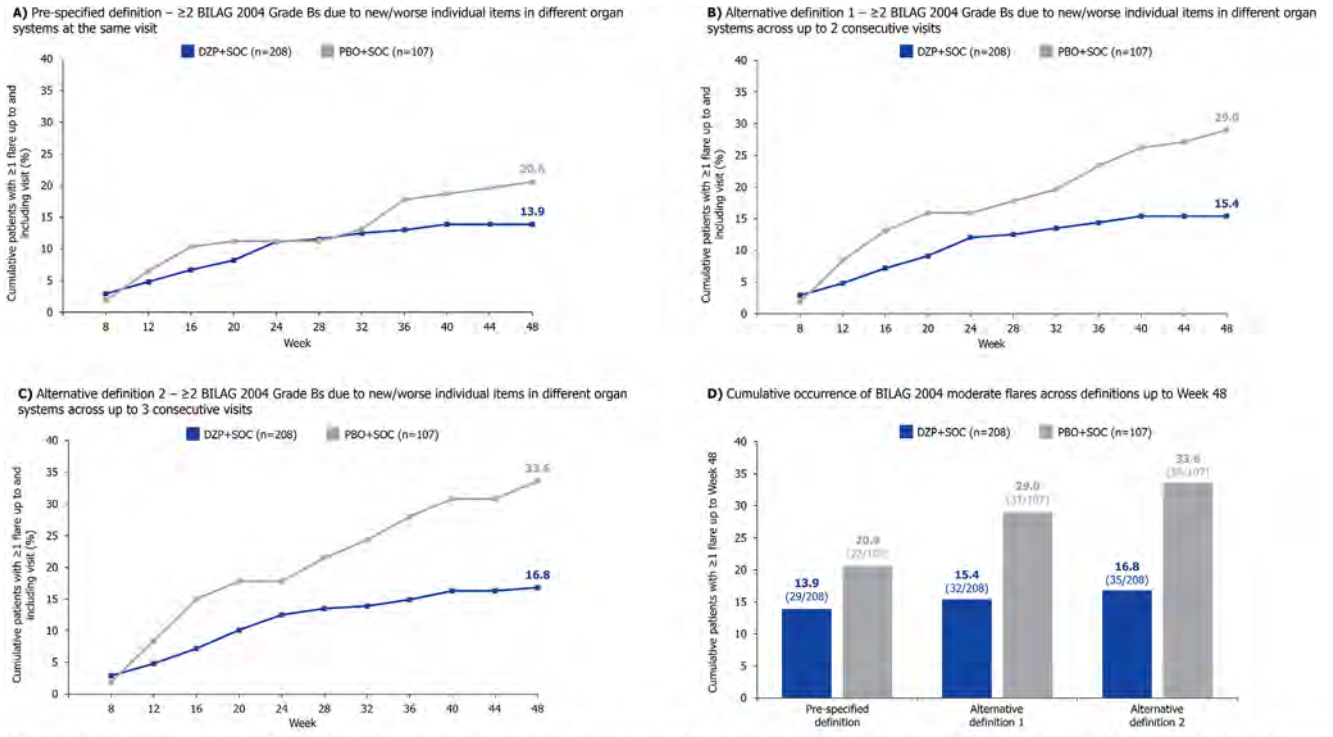
Results: Baseline characteristics are presented in the **Table**. At Wk 48, by the pre-specified definition, 13.9% (29/208) vs 20.6% (22/107) of pts receiving DZP+SOC vs PBO+SOC, respectively, had BILAG 2004 moderate flares. By alternative definition 1, BILAG 2004 moderate flares occurred in 15.4% (32/208) vs 29.0% (31/107) of pts receiving DZP+SOC vs PBO +SOC, respectively. By alternative definition 2, BILAG 2004 moderate flares occurred in 16.8% (35/208) vs 33.6% (36/107) of pts receiving DZP+SOC vs PBO+SOC, respectively (**Figure 2**). Time to BILAG 2004 moderate/severe flares through Wk 48 was shorter for pts receiving DZP+SOC vs PBO+SOC by all definitions.

Conclusion: Pts treated with DZP+SOC had fewer BILAG 2004 moderate flares, by all definitions considered, vs those treated with PBO+SOC. When allowing for longer time intervals over consecutive visits to evaluate moderate flares with the alternative definitions, greater rates of BILAG 2004 moderate flares were observed, particularly for pts receiving PBO +SOC, and greater differentiation between DZP+SOC and PBO+SOC was also observed. These results confirm a need to re-evaluate how flares are captured in SLE clinical trials; the alternative definitions of flares explored may better simulate clinical practice than the native definition of BILAG 2004 moderate flares.



Full analysis set; OC. A composite strategy was used for Escape Treatment Intervention 2, where missing data were counted as a severe flare at the time point of the intercurrent event, even if the event was after permanent discontinuation of study medication, as long as the event was ≤5 weeks after the last infusion. A composite strategy was used for Escape Treatment Intervention 3, where missing data were counted as a moderate flare. A treatment policy strategy was used for Escape Treatment Intervention 1, where data observed after the intercurrent event were considered for the analysis. A hypothetical strategy was used for permanent discontinuation of study drug or premature withdrawal from study, where data values >5 weeks after the last infusion were set to missing.
BILAG 2004: British Isles Lupus Assessment Group 2004; DZP: dapirolizumab pegol; OC: observed case; PBO: placebo; SOC: standard of care.

Figure 2. Cumulative occurrence of BILAG 2004 moderate flares across definitions

Low-Dose Aspirin Therapy in Patients with Type 2 Diabetes and Systemic Lupus Erythematosus: A Propensity-Matched Cohort Study

Sila Mateo Faxas[1], Godbless Ajenaghughrure[2], Kim Nguyen[3], Nirys Mateo Faxas[4], Gurjot Singh[3], Nicole Tejeda[5] and Kimberly Ramirez Bonetti[6], [1]Good Samaritan Hospital, Cincinnati, OH, [2]Trihealth Good Samaritan Hospital, Cincinnati, OH, [3]Trihealth Good Samaritan Hospital, Cincinnati, [4]Independent Author, Santo Domingo, Dominican Republic, [5]Independent Author, Cincinnati, [6]Independent Author, cincinnati, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with both Type 2 diabetes mellitus (T2DM) and systemic lupus erythematosus (SLE) face an increased risk of cardiovascular complications due to the compounding effects of both conditions. While low-dose aspirin is commonly prescribed for cardioprotection, its specific benefits in this dual-diagnosis population remain unclear. This study aimed to evaluate the impact of low-dose aspirin (81mg) on cardiovascular and other clinical outcomes in patients with both T2DM and SLE.

Methods: Using the TriNetX global federated health research network encompassing 101 healthcare organizations, we conducted a retrospective propensity score-matched cohort study of adults (18-99 years) with both T2DM and SLE diagnoses. Patients were divided into cohorts receiving low-dose aspirin (81mg) (n=14,221) or no aspirin (n=14,221). Propensity score matching was performed to balance demographics and comorbidities between groups. Primary outcomes included mortality, cardiac arrest, cardiovascular events, and other complications measured during a 365-day follow-up period after index date. Hazard ratios (HR) and 95% confidence intervals were calculated using survival analysis.

Results: After propensity score matching, patients receiving low-dose aspirin had significantly lower rates of all-cause mortality (HR 1.471, 95% CI 1.330-1.626, p< 0.001), cardiac arrest (HR 2.369, 95% CI 1.884-2.979, p< 0.001), sepsis (HR 1.748, 95% CI 1.601-1.909, p< 0.001), acute kidney failure (HR 1.767, 95% CI 1.660-1.880, p< 0.001), and atrial fibrillation (HR 1.836, 95% CI 1.697-1.986, p< 0.001) compared to non-aspirin users. The aspirin group also showed lower incidence of cerebral infarction (HR, 1.838, 95% CI 1.591-2.123, p< 0.001), ventricular tachycardia (HR 2.163, 95% CI

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

1.808-2.587, p< 0.001), and heart failure (HR 1.713, 95% CI 1.583-1.852, p< 0.001). Notably, aspirin users had significantly lower rates of hypoglycemic events (HR 1.992, 95% CI 1.612-2.462, p< 0.001).

Conclusion: In patients with both T2DM and SLE, low-dose aspirin therapy was associated with significantly reduced risk of mortality and major cardiovascular complications. The protective effect extended to renal outcomes and hypoglycemic events. These findings support the use of low-dose aspirin as part of comprehensive cardiovascular risk management in this high-risk population. Future prospective trials are needed to confirm these observations and optimize therapeutic strategies.

Voclosporin in Lupus Nephritis: Meta-Analysis of 6-Month and 1-Year Efficacy with 1-Year Safety Outcomes

Sri Laxmi Priya Sunkara[1], Ravi Medarametla[2], Megha Kotha[3] and Wael Jarjour[4], [1]White river medical center, batesville, AR, [2]Mamata Medical College, Guntur, Andhra Pradesh, India, [3]Ohio State University, Columbus, OH, [4]The Ohio State University, Columbus, OH

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN), is the most sever organ manifestation of systemic lupus erythematosus (SLE) and it contributes significantly to morbidity and mortality. . Standard therapies—high-dose corticosteroids combined with mycophenolate mofetil or cyclophosphamide—achieve complete renal remission in a limited subset of patients and carry substantial toxicity. Calcineurin inhibitors (CNIs) target immune dysregulation and podocyte injury. Voclosporin, a novel CNI, inhibits T-cell activation and reduces proteinuria, offering potential therapeutic benefit in LN.

Figure 1a: Complete Renal Response at 6 Months

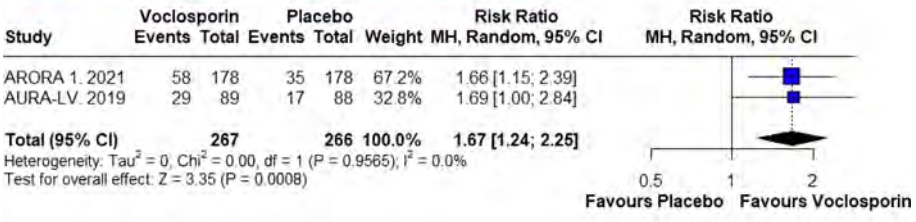

Figure 1b: Complete Renal Response at 1 Year

Methods: A systematic search of PubMed, Embase, and Cochrane databases was conducted for English-language studies evaluating voclosporin in LN and reporting relevant efficacy or safety outcomes. Two randomized controlled trials met inclusion criteria. Data were pooled using inverse variance weighting with a random-effects model in R Studio. Forest plots were used to illustrate pooled effect estimates, and heterogeneity was assessed.

Results: A total of 533 patients from two studies were included. Voclosporin significantly increased complete renal response (CRR) at 6 months (RR 1.67; 95% CI: 1.24–2.25; p=0.0008) and 1 year (RR 1.91; 95% CI: 1.48–2.48; p< 0.0001) compared to placebo. Rates of overall adverse events (RR 1.04; 95% CI: 0.98–1.10; p=0.16), serious adverse events (RR 1.26; 95% CI: 0.71–2.25; p=0.43), and infections (RR 1.15; 95% CI: 0.98–1.36; p=0.096) were similar between groups. However, voclosporin was associated with significantly higher gastrointestinal (RR 1.37; 95% CI: 1.06–1.76; p=0.016) and neurological adverse events (RR 1.79; 95% CI: 1.18–2.72; p=0.006) at 1 year.

Conclusion: Voclosporin significantly improves CRR at 6 months and 1 year in patients with LN, with an overall safety profile comparable to placebo. However, gastrointestinal and neurological adverse events were more common. Further studies are needed to assess long-term outcomes, define steroid-sparing protocols, optimize dosing, and evaluate efficacy across diverse populations to determine voclosporin's definitive role in LN treatment.

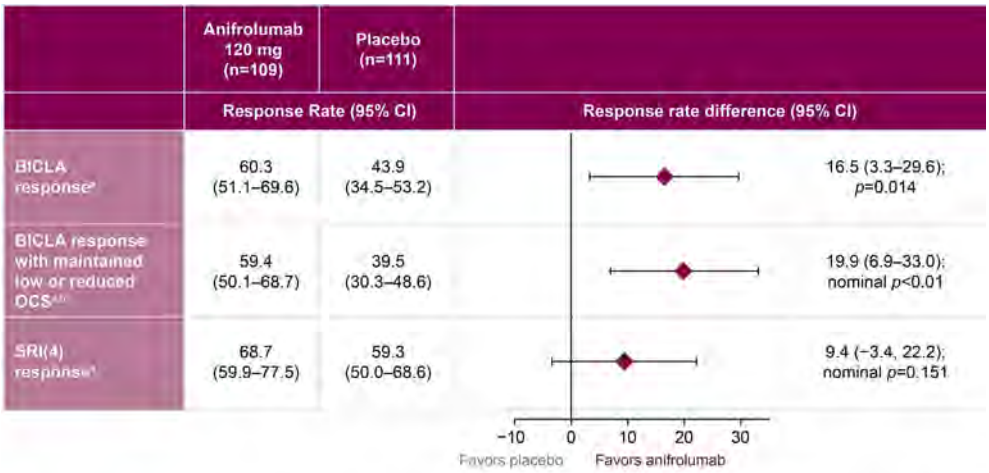
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Intravenous (IV) anifrolumab (300 mg, every 4 weeks [Q4W]) is an approved biologic add-on therapy for moderate to severe SLE;[1] a subcutaneous (SC) formulation may allow for greater personalization of treatment. Here, we report interim results from a global phase 3 study evaluating the efficacy and safety of SC anifrolumab in patients with moderate to severe SLE.

Methods: In TULIP-SC (NCT04877691), eligible adult patients with SLE (revised 1997 ACR criteria) were randomized 1:1 to receive weekly (QW) anifrolumab 120 mg SC or placebo plus standard therapy during a 52-week double-blind treatment period. This pre-planned interim analysis (IA) of 346 patients was conducted once 220 patients completed the double-blind treatment period or discontinued.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



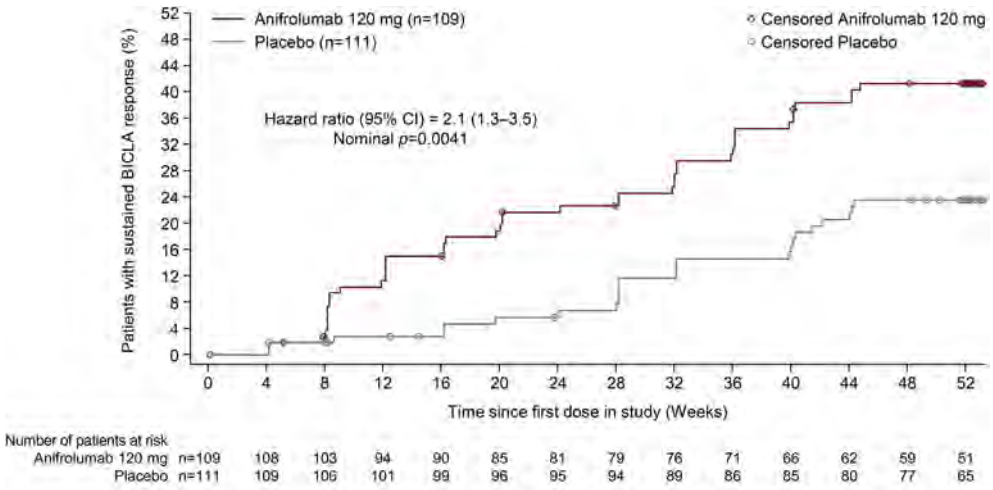
[a]The responder rates (percentages) were estimated using stratified CMH, adjusting for the stratification factors; [b]Maintained low or reduced OCS use through Week 52 is defined as follows: if baseline OCS ≥10 mg/day, an OCS dose of ≤7.5 mg/day prednisone or equivalent must be achieved by Week 40 and maintained from Week 40 to Week 52; if baseline OCS <10 mg/day, an OCS dose at Week 40 must be ≤ the OCS dose at baseline and maintained from Week 40 to Week 52.

Only patients with non-missing covariates/stratification factors were included in the interim analyses. Stratification factor levels = baseline IFNGS-high and SLEDAI <10 points, baseline IFNGS-high and SLEDAI ≥10 points, and baseline IFNGS-low.

BICLA, BILAG-based Composite Lupus Assessment; CI, confidence interval; CMH, Cochran-Mantel–Haenszel; IFNGS, type I interferon gene signature status; MAR, missing at random; OCS, oral corticosteroids; SRI, SLE Responder Index; TULIP, Treatment of Uncontrolled Lupus via the Interferon Pathway.

Figure 1: Interim efficacy results at Week 52 of the phase 3 TULIP-SC trial of weekly subcutaneous anifrolumab alongside standard therapy

Efficacy was assessed in the IA set (n=220); the safety set included all randomized patients who received ≥1 dose at time of IA data cut-off (n=346). The difference between groups in the proportions of BILAG-based Composite Lupus Assessment (BICLA) responders (primary endpoint; stratified Cochran-Mantel–Haenszel approach) was assessed at Week 52. Key secondary endpoints (proportions of BICLA responders whose oral corticosteroid [OCS] dose from Week 40 through Week 52 was ≤7.5 mg/day if baseline [BL] was ≥10 mg/day or ≤BL if BL was < 10 mg/day, time to first BICLA response sustained to Week 52, and time to first flare) and the proportion of patients achieving SLE Responder Index response (SRI[4]) at Week 52 were also assessed.



Kaplan-Meier estimate with 95% CI for each treatment group. Hazard ratios and 95% CIs were estimated using a Cox regression model with treatment groups and stratification factors.

BICLA, BILAG-based Composite Lupus Assessment; CI, confidence interval; SC, subcutaneous; TULIP, Treatment of Uncontrolled Lupus via the Interferon Pathway.

Figure 2: Time to first BICLA response sustained up to, and including, Week 52 during the phase 3 TULIP-SC trial of weekly subcutaneous anifrolumab alongside standard therapy

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Baseline demographics and key clinical characteristics were balanced between groups (anifrolumab: n=109, mean [standard deviation] age=43.0 [12.4] years, SLEDAI-2K score=11.3 [3.8]; placebo n=111, mean age=42.3 [11.4] years, SLEDAI-2K score=10.5 [2.9]), with similar discontinuation (21.1% vs 21.6%).

The primary endpoint was met: 60.3% vs 43.9% of patients achieved a BICLA response at Week 52 with anifrolumab vs placebo, respectively (**Figure 1**; difference [95% CI]=16.5% [3.3–29.6%]; p=0.014). At Week 52, the proportion of BICLA responders who met the OCS dosing criteria, and the proportion achieving SRI(4) were numerically greater with anifrolumab vs placebo (**Figure 1**). Patients receiving anifrolumab vs placebo were around twice as likely to achieve a BICLA response sustained through Week 52 (**Figure 2**). The risk of flare over 52 weeks with anifrolumab vs placebo was numerically lower (HR [95% CI]=0.69 [0.4–1.1]; nominal p=0.093).

The incidence of adverse events (AEs) was 74.4% (131/176) vs 71.2% (121/170) with anifrolumab and placebo treatment, respectively; similar proportions of serious AEs (10.8% vs 8.8%) and serious infections (6.3% vs 3.5%) were reported. Injection site reactions (ISR) occurred in 15.3% vs 17.1% with anifrolumab and placebo treatment, respectively. Most AEs, including ISRs, were of mild to moderate intensity.

Conclusion: Treatment with anifrolumab 120 mg SC QW provided a statistically significant and clinically meaningful benefit in overall disease activity over standard therapy and was well tolerated; the efficacy and safety profile was consistent with the approved IV 300 mg anifrolumab treatment regimen.[1]

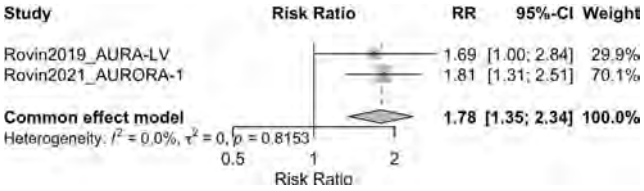
Forest plot for Tacrolimus trials



Forest plot Voclosporin trials

Background/Purpose: Lupus nephritis (LN) is seen in approximately 40–60 % of patients with systemic lupus erythematosus (SLE) and contributes significantly to morbidity and mortality in this population. The definitive diagnosis is made with a kidney biopsy, and disease severity is classified according to the International Society of Nephrology/Renal Pathology Society (ISN/RPS) system, which guides management. The approach to active class III and IV LN involves glucocorticoids and mycophenolate mofetil (MMF), with the addition of calcineurin inhibitors (CNIs) based on patient characteristics. CNIs exert potent immunosuppressive effects by blocking T-lymphocyte activation and inhibiting the production of interleukin-2 and have traditionally been used as immunosuppression in renal transplantation. Through this meta-analysis, we aim to compare the use of the CNIs tacrolimus (TAC) and Voclosporin (VOC) in active LN.

Methods: A comprehensive review of PubMed, Scopus, and the Cochrane Library was performed to locate relevant clinical trials. Five randomized controlled trials (n = 1 311) met inclusion criteria. Three trials compared TAC with conventional induction regimens (cyclophosphamide or MMF; n = 777). Two placebo-controlled trials evaluated VOC on an MMF/low-dose-steroid background (n = 534). Pooled risk ratios (RRs) were determined using Mantel–Haenszel common-effect and random-effects models. Heterogeneity among studies was evaluated with I^2 and τ^2 metrics. An indirect Bucher comparison was conducted to analyze differences between TAC and VOC. A p-value < 0.05 was considered statistically significant.

Results: We evaluated five studies in total with the network meta-analysis framework. TAC was associated with a significant increase in complete/partial renal response (RR = 1.41; 95 % CI 1.20–1.66; p < 0.0001), although substantial heterogeneity was present (I^2 = 72.8 %, τ^2 = 0.054). A random-effects synthesis attenuated the estimate (RR = 1.36; 95 % CI 1.00–1.86; p = 0.048). VOC significantly improved renal response (common-effect RR = 1.78; 95 % CI 1.35–2.34; p < 0.0001) with no observed between-study heterogeneity (I^2 = 0 %). An indirect Bucher comparison of pooled random-effects estimates showed no statistically significant difference between TAC and VOC (log RR = –0.23; SE = 0.164); the corresponding RR was 0.79 (95 % CI 0.58–1.09).

Conclusion: Based on this meta-analysis, both calcineurin inhibitors improve short-term renal response in active lupus nephritis when added to standard care. Voclosporin shows a larger and more consistent benefit across trials (RR 1.78), whereas tacrolimus exhibits greater between-study variability. Nevertheless, the indirect Bucher comparison does not establish the clear superiority of either drug. These findings highlight the need for additional studies that directly compare calcineurin inhibitors, with particular emphasis on their relative efficacy, safety, and patient adherence.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus Nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE), occurring in up to 50% of patients. Currently, Anifrolumab (ANI) is approved for moderate-to-severe SLE, based on clinical trials excluding active LN **(1,2)**. In LN, an elevated type I IFN gene signature (IFNGS) is associated with increased disease activity, high proteinuria levels, and therapeutic failure **(3)**.

In patients with LN treated with ANI in clinical practice in Spain, our aim was to assess the effectiveness and safety of ANI.

Methods: Observational multicenter study of patients diagnosed with SLE (EULAR/ACR 2019 classification criteria), treated with ANI who presented renal involvement (renal insufficiency and/or hematuria and/or proteinuria). Data were collected from medical records up to January 31 2025. Demographic, clinical, laboratory, and pathologic variables were evaluated, along with previous and concomitant therapies, disease activity indices (SLE-DAS, SLEDAI-2K, PGA), organ damage index (SLICC SDI), and safety.

Results: We studied 18 patients (16 women/2 men), mean age of 38.16±10.35 years (range 20-63 years), from 14 hospitals. Baseline characteristics, prior treatment before starting ANI and LN subtypes are summarized in TABLE. The most common renal manifestations at ANI initiation were proteinuria (n=9, 50%), hematuria (n=5; 27.8%), and renal insufficiency (n=2; 11.1%).

The mean number of immunosuppressive treatments (synthetic/biologic) received prior to ANI was 4.3 ± 2.4 (range 1-12). All of them had received belimumab, and 15 mycophenolate mofetil. The standard ANI regimen was 300 mg every 4 weeks, except in two patients who received loading doses (900 mg/4 weeks for 3 months, then 300 mg/4 weeks).

In addition to corticosteroids, ANI was administered concomitantly with antimalarials (n=16), mycophenolate mofetil (n=11), tacrolimus (n=4), azathioprine (n=2), methotrexate (n=1), and voclosporin (n=1). A rapid (from the first month) and maintained significant improvement was observed in: a) disease activity (SLE-DAS, SLEDAI-2K, PGA) (Figure 1) b) immunologic markers

(decrease in anti-dsDNA antibody titers and normalization of C3 and C4 levels) c) renal parameters (reduction in creatinine, proteinuria and improvement in glomerular filtration rate) (Figure 2).

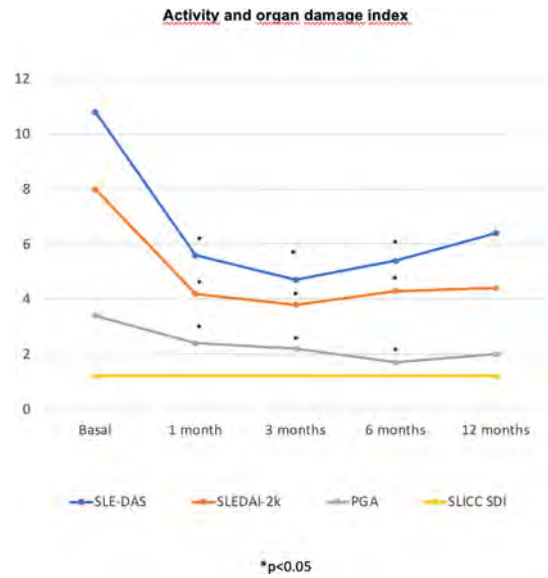

Figure 1. Evolution of activity and organ damage index after the initiation of anifrolumab.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

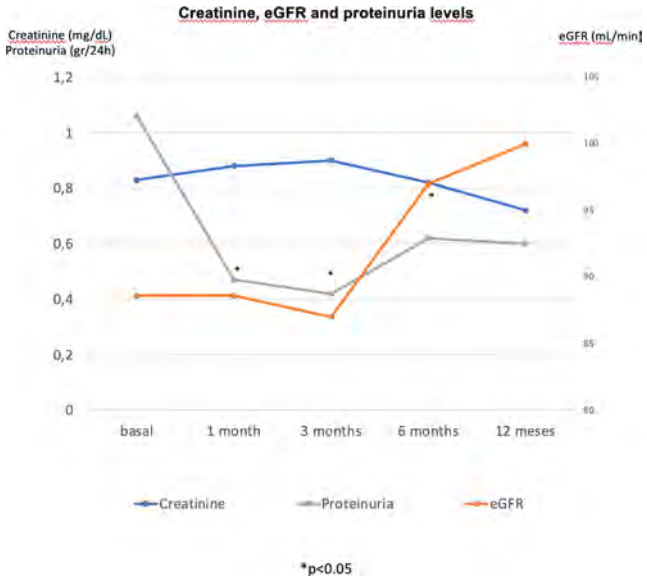

Figure 2. Evolution of creatinine levels, glomerular filtration rate and proteinuria (g/24h) after the initiation of anifrolumab.

After a mean follow-up of 8.8 ± 5.5 months, a reduction in the number of relapses was observed, from a median [IQR] of 2 [0-3] to 0 [0-0]. The organ damage index remained stable. All 18 patients remained on ANI, and the most relevant adverse events were herpes zoster (n=1) and hidradenitis suppurativa (n=1). The prednisone dose was decreased from 9.2±7.9 mg/day to 3.3±2 mg/day (p= 0.1).

Conclusion: To our knowledge, this is the first real-life study of ANI in LN. In refractory patients to multiple immunosuppressive therapies, we observed a rapid and maintained effectiveness in SLE activity and renal manifestations, with a good safety profile. These preliminary data should be confirmed in clinical trials.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Anifrolumab (ANI) is a human monoclonal antibody that binds to the type I interferon receptor subunit 1 (IFNAR1). ANI was approved by Spanish authorities for the treatment of adults with moderate to severe systemic lupus erythematosus (SLE) with positive autoantibodies, in combination with standard treatment.

In patients with SLE treated with ANI in clinical practice in Spain, our aim was to assess a) the profile of patients receiving ANI b) effectiveness and c) safety.

Methods: Observational multicenter study of patients diagnosed with SLE (EULAR/ACR 2019 classification criteria) treated with ANI. Data were collected from medical records up to April 31st 2025. Demographic, clinical, laboratory, and pathologic variables were evaluated, along with previous and concomitant therapies, disease activity indices (SLE-DAS, SLEDAI-2K, PGA), organ damage index (SDI), and safety were evaluated.

Table. Clinical manifestations and treatments received before starting anifrolumab Abbreviations in alphabetical order: ANI: anifrolumab; AZA: azathioprine; BLM: belimumab; CsA: cyclosporine; CYM: cyclophosphamide; MMF: mycophenolate mofetil; MP: methylprednisolone; MTX: Methotrexate; RTX: rituximab

Clinical manifestations at ANI initiation	N (%)
articular	180 (87.8%)
cutaneous	163 (79.1%)
hematological	132 (65%)
oral ulcers	98 (47.8%)
alopecia	90 (43.7%)
renal	57 (27.8%)
serositis	45 (21.8%)
neuropsychiatric	28 (13.6%)
digestive	17 (8.3%)
Therapy before ANI	
antimalarials	198 (97%)
BLM	137 (66.9%)
MMF	84 (41.4%)
AZA	84 (41.4%)
MP boluses	62 (30.4%)
RTX	59 (29.1%)
MTX	59 (29.1%)
CYM	30 (14.8%)
tacrolimus	19 (9.3%)
Concomitant therapy with ANI	
oral steroids	167 (82.3%)
antimalarials	158 (80.2%)
MMF	49 (24.6%)
MTX	34 (17%)
AZA	22 (11%)
tacrolimus	8 (4%)
RTX	7 (3.5%)
leflunomide	3 (2.6%)
sulfones	2 (1.4%)
CYM	1 (0.5%)
anakinra	1 (0.5%)

Results: 206 patients (183 females/23 males), mean age 44.6 ± 12.6 years (range 15-90 years) (54 hospitals) were included. Baseline characteristics of patients and prior treatment before starting ANI are summarized in TABLE.

The main reason for starting ANI was clinical activity: cutaneous (n=124, 61.7%), articular (n=98, 48.5%), hematological (n=55, 27.2%), corticosteroid dependence (n=11, 5.4%), renal (n=8, 4%), serositis (n=6, 3%), serious adverse events with other immunosuppressants (n=4, 1.9%), neurological (n=2, 1%), and Kikuchi disease (n=1, 0.5%).

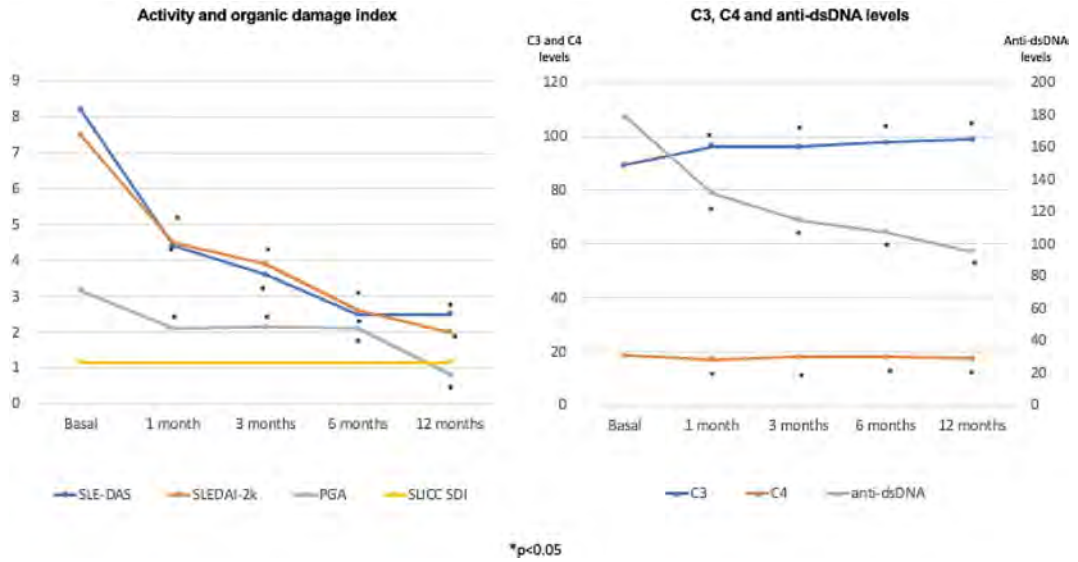

Figure 1. Evolution of C3, C4 and anti-dsDNA levels and activity and organ damage indices after starting anifrolumab.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

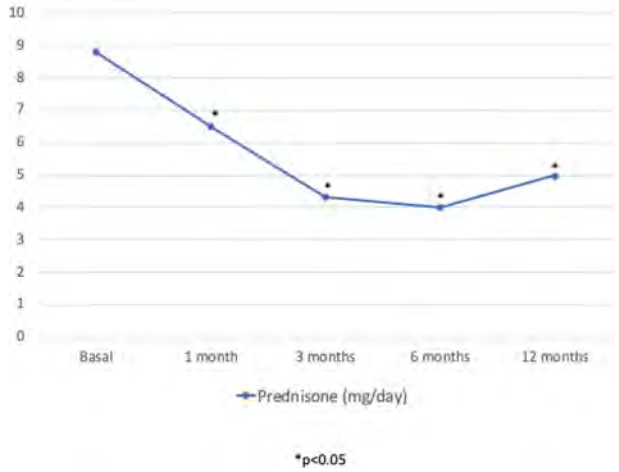

Figure 2. Reduction in prednisone dosage after initiation of anifrolumab.

The mean number of immunosuppressants (synthetic/biologic) received prior to ANI was 2.5±1.6 (range 0-8). All patients received 300 mg/4 weeks of ANI except two patients with renal involvement who received a loading dose (900 mg/4 weeks x3 months followed by 300 mg/4 weeks). In addition to corticosteroids and antimalarials, ANI was administered in many cases concomitantly with other immunomodulator drug (TABLE).

A rapid (from the 1st month) and maintained significant improvement was observed in: a) disease activity (SLE-DAS, SLEDAI-2K, PGA) (Figure 1) b) immunologic markers (decrease in anti-dsDNA antibody titers and normalization of C3 and C4 levels) (Figure 1) and c) prednisone dose (**Figure 2**). The organ damage index remained stable.

After a mean follow-up of 7.5 ± 5.3 months, a reduction in the number of relapses was observed, from a median [IQR] of 2 [1-6] prior ANI to 0 [0-0] after ANI ($p < 0.001$). The most relevant adverse events were: herpes zoster (n=5), headache (n=3), upper respiratory tract infection (n=3), pneumonia (n=3), arterial hypotension (n=2), hidradenitis suppurativa (n=2) and vaginal candidiasis (n=2). In the follow-up, 20 patients discontinued treatment due to primary failure (n=8), secondary failure (n=3), severe infections (n=6), hypotension (n=1), acute anterior uveitis (n=1), and pregnancy desire (n=1).

Conclusion: As in clinical trials, a rapid and maintained effectiveness was observed; even in severe and refractory patients. ANI was used in monotherapy or combined with other immunosuppressive drugs, including other biological therapies. The safety profile was acceptable with the limitation of short follow-up.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Inflammatory arthritis is a cardinal manifestation of systemic lupus erythematosus (SLE), limiting joint mobility and adversely affecting quality of life.[1] Joint activity in SLE can be quantified using Tender Joint Counts and Swollen Joint Counts, providing concrete data for the evaluation of treatment effectiveness.[2] Clinical trials have shown reductions in swollen and tender joint counts in patients treated with the type I interferon inhibitor anifrolumab, compared to placebo.[3] In this study, we assess changes in inflammatory arthritis before and after anifrolumab initiation among adults with SLE receiving treatment in real-world settings.

TABLE 2: Joint Activity within the Study Population

	Patients assessed	Swollen Joint Assessment			Tender Joint Assessment		
Period	N	Patients with inflammatory arthritis, N (%)	Mean number of active joints	SD	Patients with inflammatory arthritis, N (%)	Mean number of active joints	SD
Baseline	54	29 (54%)	2.9	4.2	37 (69%)	6.5	7.3
Period 1	54	25 (46%)	2.4	3.9	33 (61%)	5.0	6.3
Period 2	54	22 (41%)	2.2	3.9	30 (56%)	3.7	5.2

Baseline: 0-6 months pre-index; Period 1: 0-6 months post-index; Period 2: >6-12 months post-index.
Inflammatory arthritis: joint count ≥1.

TABLE 3: Joint Activity among Patients with Inflammatory Arthritis at Baseline

	Swollen Joint Assessment				Tender Joint Assessment			
	Patients with inflammatory arthritis		Number of active joints		Patients with inflammatory arthritis		Number of active joints	
	N	%	Mean	SD	N	%	Mean	SD
Baseline	29	100%	5.4	4.5	37	100%	9.5	7.1
Period 1	23	79%	4.3	4.5	32	86%	6.7	6.1
Period 2	19	66%	4.0	4.6	27	73%	5.2	5.7

Baseline: 0-6 months pre-index; Period 1: 0-6 months post-index; Period 2: >6-12 months post-index.
Inflammatory arthritis: joint count ≥1.

Methods: This retrospective, observational cohort study included data from adult patients with SLE in the American Rheumatology Network initiating anifrolumab (index date) from August 2, 2021 to May 31, 2023. Eligible patients adhered to anifrolumab, defined as having 6 or more infusions in a 12-month period. Tender and Swollen Joint Counts (28 joints) were captured during 6-month intervals: 6 months pre-index (baseline); 0-6 months post-index (follow-up Period 1); >6-12 months post-index (follow-up Period 2). All patients were required to have at least one joint count assessment performed in each of the 6-month intervals, with the result closest to the end of each interval being assessed. Inflammatory arthritis (joint activity) was defined as having Tender Joint Counts or Swollen Joint Counts ≥1.

Results: Of the 54 included participants, 94% were female and 44% white [TABLE 1]. The median age was 53 years (IQR 44-61). A declining number of patients had swollen joints (Baseline: 54%; Period 1: 46%; Period 2: 41%) and joint tenderness (Baseline: 69%; Period 1: 61%; Period 2: 56%) during the first year of anifrolumab therapy [TABLE 2]. Joint tenderness (37/54) occurred more frequently than joint swelling (29/54) at baseline [TABLE 3]. In patients experiencing joint swelling prior to initiation of anifrolumab, the mean (SD) number of swollen joints progressively decreased from 9.5 (7.1) joints per patient in the Baseline period to 5.2 (5.7) in Period 2. Similarly, in patients with joint tenderness at baseline, the mean (SD) number of tender joints decreased from 5.4 (4.5) to 4.0 (4.6) joints per patient [TABLE 3]. After at least six months of receiving anifrolumab treatment, 34% (10/29) of patients with joint swelling and 27% (10/37) of those with joint tenderness at baseline had no joint activity.

Conclusion: In this real-world cohort, patients with SLE on anifrolumab therapy had marked improvement, with reductions in both swollen and tender joints observed within six months of treatment initiation. After at least six months of receiving anifrolumab treatment, approximately one-third of patients with active inflammatory arthritis became asymptomatic. These findings contribute to the growing body of evidence supporting improvement of inflammatory arthritis with anifrolumab therapy.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II

Session Type: Poster Session B

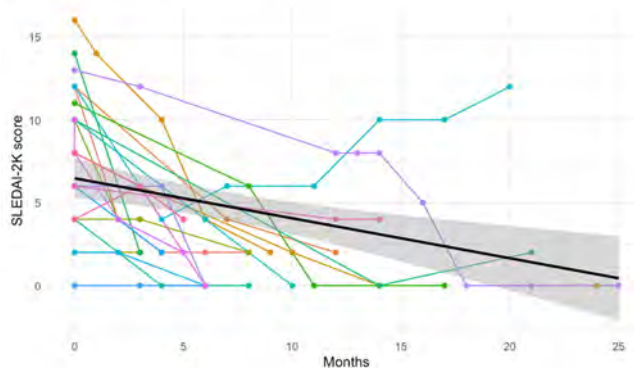
Session Time: 10:30AM–12:30PM

Background/Purpose: Anifrolumab (ANI) is a human monoclonal antibody targeting the type I interferon receptor subunit 1 (IFNAR1), blocking interferon activity and reducing disease activity in systemic lupus erythematosus (SLE). Real-world evidence is essential to understand its use and outcomes. This study aimed to describe the clinical profiles of SLE patients treated with anifrolumab for ≥3 months at the Toronto Lupus Program and to assess its efficacy and safety.

Methods: We included patients from the University of Toronto Lupus Cohort who met the 2019 EULAR/ACR classification criteria and had received anifrolumab for ≥3 months. Demographics, clinical and lab data, prior and concomitant therapies, and disease activity indices (SLEDAI-2K, CLASI, and PGA) were recorded at baseline and during follow-up. Time to symptom resolution, prednisone dose, infections, and treatment discontinuation were also assessed.

Results: Twenty-three patients (73.9% female) with a mean age of 40.4 years and mean SLE duration of 12.7 years were included. Cumulative organ involvement at anifrolumab initiation included mucocutaneous (100%), musculoskeletal (73.9%), serositis (34.8%), hematologic (34.8%), renal (30.4%), neuropsychiatric (21.7%), and persistent fever (8.7%).

Figure 1
SLEDAI-2K Scores Over Time.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The main reasons for initiating anifrolumab included skin rash (n = 20, 87.0%), musculoskeletal involvement (n = 15, 65.2%), alopecia (n = 8, 34.8%), along with the presence of concomitant hematological involvement (leukopenia) and shrinking lung syndrome. Mean follow-up was 8.4 months.

All patients were on prednisone at initiation; 82.6% were also on hydroxychloroquine. Concomitant immunosuppressives included mycophenolate (47.8%), methotrexate (17.4%), or both (4.3%). Prednisone decreased from 13.2 mg/day to 4.0 mg/day, and 69.6% discontinued it. Immunosuppressives were reduced or stopped in 52.2%. SLEDAI-2K scores decreased significantly over time (Figure 1). Median time to rash resolution was 57 days; full symptom resolution occurred in a median of 131 days.

Anifrolumab was discontinued in two patients: one after 20 months to start another biologic for lupus nephritis, and one due to refractory molluscum contagiosum after 14 months. No additional adverse events were reported.

Anifrolumab demonstrated significant effectiveness in reducing disease activity and corticosteroid use in SLE, with a favorable safety profile.

Conclusion: Anifrolumab demonstrated significant effectiveness in reducing disease activity and corticosteroid use in SLE, with a favorable safety profile.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: As new treatment options for systemic lupus erythematosus (SLE) become available, understanding patient burden and preferences is key to optimizing shared decision-making. This study evaluated patient burden and physician/patient treatment preferences through a global real-world survey.

Methods: Data were drawn from the 2024 Adelphi Lupus Disease Specific Programme™, a cross-sectional survey with retrospective data collection of rheumatologists and their patients with SLE in Germany, Italy, Spain and the US from Jul 2024 – Jan 2025; physicians provided data for their next 6 consulting patients with SLE. Physicians reported patient demographics, clinical characteristics (including SLE Disease Activity Index [SLEDAI]), and treatment preferences. Patients self-reported

Abbreviations: FACIT – functional assessment of chronic illness therapy, IQR – interquartile range, IV – intravenous, SC – subcutaneous, SD – standard deviation, SLEDAI – systemic lupus erythematosus disease activity index

[1] Europe in this study is represented by Germany, Italy, and Spain.

treatment preferences for their SLE and quality of life via the Functional Assessment of Chronic Illness Therapy – Fatigue Scale (FACIT-Fatigue). Patients and physicians rated their preference for four treatment modes including an oral pill once or twice per day, self-administered subcutaneous (SC) injection every week, or intravenous [IV] injection every 4 weeks. All analyses were descriptive.

Results: Overall, 176 physicians across the US (n=71) and Europe (n=105) reported data for 1,194 patients of which 47% were from the US and 53% from Europe. Patients' mean (SD) age was 43.3 (13.7), 72% were White, 84% female, with a median (IQR) disease duration of 2.8 (1.1, 6.6) years **(Table 1)**. Most patients (54%) had moderate/severe disease activity as defined by a SLEDAI score >6. The most reported organs affected were musculoskeletal (64%), constitutional (57%) and mucocutaneous (56%). Joint tenderness (49%), fatigue (45%), and joint stiffness (31%) were the most prevalent symptoms; 61% of patients reported moderate or severe fatigue via FACIT-Fatigue. Current treatment with injectable biologics at data collection included 23% on belimumab, 7% on anifrolumab, and 4% on rituximab. Physician-reported reasons for initiation of patient's current treatment were overall efficacy (99%), safety (55%), treatment administration (39%), quality of life (38%), and cost (23%) **(Figure 1a)**. When asked to choose among the four administration modes, a once daily oral pill was most preferred by both patients and physicians: 60% of patients and 77% of physicians respectively **(Figure 1b, Figure 1c)**. An oral pill twice daily was the least preferred option by both patients and physicians, but following this option

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Physician and Patient Treatment Preferences for SLE across the US and Europe collected from the 2024 Adelphi Lupus Disease Specific Programme™

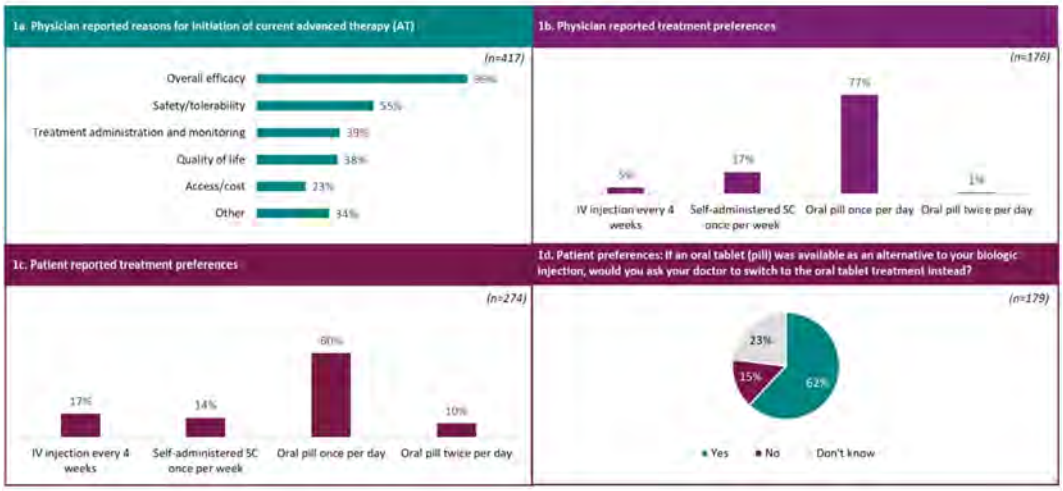

Figure 1a is derived from the physician reported patient sample, 1b is derived from the physician survey sample pertaining to physician perceptions and behaviors around SLE treatment and management, and figures 1c and 1d are derived from the patient reported sample.

there was some discordance with patients more likely to choose the every-4-week IV injection where physicians chose the weekly SC injection. There were 62% of patients who indicated they would ask their doctor to switch to an oral pill if one was available as an alternative to their biologic injection **(Figure 1d)**.

Conclusion: Despite the availability of injectable advanced treatments, patients with SLE continue to have a high disease burden. Overall efficacy, safety, and treatment administration were reported as key reasons for treatment choice by SLE treating physicians. A once-daily oral pill was the preferred route and frequency of administration by both physicians and patients. These findings may help optimize shared decision-making in SLE.

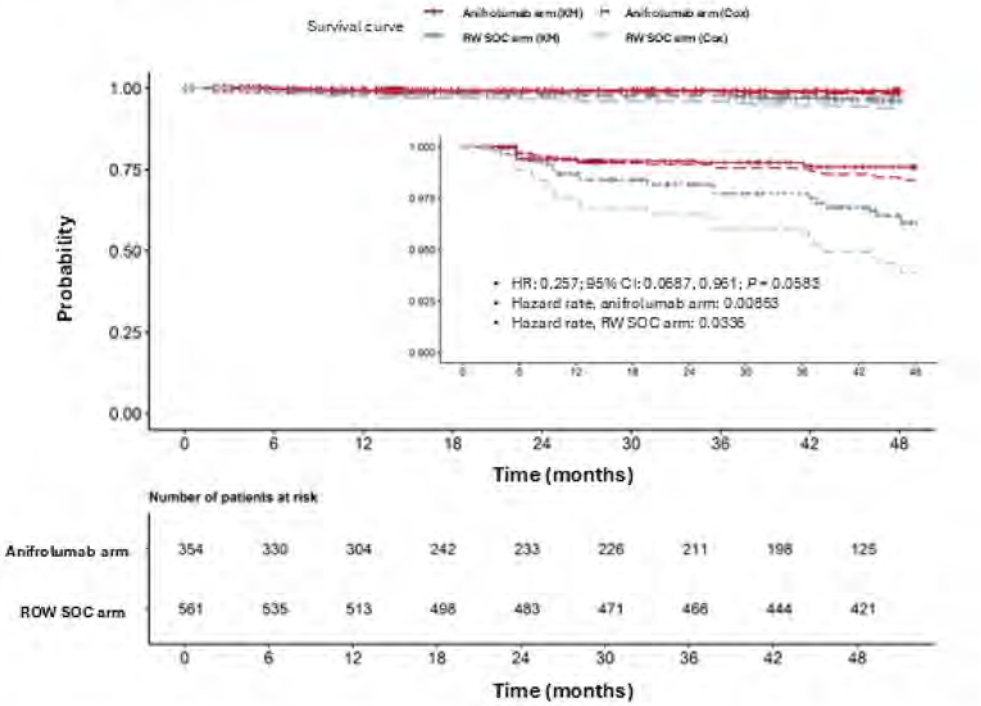
SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1517–1552) Systemic Lupus Erythematosus – Treatment Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) can develop cardiovascular (CV) damage (angina, myocardial infarction, ventricular dysfunction, valvular disease, or pericarditis for 6 months/pericardiectomy) particularly in patients with uncontrolled disease activity, flares, or under long-term glucocorticoid use. The Treatment of Uncontrolled Lupus via the Interferon Pathway (TULIP) trials and long-term extension (LTE) study demonstrated that anifrolumab can control disease activity and reduce the need for glucocorticoid use. However, evaluation of the long-term effects of anifrolumab on CV damage remains limited by patient attrition in the placebo arm and clinical trial duration. The purpose of this analysis—the Long-Term Organ Damage: Anifrolumab versus Real-World Standard of Care in Adult Patients with Active SLE (LASER; NCT06485674)—was to (1) assess the mean CV damage accrual at 4 years, and (2) estimate time to first CV event up to 4 years of therapy in adult patients with moderately to severely active SLE treated with anifrolumab or real-world standard of care (RW SOC).

Figure 1. Time to first cardiovascular event from the index date[a]



HR and hazard rates reported in **Figure 1** refer to the effect estimates by the Cox model, with the hazard rate in each arm averaged across the observed period. The Cox regression model for SMRW (untreated) + IPCW was further adjusted for SLEDAI score and proteinuria level at the index date, as these variables remained unbalanced after weighting (i.e., SMD >0.2).

[a]Restricted mean survival time, and minimum and maximum survival times, were derived while accounting for the combined SMRW + IPCW weights (i.e., the raw survival times were weighted). Hence, some extreme weighted values are beyond the 48 months of observed time.

HR, hazard ratio; **IPCW**, inverse probability of censoring weighting; **KM**, Kaplan–Meier; **RW SOC**, real-world standard of care; **SDI**, Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index; **SLEDAI**, Systemic Lupus Erythematosus Disease Activity Index; **SMD**, standardized mean difference; **SMRW**, standardized mortality ratio weighting.

Table 1. Change in cardiovascular SDI from baseline to year 4

Estimand	Type of regression analysis	Method	Parameter	TULIP cohort	UTLC cohort	Mean difference of change in SDI between groups	95% CI	Robust SE	P-value
Main analysis									
ATC	Linear regression[a]	SMRW (untreated) + IPCW[b]	N	354	561	−0.046	−0.074, −0.018	0.014	0.008
			Mean change in SDI	0.005	0.045				
			Robust SE	0.004	0.013				
			95% CI	−0.002, 0.013	0.021, 0.071				
Sensitivity analysis									
ATT	Linear regression	SMRW (untreated) + IPCW[c]	N	354	561	−0.063	−0.119, −0.007	0.029	0.001
			Mean change in SDI	0.013	0.076				
			Robust SE	0.009	0.027				
			95% CI	−0.005, 0.031	0.023, 0.129				
ATO	Linear regression	PSM[d]	N	110	110	−0.036	−0.096, 0.010	0.024	0.161
			Mean change in SDI	0.017	0.036				
			Robust SE	0.012	0.021				
			95% CI	−0.007, 0.041	0.014, 0.097				

To account for the impact of informative censoring, IPCW was utilized. Censoring weights were calculated from the ratio of stabilized censoring probability to censoring probability.

[a]The linear regression model for SMRW (untreated) + IPCW was further adjusted for SLEDAI score and proteinuria level at the index date, as these variables remained unbalanced after weighting (i.e., SMD > 0.2).

[b]Treatment weights were calculated using SMRW method, with the UTLC cohort as the target population (ATC) for the main analysis (SMRW [untreated] + IPCW).

[c]Treatment weights were calculated using SMRW method, with the TULIP cohort as the target population (ATT) for the sensitivity analysis (SMRW (treated) + IPCW).

[d]The PSM method was applied to estimate ATO in patients with ≥208 weeks of follow-up. Nearest-neighbor matching with replacement was applied to estimate propensity scores within a caliper value defined as 20% of the standard deviation for the distribution of the propensity score variable in the full sample.

ATC, average treatment effect in the control population; **ATO**, average treatment effect in the overlap population; **ATT**, average treatment effect in the treated population; **CI**, confidence interval; **IPCW**, inverse probability of censoring weighting; **PSM**, propensity score matching; **SDI**, Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index; **SE**, standard error; **SLEDAI**, Systemic Lupus Erythematosus Disease Activity Index; **SMD**, standardized mean difference; **SMRW**, standardized mortality ratio weighting; **TULIP**, Treatment of Uncontrolled Lupus via the Interferon Pathway; **UTLC**, University of Toronto Lupus Clinic.

Table 2. Description of time to first cardiovascular event from index date

Time	Parameters	TULIP[a]	UTLC[a]
Total	Number of patients	354	561
	Number of events	5	17
	Number of censored patients	348	544
	Restricted mean (SE)[b]	51.21 (146.18)	42.39 (15.57)
	Median	Not reached	Not reached
	Q1–Q3	N/A–N/A	N/A–N/A
	Minimum–Maximum[b]	0.0564–1888.99	0.0518–149.47
6 months	Number of patients	330	535
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	1.00 (0.99, 1.00)
12 months	Number of patients	304	513
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	0.99 (0.98, 1.00)
18 months	Number of patients	242	498
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	0.98 (0.97, 1.00)
24 months	Number of patients	233	483
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	0.98 (0.97, 0.99)
30 months	Number of patients	226	471
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	0.98 (0.96, 0.99)
36 months	Number of patients	211	456
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	0.98 (0.96, 0.99)
42 months	Number of patients	198	444
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	0.97 (0.96, 0.99)
48 months	Number of patients	125	421
	Probability[c] (95% CI)	0.99 (0.98, 1.00)	0.96 (0.95, 0.98)

[a]Administrative censoring at 4 years post-index was applied to both cohorts for comparability of follow-up periods.

[b]Restricted mean survival time, and minimum and maximum survival times, were derived while accounting for the combined SMRW + IPCW weights (i.e., the raw survival times were weighted). Hence, some extreme weighted values are beyond the 48 months of observed time.

[c]Kaplan–Meier estimates of survival probability were produced based on a weighted population using SMRW and IPCW (ATC estimand). The number of patients/events in the life table is reported as per observed data (i.e., without weighting applied).

ATC, average treatment effect in the control population; **CI**, confidence interval; **IPCW**, inverse probability of censoring weighting; **N/A**, not applicable; **Q**, quartile; **SE**, standard error; **SMRW**, standardized mortality ratio weighting; **TULIP**, Treatment of Uncontrolled Lupus via the Interferon Pathway; **UTLC**, University of Toronto Lupus Clinic.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This analysis used an external control arm of patients who received RW SOC from the University of Toronto Lupus Clinic (UTLC). Patients assigned to anifrolumab 300 mg in the TULIP-1 and -2 trials were included in the anifrolumab arm (n = 354). Patients from the UTLC registry (n = 561) with matching eligibility criteria comprised the RW SOC arm. Baseline confounding and possible informative loss to follow-up were accounted for using propensity scores (PS) and inverse probability censoring weights, respectively. Fourteen known predictors of CV damage were included in the PS models, and predictors that appeared imbalanced after PS weighting (e.g., standardized mean difference ≥ 0.2) were included as independent covariates in the outcome model. Mean changes in CV-related Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) from baseline to year 4 were estimated using weighted linear regression models in the average treatment effect in the control (ATC), treated (ATT), and overlap (ATO) groups. Time to first CV event up to 4 years was assessed using Kaplan–Meier estimators and a Cox proportional hazards regression model.

Results: Baseline patient characteristics were adequately balanced after PS weighting. Patients in the anifrolumab arm accrued (on average) 0.046 fewer CV SDI points (95% confidence interval [CI]: –0.074, –0.018; $P = 0.008$) at 4 years compared with patients in the RW SOC arm (**Table 1**). Results were consistent across ATC and ATT groups. A total of 6 patients in the anifrolumab arm vs 17 patients in the RW SOC arm experienced CV events (**Table 2**). Patients in the anifrolumab arm were 74.3% less likely to experience a CV event over 4 years compared to patients in the RW SOC arm (hazard ratio, 0.257; 95% CI: 0.0687, 0.961; $P = 0.0583$; **Figure 1**).

Conclusion: Patients who received anifrolumab in the TULIP trials and LTE accumulated less CV damage at 4 years compared with patients who received RW SOC in an external control arm. These results support the added benefit of anifrolumab to RW SOC in preventing long-term CV organ damage in patients with moderately to severely active SLE.

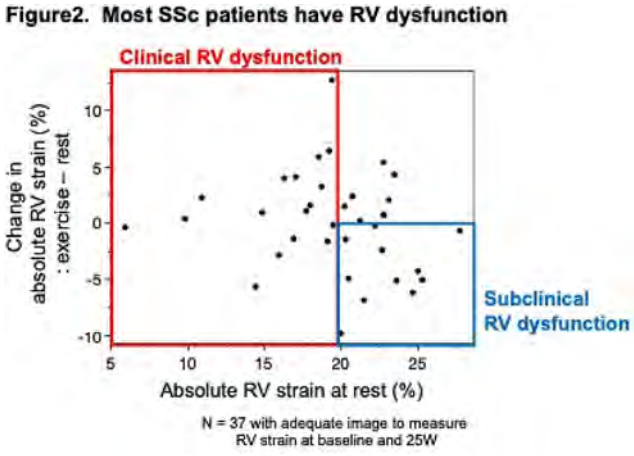
Background/Purpose: Pulmonary arterial hypertension associated with systemic sclerosis (SSc-PAH) is a life-threatening condition with obliterative pulmonary vascular remodeling, right ventricular (RV) dysfunction, and poor prognosis. Despite therapeutic advances, SSc-PAH remains a critical unmet clinical need due to its complex pathophysiology and lack of effective treatments. Chronic inflammation and immune dysregulation are believed to play a pivotal role in disease progression, but specific immune mechanisms remain poorly understood. Early detection of pulmonary hypertension (PH) and RV dysfunction is also a major challenge in clinical practice. To address this, we employed exercise echocardiography to unmask early RV dysfunction and PH and sought to elucidate the relationship between circulating immune subsets and PH and RV dysfunction severity in patients with SSc.

Methods: We prospectively enrolled 96 participants: 41 SSc-PH patients, 23 SSc-nonPH patients, 15 idiopathic PAH patients, and 17 age- and sex-matched controls. All participants underwent resting and exercise echocardiography, 6-minute walk test, electrocardiography, clinical assessments, and blood tests. We evaluated associations between immune cell subsets in peripheral blood and echocardiographic parameters of PH severity and RV function both at rest and during exercise, using univariate and multivariate linear regression models adjusted for age, sex, SSc subtype, and disease duration.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Immune cell subset distributions did not differ significantly among the groups. However, increased monocyte percentage in SSc patients was associated with greater RV end-diastolic area, higher tricuspid regurgitation velocity peak velocity (TRV)/RV outflow tract velocity time integral (RVOT-VTI) which is an echo estimate of total pulmonary resistance, and reduced tricuspid annular plane systolic excursion (TAPSE)/TRV ratio which is an indicator of worse RV-pulmonary arterial coupling (**Figure 1**). These associations remained significant after adjustment for covariates. Exercise echocardiography revealed that most SSc patients (81%) had RV dysfunction, including subclinical RV dysfunction (change in absolute RV strain from rest to exercise [ΔRV strain] < 0) or clinical RV dysfunction (absolute resting RV strain < 20%) (**Figure 2**). Notably, higher monocyte percentage was associated with worse RV contractile reserve (ΔRV strain from rest to 25W exercise): multivariable β = -1.71, 95% CI: -3.31 to -0.113, p = 0.037.

Conclusion: Increased levels of circulating monocytes are associated with greater PH severity and RV dysfunction in SSc. Dysregulation of the innate immune system potentially links cardiopulmonary dysfunction/remodeling in SSc.

Abstract Number: 1554

Demographic, Clinical, and Mortality Trends in Scleroderma Patients with Gastric Antral Vascular Ectasia (GAVE): A National Inpatient Analysis

Akanksha Sharma[1], Veera Durga Vaishnavi Kurra[2] and Neev Mehta[3], [1]UPMC Mercy hospital, Pittsburgh, PA, Pittsburgh, PA, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Lahey Hospital and Medical Center, Burlington, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Gastric antral vascular ectasia (GAVE), commonly known as "watermelon stomach," is a rare but potentially severe gastrointestinal manifestation in systemic sclerosis (SSc). Despite its known association with SSc, data regarding demographic patterns, comorbidity profiles, and inpatient mortality among this subset remain limited. This study aimed to analyze the factors associated with GAVE in hospitalized SSc patients, including age, sex, comorbidities, and mortality, using a national inpatient dataset.

Methods: A retrospective cohort study was conducted using an extensive national inpatient database to identify patients with scleroderma, stratifying them by the presence or absence of GAVE. Patient demographics, comorbidities, and inpatient mortality were compared using logistic regression and descriptive statistics. Odds ratios (ORs), standard errors, 95% confidence intervals (CIs), and p-values were reported to assess statistical significance.

Results: Among 152,971 hospitalized SSc patients, 24,451 (1.62%) had a diagnosis of GAVE. Patients with GAVE were older (mean age 68.9 vs. 63.4) and predominantly female. There were no statistically significant sex-based differences in GAVE prevalence (p=0.7498), but racial differences were significant (p=0.0002), with White and Asian patients more commonly affected. Several comorbidities were significantly associated with GAVE in SSc, including chronic kidney disease

Table 3. Comparison of Scleroderma Patients With and Without GAVE

Table 3. Comparison of Scleroderma Patients With and Without GAVE

Variable	With GAVE (N)	Without GAVE (N)	p-value
Demographics			
Male	3,751	20,700	0.7498
Female	20,710	3,741	—
Mean Age	68.9	63.4	—
Race			0.0002
White	18,265	16,333	
African-American	2,029	3,790	
Asian	3,301	3,032	
American Indian/Alaska Native	416	5,184	
Native Hawaiian/Pacific Islander	48	222	
Multiple Categories Reported	406	536	
Comorbidities			
COPD	5,648	18,803	0.0536
Diabetes Mellitus	4,010	20,441	0.9088
Obesity	2,298	22,152	0.2556
AKI	5,942	18,509	0.1631
CKD	6,101	18,350	0.0000
Hypertension	6,499	17,952	0.0597
Coronary Artery Disease	7,401	17,050	0.0000
Cancer	0	24,451	0.4132

Logistic regression for inpatient mortality in SSc patients revealed increasing age was a significant risk factor (OR 1.01, CI 1.01–1.02, p< 0.001). Male sex (OR 1.35) and African American race did not significantly impact mortality. AKI (OR 4.1), CKD (OR 1.56), heart failure (OR 2.28), myocarditis (OR 2.4), pulmonary hypertension (OR 1.7), and pulmonary fibrosis (OR 1.6) were all independently associated with increased inpatient mortality. Interestingly, obesity (OR 0.7), hypertension (OR 0.5), and GERD (OR 0.58) appeared to be protective. GAVE itself was not significantly associated with mortality (OR 0.9, CI 0.58–1.4, p=0.65).

Conclusion: This national inpatient analysis highlights significant demographic and comorbidity trends in SSc patients with GAVE. While GAVE is associated with distinct clinical features and comorbidities, it was not independently linked to an increase in inpatient mortality. Instead, traditional predictors such as AKI, heart failure, and pulmonary complications played a more prominent role in poor outcomes. Understanding these patterns may guide risk stratification and improve multidisciplinary care strategies in scleroderma.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is characterized by a wide range of clinical manifestations and available interventions still lack overall efficacy. Limited cutaneous SSc (lcSSc) and sine scleroderma constitute more than 60% of all SSc patients. Despite this high prevalence, there is a lack of high quality randomized controlled trials conducted for lcSSc. Acquiring high quality data on the natural history of early lcSSc will help design trials with a higher probability of success. CONQUER is a multicenter US-based cohort of patients with early SSc (less than 5 years after first non-Raynaud (RP) symptom), uniquely allowing assessment of the early phases of SSc.

This analysis of CONQUER aimed to describe the prevalence of organ involvement in lcSSc patients and to define the onset of key scleroderma manifestations during follow-up. Baseline characteristics predicting disease progression were also identified.

Methods: All patients from the CONQUER multicenter US cohort with physician diagnosed sine scleroderma or lcSSc at baseline were included. Patients were defined as progressors if they experienced one or more of the following events: New renal crisis, Interstitial Lung disease (ILD) progression (relative loss of ≥15% of FVC as compared to first available FVC or onset of FVC less than 80% with ILD), onset of heart failure (LVEF≤40%), pulmonary arterial hypertension on right heart catheterization, gastrointestinal dysmotility requiring enteral or parenteral nutrition, digital ulcer (DU) or gangrene, or death.

Results: 275 patients were included, with a mean (SD) disease duration of 2.6 (1.39) years since first non-RP and 6.2 (8.51) years since RP. Baseline manifestations included: active digital ulcers in 29.5%, ILD in 34.9%, SSc-related cardiac involvement in 12.4% and renal crisis in 1.5%. Only 14 patients (5%) were identified as progressors in the first 12 month of follow-up. Twenty-nine patients (11%) were identified as progressors in the first 24 months of follow-up. The main reasons

Table 1: Comparison of baseline characteristics between progression and non-progressors after 24 months of follow-up

	Progressor within 24 months of baseline			
	Non-progressors (N = 246)	Progressors (N = 29)	Odds ratio (95% CI)	P-value
Age (years) at baseline visit	52.9 (13.67)	52.7 (14.84)	1.00 (0.97, 1.03)	0.94
Sex				0.90
Male	36 (14.6%)	4 (13.8%)	0.93 (0.26, 2.58)	
Female	210 (85.4%)	25 (86.2%)	Reference	
Non-Hispanic White	184 (74.8%)	25 (86.2%)	2.04 (0.75, 7.13)	0.17
ANA/Autoantibody classification				0.07
Centromere	88 (35.8%)	6 (20.7%)	Reference	
SCL 70	55 (22.4%)	12 (41.4%)	3.20 (1.17, 9.65)	
Other	82 (33.3%)	9 (31%)	1.61 (0.56, 4.99)	
Raynaud's phenomenon as first symptom	188 (76.4%)	24 (82.8%)	1.48 (0.58, 4.55)	0.43
Disease duration from date of first Raynaud's symptom to baseline visit (years)	6.1 (8.33)	7.1 (10.06)	1.01 (0.97, 1.05)	0.56
Disease duration from date of first non-Raynaud's symptom to baseline visit (years)	2.6 (1.37)	3.0 (1.54)	1.21 (0.91, 1.62)	0.19
Disease duration from date of earliest SSc symptom (Raynaud's or non-Raynaud's) to baseline visit (years)	6.1 (8.12)	7.0 (9.92)	1.01 (0.96, 1.05)	0.62
C-reactive protein (CRP) (mg/dL)	1.8 (3.83)	1.8 (2.51)	1.00 (0.84, 1.11)	0.98
Baseline skin thickening	230 (93.5%)	28 (96.6%)	1.95 (0.37, 35.80)	0.49
Hand swelling/Puffy fingers	195 (79.3%)	19 (65.5%)	0.50 (0.22, 1.17)	0.11
Baseline finger involvement	228 (92.7%)	28 (96.6%)	2.21 (0.43, 40.50)	0.40
Baseline telangiectasia	147 (59.8%)	20 (69.0%)	1.65 (0.72, 4.12)	0.24
Baseline digital gangrene	10 (4.1%)	2 (6.9%)	1.80 (0.27, 7.31)	0.49
Baseline active digital ulcers	71 (28.9%)	10 (34.5%)	1.35 (0.58, 3.03)	0.48
Baseline calcinosis	9 (3.7%)	2 (6.9%)	2.00 (0.29, 8.29)	0.42
Baseline reflux	94 (38.2%)	11 (37.9%)	0.98 (0.42, 2.23)	0.97
Baseline GI symptoms (other than reflux)	146 (59.3%)	17 (58.6%)	0.96 (0.42, 2.34)	0.92
Baseline joint involvement	58 (23.6%)	7 (24.1%)	1.06 (0.40, 2.52)	0.90
Baseline Dyspnea (NYHA) Class II, III, or IV	82 (33.3%)	17 (58.6%)	3.05 (1.38, 7.01)	0.006
Baseline ILD diagnosis	78 (31.7%)	18 (62.1%)	4.10 (1.45, 14.69)	0.007
Baseline FVC % predicted < 80%	52 (21.1%)	12 (41.4%)	2.44 (1.06, 5.46)	0.04
FVC % predicted	91.5 (17.44)	78.7 (22.33)	0.96 (0.94, 0.98)	<0.001
Baseline DLCO % predicted < 80%	96 (39.0%)	20 (69.0%)	3.26 (1.42, 8.15)	0.005
DLCO % predicted	81.7 (25.14)	71.3 (23.45)	0.98 (0.97, 1.00)	0.06
Baseline pulmonary hypertension	11 (4.5%)	2 (6.9%)	1.58 (0.24, 6.30)	0.56
Baseline SSc-related cardiac involvement	29 (11.8%)	5 (17.2%)	1.50 (0.48, 4.02)	0.46
Baseline renal crisis	3 (1.2%)	1 (3.4%)	3.05 (0.15, 24.82)	0.39

for progression at 24 months were ILD progression (55.2%) and new DU (17.2%) during follow-up. Baseline characteristics predicting progression (**Table 1**) were positivity for anti-topoisomerase-1 antibody (antiTOPO) compared to anti centromere (OR 3.20, 95%CI(1.17-9.65)), the presence of ILD (OR 4.10, 95%CI(1.45-14.69)), the presence of dyspnea (NYHA II, III or IV) (OR 3.05, 95%CI(1.38-7.01), FVC (%pred) less than 80% (OR 2.44, 95%CI(1.06-5.46)), and DLCO (%pred) less than 80% (OR 3.26, 95%CI(1.42-8.15)).

Conclusion: In the CONQUER database of patients with early SSc, 5% and 11% of patients with lcSSc or sine scleroderma experienced disease progression at 12 and 24 months, respectively. This low rate of progression suggests that clinical trials including lcSSc or sine scleroderma patients with early disease may benefit from a trial duration of 24 months. Predictors of progression within the first 24 months included antiTOPO, ILD and cardiopulmonary-related parameters (DLCO, FVC (pred) or dyspnea). Incorporating lcSSc patients with antiTOPO and presence of ILD may help enrich clinical trials with lcSSc patients more likely to show disease progression.

Latent Profiles of Parenchymal Abnormalities and Vascular Features Measured by Quantitative CT Identifies a Subgroup of Systemic Sclerosis Patients With a Greater Lung Function Decline Over Time

Alicia Hinze[1], Nishanth Katurkuri[2], Robert Vassallo[2], Ami Shah[3], Ryan Lennon[2], Brian Bartholmai[2] and Cynthia Crowson[4], [1]Mayo Clinic - Rochester, MN, Rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]Johns Hopkins Rheumatology, Baltimore, MD, [4]Mayo Clinic, Stewartvillle, MN

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The clinical course of interstitial lung disease (ILD) in systemic sclerosis (SSc) is highly variable--some patients experience progressive loss of lung function while others remain stable. Although risk factors such as early disease, diffuse cutaneous subtype, Black race, and >20% ILD on baseline CT increase the likelihood of progression, ILD progression can also occur in their absence. This study aimed to develop radiomic profiles linked to pulmonary function decline by analyzing quantitative CT measures of lung parenchymal and vascular abnormalities in early SSc.

Methods: A retrospective cohort of adult (≥18 yrs) patients with systemic sclerosis (SSc) seen at an academic center (1/1/2007–12/31/2018) was identified using ICD-9/10 codes. Records were reviewed, and patients included if they met ACR/EULAR 2013 SSc classification criteria or ≥3/5 CREST criteria and had ILD. Inclusion required a baseline high-resolution CT (HRCT) ±2 yrs of SSc diagnosis and a PFT ±6 mo. of HRCT. Patients with infection, pleural effusion, cardiogenic edema, or non-SSc ILD were excluded. CALIPER software quantified six lung features (normal, ground glass opacities (GGO), reticular densities (RD), honeycombing (HC), hyperlucency, and pulmonary vascular related structures (PVRS)) by lung zone (upper/middle/lower, central/peripheral). Each feature was expressed as a % of lung volume for that zone. Percent predicted forced vital capacity (ppFVC) was standardized using the GLI 2022 equations.[1] Latent Profile Analysis (LPA)

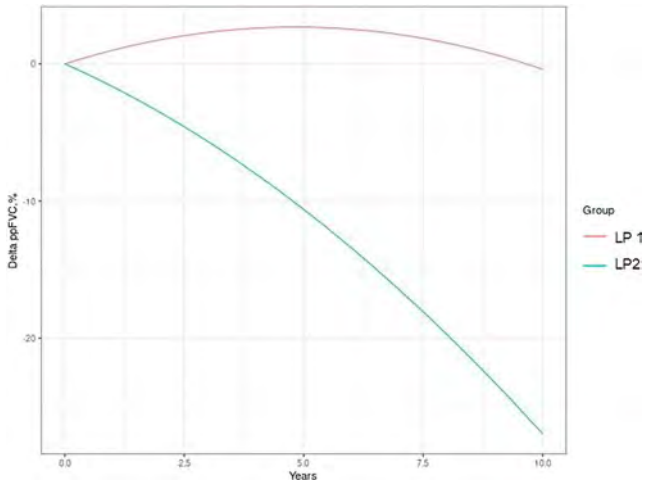

Figure 1. Difference in the Estimated Rate of Decline in percent predicted FVC (ppFVC) per year for Latent Profile (LP) 1 vs. LP 2, adjusting for age, sex, baseline ppFVC, ILD duration, diffuse cutaneous disease, and a positive Scl70

Results: Of 1,399 SSc patients identified, 712 had ILD, 315 had a CT ±2 yrs of SSc diagnosis, and 116 met inclusion criteria with ≥1 follow-up PFT. LPA identified two radiomic profiles (LP1 & LP2). LP1 had lower percentages of ILD, GGO, RD, HC, and PVRS (Table 1). There were no significant differences in demographics, smoking history, SSc dx. dur., subtype or other clinical features, anti-Scl70, or anti-centromere Abs (Table 1). RNA Pol III was less frequent in LP1 than LP2 (18% vs. 46%, p=0.048). LP1 had a shorter interval from ILD dx. to HRCT (median 0.0 vs. 0.5 yrs; p< 0.001), and better lung function at baseline (median ppFVC (85% vs. 75%) and ppDLCO (64% vs. 49%), both p< 0.001). In longitudinal analysis, LP2 had a faster rate of ppFVC decline: -2.66% per year (95% CI: –4.65 to –0.67; p=0.011) relative to LP1, adjusting for baseline ppFVC (Table 2, Model 1). This association was slightly attenuated after adjusting for age, sex, ILD dur., Scl-70(+), and diffuse subtype (–2.18% per year; 95% CI: –4.35 to 0.01; p=0.054; Table 2, Model 2; Fig 1).

Conclusion: Two early SSc-ILD radiomic phenotypes were identified. Frequencies of clinical risk factors for ILD progression were similar between profiles. One radiomic profile was associated with greater parenchymal and vascular abnormalities and faster lung function decline. Imaging-based phenotyping using radiomic biomarkers may enhance risk stratification and identify patients at higher risk for ILD progression.

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of mortality in systemic sclerosis (SSc). Little is known about the association between body composition and lung function in SSc. Thoracic computed tomography (CT) scans are routinely obtained in SSc patients to screen for ILD. Accessory respiratory muscles and subcutaneous fat (SF) measurements can be calculated from these CT scans. Our aim was to examine the association between thoracic body composition and pulmonary function in SSc patients.

Table 2. Association between body composition parameters and %predicted FVC

Body Composition Parameter	Unadjusted			Adjusted*		
	No.	β coefficient (95% CI)	p-value	No.	β coefficient (95% CI)	p-value

Methods: SSc patients who met ACR/EULAR 2013 classification criteria were recruited longitudinally from the Scleroderma Programs at two academic medical centers. We performed a cross-sectional analysis using baseline thoracic CTs and baseline pulmonary function tests. Pectoralis muscle and SF area and density from thoracic CT scans were measured using ImageJ. Pectoralis muscle area to SF area ratio (MFR) was calculated. To evaluate the relationship between pectoralis muscle and SF area and density and MFR (exposures) and the % predicted forced vital capacity (ppFVC) (outcome), we performed unadjusted and multivariable-adjusted linear regression analyses. The multivariable regression model was adjusted for potential confounders of the relationship between body composition and ppFVC, including age, sex, height, weight, disease duration, smoking status, SSc subtype, and Scl-70 positivity.

Results: One hundred-four CT scans from SSc participants were analyzed. The median (interquartile range [IQR]) age was 55.0 (44.0, 62.0) years (Table 1). The mean (standard deviation [SD]) BMI was 27.7 (7.08) kg/m^2. The majority were female (80.8%) and white (76.9%). The median (IQR) disease duration was 1.1 (0.8, 2.8) years from first non-Raynaud's symptom. Men were taller, weighed more, and had larger muscle and fat area than women. Men had lower ppFVC than women (75.0% vs 87.0%, p = 0.03). In unadjusted analyses, the following body composition measures were inversely associated with ppFVC: pectoralis muscle area (PMA) (β coefficient = -0.45, 95% confidence interval [CI] -0.89 to -0.008), SF density (β coefficient -0.56, 95% CI -0.98 to -0.14), and MFR (β coefficient = -6.72, 95% CI -13.18 to -0.28) (Table 2). In a multivariable-adjusted model, SF density remained statistically significantly inversely associated with ppFVC (β coefficient = -0.77, 95% CI -1.20 to -0.35). MFR was inversely associated with ppFVC, but only approached statistical significance (β coefficient = -7.44, 95% CI -14.96 to 0.066). There was no association between PMA and ppFVC in the multivariable-adjusted model.

Conclusion: SF density was statistically significantly inversely associated with ppFVC in a multivariable-adjusted regression model. MFR was also inversely associated with ppFVC in the adjusted model, but only approached statistical significance. High SF density and MFR may be risk factors for diminished ppFVC. However, it remains unknown whether thoracic muscle and fat composition can predict ppFVC over time. Prospective studies are needed to determine whether thoracic body composition can predict outcomes in SSc-ILD.

Table 1. Dietary patterns among systemic sclerosis patients with variable GI symptom severity (none – mild vs moderate – very severe, based on UCLA GIT 2.0) vs healthy volunteers. All data are presented as mean (standard deviation). BMI = body mass index; MUFA = mono-unsaturated fatty acids; PUFA = poly-unsaturated fatty acids; SFA = saturated fatty acids. *Note: Post-hoc analysis to assess statistically significant intergroup differences using a Dunn's multiple comparison test. 'a' denotes significant differences between None – Mild vs Healthy, 'b' between None – Mild vs Moderate – Very Severe, and 'c' between Moderate – Very Severe vs Healthy.

Background/Purpose: Systemic sclerosis (SSc) is a rare multisystem auto-immune disease characterized by peripheral vasculopathy and widespread fibrosis of the skin and internal organs. Up to 90% of SSc patients experience gastrointestinal (GI) symptoms ranging from mild to very severe. We aimed to explore how GI symptom severity correlates with dietary intake patterns and patient-reported outcome measures in SSc patients.

Methods: Adult (>18 years old) SSc patients meeting the ACR/EULAR 2013 criteria were prospectively recruited and stratified into those with none-to-mild and moderate-to-very severe GI symptoms based on The University of California Los Angeles Scleroderma Clinical Trials Consortium gastrointestinal tract 2.0 (UCLA GIT 2.0) scores.[1] Patients completed a food frequency questionnaire to assess dietary intake which was compared to historically obtained healthy volunteer dietary data. Patient-reported outcomes were assessed using a range of validated questionnaires. All variables were compared using Mann-Whitney U tests and Kruskal-Wallis tests and correlated using Spearman's rank correlation.

Results: 94 SSc participants (79 females; mean 58±12 years) were enrolled. The average UCLA GIT 2.0 score was 0.6±0.4 and participants were categorized as having none to mild (n=47, 50%), and moderate to very severe GI symptoms (n=47, 50%). Compared to healthy volunteers or those with none to mild GI symptoms, patients with moderate to very severe GI symptoms had a lower intake of vegetable proteins and empty calories as well as lower healthy eating index (HEI) scores (Table 1). Patients with moderate to very severe GI symptoms also consumed more saturated fatty acids compared to healthy volunteers. Regardless of GI symptoms, SSc patients consumed fewer whole grains compared to healthy volunteers. Additionally, patients with moderate to very severe GI symptoms reported worse physical and social function, higher levels of fatigue, pain and anxiety, and more bowel movements which were also softer when compared to those with none

Frequency (weekly)	10.7 (5.4), 42	15.4 (7.6), 43	**<0.001**
Consistency (Bristol)	4.0 (0.8), 42	4.8 (1.1), 43	**<0.001**

to mild GI symptoms (Table 2). Harder stool consistency correlated with higher HEI scores (r=0.42, p< 0.001) and a higher intake of fiber (r=0.40, p< 0.001) and vegetable protein (r=0.44, p< 0.001).

Conclusion: In this large prospective single center cohort of well characterized SSc patients, those with moderate to very severe GI symptoms exhibited suboptimal dietary intake and reported worse physical and social functioning as well as higher levels of pain, fatigue and anxiety. Future studies are needed to understand the mechanistic influence of diet in SSc patients and its impact on GI symptoms and other patient-reported outcomes.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti- Cytolethal Distending Toxin (CDT) antibodies may serve as biomarkers for post-infectious autoimmunity and aid in clinical risk stratification. In this study, we aimed to determine the prevalence of anti-CDT antibodies in a large, well-characterized cohort of patients with systemic sclerosis (SSc) and to examine associations with gastrointestinal (GI) and extraintestinal clinical features and other SSc-related antibodies.

Methods: Sera from 130 well-characterized patients with SSc enriched for GI disease were screened for anti-CDT antibodies by ELISA. Clinical features, UCLA GIT 2.0-assessed symptoms, and autoantibody profiles were compared between patients with and without anti-CDT antibodies.

Results: Anti-CDT antibodies were detected in 18% (23/130) of SSc patients. Patients with anti-CDT antibodies more frequently had significant GI disease (87% vs. 71%; p=0.19) and were significantly more likely to have antibodies to U11/U12 (RNPC3) (35% vs. 4%; p< 0.001), U1RNP (26% vs. 8%; p=0.018), and topoisomerase-1 (30% vs. 12%; p=0.044). UCLA GIT Soilage scores were significantly higher (worse) among anti-CDT -positive patients [1 (1, 2) vs. 0 (0, 2); p=0.037]. In multivariable analyses, anti-CDT antibodies remained significantly associated with anti-U11/U12 (RNPC3) [OR 19.0 (4.3, 83.4);

Table 1. Comparison of demographic, clinical and serological features between anti-CDT antibody positive and negative patients with systemic sclerosis. Longitudinal assessment of circulating fibroblast activation protein in systemic sclerosis-associated interstitial lung disease

Bo Broens[1], Conny van der Laken[1], Iris Simons[1], Tamara Dekker[1], Jan Willem Duitman[1] and Alexandre Voskuijl[2], [1]Amsterdam UMC, Amsterdam, Netherlands, [2]Amsterdam University Medical Center, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis-associated interstitial lung disease (SSc-ILD) is difficult to manage due to the heterogeneous disease course. There is a high need for biomarkers to identify patients at high risk for ILD progression. Fibroblast activation protein (FAP) has gained interest as a biomarker to reflect fibrotic activity. As circulating FAP (cFAP) can be measured in blood, we aimed to investigate the value of cFAP in SSc-ILD.

Methods: cFAP concentrations were determined in plasma samples of 210 SSc patients and 13 controls using an enzyme-linked immunosorbent assay. We compared cFAP levels in (repeated longitudinal) samples between SSc patients, with and without ILD (n=63 and n=147, respectively) and controls. Furthermore, we investigated the correlation between cFAP and ILD progression at follow-up (defined as forced vital capacity (FVC) decline ≥5%). In an exploratory analysis, we also investigated if cFAP was associated with other disease-related clinical features and all-cause mortality.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

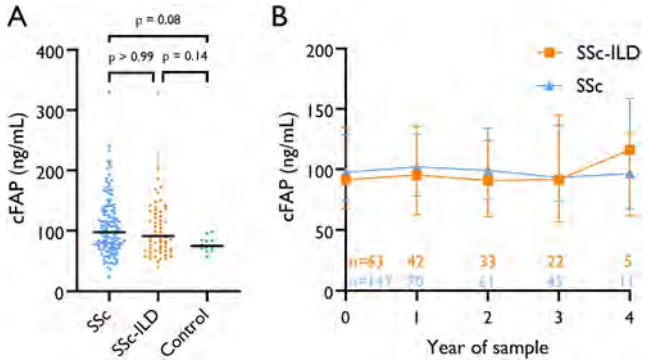

Figure 1. cFAP levels in patients with SSc - with and without ILD - and controls

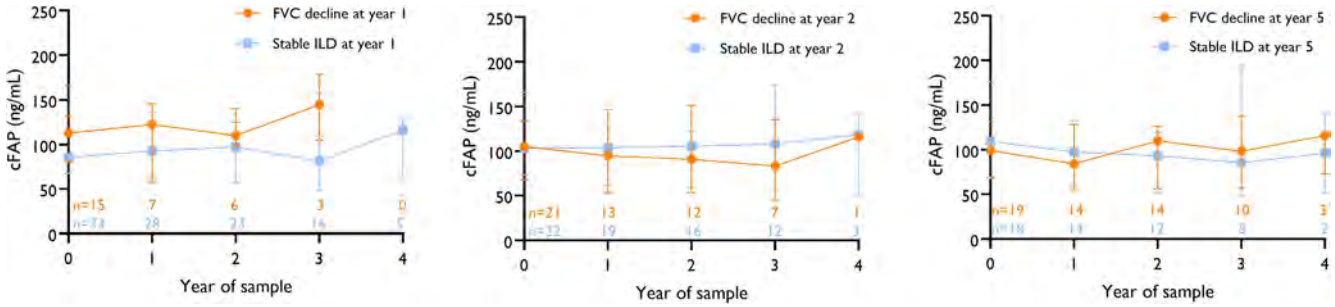

Figure 2. cFAP concentrations plotted over time in SSc patients that did or did not develop ILD progression at 1, 2 and 5 years of follow-up

Table 1. Baseline cFAP is not associated with ILD progression during follow-up

FVC decline ≥5%	ILD progression n (%)	ILD progression cFAP (ng/mL)	No ILD progression cFAP (ng/mL)	Logistic regression analysis
Year 1	15/48 (31.3%)	113.0 ± 51.3	86.0 ± 98.8	p=0.52
Year 2	21/43 (48.8%)	105.4 ± 66.3	103.5 ± 92.4	p=0.30
Year 5	19/37 (51.4%)	99.3 ± 64.1	109.7 ± 107.3	p=0.99

Results: cFAP levels were not different between SSc patients, with and without ILD, both at baseline (median 91.5 and 97.7 ng/mL; p >0.99) or during follow-up (Figure 1). Additionally, no differences were found between the cFAP levels of SSc patients, with or without ILD, and controls (median 76.9 ng/mL; p=0.08 and p=0.14). Furthermore, we found no correlations between cFAP at baseline and ILD progression at 1, 2 and 5 years of follow-up (Table 1 and Figure 2). In the entire SSc cohort, cFAP levels were elevated at baseline in patients with higher skin scores (mRSS ≥10 compared to mRSS < 10; p=0.01). Lastly, there was no association between cFAP and all-cause mortality at 5 and 10 years of follow-up.

Conclusion: In conclusion, cFAP does not seem useful as a biomarker in SSc-ILD. The relationship between cFAP and skin deserves additional investigation.

Abstract Number: 1561

Usefulness of HRCT in screening of interstitial lung disease in patients with systemic sclerosis without risk factors of clinical suspicion

Carlos de la Puente-Bujidos[1], Antia Garcia Fernandez[2], Verónica García García[1], Jesús Loarce[3] and Sandra Garrote-Corral[1], [1]Ramón y Cajal University Hospital, Madrid, Spain, [2]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [3]Ramón y Cajal University Hospital, Madrid, Spain

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: In 2019 a European expert consensus suggested that all patients with systemic sclerosis (SSc) should be screened with HRCT for interstitial lung disease (ILD) at diagnosis, regardless of the presence of risk factors (RF). However, in the absence of RF or suggestive symptoms or signs, the probability of finding ILD is low. Our aim was to assess rate of ILD and its severity in the absence of clinical suspicion (CS) or RF for ILD in patients with SSc at diagnosis.

Methods: Retrospective study of patients with a recent diagnosis of SSc from January 2020 to January 2025 who were under follow up in a dedicated SSc clinic in Madrid, Spain. Patients with CS and/or RF for ILD were compared with those without CF or RF. CS was defined as presence of dyspnea or crackles. RF were defined as ATA+, diffuse cutaneous

Table 1: Main clinical characteristics regarding presence of CS or RF for ILD

	CS or RF -	CS or RF +	Cohort	p value
n (%)	26 (41.3)	37 (58.7)	63 (100)	-

involvement or active smokers. Severe ILD was defined as disease characterized either by progression observed in PFT or the requirement for immunosuppressive and/or antifibrotic treatment. Categorical variables were described as proportions and/or percentages, while continuous variables were shown as mean or median and standard deviation (SD) or interquartile range (IQR). The Student t test and X^2 test were used to compare data, when appropriate.

Results: 70 patients were diagnosed of SSc during the study period, 90% were screened with HRCT at diagnosis, therefore 63 patients were analyzed. Main characteristics are reported in Table 1. There were no differences in age, sex, race, presence of ACA, time in follow up and organ involvement other than ILD between both groups. In 26 (41.3%) patients there were no CS or RF for ILD. ILD was diagnosed in 3 (11.5%) patients without RF or CS compared to 18 (45.9%) in the group with CS and/or RF ($p< 0.001$). After a mean of 28.4 months of follow-up, none of the patients in the group without CS or RF required treatment for ILD, compared to 10 patients (27%) and 4 patients (10.8%) in the other group who required IS and antifibrotic therapy, respectively (Table 2). Serial pulmonary function tests (PFT) were available in 15/20 (75%) patients with ILD, 2/3 patients without CS or RF had serial PFT, both without deterioration. On the contrary, 13/17 patients with CS and ILD had serial PFT, 53.8% had deterioration of PFT at baseline and 38.5% showed worsening during follow-up. There were no differences in time in follow-up PFT between groups (no CS mean 41.5 months [SD 16.3], CS: mean 32.3 months [SD 12.3], p=0.361).

Conclusion: In our cohort, in absence of CS or RF for ILD, only 11.5% had ILD and none required IS or antifibrotic therapy. Despite the presence of ILD in HRCT at diagnosis, the presence of CS or RF seems to be a key factor identifying patients requiring treatment or in risk of progression during initial follow up. It is necessary to be very cautious with the interpretation of radiological findings in patients without RF because their clinical significance is probably minimal.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Although most vasoactive vasodilating drugs (VVDs) exert anti-fibrotic effects in pre-clinical studies, randomized controlled trials assessing their efficacy in systemic sclerosis-associated interstitial lung disease (SSc-ILD) have shown mixed results. Therefore, we assessed the impact of VVDs on functional progression of SSc-ILD in an observational, real-life setting.

Methods: We identified SSc patients with ILD diagnosed on computed tomography, follow-up pulmonary function tests (PFTs) and treatment data in the EUSTAR database and excluded those with pulmonary hypertension on right heart catheterization or with systolic pulmonary artery pressure on echocardiography >50mmHg at any timepoint. VVDs included endothelin-receptor antagonists, phosphodiesterase-5 inhibitors and prostanoids, administered for at least 3 months in the observation period.

Five definitions of ILD progression within 12±3 months were tested:

A) Forced vital capacity (FVC) decline≥10%, or 5-9% with diffusion capacity for carbon oxide (DLCO) decline ≥15%

B) FVC decline ≥5% or DLCO decline ≥10%

C) FVC decline ≥10%

Table 1. Characteristics of the study population at baseline and across all visits. Biologic Disease-Modifying Anti-Rheumatic Drug (bDMARD), conventional synthetic Disease-Modifying Anti-Rheumatic Drugs (csDMARD), diffusing capacity for carbon monoxide (DLCO), digital ulcer (DU), endothelin-receptor antagonists (ERA), forced vital capacity (FVC), New York heart association (NYHA), phosphodiesterase-5 inhibitors (PDE5i)

Parameter	At Baseline	Ever during observation including baseline	Among all visits
Female sex, n (%)	1544 (79%)		81.6%
Age, mean (SD)	55 (13)		56 (13)
Disease duration (years), mean (SD)	9 (8)		11 (8)
Diffuse subset, n (%)	972 (49.8%)		48.6%
Anti-Scl70 positive, n (%)	1082 (55.4%)		57.6 %
DU ever, n (%)	655 (33.6%)		44.8%
Increased inflammatory biomarkers, n (%)	461 (23.6%)		22.4%
FVC%, mean (SD)	86 (21)		86 (21)
DLco%, mean (SD)	62 (19)		62 (19)
bDMARDs, n (%)		178 (9.1%)	9.2%
csDMARDs, n (%)		978 (50.1%)	56.6%
Glucocorticoids >10 mg/day, n (%)		206 (10.6%)	12.4%
ERAs, n (%)		351 (18.0%)	20.2%
PDE5i, n (%)		156 (8.0%)	9.6%
Prostanoids, n (%)		457 (23.4%)	25.7%
Progression A) FVC decline ≥10%, or 5-9% DLCO decline ≥15%			18.3%
Progression B) FVC decline ≥5% or DLCO decline ≥10%			42.1%
Progression C) FVC decline ≥10%			13.2%
Progression D) FVC decline ≥5%			28.2%
Progression E) Worsening of NYHA class.			17.5%

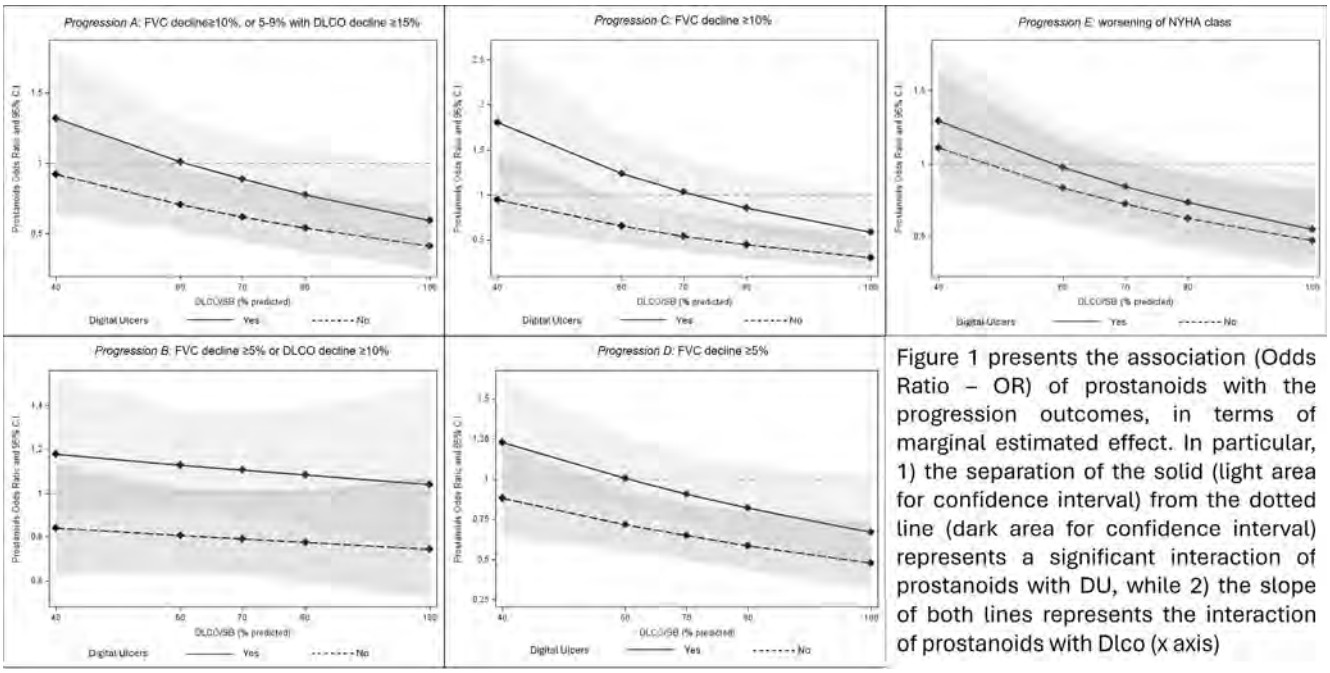

Figure 1 presents the association (Odds Ratio – OR) of prostanoids with the progression outcomes, in terms of marginal estimated effect. In particular, 1) the separation of the solid (light area for confidence interval) from the dotted line (dark area for confidence interval) represents a significant interaction of prostanoids with DU, while 2) the slope of both lines represents the interaction of prostanoids with Dlco (x axis)

Figure 1.

D) FVC decline ≥5%

E) Worsening of NYHA class.

Generalized estimated equation mixed models were performed separately for each ILD progression outcome.

A Cox regression model with time-dependent variables was applied for the survival analysis, with mortality as outcome.

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Interaction terms were computed between VVDs and markers of peripheral/pulmonary vasculopathy (digital ulcers – DU, DLCO).

All models were adjusted for known risk factors for ILD progression or mortality and ongoing immunosuppression.

Results: Among 5360 yearly visits of 1950 SSc-ILD patients, progression events ranged from 13 to 42%, according to the definition used (Table 1). Similarly, exposure to VVDs varied from 10 to 25% of the visits, with prostanoids being the most frequent.

The interaction of prostanoids and DU was associated with progression A (p=0.057), B (p=0.028), C (p=0.006) and D (p=0.048). This translated into a protective effect of prostanoids against PFT decline in patients without DU, compared to patients with DU (Figures A-D).

Additionally, prostanoids interacted significantly with DLCO, and this associated significantly with all progression definitions (A: p=0.022, B: p=0.003; C: p=0.001; D: p=0.023; E: p=0.010). Figures A-E show how higher DLCO values impact positively on the effectiveness of prostanoids.

Combining all effects, prostanoids significantly associated with less PFT progression when used in patients without DU and with DLCO >70%, while DLCO values >100% would be needed for prostanoids to exert similar effects in DU patients.

Over a median follow-up of 5.7 (2.8-9.9) years, 178/1950 (15.6%) SSc-ILD patients died. In the survival analysis, VVDs did not show any significant, independent impact on mortality.

Conclusion: Exposure to prostanoids is associated with lower risk of ILD progression in patients with mild vasculopathy (absence of DU, higher DLCO). Given our positive preliminary results on short-term progression, but the lack of independent impact on mortality, further studies are needed to confirm the beneficial effects of prostanoids on SSc-ILD.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The treatment goals for systemic sclerosis (SSc) are to control disease activity, limit progression of organ damage and decrease long-term morbidity and mortality. Therapies providing durable clinical responses without requiring chronic administration are lacking. Rese-cel (formerly CABA-201) is a fully human, autologous 4-1BB CD19-CAR T cell therapy designed to deeply and transiently deplete CD19 positive cells following a weight-based, single infusion to enable an "immune system reset" with the potential for durable response without chronic immunomodulatory (IM) therapy. RESET-SScTM (NCT06328777) is an ongoing Phase 1/2 trial evaluating rese-cel in 2 independent cohorts of adults with SSc and either severe skin or organ involvement.

Methods: Eligible patients were 18 to 75 years with SSc. A weight-based infusion of $1x10^6$ CAR T cells/kg was administered following preconditioning with fludarabine and cyclophosphamide. All non-glucocorticoid (GC) IM agents were stopped by Day -5. Adverse events, modified Rodnan skin score (mRSS), pulmonary function test (PFTs), nailfold capillaroscopy (NFC) and use of IM medications were evaluated. CAR T cells and B cells were profiled in peripheral blood pre- and post-infusion by digital PCR and flow cytometry, respectively. Serum cytokines were measured using the mesoscale discovery platform. Inguinal lymph node biopsies were taken from SSc-Skin-1 before and 21-days after rese-cel under a biorepository at University of Michigan; tissue was labeled for B cells (CD19, CD20, and PAX5, not shown) and T cells (CD3).

Results: As of 31 March 2025, 2 patients were infused with rese-cel (Table 1); SSc-Skin-2 did not have sufficient follow-up for efficacy or translational assessments. A third patient was recently infused.

SSc-Skin-1 had grade 2 cytokine release syndrome (CRS) but no dose-limiting toxicity (DLT) or immune effector cell-associated neurotoxicity syndrome (ICANS). SSc-Skin-2 experienced grade 3 ICANS based on a transient period of isolated confusion without seizures, motor findings, or signs of cerebral edema, which resolved in < 2 days with GC alone.

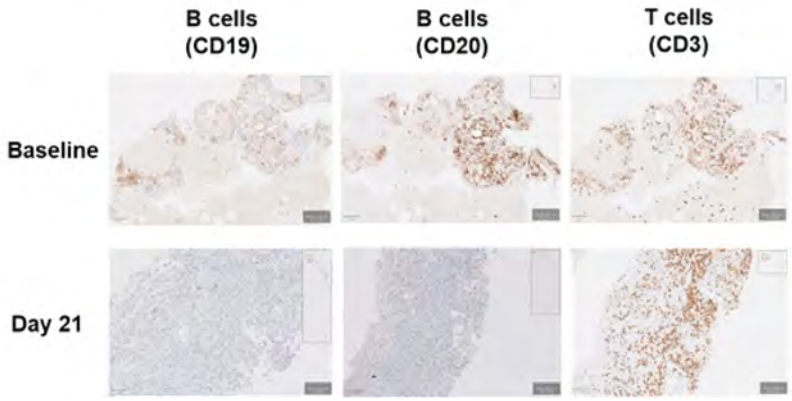
Cabaletta Bio: Data on file

Figure 1. B cells depleted from LN tissue at Day 21 post-infusion in SSc-Skin-1.



SSc-Skin-1 showed improvement on mRSS, PFT and NFC at 6 months off all IM therapy. MRSS gradually improved from 42 to 34. NFC showed preliminary evidence of improvement of capillary density and size.

SSc-Skin-1 exhibited robust expansion of rese-cel that peaked at Day 15 post-infusion and was undetectable by Day 29. Serum IFNγ levels increased post-infusion and peaked prior to rese-cel peak expansion. Peripheral B cells were rapidly reduced in circulation by Day 15 and in lymphoid tissue (Figure 1) at Day 21. B cells reconstituted by 8 weeks post-infusion with a transitional naïve phenotype (CD19+CD20+CD38++CD24++) and switched to predominantly mature naïve by 6 months.

Conclusion: Data from the first SSc patient infused with rese-cel shows early IM-free clinical response and acceptable safety profile in the setting of CAR T cell expansion and complete peripheral and lymph node B cell depletion. These initial data suggest the potential for rese-cel to reset the immune system in SSc, allowing patients to achieve meaningful clinical responses off all IM therapies.

Abstract Number: 1564

Validation of a Composite Endpoint for Systemic Sclerosis-Associated Interstitial Lung Disease

Elizabeth Volkmann[1], Holly Wilhalme[2], Samuel Good[2], Grace Kim[2], Jonathan Goldin[2], Michael Roth[2] and Donald Tashkin[2], [1]Division of Rheumatology, Department of Medicine, University of California, David Geffen School of Medicine, Los Angeles, CA, USA, Los Angeles, CA, [2]UCLA, Los Angeles

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The forced vital capacity (FVC) is the most commonly used endpoint in registrational trials for systemic sclerosis-associated interstitial lung disease (SSc-ILD). However, the FVC has known methodological pitfalls, is affected by extra-pulmonary manifestations of SSc and may not be clinically meaningful to patients. Composite endpoints offer promising benefits for SSc-ILD trials in augmenting trial statistical efficiency and including patient-centered components.

Methods: We previously developed a composite endpoint for SSc-ILD using data from the Scleroderma Lung Study (SLS) I, comprised of the FVC, Transitional Dyspnea Index (TDI), Health Assessment Questionnaire Disability Index (HAQ-DI), and the quantitative extent of radiological fibrosis in the zone of maximum fibrosis (QLF-ZM), which demonstrated a more robust treatment effect of cyclophosphamide (CYC) versus placebo than the FVC alone [1]. The purpose of this study was to validate this composite endpoint using data from the SLS II (comparing CYC versus mycophenolate [MMF]). A secondary goal was to determine how the composite endpoint predicted long-term mortality in SLS I and II compared with the change in FVC.

Results: Seventy-two of the 142 randomized participants in SLS II had all of composite endpoint components assessed at 24 months and were included in this analysis. The composite endpoint distributions for SLS I and II were similar (Figure 1). In both SLS I and II, the standardized effect size as determined by Cohen's d was greater when the composite endpoint model was applied than when the FVC alone model was applied (Table 1). In SLS I and II, the composite endpoint was a better predictor of long-term mortality (HR 0.76 vs 0.98 and 0.59 vs. 0.98, for the composite index vs. FVC based on Cox proportional hazards models in SLS I and II, respectively), although both analyses were likely underpowered to detect statistical significance (Table 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

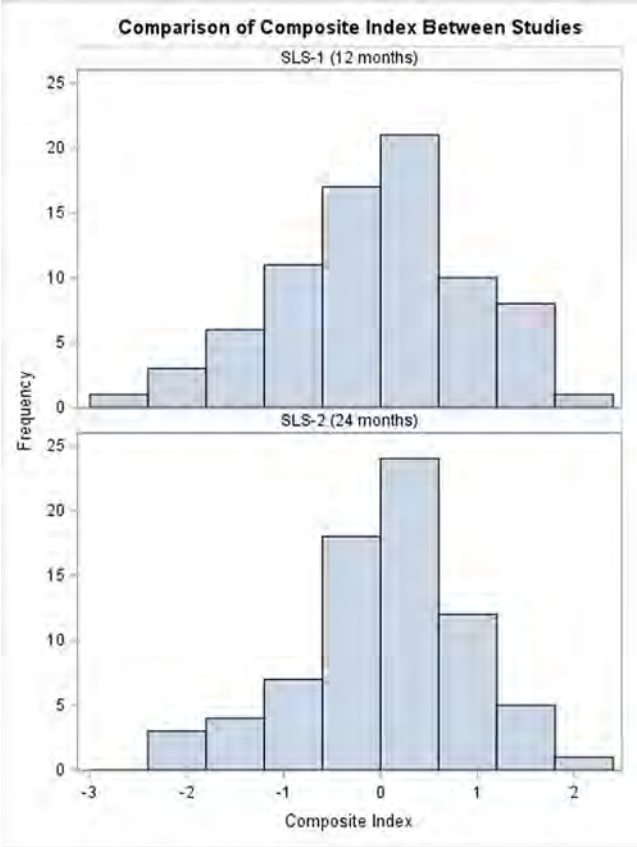

Figure 1. Histogram of composite index distributions in SLS I (top, composite endpoint measured at 12 months) and SLS II (bottom, composite endpoint measured at 24 months). In SLS II, the composite index had a mean (SD) of 0.06 (0.86), indicating slightly reduced variability compared to SLS I (standard normal). This variation may reflect differences in the two cohorts, rates of disease progression, and/or collection timepoints.

Conclusion: The results of this post-hoc analysis provide further evidence that a composite endpoint for SSc-ILD comprised of radiological, physiological and patient-reported outcomes is a promising endpoint for SSc-ILD trials. The composite endpoint may also serve to reduce the sample size required in clinical trials as more patients are needed to detect a significant treatment effect when a single outcome, such as the FVC, is used.

Table 1. Comparison of the treatment effects between the composite endpoint model and the FVC model in SLS I and II.

	Composite Endpoint Model	FVC Model
SLS I		
Treatment Effect (CYC vs. placebo)	Estimate 0.696 (SE 0.193), p=0.0006	Estimate 3.019 (SE 1.885), p=0.1133
Cohen's d (Standardized Effect Size)[1]	0.848	0.359
Sample Size Needed to Detect Treatment Effect (per group)[2]	23	123
SLS II		
Treatment Effect (CYC vs. MMF)[3]	Estimate 0.061 (SE 0.153), p=0.692	Estimate -0.184 (SE 1.594), p=0.909
Cohen's d (Standardized Effect Size)	0.094	-0.071

[1]Note that the root mean squared error from the adjusted linear model is used as the denominator of the effect size.
[2]Sample size calculation assumes a two-sample t-test with 80% power and alpha of 0.05.
[3]In SLS II, there was no significant difference in the FVC endpoint, nor any of the other efficacy endpoints included in the composite endpoint, between patients randomized to CYC vs. MMF; therefore, a sample size calculation was not performed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Cox proportional hazards model analysis for predicting long-term mortality in SLS I and II: Comparison of using the composite endpoint vs. the change in FVC. Follow up time for patients in SLS I and II was up to 12 and 8 years, respectively, from the time the first patient was randomized in each study.

Dataset	Number of Deaths/Total	Hazard Ratio (CI)	P-Value	C-Statistic
SLS I				
Composite Index (12 months)	27/77	0.763 (0.529 - 1.099)	0.1462	0.61
Change in FVC (12 months)	27/77	0.982 (0.956 - 1.008)	0.1642	0.58
SLS II				
Composite Index (24 months)	4/69	0.589 (0.190 - 1.830)	0.3604	0.71
FVC (24 months)	4/69	0.980 (0.897 - 1.071)	0.6575	0.59

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: GI disease is highly prevalent in systemic sclerosis (SSc) and adversely affects quality of life and survival in SSc. The pathogenesis of GI disease in SSc is poorly understood; however, accumulating evidence suggests that alterations in the GI microbiome occur early in the SSc disease course [1] and are associated with specific SSc phenotypes [2]. No prior studies have investigated whether specific bacterial species associate with GI symptoms. The purpose of this study was to identify bacterial species associated with GI symptom severity in patients with SSc from across the world.

Methods: SSc patients from 7 SSc centers across 5 continents provided a stool sample. Shotgun metagenomic sequencing was performed using the Illumina NovaSeq 6000 to characterize microbial composition at the species level. The UCLA GIT 2.0 was administered at the time of the stool collection to evaluate GI symptom severity. Multivariate Sparse Partial Least Squares Regression (sPLS-R) was used to examine whether there was a species signature associated with GI symptom

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

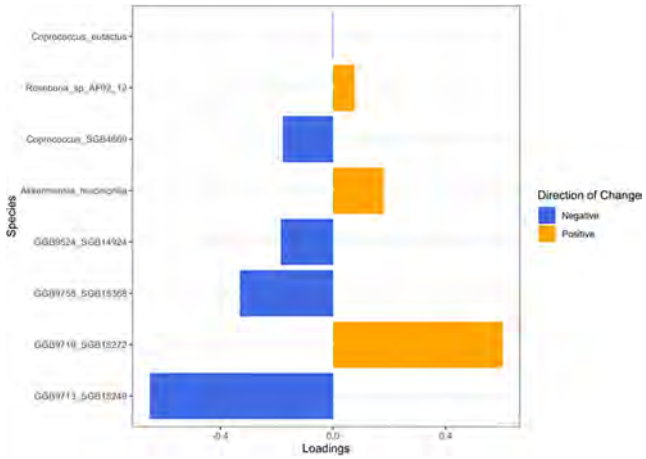

Figure 1. Feature loadings on the species-derived Total GIT 2.0 symptom severity signature from sPLS-R analysis (N=172). Features are ranked from highest (bottom) to lowest (top); species with higher loadings (i.e., weights) contributed the most to the signature score. For each species, positive and negative loadings reflect positive (orange bars) and negative association (blue bars) between that species and Total GIT 2.0 scores.

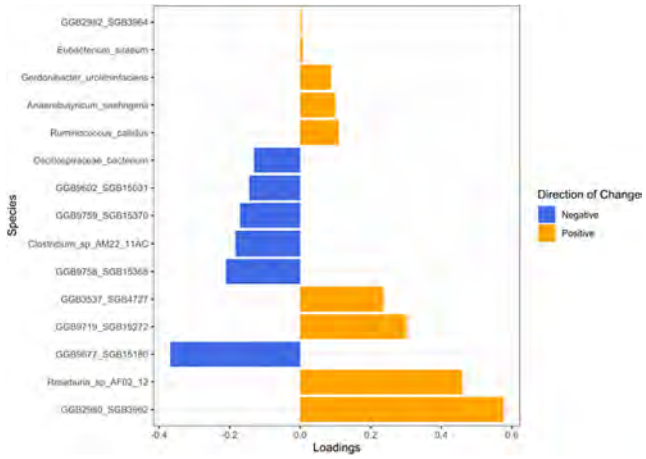

Figure 2. Feature loadings on the species-derived constipation severity signature from sPLS-R analysis (N=172). Features are ranked from highest (bottom) to lowest (top); species with higher loadings (i.e., weights) contributed the most to the signature score. For each species, positive and negative loadings reflect positive (orange bars) and negative association (blue bars) between that species and constipation scores.

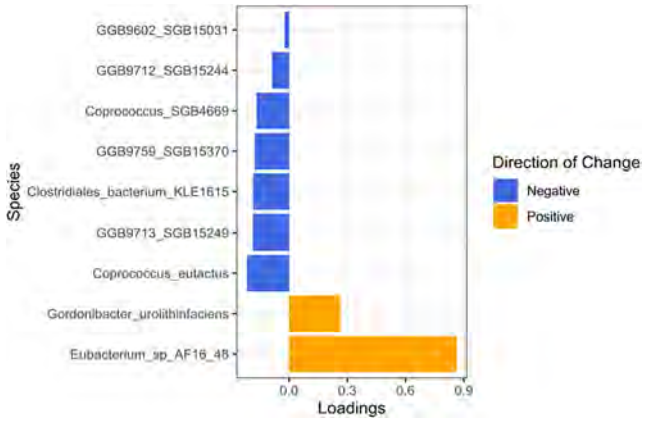

Figure 3. Feature loadings on the species-derived distension severity signature from sPLS-R analysis (N=172). Features are ranked from highest (bottom) to lowest (top); species with higher loadings (i.e., weights) contributed the most to the signature score. For each species, positive and negative loadings reflect positive (orange bars) and negative association (blue bars) between that species and distension scores.

23265205, 2025, S9, Downloaded from https://acgjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. severity, controlling for body mass index, current proton pump inhibitor use, current supplemental probiotic use, current or prior immunomodulatory therapy, presence of small intestinal bacterial overgrowth, interstitial lung disease and study site.

Results: Of the 274 participants, 83.5% were female, and 13.9% had SIBO. The mean (SD) disease duration was 9.49 (9.29) years. Among 257 bacterial species, the multivariate s-PLS-R identified a linear combination of 8 species associated with total GIT 2.0 score (r=0.38 (95% CI 0.24, 0.50), t(170)=5.29, p< 0.0001) (Figure 1). In terms of specific lower GI symptoms, s-PLS-R identified a linear combination of 15 species associated with constipation score (r=0.45 (95%CI 0.32, 0.56), t(171)=6.60, p< 0.0001) (Figure 2) and a linear combination of 9 species associated with distension score (r=0.37 (95%CI 0.23, 0.49), t(174)=5.18, p< 0.0001) (Figure 3). Six of the 8 species associated with total GIT 2.0 scores overlapped with species associated with either constipation or distension scores.

Conclusion: The results of this cross-sectional, international study demonstrate that the abundance of specific intestinal bacterial species in patients with SSc is associated with the severity of GI disease. These species and/or their metabolic products may serve as markers of GI disease severity in SSc and potentially contribute to SSc-GI pathogenesis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Global assessments by patients and physicians provide unique but complementary perspectives of disease severity. This study aimed to determine the clinical and patient-reported factors associated with patient and physician global assessments in systemic sclerosis.

Methods: Adult patients with early systemic sclerosis (SSc) (< 5 years from first non-Raynaud's phenomenon symptom) from the COllaborative National QUality and Efficacy Registry (CONQUER) were included. Global disease assessments by patients (PtGA) and physicians (PhGA)(0-10, higher is worse, 7-day recall), clinical evaluations, and patient-reported outcomes were collected at enrollment. Multivariable linear regression models determined factors associated with each global assessment using i) pre-specified clinical variables only (Model 1), and ii) clinical variables plus patient-reported outcomes (Model 2). Relative weight analysis (RWA), an approach to evaluate variable importance among correlated variables, determined the relative importance of each factor as a portion of the total variance explained by the models.

Results: Data from 1113 patients (83% female, 35% limited cutaneous disease, mean (standard deviation, SD) disease duration 2.5 (1.4) years) are included **(Table 1)**. Mean (SD) global assessment scores at enrollment were 4.2 (2.6) and 3.5 (2.0) among patients and physicians, respectively (p< 0.001). Clinical variables explained 20% of the variability in the PtGA and 42% of the variability in the PhGA. Clinical and patient-reported variables explained 39% of the variability in the PtGA and 49% of the variability in the PhGA. RWA from Model 1 identified modified Rodnan skin score (mRSS) and New York Heart Association (NYHA) Function Class as clinical variables with the highest importance for both PtGA and PhGA **(Figure 1a, 1b)**. RWA from Model 2 demonstrated a shift in the most important contributors to PtGA from clinical measures to patient-reported measures including overall pain/discomfort (16.1%), PROMIS physical function (9.7%), PROMIS Pain

Table 1. Demographics and clinical characteristics at enrollment of patients with systemic sclerosis

Number of patients	1113
Age at baseline visit (years)	52.5 (13.56)
Female sex	927 (83.3%)
Race/ethnicity	
Hispanic	120 (10.8%)
Non-Hispanic White	770 (69.2%)
Non-Hispanic Black or African American	123 (11.1%)
Non-Hispanic Asian	70 (6.3%)
Non-Hispanic Other	25 (2.2%)
Unknown	5 (0.4%)
Disease duration at enrollment (years)	2.5 (1.42)
Limited cutaneous disease	387 (34.8%)
ANA/Autoantibody classification	
Centromere	201 (18.1%)
Scl-70	275 (24.7%)
RNA Polymerase III	241 (21.7%)
Two sub-serologies	55 (4.9%)
ANA only (no sub-serology)	81 (7.3%)
ANA negative or Other*	141 (12.7%)
Modified Rodnan Skin Score (mRSS)	12.3 (10.98)
ILD diagnosis	
ILD present	414 (37.2%)
ILD absent	323 (29.0%)
Unknown, no HRCT performed	376 (33.8%)
Renal crisis	42 (3.8%)
Global Assessments	
Physician Global Assessment (0-10)	3.5 (2.04)
Patient Global Assessment (0-10)	4.2 (2.56)

Values presented as n (%) or mean (standard deviation). *Other includes U1 anti-ribonucleoprotein, anti-polymyositis-scleroderma, anti-fibrillarin, anti-Th/To, anti-Ku, anti-Ro, anti-Ro, anti-La antibodies. Global assessments are rated from 0 (excellent health in past 7 days) to 10 (worst possible health). ANA, anti-nuclear antibody; ILD, interstitial lung disease; HRCT, high-resolution computed tomography chest imaging; RNA polymerase III, anti-ribonucleic acid polymerase III antibody; Scl-70, anti-topoisomerase antibody

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Relative weights of clinical variables associated with the patient and physician global assessment of disease in systemic sclerosis. Relative weight analysis (RWA) using enrollment visit data determined the relative importance of clinical variables (Model 1) associated with the a) patient global assessment and b) physician global assessment. Relative weights (%) indicate the proportion of variance explained by the variable out of the total variance explained by the model. Plots depict the 20 variables with the highest relative weights. For the patient global, R-squared = 0.20 and the 20 variables shown account for 74% of the total variance. For the physician global, R-squared = 0.42 and the 20 variables shown account for 90% of the total variance. Abbreviations: DLCO, diffusing capacity of the lung for carbon monoxide; FEV1, forced expiratory volume in 1 second; FVC, forced vital capacity; NYHA, New York Heart Association; PROMIS, Patient-reported outcomes measurement information system; RNA polymerase III, anti-ribonucleic acid polymerase III antibody; Scl-70, anti-topoisomerase antibody; SHAQ, Scleroderma Health Assessment Questionnaire; VAS, visual analogue scale.

Interference (9.4%), Patient Skin Assessment (8.7%), and PROMIS Social Roles (6.9%) **(Figure 2a)**. For the PhGA, RWA based on Model 2 demonstrated that mRSS (13.1%), NYHA Class III/IV (7.2%), Patient Skin Assessment (6.5%), diffusing capacity of the lung for carbon monoxide (DLCO) %-predicted (5.4%), and overall pain/discomfort (5.0%) had the highest importance **(Figure 2b)**.

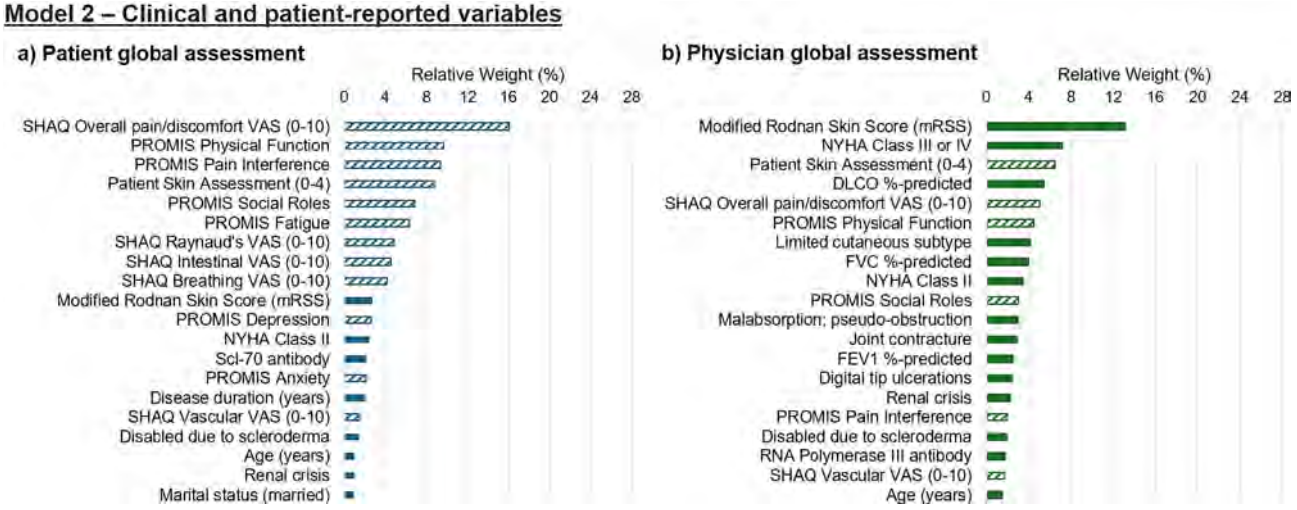

Figure 2. Relative weights of clinical and patient-reported variables associated with the patient and physician global assessments of disease in systemic sclerosis. Relative weight analysis (RWA) using enrollment visit data determined the relative importance of clinical and patient-reported variables (Model 2) associated with the a) patient global assessment and b) physician global assessment. Plots depict the 20 variables with the highest relative weights. Patient-reported variables are indicated by striped bars. For the patient global, R-squared = 0.39 and the 20 variables shown account for 90% of the total variance. For the physician global, R-squared = 0.49 and the 20 variables shown account for 79% of the total variance. Abbreviations: DLCO, diffusing capacity of the lung for carbon monoxide; FEV1, forced expiratory volume in 1 second; FVC, forced vital capacity; NYHA, New York Heart Association; PROMIS, Patient-reported outcomes measurement information system; RNA polymerase III, anti-ribonucleic acid polymerase III antibody; Scl-70, anti-topoisomerase antibody; SHAQ, Scleroderma Health Assessment Questionnaire; VAS, visual analogue scale.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: Factors associated with global assessments in early SSc differ between patients and physicians. Measures of skin involvement and functional status are important contributors to both PtGA and PhGA. However, the PtGA is most influenced by health-related quality of life symptoms that are not well-captured with traditional disease measures. The PhGA is influenced more heavily by traditional clinical factors, but physicians may underestimate the impact of patients' symptom burden. These findings highlight the broad impact of patients' experiences and the importance of collecting both patient- and clinician-reported outcomes in research in SSc.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is a major complication in systemic sclerosis (SSc) patients, associated with substantial morbidity and mortality. Functional, imaging, and clinical measures of lung involvement could be biased in SSc due to its multiorgan nature and extra-articular involvement (e.g., cardiac, musculoskeletal). Artificial intelligence (AI) reading of high-resolution computed tomography (HRCT) has emerged as a novel tool for the objective and reliable assessment of pulmonary diseases. The aim of this study is to correlate AVIEW measures, an Deep learning based software for HRCT image assessment, with ILD-progression and disease-related mortality in SSc patients.

Methods: The AVIEW software (Coreline Soft, South Korea) was employed to analyze HRCT images from a cohort of consecutive SSc-ILD patients at baseline and after 24±3 months. Quantitative analyses included lung volume, texture, airways, and vascular anatomy. Baseline metrics were assessed for their association with ILD progression, defined by clinical, functional, and imaging criteria based on the INBUILD study parameters over 24 months. Furthermore, changes in AVIEW-derived measurements between consecutive HRCT evaluations over the 24-month period were analyzed for their association with SSc-related mortality during the subsequent 36 months. All absolute measurements were normalized to body surface area.

Results: A total of 146 HRCT scans from 73 SSc-ILD patients were assessed (mean age 58.4±14.3 years; male 16.4%; diffuse skin variant 49.3%). Thirty-one patients (42.4%) experienced ILD progression, which was predicted at baseline by higher percentages of ground glass opacities (GGO) (p=0.05) and reticulation (p=0.05), higher subpleural vessel volumes (p=0.017), and a tendency toward larger distal airways (p=0.066). Serial evaluations demonstrated that INBUILD progression was associated with a reduction in the percentage of normal lung (p=0.044) and absolute volumes (p=0.009), without significant changes in reticulation, GGO, vessels, or airways when considered individually.

Twelve patients died due to SSc within 36 months following the second HRCT evaluation. Patients in the upper quartile for changes in reticular score and airway volume exhibited a higher mortality risk, independent of INBUILD progression (reticular score: OR 3.30, 95% CI 1.03–10.61, p=0.045; airway volume: OR 3.37, 95% CI 1.08–10.51, p=0.036).

Conclusion: Deep learning-based assessment in SSc-ILD identified distinct modifications and prognostic significance in lung anatomical components, offering potential improvements in patient evaluation and stratification beyond conventional clinical tools.

A Novel Endothelial Cell Profiling Assay to Identify Systemic Sclerosis Patient Characteristics at the Endothelial Cell Level

Eva Hoekstra[1], Rudmer Postma[1], Nils Steinz[2], Wieke van Oostveen[1], Roel Bijkerk[1], Vincent van Duinen[2], Rachel Knevel[2], Tom Huizinga[2], Anton jan van Zonneveld[1], Jeska de Vries-Bouwstra[2] and Cynthia Fehres[1], [1]Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Vasculopathy, a hallmark clinical feature in systemic sclerosis (SSc), is a consequence of endothelial cell (EC) damage and dysfunction and might precede tissue fibrosis. Clinical disease progression in SSc is highly heterogeneous, with some patients developing severe fibrotic complications while others are affected by severe vascular complications including pulmonary arterial hypertension (PAH). The underlying mechanisms of this variability are poorly understood. We hypothesize that these distinct clinical phenotypes can be identified at the EC level. The objective is to investigate whether SSc patient plasma induces specific EC profiles and to examine correlations between these EC signatures and patients' clinical features.

Methods: Human umbilical vein endothelial cells (HUVECs) were exposed to 25% citrate plasma from SSc patients from the Leiden CCISS cohort (n = 199; 61 at baseline, and 69 at baseline and 1-year follow-up) and healthy controls (HC; n = 35), according to previously published protocol (Postma RJ, 2024; doi:10.1016/j.gastha.2023.10.006). After staining, Max-projections of 9 z-steps with 0.7 μm step size were acquired using a high content confocal microscope. Single-cell morphological profiles were computed from the images and averaged to create single-patient profiles (Fig 1). The Leiden algorithm was used to detect densely connected clusters in the constructed dataset. Performance of Support Vector Machine models predicting different clinical characteristics was evaluated by repeated cross validation. Sankey plots were generated to visualize transitions between clusters after 1 year of follow-up. Validation experiments are pending.

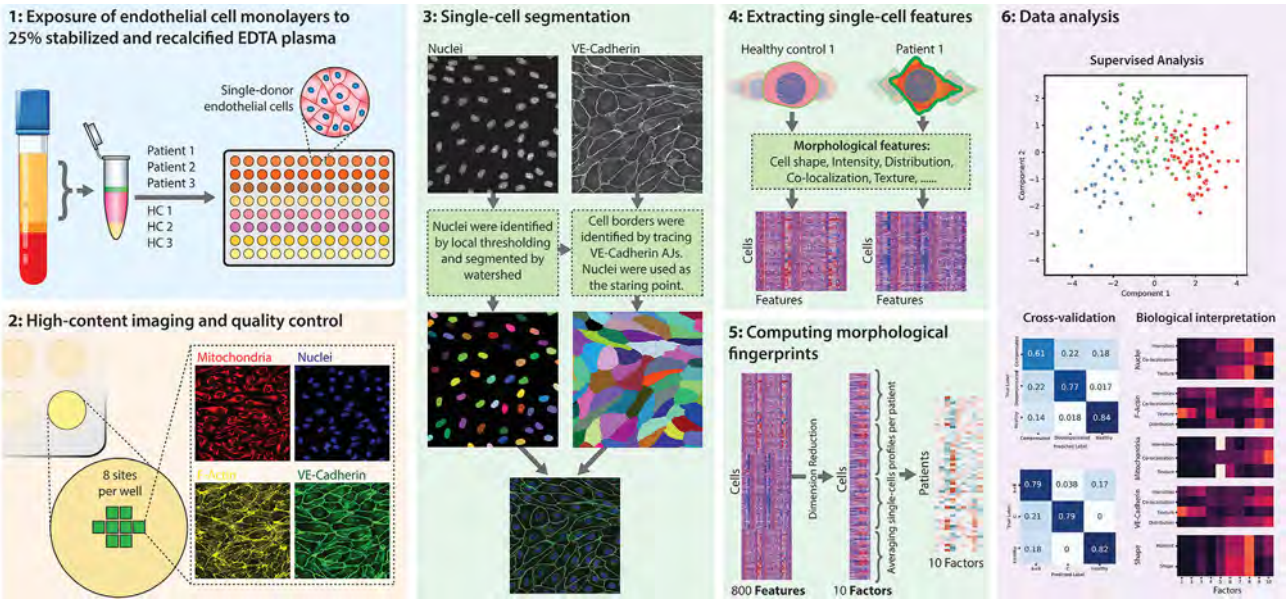

Figure 1. Morphological profiling on endothelial cell level.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. ROC curves of cross validation of SVM models with clinical characteristics.

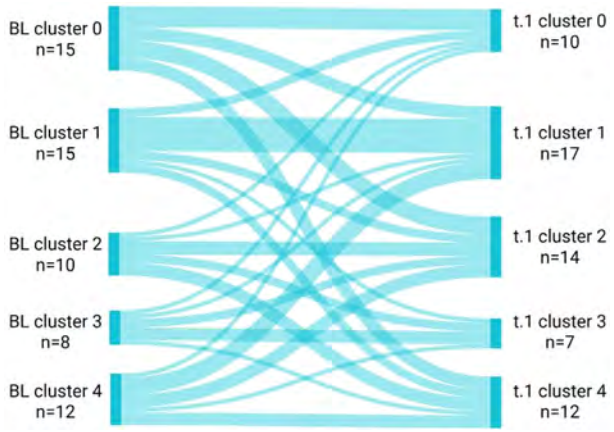

Figure 3. Transition of patients between cluster at baseline to cluster at 1-year follow-up.

Results: Graph-based cluster analysis of the morphological profiles identified 6 separate clusters, with high similarity between all 6-cluster solutions (adj. RAND index: 0.92). Cluster 6 represented outliers of the experiment and was therefore excluded from further analysis. HCs were predominantly found in cluster 0 (27.3%) and cluster 3 (55.9%). Figure 2 shows different SVM models that classify clinical features based on morphological data, specifically discriminating well between HC and patients (AUC 0.88 ± 0.09). Among patients, U1RNP+ patients and PAH patients showed distinct EC profiles (Fig 2). Strikingly, among patients EC profiles were clearly different between males and females, but this was not the case in HC (AUC 0.84 ± 0.08, and 0.68 ± 0.25, respectively). After 1 year follow up most patients (64.2%) migrated to a different cluster (Fig 3); patients who migrated from an SSc cluster to a HC enriched cluster (n = 8) showed stable, mild disease, whereas 50% of patients who migrated from a HC enriched to an SSc cluster (n=7/14) had disease progression.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Distinct morphological endothelial cell profiles were identified in SSc, especially for PAH. Interestingly, male and female EC profiles could be discriminated more clearly in SSc than in HC, indicating that sex-differences in SSc could be identified at the EC level. After 1 year follow-up, patients more often switched than remained in their original cluster, suggesting EC clusters could potentially reflect disease activity.

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Home-monitoring is a suitable strategy to reduce the frequency of hospital visits, and alleviate strain on healthcare resources. However, in systemic sclerosis (SSc) this is challenging because of the heterogenous nature of the disease with regards to multi-organ involvement and trajectories of disease. The aim of this study was to explore the feasibility of using patient reported outcomes measures (PROMs) for home-monitoring by: (1) studying the association between

Table 1. Baseline characteristics of SSc patients in the CCISS cohort.

	Total (n = 767)	Stable disease* (n = 174)

Table 2. Responses to SF-1 and SF-2 in the CCISS cohort.

In general, would you say your health is:		Compared to one year ago, how would you rate your health in general now?	
Total number of responses	3186	Total number of responses	3186
Excellent	40 (1.3)	Much better now	169 (5.3)
Very good	151 (4.7)	Somewhat better now	334 (10.5)
Good	986 (30.9)	About the same	1286 (40.4)
Fair	1620 (50.8)	Somewhat worse now	1091 (34.2)
Poor	389 (12.2)	Much worse now	306 (9.6)

Table 3. Diagnostic test accuracy of patient reported health in stable SSc.

"In general, how would you rate your health?"	No disease progression (n = 148)	Disease progression (n = 26)
Excellent	4 (80.0)	1 (20.0)
Very good	10 (76.9)	3 (23.1)
Good	50 (90.9)	5 (9.1)
Fair	68 (81.0)	16 (19.0)
Poor	16 (94.1)	1 (5.9)
Diagnostic test accuracy for the comparison "excellent + very good" versus "fair + poor": - Sensitivity: 81.0% - Specificity: 1.6% - Positive predictive value: 16.8% - Negative predictive value: 80.0%		
"Compared to one year ago, how would you rate your health in general now?"	No disease progression (n = 148)	Disease progression (n = 26)
Much better	6 (85.7)	1 (14.3)
Somewhat better	13 (92.9)	1 (7.1)
About the same	64 (84.2)	12 (15.8)
Somewhat worse	50 (82.0)	11 (18.0)
Much worse	15 (93.8)	1 (6.3)
Diagnostic test accuracy for the comparison "somewhat worse + much worse" versus "much better + somewhat better": - Sensitivity: 85.7% - Specificity: 22.6% - Positive predictive value: 15.6% - Negative predictive value: 90.5%		

PROMs assessing general health (question 1 and 2 of the 36-Item Short Form Health Survey [SF-36]) and disease progression, and (2) studying the discriminative ability of these PROMs to identify patients with active disease.

Methods: SSc patients fulfilling ACR/EULAR 2013 criteria, with complete SF-36 data, were included from the prospective Leiden CCISS cohort. The first two questions of the SF-36 comprise: "In general, how would you rate your health?" (SF-1) and "Compared to one year ago, how would you rate your health in general?" (SF-2), with possible responses on a 5-point ordinal scale. Disease progression was defined as a worsening of mRSS ≥ 5 and 25%, or ≥ 10% relative decrease in forced vital capacity (FVC), or ≥10% relative decrease in diffusing capacity for carbon monoxide (DLCO), compared to the previous visit). Considering informative follow-up and within-subject correlation we performed mixed-effects logistic regression correcting for age and sex to estimate the association between SF-1 and SF-2 response and disease progression, including time as a fixed effect and random intercept for each patient. A sensitivity analysis was performed in patients who had had three consecutive 'disease progression free' – visits, to determine diagnostic test accuracy of SF-1 and SF-2 for disease progression.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In total, 767 SSc patients (n=3186 visits) were identified. Mean age of included patients was 55.2 ± 13.9 years, and 78% was female. Disease progression occurred in 287 patients (n=548 visits; Table 1 and 2). After correcting for age and sex both SF-1 and SF-2 response were not associated with disease progression (very good β -0.2 [-1.4-1.0], good β 0.4 [-0.7 – 1.4], fair β 0.6 [-0.5 – 1.6], poor β 0.7 [-0.4 – 1.8]; and somewhat better β 0.2 [-0.3 – 0.8], about the same β -0.3 [-0.8 – 0.2], somewhat worse β -0.1 [-0.8 – 0.3], much worse β -0.3 [-0.8 – 0.3]). In total, 174 patients (n=1279 visits) had three consecutive progression-free visits. In this subgroup, disease progression was observed in 26 visits. Both SF-1 and SF2 showed good sensitivity (>80%) and NPV (≥80%) to identify the patients with progression (Table 3).

Conclusion: Patient reported general health and change in health, as assessed with SF-36, are not associated with disease progression in the general SSc population, and are therefore not helpful for home-monitoring purposes for this population. However, when selecting a subgroup of patients with stable and mild disease for ≥ 3 years, general PROMs show good sensitivity and negative predictive value to identify patients with stable disease. We conclude that general PROMs hold potential for implementation in home-monitoring of SSc patients with mild disease.

Hydroxychloroquine and Disease Progression in Systemic Sclerosis: Insights from Antibody-Stratified Survival Analyses

Francesco Bonomi[1], Ilaria Bisconti[2], Ilenia Mallia[3], Greta Pellegrino[4], Gabriele Ciuti[5], Gloria Muolo[2], Martina Salerno[2], Simona Truglia[2], Cristiano Barbetta[3], Silvia Peretti[5], Serena Guiducci[6], Valeria Riccieri[7] and Silvia Bellando Randone[3], [1]University Hospital Careggi, Florence, Florence, Toscana, Italy, [2]Sapienza University of Rome, Rome, Rome, Italy, [3]University of Florence, Florence, Italy, [4]Rheumatology Unit, IRCCS Ospedale Galeazzi Sant'Ambrogio, Milano, Italy; Department of Biomedical and Clinical Sciences, University of Milan, Milan, Italy, [5]University Hospital Careggi, Florence, Italy, [6]Division of Rheumatology, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, Florence, Italy, [7]Sapienza University of Rome, Rheumatology Clinic, Rome, Italy, Roma, Italy

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is an antimalarial drug that interferes with dendritic cells and monocytes, acidifies endosomes, and modulates toll-like receptors, reducing autoimmune responses and cell proliferation through autophagy inhibition. HCQ is widely used in rheumatic diseases for its immunomodulatory properties and is often prescribed in systemic sclerosis (SSc), despite the lack of confirmation of its efficacy in randomized trials.

The aim the study was to compare disease progression trajectories between HCQ-treated and -untreated SSc patients.

Methods: This retrospective, multicenter observational study included patients diagnosed with SSc according to the ACR/EULAR 2013 criteria, recruited from two Italian Rheumatology centers. Patients were grouped based on HCQ treatment. Demographic, clinical, serological, and capillaroscopic (NVC) data, as well as concomitant therapies, were recorded at baseline. At 6, 12-, 24-, 36-, and 60-months follow-up visits disease progression was determined according to validated criteria (Khanna D, 2016; Hoffmann-Vold AM, 2024) encompassing cutaneous, pulmonary, cardiac, and musculoskeletal

domains, or the need to escalate immunosuppressive therapy. Progression-free survival was defined as the absence of worsening or new organ involvement. To test the study hypothesis Kaplan-Meier survival curves and Cox proportional hazards models were applied, stratifying the population by antibody profile (anticentromere, ACA+ or anti-topoisomerase I, Scl70+).

Results: A total of 301 patients with SSc were included (167 in the HCQ group and 134 in the non-HCQ group). Baseline characteristics were broadly similar between groups (Table 1), with no significant differences in age or disease duration. The HCQ group had a higher prevalence of ACA+ (50.8% vs 36.5%, p=0.036), and a lower prevalence of Scl70+ (25.7% vs 44.7%, p< 0.001) and interstitial lung disease (ILD, 13.1% vs 31.3%, p< 0.001). Mean mRSS was lower in the HCQ group (3±5 vs 5±7, p=0.004), while MMF use was more frequent in non-HCQ group (13.1% vs 6.0%, p=0.002). Kaplan-Meier curves demonstrated significant differences in progression-free survival between HCQ-treated patients in both ACA+ and Scl70+ (p< 0.001) subgroups (Figure 1).

In multivariable Cox regression models, HCQ treatment was independently associated with a reduced hazard of progression in both ACA+ (n=134, events=16; HR=0.05, 95% CI 0.01–0.25) and Scl70+ (n=103, events=39; HR=0.14, 95% CI 0.06–0.34) subgroups. However, baseline imbalances and confounding by indication may partially explain these associations.

Older age was also linked to reduced risk (HR=0.95, 95%CI 0.91–0.99) among ACA+ patients, while MMF showed a protective association (HR=0.37, 95%CI 0.15–0.88) in Scl70+ group.

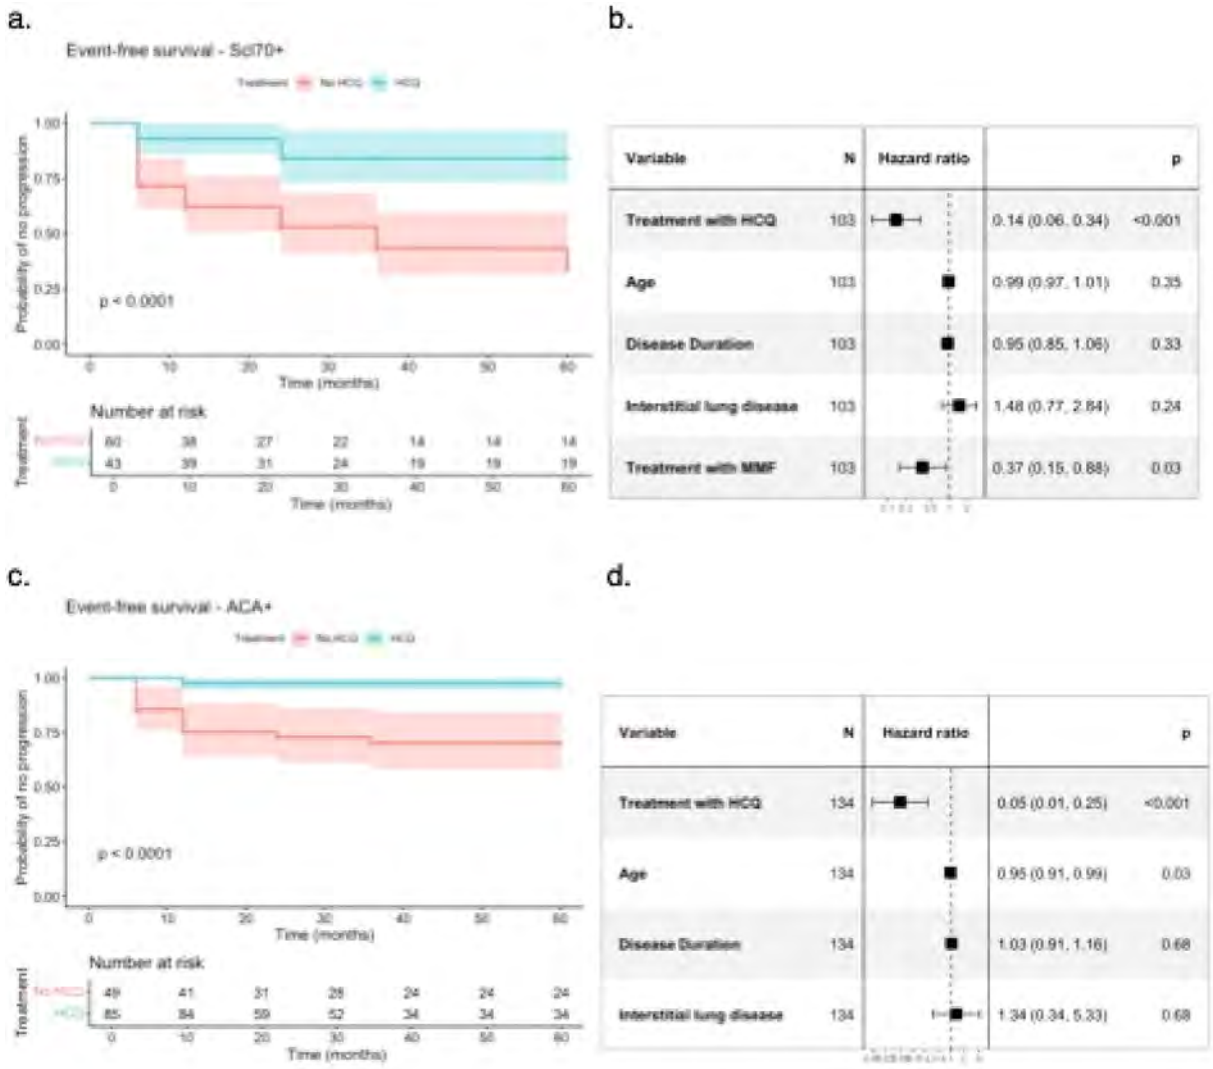

Figure 1. a. Kaplan-Meier curve showing the probability of remaining free from immunosuppressive therapy intensification in anti-Scl70 positive SSc patients, stratified by HCQ treatment. b. Forest plot illustrating the hazard ratios for progression in anti-Scl70 positive SSc patients. c. Kaplan-Meier curve showing the probability of remaining free from immunosuppressive therapy intensification in ACA-positive SSc patients, stratified by HCQ treatment. d. Forest plot illustrating the hazard ratios for progression in ACA-positive SSc patients.

Conclusion: In this retrospective study, HCQ use was associated with a lower risk of disease progression in patients with SSc, in both ACA+ and Scl70+ subgroups, over a 60 -months follow-up period. While the findings might suggest a potential protective role of HCQ, they must be interpreted with caution due to residual confounding. Prospective studies are warranted to validate these results.

Spatial Transcriptomics of Perivascular Subepidermal Regions in Very Early Systemic Sclerosis Unveils Cellular and Mitochondrial Stress-Driven Innate Immune Signatures that Initiate Stromal Remodeling

Ifeoluwa Emmanuel Bamigbola[1], Jayakumar Vadakekolathu[1], Stefano Di Donato[2], Vishal Kakkar[3], Rebecca Ross[4], Yasser El-Sherbiny[1] and **Francesco Del Galdo**[3], [1]1Nottingham Trent University, Department of Biosciences, School of Science and Technology, Nottingham, United Kingdom, [2]University of Leeds, Canosa Sannita, Chieti, Italy, [3]University of Leeds, Leeds, United Kingdom, [4]Medicine and Health, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: The skin from patients with Very Early Diagnosis of Systemic Sclerosis (VEDOSS) already exhibits fibrotic alterations such as collagen deposition and perivascular infiltration (1), despite the absence of clinically detectable skin thickening. A distinct immune-mediated structural organization across the epidermis, sub-epidermal region, and dermis, is involved in both early and late stages of SSc [2] The sub-epidermal perivascular area, located between these layers, serves as a crucial immune-fibro-vascular niche that may play a role in early fibrotic remodeling useful for determining SSc progression and identifying novel therapeutic applications.

Objectives: To identify key signaling and cell types involved in the sub-epidermal perivascular regions within Very Early Diagnosis of Systemic Sclerosis (VEDOSS) compared to those with established disease and healthy control using spatial transcriptomic analyses.

Methods: We employed digital spatial transcriptomics to map whole genome transcriptome expression in the area immediately surrounding CD34-stained vessels in the sub-epidermal regions. Differentially expressed genes ($p < 0.05$, log2FC >0) were analyzed to identify relevant canonical pathways and biological processes.

Results: Six skin biopsies from VEDOSS were compared with six biopsies from healthy individuals or patients with developed systemic sclerosis (SSc). Cell deconvolution revealed that the sub-epidermal region was dominated by diverse fibroblast subsets and vascular endothelial cells, with notable representation of immune populations such as T cells and macrophages. Disease-associated shifts included early depletion of secretory papillary fibroblasts in VEDOSS, enrichment of lymphatic endothelial cells, and progressive erythrocyte loss. Pathway Analysis of the sub-epidermal region in VEDOSS compared to healthy controls revealed significant upregulation of key stress and immune-related pathways. Notable among these were Cellular response to hypoxia, Oxidative Phosphorylation, Neutrophil Degranulation, Mitochondrial Dysfunction, and pulmonary idiopathic fibrosis signaling pathway. Key genes significantly upregulated included cyclophilin A, CD47, ATP5MG, COX10, NDUFB9, S100A4, COL1A1, COL16A1, COL17A1, COL21A1, FN1, PIK3R2, PIK3C2B, PDGFRB, implying cellular remodeling and stromal transitions through associated signaling pathways involved in fibrosis.

Conclusion: We demonstrate that the sub-epidermal perivascular region is a transcriptionally dynamic niche in VEDOSS skin, where early immune, metabolic, and fibrotic reprogramming converges to initiate stromal remodeling before the onset of clinically detectable fibrosis and progression to SSc.

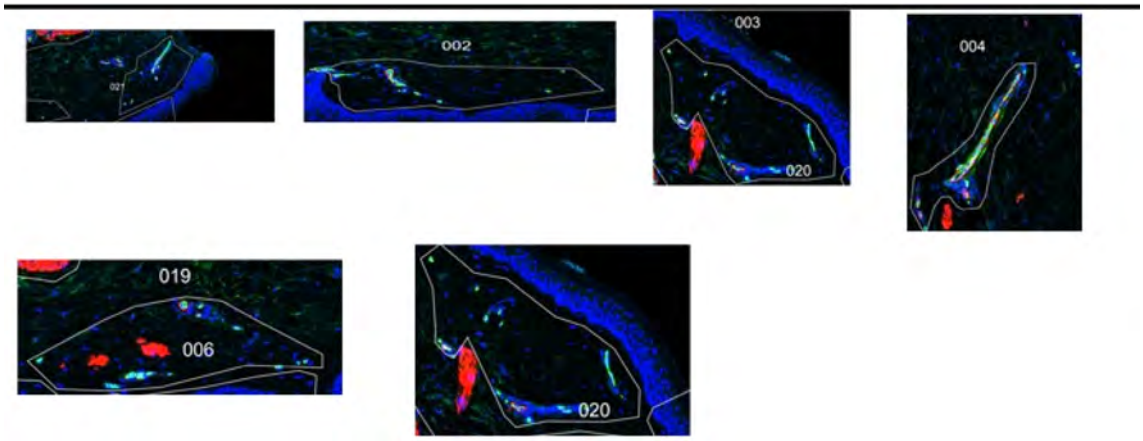
Ingenuity Pathway Analysis (IPA) of differentially expressed genes (DEGs) from the subepidermal region of interest (ROI), comparing VEDOSS with healthy controls. Pathways with an absolute z-score > 2 and p-value < 0.001 were considered significantly activated ($z \geq 2$) or inhibited ($z \leq -2$). Orange are predicted activated pathways and blue predicted inhibited.



Representative examples of subepidermal regions of interest (ROIs) selected from the 54 ROIs analyzed.

Abstract Number: 1572

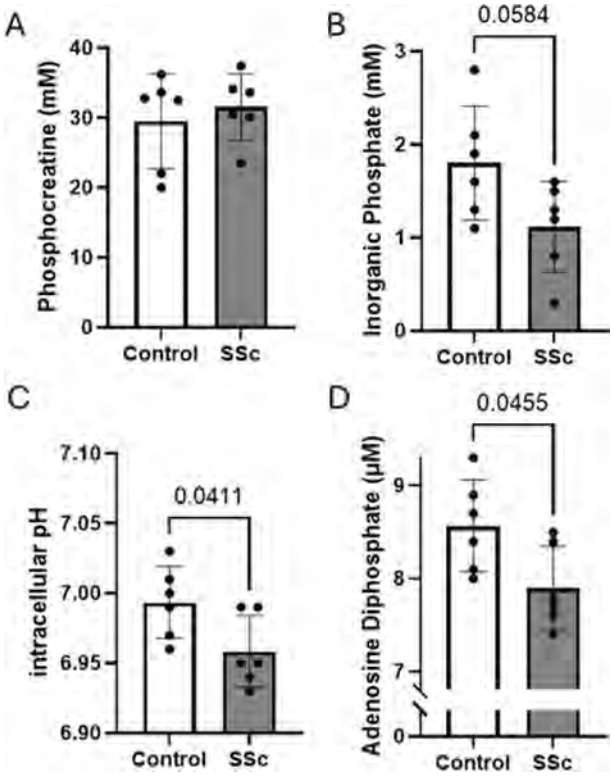
Compromised intracellular oxygen availability and severe mitochondrial dysfunction in the skeletal muscle of patients with systemic sclerosis

Gwenael Layec[1], Tracy Frech[2] and Anthony Donato[3], [1]University of Nebraska, Omaha, NE, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Salt Lake Veterans Affairs Medical Center, Salt Lake City, UT

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

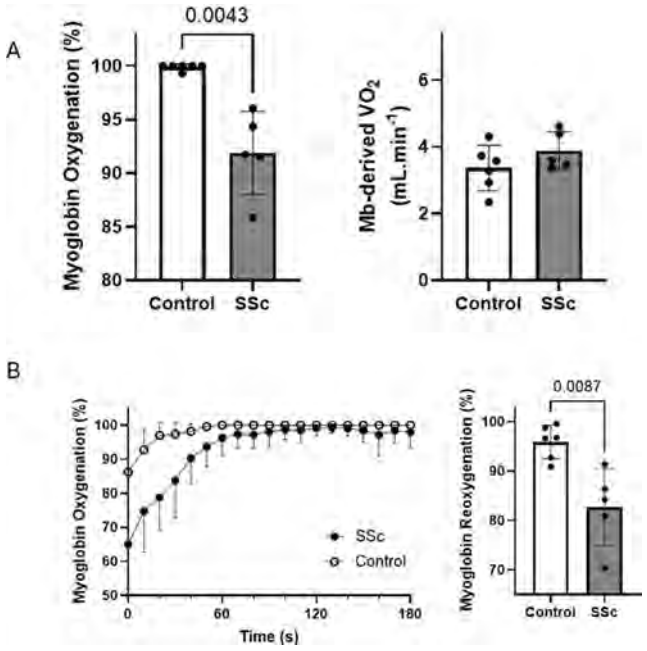
Background/Purpose: Muscle weakness and fatigue are frequent manifestations associated with systemic sclerosis (SSc). However, significant gaps remain in our understanding of the effects of SSc on skeletal muscle oxygenation and mitochondrial function. Using a non-invasive approach combining phosphorus- (31P) and proton- (1H) MRS of deoxy-myoglobin (dMb), the purpose of this study was to examine intracellular oxygen (O2) availability, muscle energetics, and mitochondrial function *in vivo* in the plantar flexor muscles of SSc patients and age-matched healthy controls.

Methods: Six adult with SSc and six healthy controls volunteered to participate in this study after signing a written informed consent. All patients were ANA positive with a SSc-specific antibody with a disease duration of less than 7 years disease duration from first non-Raynaud's phenomenon. No patients were classified as a myositis overlap. After familiarization, individual WRmax was determined during an incremental dynamic plantar flexion exercise to exhaustion (1 min stages). On a separate day, subjects performed two short bouts of submaximal plantar flexion at ~ 40% of WRmax (frequency of 1 Hz)

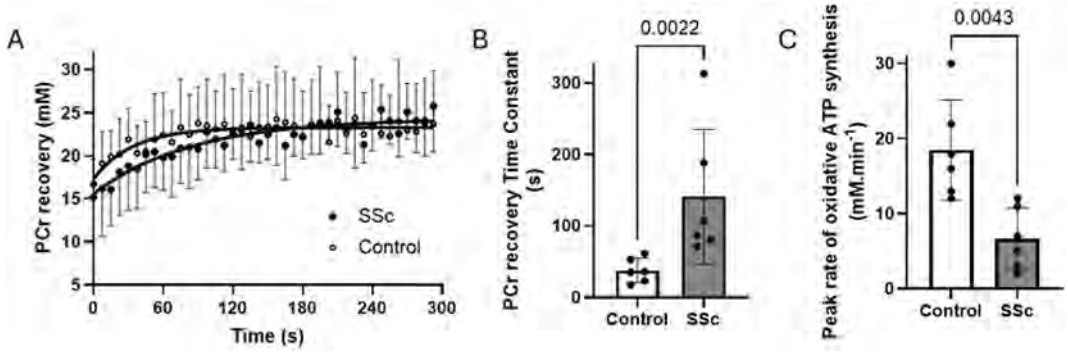


Resting concentrations of phosphocreatine (A), inorganic phosphate (B), intracellular pH (C), and adenosine diphosphate (D) in healthy controls and systemic sclerosis patients. Values are presented as mean ± SD with individual data (n = 6 in both groups).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Resting myoglobin oxygen saturation (left panel) and myoglobin-derived O2 consumption (right panel) in healthy controls and systemic sclerosis patients (A) and Post-exercise myoglobin reoxygenation kinetics (left panel) and the corresponding mean Mb O2 level during the first minute of recovery (right panel) in healthy controls and systemic sclerosis patients (B). Values are presented as mean ± SD with individual data (n = 6 in healthy control; n = 5 in SSc).



Post-exercise phosphocreatine resynthesis kinetics (A) and the corresponding time constant of the monoexponential fit of the individual data (B) in healthy controls and systemic sclerosis patients. Figure 3C displays the estimated peak rate of mitochondrial ATP synthesis in healthy controls and systemic sclerosis patients. Values are presented as mean ± SD with individual data (n = 6 in both groups).

in the whole-body MR system to assess skeletal muscle mitochondrial function and intracellular oxygenation, respectively. Specifically, after 4 min of data collection at rest, subjects exercised for 4 min followed by 5 min of recovery while 31P-MRS was continuously recorded. After ∼20 min of rest, this protocol was repeated using 1H-MRS of deoxy-myoglobin (dMb). At the end of this second protocol, an air-cuff wrapped above the knee was inflated to 250 mmHg for 8 min to achieve complete vascular occlusion and determine the maximum dMb signal. Due to safety concerns, the circulatory occlusion was not completed in one of the SSc patients. All experimental trials were performed in a thermoneutral environment with participants in an overnight fasted state.

Results: Resting concentrations of phosphocreatine, inorganic phosphate, intracellular pH, and adenosine diphosphate in HC and SSc patients are shown in Figure 1. Values are presented as mean ± SD with individual data (n = 6 in both groups). As shown in Figure 2, at rest SSc patients demonstrated significantly lower MbO2 saturation in the calf (SSc: 93 ± 4 % and controls: 99.9 ± 0.3%), although myoglobin-derived O2 consumption and phosphocreatine resynthesis kinetics [PCr] were

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

not significantly different between groups. During the post-exercise recovery period Mb reoxygenation was delayed in patients with SSc as indicated by the significantly lower mean Mb O2 saturation in the calf muscle of SSc patients during the first min of recovery compared with healthy controls (SSc: 83 ± 8 % and controls: 96 ± 3 %). As a result of this limited O2 supply, both the PCr recovery time constant and the peak rate of mitochondrial ATP synthesis (Vmax) were markedly lower in SSc patients than healthy controls (Vmax, SSc: 6.7 ± 4.1 mM·min-1 and 18.4 ± 6.7 mM·min-1) (Figure 3).

Conclusion: These findings suggest that both compromised intracellular O2 availability and impaired mitochondrial oxidative phosphorylation capacity play a central role in the development of muscle weakness and fatigue experienced by SSc patients.

A Rise in Serum KL-6 Levels Predicts Subsequent Progressive Pulmonary Fibrosis in Patients with Systemic Sclerosis-associated Interstitial Lung Disease

Keina Yomono[1], Suiyuan Huang[2], Dinesh Khanna[2] and Masataka Kuwana[3], [1]Nippon Medical School, Bunkyo-ku, Tokyo, Japan, [2]University of Michigan, Ann Arbor, MI, [3]Nippon Medical School Graduate School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is leading cause of morbidity and mortality in patients with systemic sclerosis (SSc). Given the high variable clinical course of SSc-associated ILD (SSc-ILD), accurate prediction of ILD progression is crucial for both clinical practice and trial designing. Circulating biomarkers have emerged as convenient, non-invasive tools for the diagnosis and prognostication of SSc-ILD. Among these, elevated levels of Krebs von den Lungen-6 (KL-6), a marker for alveolar epithelial injury, has been consistently associated with subsequent decline in forced vital capacity (FVC) and progression to end-stage lung disease [1,2]. However, it remains unclear whether serial changes in KL-6 levels can predict ILD progression. This study aimed to determine whether rising KL-6 levels are predictive of progressive pulmonary fibrosis (PPF) in patients with SSc-ILD using a single-center prospective cohort.

Methods: A total of 136 patients with SSc-ILD were enrolled from a prospective SSc registry at Nippon Medical School Hospital. Patients were categorized into PPF and non-PPF groups based on the proposed criteria [3]. Baseline characteristics were compared between the groups, and a Cox proportional hazards model was used to identify baseline predictors of PPF. To assess the prognostic significance of dynamic KL-6 changes, a time-varying Cox model was applied using KL-6 measurements taken 12 and 6 months prior to either the first PPF event (PPF group) or the last follow-up visit (non-PPF group). KL-6 values were log2-transformed to facilitate interpretation per doubling. Models were adjusted for clinically relevant covariates.

Results: Over a median follow-up of 34 months, 26 patients (19%) developed PPF. Comparison to the non-PPF group, the PPF group had higher prevalence of anti-topoisomerase I antibody (P = 0.034), and a greater ILD extent on high-resolution computed tomography (HRCT) (P = 0.012). Baseline serum KL-6 levels were significantly higher in the PPF group

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. KL-6 (U/mL)	609 (384–939) (n=104)	963 (640–1,365) (n=25)	**0.009**
Chest HRCT findings			
ILD extent on HRCT (%)	8 (4–18)	16 (8–22)	**0.012**
UIP pattern	11 (10.1%) (n = 109)	6 (23.1%)	0.097
Pulmonary function test			
FVC (L)	2.26 (1.84–2.84) (n=102)	2.38 (2.11–3.00) (n=25)	0.33
FVC (% predicted) (%)	88.5 (75.6–104.0) (n=102)	83.2 (75.4–97.1) (n=25)	0.53
DL_{CO} (% predicted) (%)	73.0 (58.4–86.5) (n=91)	75.7 (45.2–84.0) (n=21)	0.60
ILD extensive disease	32 (31.4%) (n = 102)	11 (44.0%) (n=25)	0.34

*Mean (SD); Median (IQR); n (%), **Wilcoxon rank sum test; Fisher's exact test, Pearson's Chi-squared test
CRP: C-reactive protein; dcSSc: diffuse cutaneous systemic sclerosis; DL_{CO}: diffusing capacity for carbon monoxide; ESR: erythrocyte sedimentation rate; mRSS: modified Rodnan total skin thickness score; GI: gastrointestinal; HRCT: high-resolution computed tomography; ILD: interstitial lung disease; IQR: interquartile range; KL-6: Krebs von den Lungen-6; PAH: pulmonary hypertension; FVC: forced vital capacity; PPF: progressive pulmonary fibrosis; SD: standard deviation; SSc-ILD: systemic sclerosis-associated ILD; UIP: unusual interstitial pneumonia

(P = 0.009). In the Cox model, positive anti-topoisomerase I antibody was associated with 236% higher risk of future PPF development (HR: 3.36, 95% confidence interval (CI): 1.17-9.62, P = 0.024), while ILD extent, usual interstitial pneumonia (UIP) pattern on HRCT, and FVC didn't show significant association. In the time-varying Cox model, a doubling of KL-6 levels was associated with 72% higher risk of subsequent PPF (HR 1.72; 95% CI 1.09–2.71; P = 0.020). This association remained significant and was even strengthened after adjusting for clinically relevant covariates, including anti-topoisomerase I antibody status (HR 2.17; 95% CI 1.06–4.45; P = 0.034).

Conclusion: A rise in serum KL-6 levels was significantly associated with the near-term development of PPF in patients with SSc-ILD. These findings support the use of serial KL-6 measurements as a non-invasive biomarker to monitor disease progression and guide clinical decision-making in SSc-ILD.

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Mixed connective tissue disease (MCTD) is an entity defined by clinical features of differentiated connective tissue diseases (dCTD), such as systemic lupus erythematosus (SLE), systemic sclerosis (SSc), or idiopathic inflammatory myopathies (IIM) and the presence of autoantibodies directed toward ribonucleoprotein U1. Although juvenile onset MCTD (jMCTD) occurs in 7-23% of all MCTD cases, few studies have examined the course of jMCTD patients. The aim of the present study was to describe the characteristics, treatments, long-term outcomes of jMCTD, in comparison to adult onset MCTD patients.

Methods: We conducted a multicentric case-control, retrospective, observational, and longitudinal study in the French MCTD cohort. Adult and jMCTD patients were included if they fulfilled, at time of disease onset, at least one of the 4 sets of MCTD diagnosis criteria without fulfilling any current classification criteria for a dCTD. jMCTD patients were defined by an age < 18 years old (y.o) at disease onset. For each jMCTD, 3 adult controls were randomly matched for sex, date of inclusion and follow-up duration.

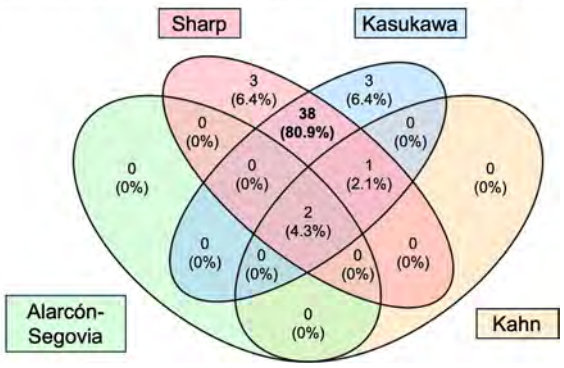
RA	2 (1.1)	0 (0)	2 (1.4)	-
SjD	8 (4.3)	1 (2.1)	7 (5)	-
Overlap	11 (5.9)	2 (4.3)	9 (6.4)	-

Data are presented as number (percentage). P-value were calculated thanks to Chi-squared test or Fisher's exact test as appropriate
dCTD: differentiated connective tissue disease; IIM: idiopathic inflammatory myopathies; ILD: interstitial lung disease; MCTD: mixed connective tissue disease; n: number; PF: pulmonary fibrosis; RA: rheumatoid arthritis; SjD: Sjögren's disease; SLE: systemic lupus erythematosus; SSc: systemic sclerosis

Results: Forty-seven jMCTD patients (44 (93.6%) girls with a median age of 14 [11-16] y.o) at disease onset were included. Forty-four (93.6%) patients met either Sharp or Kasukawa diagnostic criteria and 41 (87.2%) met both diagnostic criteria while none met other classification criteria without fulfilling Sharp or Kasukawa criteria (**Figure 1**). At diagnosis, jMCTD patients had less frequently puffy fingers ($p < 0.0001$) and higher creatine kinase level ($p< 0.001$) compared to adult-onset

Figure 1. Numbers (percentages) of juvenile onset patients fulfilling diagnosis criteria for mixed connective tissue disease.



patients (**Table 1**). Among jMCTD, 26 (55.3%) had received hydroxychloroquine at MCTD diagnosis and 45 (95.7%) during follow-up. jMCTD patients were treated with higher dose of glucocorticoids (p=0.02) and more frequently with rituximab (p=0.01) than adults. After 118 [79-194] months follow-up, jMCTD patients had less frequently puffy fingers (p=0.003), oral dryness (p=0.02) but more renal disease (p=0.02) and were more often in remission than adult-onset patients (p=0.04). In addition, 2 (4.3%) jMCTD patients developed pulmonary hypertension (vs. 12, 8.5% in adults; p=0.5), 11 (23.4%) interstitial lung disease (*vs*. 45, 31.9%; p=0.3 in adults) and 1 (3.1%) died (*vs*. 7, 5% in adults). Seventeen (36.2%) jMCTD patients evolved toward a dCTD (*vs*. 43, 30.5% in adult-onset, p=0.5) (**Table 2**). During follow-up, occurrence of dyspnea (p=0.02), restrictive pattern (p=0.002) or altered DLCO on pulmonary function tests (p=0.005), lymphopenia (p=0.03), and hypergammaglobulinemia (p=0.05), were associated with absence of remission.

Conclusion: This works reports that jMCTD and adult-onset patients share the same phenotype. As for adult-onset patients, Sharp and Kasukawa criteria are sufficient to diagnose MCTD. It shows that jMCTD are treated with higher doses of GC and more frequently with rituximab than adult-onset patients. Importantly, jMCTD patients develop more frequently renal disease but more often reach remission, especially in the absence of respiratory function impairment, as compared to adult-onset patients.

understood. This study aimed to assess the effect of prior COVID-19 infection on fibrosis progression in CTD-associated ILD (CTD-ILD) using artificial intelligence (AI)-based quantitative CT (QCT) analysis.

Methods: We conducted a single-center retrospective study of CTD-ILD patients with confirmed COVID-19 pneumonia who underwent at least two high-resolution CT (HRCT) scans: one within 18 months before infection and one ≥6 months after infection. Only follow-up scans obtained >1 year post-infection were included in the final analysis. Controls were CTD-ILD patients without a history of COVID-19, matched for baseline HRCT and follow-up interval (12–18 months). Fibrosis progression was quantified using both visual and AI-based QCT analysis (Figure 1). Clinical characteristics, pulmonary function tests (PFTs), and immunosuppressive treatment history were collected. Multivariable linear regression identified independent predictors of fibrosis progression.

Results: A total of 110 patients were included (COVID-19 group: n=53; control group: n=57). The cohort comprised various CTD subtypes: systemic sclerosis (54.7%), Sjögren's syndrome (23.2%), rheumatoid arthritis (15.8%), polymyositis (3.2%), dermatomyositis (1.1%), and mixed connective tissue disease (2.1%). Baseline CTD subtype, COVID-19 treatment history, baseline PFTs, and initial fibrosis extent and pattern were comparable between groups. At follow-up, the COVID-19 group showed a significantly greater extent of reticulation on QCT (3.1% vs. 1.4%, p=0.044) and a trend toward increased honeycombing. Multivariable analysis revealed that prior COVID-19 infection (β=4.332, p=0.044), older age (β=0.211, p=0.004), lower baseline FVC (β=–0.187, p=0.001), and rituximab use (β=6.607, p=0.022) were independently associated with greater fibrosis scores (Table 1).

Conclusion: In CTD-ILD patients, prior COVID-19 infection was independently associated with increased fibrosis progression on follow-up CT. These findings highlight the long-term pulmonary impact of COVID-19 in a vulnerable population, warranting close radiologic surveillance and personalized management strategies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in patients with systemic sclerosis (SSc). Randomized controlled trials favoured the use of cyclophosphamide (CYC) for treating SSc related ILD (SSc-ILD) (1,2). However, the effects of CYC waned after an additional year off therapy (3) and patients included did not fulfil progressive ILD criteria.

Methods: We conducted a randomized, prospective, double-blind, placebo-controlled multicenter trial to evaluate the efficacy and safety of CYC in combination with prednisone in patients with progressive SSc-ILD (Clinical trial NCT01570764).

Patients (≥ 18 years old) with SSc (defined by the American College of Rheumatology (ACR) and/or Leroy and Medsger criteria) and progressive SSc-ILD (defined as ≥ 10% decrease in forced vital capacity (FVC) and/or total lung capacity (TLC), and/or ≥ 15% decrease in diffusing capacity of the lung for carbon monoxide (DLCO) within 3 to 18 months prior to inclusion) were randomly assigned, in a 1:1 ratio, to receive either 0.7 g/m^2 (maximum 1200 mg) of intravenous (IV) CYC every 4 weeks during 12 months, or placebo. Both groups received 15 mg/day prednisone. The primary endpoint was the proportion of patients who improved or stabilized FVC at 12 months.

Results: Forty patients (13 males and 27 females, 24 (60%) with diffuse cutaneous SSc) were included between January 2013 and March 2017, with 20 patients randomized to each group. In the primary endpoint analysis, the proportion of patients who improved or stabilized FVC at 12 months was 17/20 (85%) in the CYC group and 16/20 (80%) and in the placebo group (relative risk (RR) 1.06 95% confidence interval (CI) (0.51 to 2.19)).

Sensitivity analyses showed that the mean change from baseline in FVC at 12 months was 252.1 mL (122.8 to 381.4) in the CYC group and 3.8 mL (-129.3 to 136.9) in the placebo group (mean difference 248.3 (64.3 to 432.4)). The mean change from baseline in the health assessment questionnaire (HAQ) was lower at 12 months in the CYC group (-0.23 [-0.43; -0.02]) compared to the placebo group (0.27 [0.06; 0.48]) (mean difference -0.50 (-0.79 to -0.21)). Similarly, the mean change in the scleroderma-HAQ was significantly lower in the CYC group (-0.22 (-0.42; -0.02)) compared to the placebo group (0.28 (0.08; 0.48)) (mean difference -0.50 (-0.78 to -0.21)). The mean change in the physical component of the SF-36 was also greater in the CYC group (5.5 (0.9; 10.1)) than in the placebo group (-2.6 (-7.0; 1.9)) (mean difference 8.1 (1.7 to 14.3)). There was no significant difference in the mental component scale of the SF-36, nor in DLCO, New York Health Association, or six-minute walk distance. The proportion of patients who developed severe adverse events was similar between the groups ((5/20 (25%) in the CYC group vs. 7/20 (35%) in the placebo group). Two patients died, one in each group.

Conclusion: In patients with progressive SSc-ILD, treatment with oral prednisone and IV CYC did not significantly increase the proportion of patients who improved or stabilized FVC and/or DLCO at 12 months. However, it significantly increasedFVC, and improved HAQ, Scleroderma-HAQ scores, and the physical component of the SF-36 at 12 months.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose:

Systemic sclerosis (SSc) is a severe autoimmune disease with limited treatments. While anti-CD19 CAR T-cell therapy shows promise, its use is limited by cost and complexity. Blinatumomab, a bispecific T-cell engager targeting CD3 and CD19, may offer a simpler and more affordable alternative and may be effective in severe SSc.

We aim to evaluate the safety and effectiveness of blinatumomab in managing severe refractory systemic sclerosis in real-world settings.

Methods: Patients with severe, refractory, Scl70-positive SSc were considered for treatment with blinatumomab following a multidisciplinary review to validate its off-label use. Informed, written consent was obtained from patients to participate in a translational study evaluating the impact of blinatumomab on their immune system. The treatment protocol included premedication with hydrocortisone (100 mg), acetaminophen (1 g), and dexchlorpheniramine (5 mg), followed by continuous intravenous infusion of blinatumomab at 9 µg/day for 7 days, then 28 µg/day for another 7 days. Patients were closely monitored in a hospital setting throughout the intravenous treatment phase and then followed ambulatorily.

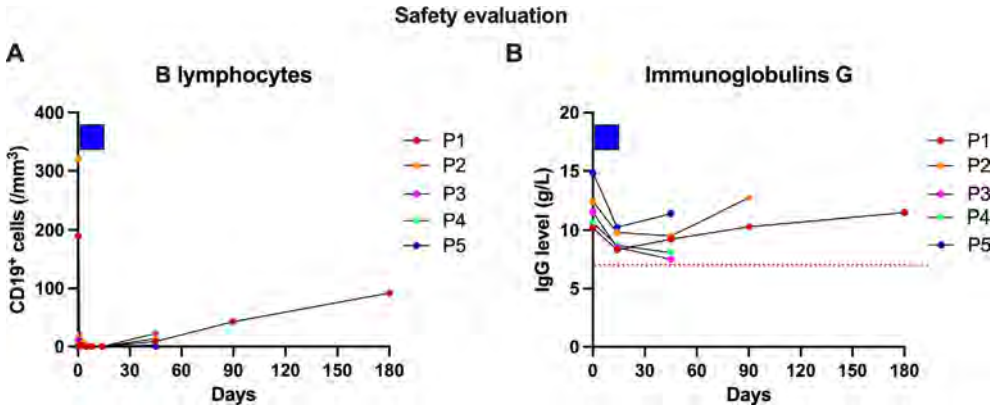

Figure 1: Safety evaluation after blinatumomab treatment. (A) Peripheral CD19+ B cells, (B) total immunoglobulin levels.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Efficacy evaluation blinatumomab treatment. (A) modified Rodnan Skin Score (mRSS), and (B) forced Vital capacity (FVC) expressed in % of the theoric value.

Results: Five patients from three different departments were included in the study: four women (P1, P2, P3,P4) and one man (P5) of median age 64 (IQR : 61-65) years. All patients had recent (≤6 years) and progressive Scl70-positive SSc that was refractory to a median of four immunosuppressive therapies (3-8), including autologous stem cell transplantation for P2. The median modified Rodnan skin score (mRSS) was 16 (15-23). All patients had fibrosing interstitial lung disease; four had cardiac fibrosis and one had pulmonary hypertension.

At the time of submission, all patients had received the complete treatment.. During infusion, 4 patients developped a grade 1 cytokine release syndrome (isolated fever) treated with acetaminophen, and one a grade 2 (fever and transient hypotension) that was treated with acetaminophen and fluids without need for tocilizumab. No Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS) was observed.

All patient completed month 1 of follow-up, two completed month 3 and one month 6. Peripheral B-cell depletion was complete by day 3, persisted until day 14, and B cell repopulation was seen at month 1 (**Fig. 1A**). Despite a small decrease in total IgG, all patients remained above the lower limit (**Fig. 1B**). There was no impact on post-vaccination serologies, and no severe infections during follow-up was identified.

Clinically, a notable decrease in mRSS was observed in the two patients who completed the 3-month follow-up (**Fig. 2A**). While antinuclear and anti-Scl70 antibodies remained unchanged post-treatment, there was a marked reduction in the type I interferon signature. Pulmonary function, as indicated by lung volumes (e.g., forced vital capacity), showed significant improvement after treatment (**Fig. 2B**). B-cell receptor (BCR) sequencing is currently underway.

Conclusion: This real-world study indicates that blinatumomab is safe for use in systemic sclerosis and may lead to clinically significant improvements, including benefits for skin and lung manifestations.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is the main cause of mortality in systemic sclerosis (SSc). Among radiomics features, the automated quantification of pulmonary vascular volume (PVV) on high-resolution computed tomography (HRCT) was predictive of survival and functional changes in idiopathic pulmonary fibrosis (IPF) and rheumatoid arthritis (RA)-associated ILD (Jacob, 2018). In SSc, PVV was associated with ILD severity (extent on HRCT, pulmonary function tests values: pFVC%, pDLCO%). Here, we explored the predictive value of CT-derived radiomics features for mortality and ILD progression in SSc-ILD.

Methods: We included SSc patients from a single referral centre with ILD present on HRCT and at least one follow-up visit. The progression analysis focused on patients with lung function repeated within 12±3 months. ILD progression was defined as at least one of the following:

- FVC relative decline ≥ 10 %
- FVC relative decline ≥ 10 % or FVC 5-9% and DLCO relative decline ≥ 15%
- FVC absolute decline ≥ 5%
- FVC absolute decline ≥ 5 or DLCO absolute decline ≥ 10%

HRCT scans underwent lung texture analysis (LTA, Imbio). The percentage distribution of ground-glass, reticular, honeycombing (the latter two defining “fibrotic alterations”), hyperlucency, normal lung and PVV was quantified in upper, middle and lower zones and the whole lung.

Survival analysis was performed from the first ILD-positive CT until last contact (death or alive status), using Cox proportional hazards models, with radiomics parameters adjusted for the SCOpE score (Elhai, 2017). Radiomics predictors of ILD progression were assessed using the logistic Generalized Estimating Equations (GEE), adjusted for established risk factors.

Results: Among 267 SSc-ILD patients, 65 (24%) deaths were recorded over a median follow up of 42 (27-110) months. Patients who died were older, clinically and functionally more severely impaired (Table I) and with higher extent of PVV% and parenchymal alterations in all lung zones (Table II). In a multivariable Cox model, the PVV% of the upper zones (HR 1.28, 95% CI 1.12-1.47) and the SCOpE score (HR 1.22, 95% CI 1.15-1.28) independently predicted mortality (Fig IA).

Among the 261 yearly follow-ups from 160 SSc-ILD patients, we recorded 99 episodes of ILD progression (38%), occurring in 64 patients (40%). Patients with progressive ILD had more frequently increased inflammatory markers, better-preserved pulmonary function tests (Table I), but comparable radiomics changes versus non-progressors (Table II). In a multivariable model integrating clinical and radiomics predictors selected through univariable analysis, only pDLCO% (OR 1.02, 95% CI 1.01-1.04) and pFVC% (OR 1.03, 95% CI 1.01-1.05) were independently associated with ILD progression (Fig IB). Comparable results were obtained when each progression definition was analysed separately.

Conclusion: In line withRA-ILD and IPF, PVV% of the upper zones significantly predicts mortality in SSc-ILD. Conversely, we could not detect radiomics predictors for ILD progression. Further studies are needed to support the identification of patients at risk of ILD progression and prompt therapeutic interventions.

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Interstitial lung disease (ILD) is highly prevalent in systemic sclerosis (SSc) and a leading cause of mortality. Recent studies have identified clinical risk factors for new onset of ILD at both 1-year and long-term follow-up (1,2), still not optimally identifying patients at high risk. Pulmonary vascular volume (PVV%) quantified on high-resolution computed tomography (HRCT) is associated with both presence and severity of SSc-ILD (3).

In this study, we investigate the potential of radiomics in identifying patients with risk of developing ILD.

Methods: We included patients from a single SSc referral centre, with no ILD on baseline HRCT and at least one clinical and HRCT follow-up. Images 1) were assessed by experienced thoracic radiologist for presence/absence of ILD at all timepoints, 2) underwent lung texture analysis (LTA, Imbio), quantifying PVV, normal lung, lung pathologies (hyperlucency, ground-glass, reticular, honeycombing), as percentage of the lung volume, both for whole lungs and for upper, middle, lower zones.

Univariable and multivariable prediction models were developed to identify radiomics risk factors for ILD onset, using Cox regression and generalizes estimating equation (GEE) analysis for ILD onset ever and at 1-year, the latter allowing for multiple observations of the same patient. Both models were adjusted for the established clinical risk factors (1,2).

Table I. Clinical characteristics and functional features of SSc patients with and without ILD onset ever and ILD onset 1-year ACA: anti-centromere antibodies ATA: anti-topoisomerase I antibodies; ARA: anti-RNA polymerase III antibodies; antiPm/Scl: anti-PM-scleroderma-antibodies; dcSSc: diffuse cutaneous systemic sclerosis; NVC: nailfold videocapillaroscopy; NYHA: New York Hearth Association; pFVC%: predicted forced vital capacity; pDLCO/SB%: predicted diffusion of the lung for carbon monoxide on single breath; 6MWT: 6 minutes walking test; SD: standard deviation. Increased inflammatory markers defined as ESR or/and CRP above normal limit

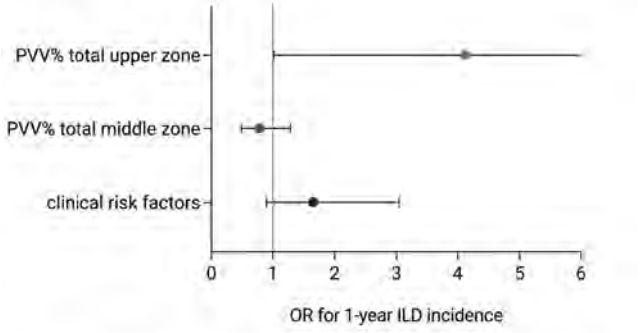
A) clinic risk score incorporates age, sex, SSc specific autoantibodies, pDLCO%, inflammatory markers, DUs, NYHA class ≥ II, haemoglobin levels in long-term ILD analysis



B) clinic risk score incorporates age, sex, SSc specific autoantibodies, pDLCO%, inflammatory markers, NYHA class ≥ II, haemoglobin levels in the 1-year analysis

Fig I: Forrest plot showing predictive radiomics and clinical risk factors for long-term ILD incidence (A) and 1-year ILD incidence (B)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 248 SSc patients with no ILD at baseline HRCT, new onset of ILD occurred in 54 (22%) cases over a median follow-up of 39 (24-72) months. Patients developing ILD were more frequently males, with diffuse skin involvement, anti-topoisomerase I antibodies and shorter disease duration (Table I, left panel). Additionally, patients with new onset ILD over the study period presented higher values of PVV across all lung zones at baseline HRCT (Table II). In multivariable Cox regression analysis, new ILD onset was independently predicted by PVV% from the whole lung [HR 1.054 (1.030-1.078)], as well as from each individual zone. When integrating the PVV% of each single zone with the clinic risk factors in the multivariable analysis, we observed the significant, independent impact of the lower zone PVV% [HR 1.217 (1.113–1.332)], in addition to the known risk associated with clinical features [HR 3.281 (2.145–5.021)] (Fig IA).

Focusing on 1-year ILD onset, we analysed 279 follow-up visits from 193 patients and observed 22 (11.4%) new onset ILD (Table I, right panel). On univariable GEE, we confirmed the association of PVV from the whole lung on ILD onset, with particular focus on the middle and upper zones, alongside the clinical risk factors. When tested in a multivariable model adjusted for clinical risk factors, PVV% of the upper zone remained significantly associated with ILD onset [OR 4.127 (1.016–16.761)] (Fig IB).

Conclusion: PVV% from HRCT scans of SSc patients without ILD can predict new onset of ILD at both 1-year and long-term follow-up, supporting the use of radiomics in clinical risk phenotyping.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Calcinosis is a high-burden, key manifestation of systemic sclerosis (SSc), with a challenging therapeutic management. Yet, its precise prevalence and association with SSc charcateristics remain poorly defined. This study aimed to (i) assess the overall prevalence of calcinosis in SSc, and (ii) describe its association with clinical and serological phenotypes of SSc, through a systematic review of the literature with meta-analysis.

Methods: A systematic review of the literature available from inception to September 2024 was carried out in Pubmed, Embase and Web of Science databases. Meta-analyses were performed using collected data on demographic, clinical, biological and imaging characteristics of SSc patients with and without calcinosis.

Results: Eighty-one studies corresponding to a total of 18,643 SSc patients from 37 different countries were included in the meta-analysis. In this population, the overall prevalence of calcinosis was 24% (95% confidence interval [CI]: 21-27), with a high degree of heterogeneity (I^2 = 90.4%, p het < 0.001). Meta-regression revealed that the publication date (p = 0.02) and country (p = 0.001) of each report, could partially explain this observed disparity across studies. Calcinosis screening method also influenced its prevalence. When calcinosis diagnosis was based exclusively on clinical examination, its prevalence was 21% (95%CI: 16-27), whereas it increased to 28% (95%CI: 21-35) when the diagnosis was radiographic, alone or combined with clinical examination (p = 0.04) (**Figure 1**). Calcinosis was positively associated with female gender (OR: 1.43 [1.17; 1.76]), a longer disease duration (14.5 years vs 11.1 years, p = 0,03), pulmonary hypertension (OR: 1.76

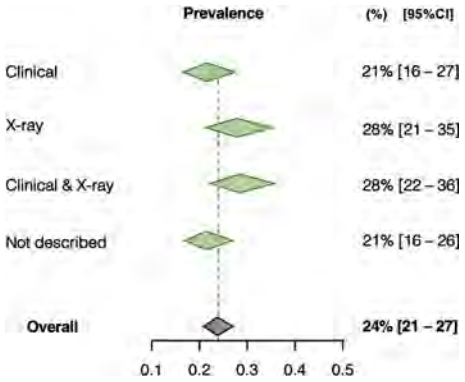

Figure 1. Prevalence of calcinosis in SSc patients, according to the diagnostic method. Diamonds represent the pooled prevalence for each diagnostic method and the overall prevalence.

Figure 2. Association between calcinosis and SSc features. p asso: p-value for association, p het: p-value for heterogeneity, LcSSc: limited cutaneous systemic sclerosis, GI involvement: gastrointestinal involvement, Ab: antibodies, NVC: nailfold video capillaroscopy. Statistically significant associations are represented in bold.

[1.25-2.49]), digital ulcerations (OR: 2.29 [1.48; 3.54]), telangiectasia (OR: 2.79 [1.35; 5.79], an active nailfold capillaroscopy pattern (OR: 2.78 [1.11-7.01]), anti-centromere antibodies (ACA) (OR: 2.39 [1.65; 3.45] and, negatively associated with anti-topoisomerase I antibodies (OR: 0.86 [0.75; 0.99]). A positive association was also found between calcinosis and heart (OR: 1.69 [1.40; 2.05] or gastro-intestinal involvement (OR: 2.62 [1.24; 5.55]), but with a small number of studies (**Figure 2**). No statistically significant association was found between calcinosis and other available clinical features, including cutaneous subset.

Conclusion: Calcinosis is a highly prevalent clinical finding in SSc, occurring in almost one out of four SSc patients. Our work confirmed that, across multiple centers worldwide, calcinosis preferentially develops in female patients, with ACA, and a predominantly vascular phenotype. These findings also highlight the potential clinical relevance of a more systematic radiological evaluation of calcinosis, both to prevent a destructive local evolution, and to identify SSc patients who require closer monitoring of vascular complications, especially pulmonary hypertension. Further studies are needed to decipher the precise implication of vascular involvement in this manifestation, with the prospect of new therapeutic opportunities.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: There have not been large US-based studies of digital pitting scars (DPS) and digital ischemic ulcers (DIU) in systemic sclerosis. Utilizing the Collaborative National Quality and Efficacy Registry (CONQUER) cohort, we describe the prevalence, incidence, and quality of life impact of DPS and DIU and determine factors associated with the development of DPS or DIU.

Methods: CONQUER is a US-based, prospective, multi-center cohort of adults (age ≥18) with SSc who meet 2013 ACR/EULAR Classification Criteria and have a disease duration ≤5 years from first non-Raynaud's symptom at enrollment. As of December 31st, 2024, 1113 participants with mean follow-up of 24 months were enrolled. At each visit, investigators noted the presence of DPS and DIU and collected demographic, clinical and laboratory variables. Multivariable logistic regression models were designed using directed acyclic graphs.

Results: The mean age at study entry was 52.5 years, 83% were female, 65% had diffuse cutaneous SSc and 64% had interstitial lung disease. At baseline, 20% had current DPS and 5% had DIU. Younger age at baseline, non-Hispanic Black or African American race, telangiectasias of face or lips, and positive Scl-70 antibody were associated with DPS at baseline (Table 1). Younger age was associated with DIU at baseline (Table 1). In contrast to the variables associated with DPS, positive Scl-70 antibody was associated with lower odds of DIU at baseline. During the first year in CONQUER, 14% developed new DPS and 15% developed new DIU. Analyses of demographic and SSc-related factors did not reveal significant predictors for time to development of first DPS or DIU (Figures 1 and 2). The presence of DIU, but not DPS, was associated with higher PROMIS-29 scales (worse symptom burden) from anxiety (OR 1.38, 95% CI 1.05 to 1.81), depression (OR 1.57, 95% CI 1.18 to 2.10), and pain (OR 1.40, 95% CI 1.04 to 1.89).

Conclusion: In this large, prospective US cohort of participants with early SSc, 14% developed DPS and 15% developed DIU in the first year of study. Non-Hispanic Black or African American race and younger age were associated with DPS, while

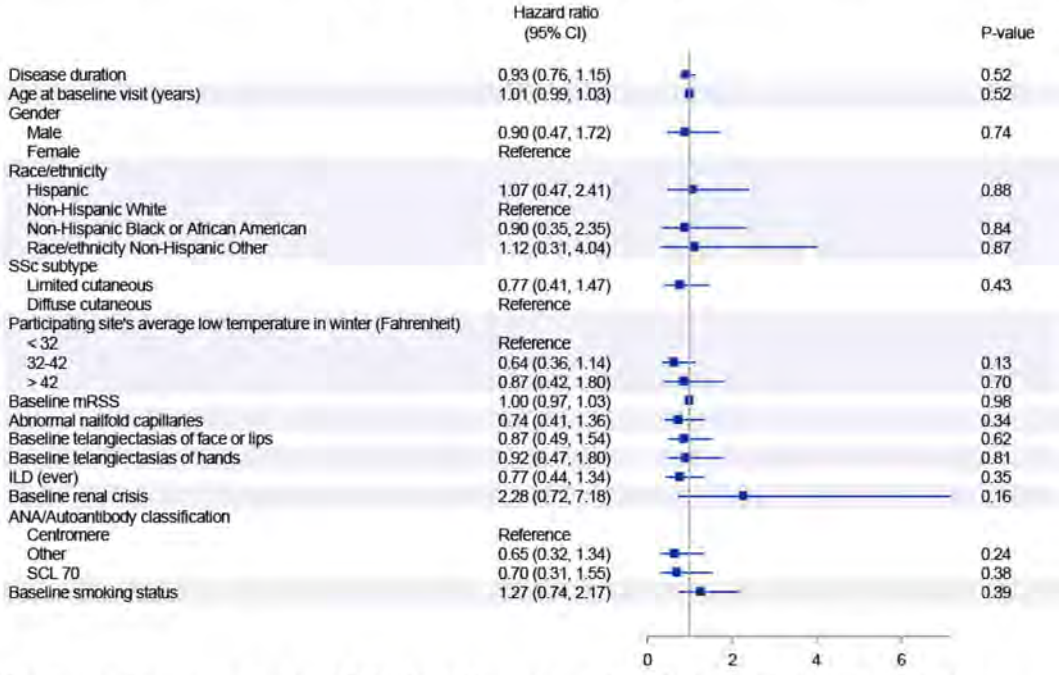
Figure 2: Survival analysis of demographic and systemic sclerosis-related factors in association with time to ischemic digital ulcers



Participants with presence of ischemic digital ulcers at baseline are not included in analysis. Analysis uses time from baseline to first ischemic digital ulcers (months).

younger age was associated with DIU. Although we did not identify significant predictors of incident DPS or DIU, DIU were associated with worse symptom burden. These findings underscore the importance of early vascular assessment in SSc and support further study to reduce ischemic complications and improve patient outcomes.

Abstract Number: 1583

Epidemiology, Outcome and Expenditures of Hospitalized Patients with Systemic Sclerosis: National Inpatient Sample 2021

Patompong Ungprasert[1] and Paul Kroner[2], [1]Cleveland Clinic, Cleveland, OH, Cleveland Heights, OH, [2]Riverside Health System, Newport News, VA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The inpatient epidemiology, morbidity, mortality, and healthcare expenditures of patients with systemic sclerosis (SSc) are not well-characterized. This study aims to utilize a nationwide inpatient database to better describe these parameters.

Methods: Patients with SSc were identified in the 2021 Nationwide Inpatient Sample (NIS) using ICD-10-CM codes. The NIS is the largest all-payer inpatient database in the United States, encompassing data from over 4,000 non-federal acute care hospitals, and is representative of all U.S. acute care hospitalizations. A comparison cohort without SSc was created for comparative analysis. Extracted data included demographics, primary admission diagnoses, length of stay, mortality, morbidity, expenditures, and comorbidities. Comparative analyses were adjusted for age, sex, ethnicity, Charlson Comorbidity Index, payer type, income, and hospital characteristics.

Results: The inpatient prevalence of SSc was 86.7 per 100,000 admissions. The most common primary admission diagnoses among SSc patients were sepsis (22.7%), hypertension with heart failure (14.4%), and COVID-19 infection (11.5%). The SSc cohort was predominantly female (84.2%) with a mean age of 63.5 years. Compared with non-SSc hospitalizations, those with SSc had significantly longer hospital stays (by 0.7 days; 95% CI: 0.5–0.9) and higher costs, including an adjusted mean increase of $3,277 (95% CI: $2,051–$4,504) in total hospital costs and $11,801 (95% CI: $6,485–$17,116) in total hospitalization charges. Patients with SSc also experienced worse outcomes, including higher risk of in-hospital mortality (adjusted OR 1.42; 95% CI: 1.26–1.61), shock (OR 1.30; 95% CI: 1.17–1.44), systemic inflammatory response syndrome (OR 1.32; 95% CI: 1.01–1.74), and acute respiratory distress syndrome (OR 1.45; 95% CI: 1.12–1.87). Additionally, hospitalized SSc patients had a higher prevalence of multiple comorbidities compared to the control group (see Table 1).

Table 1: Adjust odds ratio comparing comorbidity between hospitalized patients with systemic sclerosis and comparators without systemic sclerosis

Table 1: Adjust odds ratio comparing comorbidity between hospitalized patients with systemic sclerosis and comparators without systemic sclerosis

	Adjusted OR	95% CI	p-value
Pulmonary hypertension	7.21	6.68-7.78	<0.01
Interstitial lung disease	26.33	23.83-29.10	<0.01
Sjögren's syndrome	21.42	19.21-23.87	<0.01
Osteoporosis	2.41	2.18-2.67	<0.01
Hypertension	1.25	1.17-1.34	<0.01
Myocardial infarction	0.97	0.87-1.09	0.63
Mesenteric ischemia	1.42	0.90-2.22	0.13
Chronic kidney disease	0.92	0.85-1.04	0.23
Autoimmune thyroid disease	2.79	2.10-3.70	<0.01

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The inpatient prevalence of SSc is substantially higher than its prevalence in the general population, suggesting that individuals with SSc require inpatient care more frequently. SSc hospitalizations are associated with poorer clinical outcomes and significantly higher healthcare expenditures.

Evaluation of Adverse Childhood Experiences in Systemic Sclerosis: Prevalence and Patient Characteristics

Samuel Good[1], Nahal Ghanoongooi[1], Ju Young Lee[2], Arissa Young[3] and Elizabeth Volkmann[1], [1]David Geffen School of Medicine at University of California, Los Angeles, Department of Medicine, Division of Rheumatology, Los Angeles, CA, [2]David Geffen School of Medicine at University of California, Los Angeles, Department of Medicine, Los Angeles, CA, [3]UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: There is growing evidence that trauma, and in particular adverse childhood experiences (ACEs), play a role in the pathogenesis and exacerbation of systemic autoimmune disease.[1] ACEs likely affect autoimmunity through multiple pathways, including pro-inflammatory processes and associations with psychosocial influences on the development of autoimmunity, such as substance use and mental health disorders. To date, no studies have evaluated the association between ACEs and disease manifestations in systemic sclerosis (SSc). The purpose of this study is to evaluate the prevalence of ACEs in SSc patients and to describe the clinical characteristics of patients with SSc with high adversity.

Methods: We recruited consecutive patients who met 2013 ACR/EULAR criteria for SSc seen in our UCLA Scleroderma Center from September 4, 2024 to April 9, 2025. The Adverse Childhood Experiences Questionnaire (ACE-Q), was administered to assess the frequency of ACEs experienced by respondents.[2] The ACE-Q categorizes ACEs into 2 subdomains: abuse/neglect and household dysfunction. Descriptive statistics were used to demonstrate the demographic and clinical characteristics of patients with SSc with high vs. low-moderate total ACE-Q scores based on the validated threshold for high adversity (4 or more ACEs). This threshold is associated with significantly elevated risk for severe and complex health problems.[2]

Results: Among 98 patients with SSc, 85 (86.7%) were female, 63 (64.3%) identified as White, 34 (34.6%) had diffuse cutaneous disease, and 59 (60.2%) had ILD (**Table 1**). In the total SSc population, 63 (64.2%) patients reported at least one ACE, and 22 (22.4%) reported 4 or more ACEs (**Table 1**). The mean number of ACEs was 2.02 (SE 0.23) for the entire SSc cohort (**Figure 1**). The proportion of patients with ILD was numerically higher in the high adversity compared with low to moderate adversity groups (68.2% vs. 57.9%, respectively).

Conclusion: The majority of patients with SSc reported at least one ACE, and the prevalence of high adversity was greater in SSc patients compared with the general population in the US (22.4% vs. 17.3%, respectively).[3] The high prevalence of ACEs and, in particular high adversity, in this SSc cohort highlights the need for further research into the effects of trauma on SSc pathogenesis. Moreover, the finding that high adversity was more prevalent in patients with ILD warrants future investigation into the relationship between trauma and the diverse clinical phenotypes of SSc.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a complex systemic autoimmune disease characterized by vasculopathy, fibrosis, and immune dysregulation. While JAK inhibitors (JAKi) have shown promising immunomodulatory and antifibrotic effects in early-phase studies, their real-world impact on SSc patients remains poorly studied. We aimed to assess safety and explore the efficacy in JAKi-treated SSc patients compared to conventional immunosuppressants.

Methods: We conducted a longitudinal retrospective cohort study within the European Scleroderma Trials and Research group (EUSTAR) database. Patients receiving JAK inhibitors (JAKi) were matched 1:5 to patients initiating mycophenolate mofetil (MMF), rituximab (RTX), or methotrexate (MTX) using nearest-neighbour propensity score matching based on age, sex, disease duration, antibody profile, skin subset, presence of digital ulcers (DUs), and baseline lung function.

Primary outcomes included adverse events and drug survival (time to permanent discontinuation). Efficacy endpoints were change in FVC% and mRSS at 12 and 24 months, improvement in swollen joint count (SJC) in patients with synovitis, time to new DUs, and a composite disease progression outcome (new PAH, SRC, or ILD progression). Safety events, reasons for discontinuation, and use of vasodilators were also recorded. Time-to-event analyses were performed using Kaplan–Meier

and restricted mean survival time (RMST); continuous outcomes were analysed via linear models and paired tests. Follow-up was censored at drug discontinuation for patients without outcome events.

Results: We included 36 JAKi-treated patients (44% baricitinib, 42% tofacitinib, 14% upadacitinib), predominantly female (81%), with a median disease duration of 76 months. Over 98.7 patient-years, 23 adverse events occurred (23.3/100 patient-years), including 12 infections (8 severe, 1 fatal), 7 lab abnormalities, and 3 malignancies. JAKi was permanently discontinued in 14 patients (39%), and transiently interrupted in 7 (19%).

At 12 months, FVC remained stable (+1.7%, p=0.530); skin fibrosis improved modestly (–1.1 mRSS, p=0.036), particularly in diffuse cutaneous SSc. Swollen joint count improved in patients with baseline synovitis (median –1, p=0.052). No new calcinosis developed, and two pre-existing cases improved.

Time-to-event analyses over 60 months showed comparable risk of recurrent digital ulcers and composite progression events between JAKi and matched MMF, RTX, and MTX arms (RMST differences non-significant; DU log-rank p=0.24). JAKi-treated patients had similar or slightly better RMST for disease progression versus MTX (+3.1 months), though differences did not reach significance.

Conclusion: In this cohort, treatment with JAK inhibitors was not associated with an increased risk of fibrosing or vascular complications compared to conventional immunosuppressive therapies. While these findings suggest a favourable safety profile and potential efficacy of JAKi in SSc, prospective, controlled studies are needed to confirm these results and to explore their potential disease-modifying effects.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: JAK inhibitors (JAKi) have shown promising early results in systemic sclerosis (SSc) patients, yet real-world data on their longitudinal effects across different disease domains remain limited. We aimed to explore the safety and intra-patient evolution of pulmonary, cutaneous, and articular parameters in a well-characterized cohort of SSc patients treated with JAKi, using standardized efficacy metrics over 12 and 24 months.

Methods: Ours was an international, multi-center longitudinal retrospective cohort study. Continuous variables were reported as means (SD) or medians (IQR) as appropriate and categorical variables were reported as counts (%). Incidence rates were calculated per 100 patient-years, and descriptive statistics were used for calcinosis and DU events. To assess treatment efficacy, we evaluated changes in FVC%, DLCO%, modified Rodnan skin score (mRSS), tender and swollen joint counts (TJC, SJC), digital ulcers (DU), and calcinosis status. Baseline was defined as the first available measurement at JAKi initiation; follow-up values were taken within a ±2-month window from 12 and 24 months. For each parameter, the primary outcome was the delta from baseline. Paired comparisons used the Wilcoxon signed-rank test. Effect size was quantified using standardized mean change (SMC). Analyses were performed in R (version 4.3.3).

Results: Among the 32 patients treated with the 4 avaliable JAK inhibitors, the median (IQR) follow-up time on treatment was 16.9 (10.3-31.8) months, with a range from 1.4 to 52.0 months, amounting to 52.8 patient-years. At 12 months, pulmonary function parameters (FVC% and DLCO%) remained stable over time. Although small positive changes were observed (SMC +0.22 for FVC and +0.23 for DLCO), neither reached statistical significance (p=0.10 and p=0.33, respectively) (Figure 1A and 1B). At 12 months, the median mRSS showed a significant improvement (p=0.030), with an SMC of -0.29 (Figure 1C). Similarly, both TJC and SJC showed decreases, (p=0.0002 and p=0.0012, respectively) with SMCs of -1.19 for TJC and -0.69 for SJC (Figure 1D and 1E). At 24 months, mRSS, TJC, and SJC showed numerical improvements which were marginally significant for joints domain (SMC: -0.21, -1.13, and -1.14; p=0.17, p=0.054, and p=0.058, respectively). FVC% and DLCO% remained stable with no significant changes. Among 11 patients with calcinosis at baseline, 5 (45.5%) showed improvement, 3 (27.3%) experienced worsening, and 3 (27.3%) remained stable during follow-up. During follow-up, 10 patients developed at least one episode of active DUs, corresponding to an incidence rate of 21 events per 100 patient-years. Among patients treated with glucocorticoids (n=15), a trend toward dose tapering over time was observed (-0.038 mg/month), although borderline significant (p=0.1).

Table 1. Baseline clinical and demographic parameter of the JAK inhibitor-treated Systemic Sclerosis cohort.

Characteristic	Patients N = 32[1]
LeRoy subset	
Diffuse cutaneous	13 (41%)
Limited cutaneous	19 (59%)
ANA positive	31 (97%)
Rheumatoid Factor	7 (22%)
Anti CCP	2 (6.3%)
Anti Ro52	2 (6.3%)
Anti Centromere	8 (25%)
Anti Topoisomerase I	12 (38%)
Anti RNA polymerase III	2 (6.3%)
Pitting scars	14 (44%)
Telangiectasia	21 (66%)
History of Digital Ulcers	22 (69%)
Active Digital Ulcers	7 (22%)
Puffy fingers	17 (53%)
Calcinosis	11 (34%)
Acro osteolysis	3 (9.4%)
Pulmonary Arterial Hypertension	8 (25%)
Interstitial Lung Disease	16 (50%)
Glucocorticoids treatment	15 (47%)
Forced Vital Capacity (% predicted)	92 (78, 108)
Diffusing Lung Capacity (% predicted)	71 (57, 84)
Swollen Joints Count	4.0 (2.0, 10.0)
Tender Joints Count	6.0 (2.5, 10.0)
Raised C-reactive protein	10 (31%)
Antiplatelets treatment	8 (25%)
Mycophenolate Mofetil	3 (9.4%)
Calcium Channel Blockers	11 (34%)
Endothelin Receptors Antagonists	7 (22%)
Phosphodiesterase 5 inhibitors	10 (31%)
Iloprost	6 (19%)
Methotrexate	12 (38%)
Leflunomide	2 (6.3%)
Tocilizumab	1 (3.1%)
Nintedanib	1 (3.1%)
Rituximab	1 (3.1%)
Cyclophosphamide	0 (0%)
JAK inhibitor type	
Baricitinib	10 (31%)
Filgotinib	7 (22%)
Tofacitinib	10 (31%)
Upadacitinib	5 (16%)

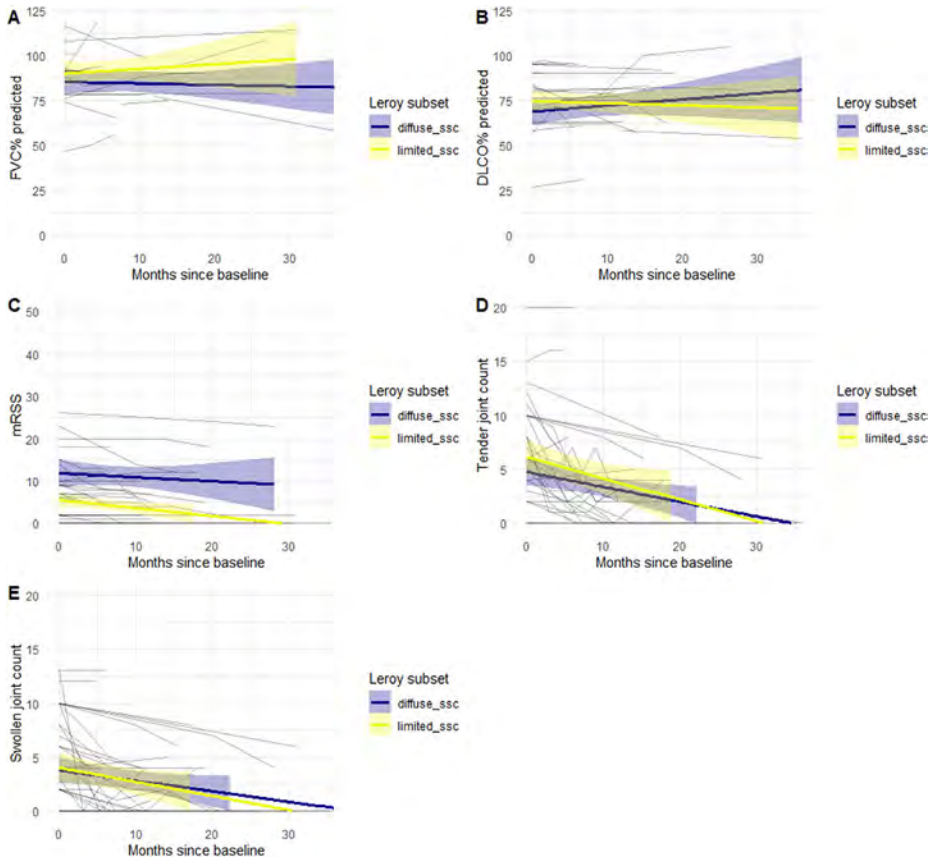

Figure 1. Longitudinal changes in clinical parameters during JAK inhibitor treatment in systemic sclerosis. (A) FVC% predicted, (B) DLCO% predicted, (C) modified Rodnan skin score (mRSS), (D) tender joint count (TJC), and (E) swollen joint count (SJC), stratified by LeRoy subset. Each line represents an individual patient; solid lines and shaded areas represent linear trends with 95% confidence intervals.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: In this real-life SSc cohort, JAK inhibitors were associated with significant improvements in skin and joint involvement. Importantly, pulmonary function remained stable over time, suggesting a potential disease-modifying effect across multiple clinical domains. A steroid sparing effect was noted, and with improvement in calcinosis seen in some treated patients.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSC) is a chronic, multisystem autoimmune disease characterized by immune dysfunction, microangiopathy, and tissue remodelling. Orofacial manifestations, including xerostomia, microstomia, tooth decay, and periodontitis, affect up to 80% of SSC patients and significantly impact their quality of life. Despite their prevalence, these manifestations are often neglected compared to more life-threatening complications such as lung or kidney involvement. This study was designed to estimate the prevalence of oral-manifestations and to find their association with clinical and serological profiles in SSC patients.

Methods: A multi-centre study was conducted involving 131 SSC patients fulfilling ACR/EULAR-criteria. Comprehensive clinical-evaluation was performed including Modified-Rodnan-Skin-Score (MRSS) for skin tightness and Medsger's-disease-severity-score for organ involvement. Oral-manifestations like presence of sicca symptoms, GERD were noted. Standardised-questionnaires like, Indian Cochin hand function Scale (ICHFS), Mouth Handicap in Systemic Sclerosis Scale (MHISS) were used to assess functional-impairment. Oro-facial health was evaluated using standardized dental indices such as Debri-Index(DI), Calculus-index(CI), number of missing-teeth, tooth-mobility, probing-depth(PD), gingival-bleeding (GB) and Clinical-attachment-level(CAL), Recession(REC) by a periodontist. Statistical-analysis was conducted using SPSS software V20, with statistical significance set at $p < 0.05$.

Results: Among 131 SSC patients, 45 were Limited Cutaneous SSC (LCSSC), 83 were Diffuse Cutaneous SSC (DCSSC) and 3 were sine scleroderma. The mean age was 42 years. Prevalence of oral manifestations like sicca symptoms was 59.5%, halitosis was 31.3%, Dysguesia was 36.6%, Reduced mouth opening was 63.4%, caries tooth was 60.3%%. Most of the oral manifestations were seen with a higher prevalence in DCSSC. Among the dental-examination findings, GB20,30,40, mean CAL, mean REC, DI and CI were higher in DSCC. The patients with early-disease (< 5 years from first non-Raynauds symptom) constituted 43.5% and late-disease constituted 56.5%. All the oral-manifestations and dental-

MHISS	9.14	8.82	**0.02***

Functional Measures Among Limited and Diffuse Cutaneous Systemic Sclerosis Patients

	EARLY	LATE	P VALUE
ICHFS	14.0	20.2	**0.02***
MHISS	12.4	14.0	0.31

Functional Measures Among Early and Late Systemic Sclerosis Patients

examination findings were higher in patients with late disease. The IC-HFS is higher in DCSSC patients with a mean score of 16.45 ($p < 0.05$) and among those with late disease with a mean score of 20.2($p < 0.05$). Disease severity assessed by Medsger's score correlated positively with DCSSC, periodonditis, missing teeth, teeth mobility, GB, mean REC.

Conclusion: In this multicentre study, DCSSC exhibited significantly higher oral and dental manifestations with increased IC-HFS scores, GERD, reduced mouth opening, greater number of missing-teeth and periodontitis. Patients with late disease had more pronounced oral-manifestations and higher CAL, REC scores. These findings suggest that DCSSC and extended disease-duration are associated with more severe oral health complications, highlighting the importance of early dental intervention. Disease severity as assessed by Medsgers-score correlated-positively with presence of periodontitis indicating its possible role in disease pathogenesis.

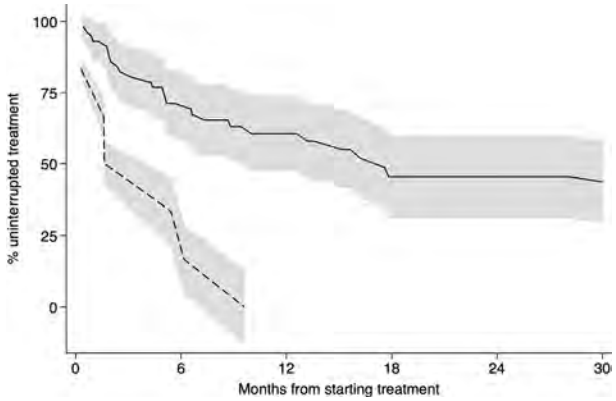

Figure 1 Smoothed representation of the Kaplan-Meier survival curve showing the proportion of patients remaining on uninterrupted treatment over time, stratified by body mass index (BMI) (<18.5 vs ≥18.5 kg/m^2). The dashed line represents patients with BMI<18.5 kg/m^2; the solid line represents patients with ≥18.5 kg/m^2. Shaded areas represent the 95% Confidence Interval (C.I).

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Nintedanib slows the progression of systemic sclerosis-associated interstitial lung disease (SSc-ILD). However, potential high discontinuation rates due to adverse side-effects raise concerns about its tolerability in this patient group.

Methods: In this multicenter study, nintedanib tolerability and body weight changes were assessed. Nintedanib interruption was defined as any interruptions due to treatment-related side effects. Predictors of nintedanib interruption were assessed using logistic regression, with multivariable analysis adjusting for potential confounders. Fisher's exact test was used when complete separation precluded logistic regression and time to first treatment interruption was analysed by Cox proportional hazards analysis. The Wilcoxon signed-rank test was used to compare body weight changes before and after nintedanib initiation.

Results: Among 63 patients (mean age 56.5±13.8 years, 22% male and 56% ever smokers), 76.2% received nintedanib 150 mg twice daily, the remainder 100 mg twice daily. Both concomitant mycophenolate mofetil use and baseline gastrointestinal (GI) symptoms were reported in 85.7% of patients. Patient-reported GI symptoms included diarrhoea (58.7%, 41.3% requiring loperamide), reflux (47.6%), weight loss (38.1%), and nausea/vomiting (33.3%). Over a median follow up of 22.2 months (95% CI 18.1-26.2), Nintedanib was interrupted in 50.8% of patients. Older age ($p< 0.03$ on univariable and multivariable analyses) and BMI <18.5 kg/m^2 ($p = 0.024$) were significant predictors of interruption. Patients with BMI <18.5 kg/m^2 had a significantly shorter time to treatment interruption compared to those with higher BMI (Figure 1) and remained significant after adjustment for FVC or DLCO and demographic variables. Baseline GI symptoms and concurrent Disease-Modifying Antirheumatic Drugs used were not associated with interruption. Most patients who experienced interruption were able to restart treatment, either at reduced or full dose. Permanent discontinuation occurred in 22.2%, with no significant risk factors identified. Mean weight loss over 12 (±6)months after initiation was 1.93 kg (95% CI: 0.64-3.22, p=0.0041), significantly greater than in the 12 (±6)months before treatment (1.38 kg) (p=0.0008).

Conclusion: Among patients with SSc-ILD treated with nintedanib, adverse effects and weight loss frequently led to treatment interruptions. Older age and lower BMI were significant predictors of interruption, while no clear predictors of permanent discontinuation were identified, such as baseline GI symptoms, larger studies are needed to confirm these findings. Most patients were able to resume treatment, underscoring the need for close monitoring and accessible healthcare professional support.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Soluble CD13 (sCD13), released by the cleavage of cell surface CD13 by matrix metalloproteinase-14 (MMP14), has potent proinflammatory, angiogenic, and arthritogenic activities. The receptors for sCD13 are bradykinin receptor B1 (B1R) and protease-activated receptor 4 (PAR4). Building on our recent study showing that the sCD13-B1R axis was critically involved in promoting fibrosis in systemic sclerosis (SSc)[1], we hypothesized that plasma sCD13 levels are associated with SSc clinical features. This study aimed to measure plasma sCD13 levels in SSc patients and examine their correlations with disease phenotype, vascular complications, skin and lung fibrosis, and other clinical characteristics. The expression of genes associated with the sCD13-B1R pathway was also examined in peripheral blood cells.

Methods: Plasma sCD13 was measured using ELISA. SSc patients and healthy controls were recruited at the University of Michigan Scleroderma Program. Three patient cohorts were used to evaluate sCD13 levels for disease subtypes, vascular involvement, and early disease. Clinical data was recorded. Vascular complications were defined as a history of at least one of the following: digital ulcers, pulmonary arterial hypertension, or SSc renal crisis. Transcriptomic data from the GEO dataset GSE181228 was extracted to evaluate genes relevant to CD13 in peripheral blood cells. Statistical analyses were performed using t-tests, chi-square tests, and correlation analysis, and $p < 0.05$ was considered significant.

Results: Plasma sCD13 levels were significantly higher in diffuse cutaneous (dc)SSc patients compared to limited cutaneous SSc patients and healthy controls. There was no significant association between vascular complications and plasma sCD13 levels in SSc patients with vascular complications compared to those without. Among early-stage SSc patients (diagnosed within 3 years of disease onset), there was no significant difference in mRSS between the high and low sCD13 groups (Table 1). However, the change in mRSS at one-year follow-up showed a significant decrease in the high sCD13 patient group (Figure 1). The transcriptomic analysis showed that *ANPEP* (gene encoding CD13), *MMP14* and *F2RL3* (encoding PAR4) were upregulated in SSc patients compared to healthy controls, and a positive correlation was observed between *ANPEP* and *MMP14*, as well as between *ANPEP* and *F2RL3*. Furthermore, significant positive correlations were observed between *ANPEP* and *TGFB1* or *IL6*, as well as between *MMP14* and *TGFB1* or *IL6*. *F2RL3* also showed a significant correlation with *TGFB1* (Figure 2).

Glucocorticoid use, n (%)	7 (9.4)	4 (8.7)	3 (10.7)	>0.99
sCD13, mean (SD), ng/mL	425.6 (92.9)	480.0 (72.8)	336.0 (34.5)	<0.001

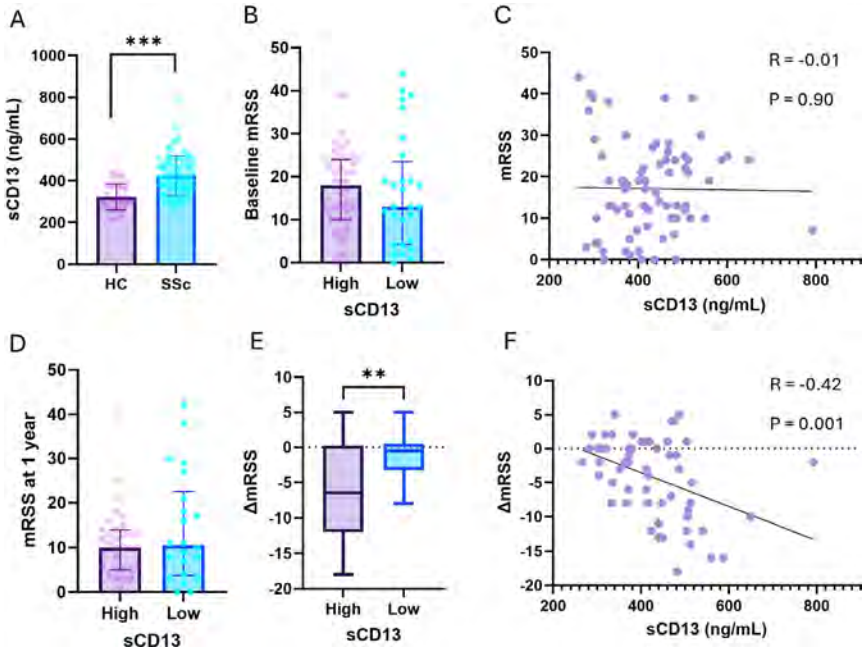

Figure 1. Comparison of mRSS changes between High and Low sCD13 groups in SSc patients within 3 years of disease onset. (A) Plasma sCD13 levels were significantly higher in SSc patients within 3 years of disease onset compared to HC. (B) No significant difference in baseline mRSS was observed between the high and low sCD13 groups. (C) No significant correlation was observed between plasma sCD13 levels and baseline mRSS. (D) mRSS measured one year follow up visit showed no significant difference between the high and low sCD13 groups. (E) The change in mRSS (ΔmRSS) over one year showed a significant decrease in the high sCD13 group. (F) A significant negative correlation was observed between ΔmRSS over one year and plasma sCD13 levels. Results are expressed as mean ± SD or median [IQR]. *P < 0.05, **P < 0.01, ***P < 0.001. sCD13, soluble CD13; HC, healthy controls; SSc, systemic sclerosis; mRSS, modified Rodnan skin score; SD, standard deviation; IQR, interquartile range.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

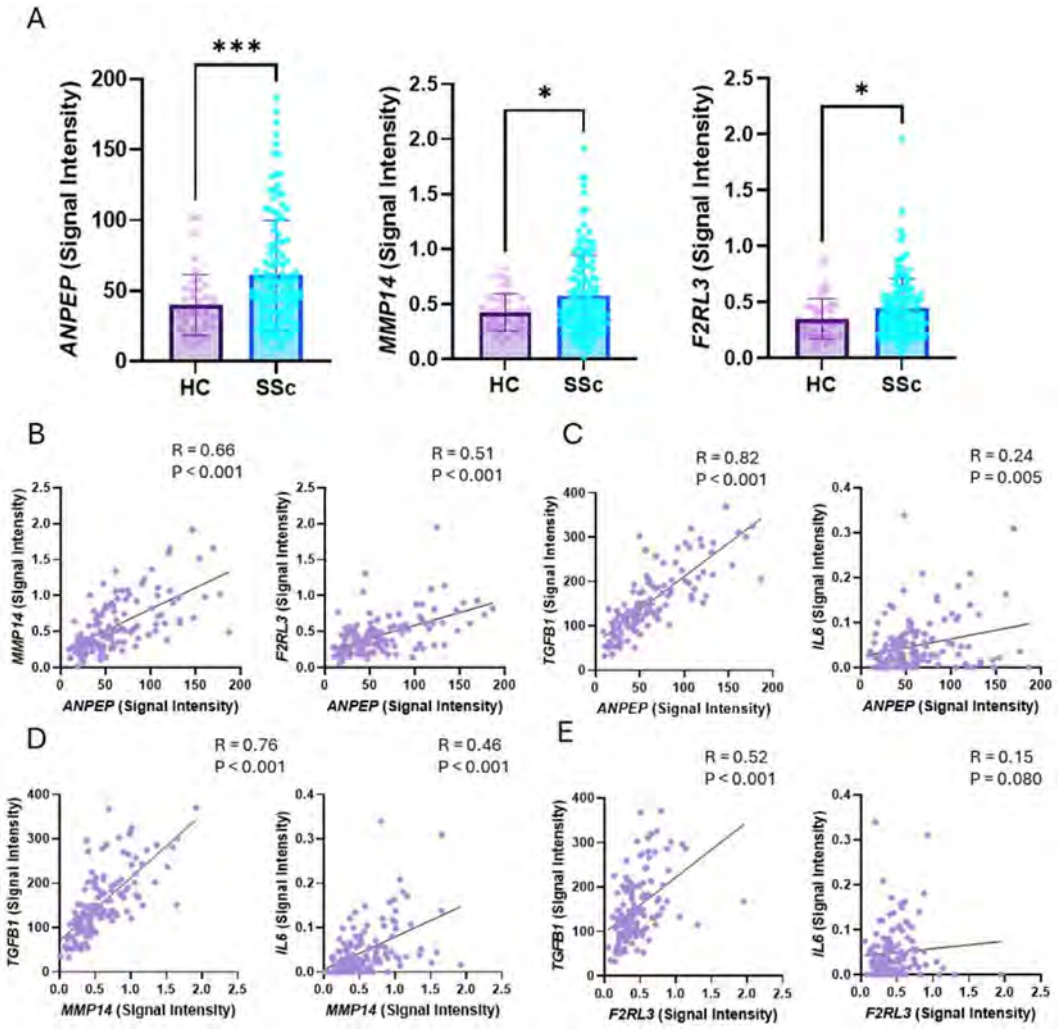

Figure 2. Evaluation of CD13, MMP14 and PAR4 expression in SSc patients and healthy controls (A) Expression levels of ANPEP, MMP14 and F2RL3 were significantly higher in SSc patients compared to healthy controls. (B) ANPEP expression levels were significantly and positively associated with MMP14 and F2RL3. (C) ANPEP, MMP14 and F2RL3 expression levels showed a significant correlation with TGFB1 and IL6, key cytokines involved in fibrosis and inflammation in SSc, although the correlation between F2RL3 and IL6 was not statistically significant (P = 0.08). Results are expressed as mean ± SD. *P < 0.05, **P < 0.01, ***P < 0.001. Significance was determined by (A) Mann-Whitney test and (B-C) Spearman correlation. SSc, systemic sclerosis.

Conclusion: Our study showed that the increased plasma sCD13 levels in patients with SSc did not correlate with the clinical features of the disease. Given that sCD13 is elevated in dcSSc patients and that it promotes myofibroblast transformation in SSc skin, these results suggest that tissue-level sCD13 might be more significant than systemic levels. In addition, MMP14 and CD13 expression on blood cells, potentially enhanced by TGF-β and IL-6, could influence circulating CD13 levels in SSc.

Abstract Number: 1591

Novel autoantibodies in patients with systemic sclerosis and gastrointestinal dysfunction provide insight into disease pathogenesis

Zsuzsanna McMahan[1], Claudia Pedroza[2], Katie Lee[3], Bingrui Chen[3], Ami Shah[4], Jody Hooper[5], Srinivas Puttapaka[6], Livia Casciola-Rosen[7] and Subhash Kulkarni[8], [1]UT Health Houston, Houston, TX, [2]UTHealth Houston Institute for Clinical Research & Learning Health Care, Texas, TX, [3]UTHealth Houston, Houston, TX, [4]Johns Hopkins Rheumatology, Baltimore, MD, [5]Stanford University, Stanford, CA, [6]BIDMC/Harvard, Boston, MA, [7]Johns Hopkins University, Baltimore, MD, [8]BIDMC, Boston, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1553–1591) Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Gastrointestinal (GI) dysfunction is common and often debilitating in systemic sclerosis (SSc). Though it affects most patients, mechanisms are poorly understood and biomarkers for risk stratification and disease activity are limited. Here we sought to identify novel autoantibodies in patients with SSc GI disease and to determine whether they provide insight into clinical phenotype and disease mechanism.

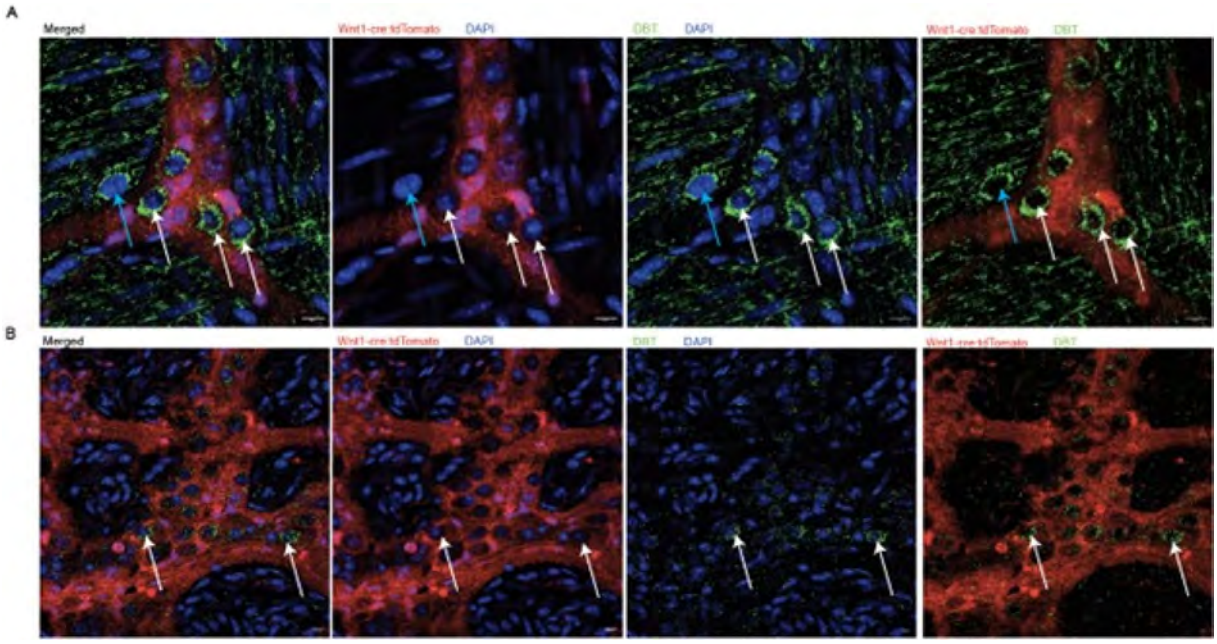

Figure 1: DBT staining of murine LMMP. Mitochondria-specific enzyme DBT is expressed abundantly by MENs in the adult ENS. Immunostaining adult murine (A) small intestinal and (B) colonic longitudinal muscle – containing myenteric plexus (LM-MP) tissues from a neural crest lineage fate mapping mouse model Wnt1-cre:tdTomato, where tdTomato (red) labels all derivatives of the neural crest, with commercially available anti-DBT antibodies (green), which labels the mitochondria-specific Dihydrolipoamide Branched Chain Transacylase (DBT) enzyme (also known as the E2 subunit of the branched-chain alpha-keto acid dehydrogenase complex (BCKD)) shows that DBT protein is localized specifically in the tdTomato-negative non-neural crest cells of the tissue. Mesoderm-derived enteric neurons (MENs, white arrows) in (A) small intestinal LM-MP show abundant expression of DBT, while (B) colonic MENs show relatively reduced abundance of MENs. Nuclei are labeled with DAPI (blue). Scale bar = 10 μm.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

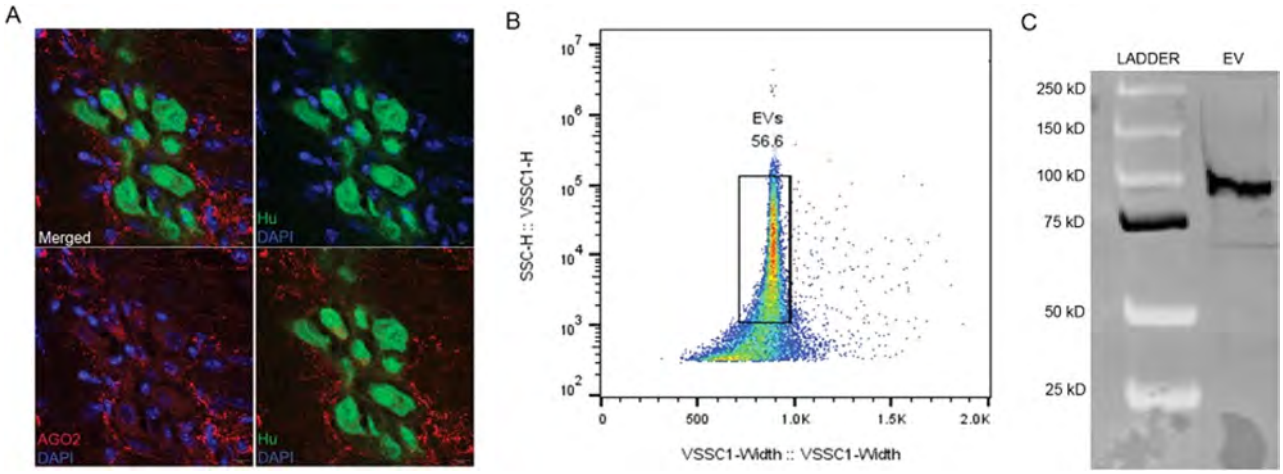

Figure 2: AGO staining of LMMP. Small intestinal ENS releases AGO2-containing extracellular vesicles (EVs). (A) Immunostaining adult murine small intestinal longitudinal muscle – containing myenteric plexus (LM-MP) tissues with antibodies against neuronal marker Hu (green) and EV-marker AGO2 (Argonaut 2, red) shows presence of AGO2 around the Hu-labeled neurons, showing that the neurons release AGO2. (B) Short-term cultured preparations of adult murine small intestinal LM-MP release significant amounts of EVs in the culture media, as assessed by nanoparticle-detecting flow cytometry. (C) Western blot of isolated EVs from cultured LM-MP (shown in (B)) when assayed for the presence of AGO2 (estimated size of 99 kD) using anti-AGO2 antibodies shows a strong and specific band around 100kD providing evidence that small intestinal ENS releases abundant AGO2-containing EVs.

Methods: Sera from patients from the Gastrointestinal Assessment Protocol (GAP), a subcohort of a large Scleroderma Research Registry, were screened for novel autoantibodies. Immunoprecipitations performed with murine myenteric plexus lysates were on-bead digested, and autoantigens were identified by mass spectrometry and then validated. Prevalence was determined, and clinical features associated with the validated autoantibodies were identified using both an all-comers cohort (n=179) and the GAP cohort (n=140). We also examined whether the identified specificities, anti-AGO and anti-DBT antibodies, associated with other known SSc antibodies using an unbiased clustering analysis. The expression of AGO2 and DBT in murine GI tract tissue was then examined by immunohistochemistry. Extracellular vesicles released by ENS and associated cells were captured from cultured longitudinal muscles – containing myenteric plexus (LM-MP) tissues, and their size, abundance, and presence of AGO protein as EV-associated cargo was ascertained by flow cytometry and western blot, respectively.

Results: Using sera from SSc patients with GI dysmotility, we identified AGO1, AGO2, and DBT as candidate autoantigens, which were validated in subsequent cohorts. Anti-AGO antibodies were present in 9.4% (17/179) and anti-DBT in < 1% (1/178) of patients in the all-comers cohort, but absent in healthy controls (0/38 for anti-AGO, 0/36 for anti-DBT). Anti-AGO–positive patients had significantly more GI-related social problems (p=0.02), stomachaches (p=0.005), bloating

Table 1. Gastrointestinal symptom severity is associated with anti-Ago2 antibodies in the all-comers cohort

UCLA GIT 2.0 domain and subdomain	Anti-Ago2 positive	Anti-Ago2 negative	p-value
Reflux (total score)	0.8 (0, 1.9)	0.4 (0, 0.8)	0.45
Acid reflux	2 (0, 2)	0 (0, 1)	0.07
Distention (total score)	1.3 (0.5, 2)	0.5 (0, 1.3)	0.20
Bloating	2 (1, 2)	1 (0, 1)	0.06
Soilage (total score)	0 (0, 1)	0 (0, 0)	0.43
Diarrhea (total score)	0.5 (0, 1.5)	0 (0, 0.5)	0.13
Loose stools	1 (0, 2.5)	0 (0, 1)	**0.04**
Social functioning (total score)	0.3 (0, 1)	0 (0, 0.3)	0.08
Stomachache or pain	0 (0, 1)	0 (0, 0)	**<0.01**
Bloated sensation	1 (0, 2)	0 (0, 1)	**0.02**
Emotional well-being (total score)	0.3 (0, 0.9)	0 (0, 0.3)	0.08
Feel worried or anxious about your bowel problems	1 (0, 2)	0 (0, 1)	**0.01**
Fear of not finding a bathroom	0 (0, 1)	0 (0, 0)	**0.02**
Constipation (total score)	0.8 (0, 1.6)	0.1 (0, 0.8)	0.14
Harder time emptying bowels	1 (0, 2.5)	0 (0, 1)	0.06
Hard stools	0.5 (0, 2)	0 (0, 1)	0.07
Total GIT score	0.8 (0.1, 1.1)	0.3 (0.1, 0.6)	0.09

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(p=0.02), and emotional distress including worry (p=0.012) and fear (p=0.02). In a GI-enriched validation cohort, anti-AGO antibodies were found in 11% (15/140), with higher titers correlating with more severe constipation (p=0.03) and bloating (p=0.02). Conversely, anti-DBT antibodies, present in 3% (4/126), were associated with significantly less constipation (p=0.02). Immunofluorescence demonstrated that anti-DBT antibodies specifically target mesodermal-derived enteric neurons and smooth muscle, while anti-AGO antibodies may target AGO2-containing extracellular vesicles (EV's) released from the gut.

Conclusion: Antibodies in patients with SSc may provide insight into distinct clinical phenotypes and disease mechanism(s). Understanding the targets of the immune response and identifying immune biomarkers may shed light on important mechanisms of disease and novel therapies.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Glucocorticoid (GC)-dependent asthma and ENT exacerbations may persist in more than half of patients with eosinophilic granulomatosis with polyangiitis (EGPA). Mepolizumab and benralizumab, monoclonal antibodies targeting IL-5 and its receptor, respectively, have demonstrated comparable remission rates in patients with relapsing or refractory EGPA. As mepolizumab was the first approved agent for the treatment of EGPA, a switch to benralizumab is often considered in case of failure of mepolizumab. We aimed to describe the use of benralizumab after mepolizumab failure in patients with refractory EGPA.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective multicenter European study of patients with EGPA according to ACR/EULAR classification criteria 2022 who received benralizumab after mepolizumab for inadequate disease control. Complete response was defined as no disease activity (BVAS=0) and a prednisone-equivalent dose ≤4 mg/day, and partial response as no disease activity and a prednisone-equivalent dose >4 mg/day.

Results: Fifty-nine patients (median age 55 years [IQR 47; 63]) were included. ANCA was positive in 18 (31%) patients at the time of EGPA diagnosis. Mepolizumab was initiated at a median of 4 years [1; 9] after diagnosis, mainly for uncontrolled asthma (100%) and/or ENT manifestations (61%). The majority of patients received a dose of 100 mg/month (76%), while 14 (24%) received a dose of 300 mg/month. Mepolizumab was discontinued due to lack of efficacy or partial efficacy in 27 (46%) and 25 (42%) patients, respectively, while 7 patients (12%) experienced a respiratory relapse after an initial complete response.

Benralizumab was started a median of 15 months [11; 24] after starting mepolizumab at a dose of 30 mg every 8 weeks in all but one patient. The median follow-up for benralizumab was 33 months [23; 43]. Complete response was achieved in 23 patients (39%) and partial response in 14 patients (24%). However, only 11 of the 23 patients maintained a complete response at the last follow-up. GCs were discontinued in 35 patients (59%) but restarted in 11 (31%). Six patients (10%) experienced a relapse of vasculitis during follow-up, a median of 25 months [16; 25] after starting benralizumab.

Primary refractoriness to mepolizumab to mepolizumab (OR 4.46, 95% CI 1.44–13.83) and the presence of ENT manifestations at the time of benralizumab initiation (OR 4.00, 95% CI 1.22–13.13) were associated with lack of response to benralizumab. FEV1 and eosinophil count at the start of benralizumab were not associated with response.

Conclusion: After mepolizumab failure, switching to benralizumab provides a complete response and GC withdrawal in one third of patients. However, this efficacy declines over time in half of the patients. These data suggest that targeting a pathway other than IL-5 may be more effective in patients who do not respond to mepolizumab.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: For the treatment of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), rituximab (RTX) may be given as a 4-dose regimen (375 mg/m^2 weekly for 4 weeks) or a 2-dose regimen (1000 mg on day 0 and 14, D0-D14) to induce remission. Once the remission is achieved, RTX is administered in the maintenance phase (starting 4 to 6 months after the first induction dose) at 500 mg every 6 months (Q6M) for 18 months or at 1000 mg every 4 months (Q4M) for 20 months. In the absence of direct comparison of these dosing regimens, there is a need to better define the optimal regimen as well as the duration of the maintenance phase in order to improve the risk-benefit ratio while reducing treatment costs. We aimed to provide pharmacokinetic-pharmacodynamic (PK/PD) rationale for the selection of optimal induction and maintenance dosing regimens in AAV using a population modeling approach based on longitudinal data (RTX concentrations, MPO-ANCA, PR3-ANCA and gammaglobulins) from a real-world cohort.

Methods: A total of 121 patients with 296 plasma RTX concentrations (99 and 197 in the induction and maintenance phases, respectively), 439 ANCA levels (215 in the induction, 224 in the maintenance) and 559 gammaglobulin levels (249 in the induction, 310 in the maintenance) were included in the analysis. The modeling of the effect of plasma RTX concentrations on gammaglobulin and ANCA levels over time was preformed using non-linear mixed effects models in Monolix Suite. Simulations of induction (375 mg/m^2 weekly for 4 weeks, 1000 mg D0-D14) and maintenance regimens (500 mg every 6 months [Q6M], 500 mg Q6M starting at month 4, 1000 mg Q4M, 500 mg Q4M) were performed in 1000 virtual patients with the final PK/PD model. Dosing regimens were compared based on the percentage of patients in serological remission and at risk of hypogammaglobulinemia. In addition, a utility score was calculated taking into account both the expected gain in efficacy and the increased risk of adverse events with increased drug exposure.

Results: The final PK/PD model satisfactorily described the relationship between RTX concentrations, gammaglobulins and ANCA levels over time. Simulations showed that both induction regimens resulted in a similar number of patients achieving serological remission and hypogammaglobulinemia at 6 months (Table 1). In the maintenance phase, increasing the dose (1000 mg) or frequency of administration (Q4M versus Q6M) was associated with a higher number of patients with serological remission at month 24 but also with higher risk of hypogammaglobulinemia (Table 2). Starting the maintenance phase earlier, i.e. 500 mg Q6M from month 4 versus from month 6, was associated with a higher number of patients with negative MPO-ANCA and PR3-ANCA at month 24 (68% versus 59% for MPO-ANCA and 58% versus 46% for PR3-ANCA, respectively). Based on the benefit-risk ratio, both 500 mg Q6M and 500 mg Q4M regimens appear to be optimal for maintenance therapy.

Table 1.

Table 1. Comparison of rituximab induction regimens.

Time after first induction dose	Percentage of patients with MPO-ANCA < 20 U/mL		Percentage of patients with PR3-ANCA < 20 U/mL		Percentage of patients with gammaglobulins < 6 g/L		Median plasma rituximab concentration (mg/L) (10^{th}-90^{th} percentile)	
	375 mg/m^2 Q1W	1000 mg D0–D14	375 mg/m^2 Q1W	1000 mg D0–D14	375 mg/m^2 Q1W	1000 mg D0–D14	375 mg/m^2 Q1W	1000 mg D0–D14
4 months	45	50	41	38	81	75	38.5 (7.94, 101)	25.4 (5.32, 67.9)
6 months	50	55	46	42	49	43	10.3 (<1.0, 46.1)	6.78 (<1.0, 30.0)

MPO-ANCA, myeloperoxidase antineutrophil cytoplasmic antibodies; PR3-ANCA, proteinase 3 antineutrophil cytoplasmic antibodies; D0, day 0; D14, day 14; Q1W, every week.

Table 2.

Table 2. Comparison of rituximab maintenance regimens.

	500 mg Q6M (MAINRITSAN regimen)	500 mg Q6M, start at month 4	500 mg Q4W	1000 mg Q4W (RITAZAREM regimen)
Median rituximab $C_{trough,ss}$ (mg/L) (10^{th}, 90^{th} percentile)[a]	1.53 (<1.0, 8.16)	1.61 (<1.0, 8.54)	5.77 (1.03, 19.2)	11.1 (1.81, 40.3)
Percentage of patients with rituximab plasma concentration < 4 mg/L at month 3 after the 1st maintenance dose	16	13	14	6.2
Percentage of patients with MPO-ANCA < 20 U/mL				
12 months	52	62	67	67
24 months	59	68	75	79
Percentage of patients with PR3-ANCA < 20 U/mL				
12 months	49	55	56	65
24 months	46	58	65	77
Percentage of patients with gammaglobulins < 6 g/L				
Before 3rd cycle[b]	18	19	38	50
At the end of treatment[c]	17	19	20	28

MPO-ANCA, myeloperoxidase antineutrophil cytoplasmic antibodies; PR3-ANCA, proteinase 3 antineutrophil cytoplasmic antibodies; Q4W, every 4 months; Q6W, every 6 months.

[a] $C_{trough,ss}$ was extracted at month 20 for 500 mg Q4M and 1000 Q4M regimens, at month 22 for 500 mg Q6M start at 4 month regimen and at month 24 for 500 mg Q6M regimen

[b] % of patients with hypogammaglobulinemia was extracted at month 12 for 500 QM4 and 1000 mg Q4M regimens, at month 16 for 500 mg Q6M start at month 4 and at month 18 for 500 mg Q6M

[c] % of patients with hypogammaglobulinemia was extracted at month 26 for 500 QM4 and 1000 mg Q4M regimens, at month 28 for 500 mg Q6M start at month 4 and at month 30 for 500 mg Q6M

Conclusion: This first PK/PD study may inform clinical decisions regarding the choice between different rituximab induction and maintenance regimens in AAV patients in daily practice.

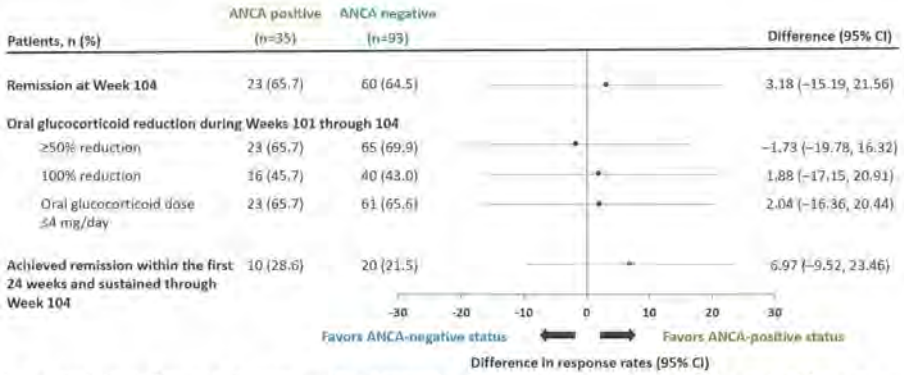
Figure 1. Efficacy endpoints by ANCA status



Rates and the difference in rates were estimated using marginal standardization method from a logistic regression model. For BVAS = 0, covariates included ANCA-positive status, baseline OGC dose, and baseline BVAS. For others, the covariates included ANCA-positive status, baseline OGC dose, baseline BVAS, and region.

Remission was defined as BVAS = 0 and OGC dose ≤4 mg/day (patients achieving remission who had, at any subsequent visit, a BVAS = 1 that did not require an increase in OGC dose >4 mg/day or any other significant clinical intervention/investigation, were considered to be in continued remission).

BVAS, Birmingham Vasculitis Activity Score; CI, confidence interval; OGC, oral glucocorticoids.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The MANDARA trial (NCT04157348) demonstrated that after two years of anti-interleukin-5/receptor (anti-IL-5/R) therapy over 60% of patients with relapsing or refractory eosinophilic granulomatosis with polyangiitis (EGPA) without active organ- or life-threatening disease manifestations achieved remission, and more than 40% discontinued oral glucocorticoids (OGCs). The clinical presentation of EGPA may vary with anti-neutrophil cytoplasmic antibodies (ANCA) status. ANCA-positive patients may exhibit more "vasculitic" features, such as glomerulonephritis, while ANCA-negative patients may tend toward manifestations thought driven by eosinophilic inflammation, such as cardiomyopathy, although there is some overlap of symptoms. Consequently, both ANCA-positive and ANCA-negative patients with EGPA can present with a range of disease manifestations. This analysis evaluated the efficacy of anti-IL-5/R therapies in patients with EGPA according to ANCA status over the combined double-blind (DB) and first year of the ongoing open-label extension (OLE) period in MANDARA.

Methods: Following the 52-week DB period, eligible patients entered the OLE, where they either continued benralizumab or switched from mepolizumab to benralizumab. Remission was defined as Birmingham Vasculitis Activity Score (BVAS) = 0 and oral glucocorticoid (OGC) ≤4 mg/day. The OGC-sparing capacity of the anti-IL-5/R therapies was also assessed, as was disease activity (BVAS and Vasculitis Damage Index [VDI]). Data from both study phases were pooled to evaluate remission and OGC reduction over two years (up to Week 104) according to patients' ANCA status. ANCA-positive patients were defined as those positive for myeloperoxidase (MPO)-ANCA and/or proteinase 3 (PR3)-ANCA at study screening or with a historical record of ANCA-positivity.

Results: Of the 128 patients that entered the OLE 35 (27.3%) were ANCA-positive and 93 (72.7%) were ANCA-negative at the beginning of the double-blind period of the study (baseline). BVAS and VDI scores were similar between the ANCA-positive and -negative groups at baseline, whereas the proportion of patients who had an ACQ-6 score ≥1.5 was higher, and the time since diagnosis was shorter in the ANCA-positive versus -negative group (**Table 1**). At Week 104, the proportion of patients achieving remission was similar regardless of ANCA status (ANCA-positive: 65.7%, ANCA-negative: 64.5%; difference: 3.18; 95% confidence interval [CI]: –15.19, 21.56, p=0.7341) (**Figure 1**). During Weeks 101 through 104, 65.7% and 69.9% in the ANCA-positive and -negative groups, respectively, had a reduction in OGC dose of ≥50% from baseline, and 45.7% versus 43.0%, respectively, were fully withdrawn from OGCs. The proportion of patients with ≥1 relapse was similar between ANCA-positive (37.1%) and ANCA-negative groups (44.1%). Most patients had ≤3 or no relapses (ANCA-positive: 97.1%; ANCA-negative: 93.5%).

Conclusion: This analysis demonstrated that in patients without active organ- or life-threatening EGPA, historic or baseline ANCA status is not associated with response to treatment with anti-IL-5/R therapies.

Abstract Number: 1595

Subcordal Stenosis is a Glucocorticoid-Responsive Manifestation of Granulomatosis with Polyangiitis

Brendan Denvir[1], Brendan Antiochos[2], Philip Seo[3] and Alexander Hillel[3], [1]Johns Hopkins, Baltimore, MD, [2]Johns Hopkins, CLARKSVILLE, MD, [3]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Subglottic stenosis (SGS) is a recognized manifestation of granulomatosis with polyangiitis (GPA), occurring in 8–23% of patients. A distinct variant, identified in this study, involves edema of the inferior true vocal folds, termed "subcordal stenosis." This pattern results in significant narrowing at a higher airway level than typical SGS, often extending inferiorly to involve the conventional subglottic region. Based on clinical observations, this pattern appears particularly responsive to glucocorticoid therapy. The objective of this study was to characterize the clinical presentation and treatment outcomes of subcordal stenosis and compare it to typical SGS associated with GPA. We hypothesized that patients with subcordal disease would require fewer dilations within two years of SGS diagnosis due to its glucocorticoid responsiveness.

Methods: Following IRB approval, we reviewed records of patients treated for SGS at the Johns Hopkins Vasculitis Center, identifying two groups: patients with subcordal involvement and those with typical SGS. Patients were excluded if they were procedurally treated for SGS before being seen at our institution. Subcordal cases were identified by searching laryngoscopy reports for "subcordal" and confirmed by otolaryngologist review as narrowing at the inferior true vocal folds (Figure 1).

Baseline demographic and clinical characteristics were obtained through chart review. Longitudinal data on immunosuppressive treatments (start and stop dates) and tracheal dilation procedures were also collected. The number of tracheal dilations at two years was compared between groups using the Wilcoxon rank-sum test. Time-to-event analyses were performed, and Kaplan-Meier curves were compared using the log-rank test. All statistical analyses were conducted using R.

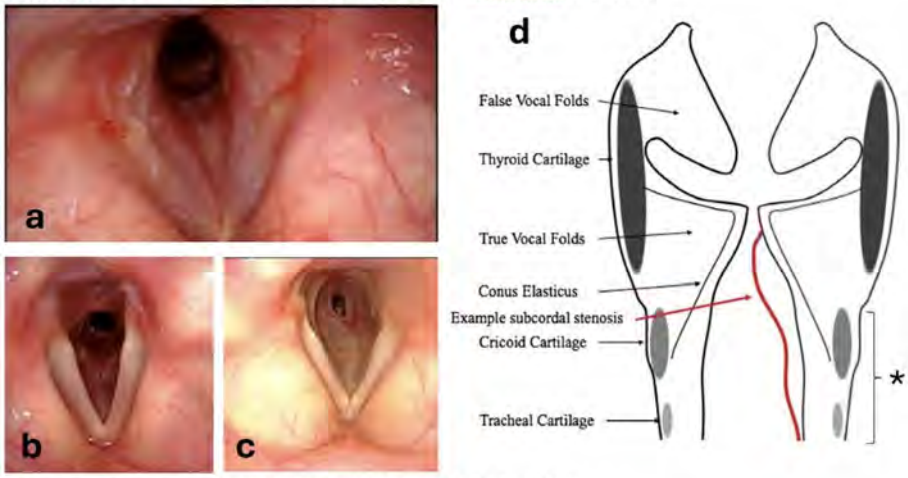
Table 1. Baseline demographic, clinical, and treatment characteristics, and outcome comparisons between SGS patients with and without subcordal involvement

	Subcordal Involvement n=11	No Subcordal Involvement n=38	p-value*
Demographics			
Age, mean (sd)	44.5 (12.3)	42.6 (15.3)	0.69
Female, n (%)	7 (63.6)	28 (73.7)	0.71
Male, n (%)	4 (36.3)	10 (26.3)	
Diagnosis			
GPA, n (%)	8 (72.7)	33 (86.8)	0.50
Severe	3 (27.3)	4 (10.5)	0.18
Non-severe	5 (45.5)	29 (76.3)	
ANCA positive	7 (63.6)	26 (68.4)	0.81
Idiopathic SGS, n (%)	3 (27.3)	5 (13.2)	
Airway Involvement			
Subglottic	5 (45.4)	38 (100)	-
Subcordal	11 (100)	0 (0)	-
Airway Symptoms, n (%)			
Dyspnea	9 (81.8)	29 (76.3)	1
Stridor	5 (45.5)	15 (39.5)	0.74
Cough	2 (18.2)	6 (15.8)	1
Dysphonia	5 (45.5)	12 (31.6)	0.48
Immunosuppression, n (%)			
Prednisone	10 (90.9)	27 (71.1)	0.41
Rituximab	3 (27.3)	13 (34.2)	1
Methotrexate	2 (18.2)	13 (34.2)	0.46
Azathioprine	3 (27.3)	4 (10.5)	0.12
Leflunomide	3 (27.2)	3 (7.9)	0.18
Cyclophosphamide	1 (9.1)	1 (2.6)	0.40
Mycophenolate mofetil	0 (0)	1 (2.6)	1
Outcomes at 2 Year Follow-up			
Tracheal Dilations, median (IQR)	0 (0-1)	1 (0-2.75)	0.049
Patients with 0 dilations, n (%)	6 (54.5)	11 (28.9)	0.23

*Statistical comparisons between groups were made using fisher's exact tests, t-tests and wilcoxon rank sum tests where appropriate.
Immunosuppression indicates medication patients were on in the first year after airway disease diagnosis

Results: Baseline characteristics of SGS patients with and without subcordal involvement are summarized in Table 1. Most patients in both groups had GPA diagnosed by rheumatologists. Five patients with subcordal disease also had typical subglottic involvement, while six had isolated subcordal disease. Among patients with subcordal involvement, 10 of 11 received

Figure 1. Representative laryngoscopic images of subglottic stenosis with and without subcordal involvement and animated depiction of subcordal stenosis.



Panel A: Subcordal stenosis with swelling and erythema of the inferior TVF.
Panel B: Typical SGS-GPA appearance with stenosis starting distal to the inferior TVF.
Panel C: Typical iSGS with 80% stenosis distal to the inferior TVF.
Panel D: Animated depiction of laryngeal anatomy highlighting the area of subcordal stenosis. The asterisk (*) indicates the typical level of subglottic stenosis.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

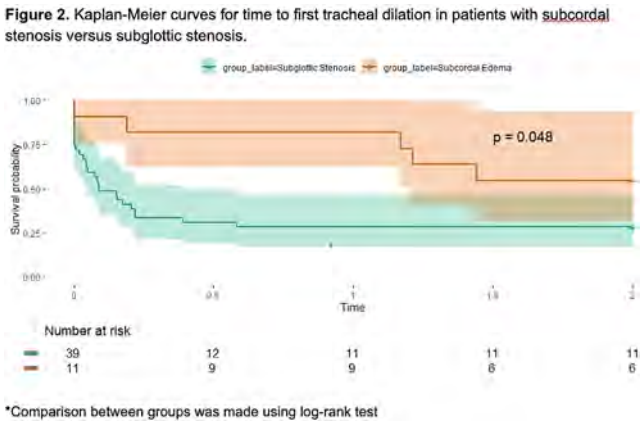


Figure 2. Kaplan-Meier curves for time to first tracheal dilation in patients with subcordal stenosis versus subglottic stenosis.

*Comparison between groups was made using log-rank test

prednisone at the time of SGS diagnosis. Patients with subcordal disease underwent fewer dilations within two years compared to those without subcordal involvement (median 0 vs. 1 dilation, p = 0.05, Table 1). Kaplan-Meier analysis showed that patients with subcordal involvement had a significantly longer time to first dilation, with a median of 792 days compared to 44 days in those without subcordal disease (p = 0.048, Figure 2).

Conclusion: Among patients with SGS seen at our vasculitis center (most of whom have GPA), those with subcordal involvement exhibit a reduced need for tracheal dilation and a longer interval before first dilation compared to patients without subcordal disease. These findings likely reflect greater corticosteroid responsiveness in patients with subcordal airway involvement.

Abstract Number: 1596

GPA-Associated Tracheobronchial Stenosis: Immunosuppressant Use and Dilation Frequency

Brendan Denvir[1], Alexander Hillel[2], Ami Shah[3], Ji Soo Kim[1], Philip Seo[2] and Brendan Antiochos[4], [1]Johns Hopkins, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins Rheumatology, Baltimore, MD, [4]Johns Hopkins, CLARKSVILLE, MD

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Granulomatosis with polyangiitis (GPA) is an anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis that affects all levels of the respiratory tract. Tracheobronchial stenosis (TBS) occurs in 8–23% of patients with GPA and may cause life-threatening airway compromise requiring repeated tracheal dilation. Despite advances in GPA treatment, TBS remains difficult to manage, with frequent relapses and high procedural burden. The objective of this study was to evaluate the relationship between observed immunosuppressant use and tracheal dilation frequency in patients with TBS-GPA.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We queried our electronic health record for patients with GPA and TBS evaluated at Johns Hopkins Medical Institute between January 2003 and September 2024. Diagnoses were confirmed by retrospective chart review. Baseline demographic and clinical characteristics, immunosuppressant exposure, and tracheal dilation procedure dates were extracted. We performed longitudinal analyses using annual dilation count as our outcome measure, and time-varying binary indicators of immunosuppressant use as categorical predictor variables. Data from an example patient is depicted in Figure 1. A multivariate mixed effects Poisson regression model was used to assess the association between immunosuppressant exposures (rituximab, cyclophosphamide, methotrexate, azathioprine, leflunomide, and mycophenolate) and annual tracheal dilation count, adjusting for age, sex, years since TBS diagnosis, ANCA status (positive vs. negative), and GPA disease severity (non-severe vs. severe). A random intercept term was included to account for patient-level variability in dilation frequency.

Results: A total of 52 patients with tracheobronchial GPA were included in the analysis, with a mean follow-up duration of 9.9 years. Baseline clinical characteristics and immunosuppressant exposures are summarized in Table 1. In the adjusted mixed-effects Poisson regression model, patient-years on leflunomide were associated with a 68% lower incidence of tracheal dilations compared to periods off leflunomide (IRR 0.32, $p < 0.001$), while patient-years on rituximab were associated with a 40% lower incidence compared to periods off rituximab (IRR 0.57, $p = 0.021$) (Table 2). No statistically significant associations were observed for methotrexate, azathioprine, cyclophosphamide, or mycophenolate. Among other tested covariates, time since TBS diagnosis and age over 40 were also associated with lower dilation frequency (Table 2).

Table 1. Baseline demographic, clinical, and treatment characteristics of patients with tracheobronchial GPA.

	Overall (n = 52)
Sex, n (%)	
Male	17 (32.7)
Female	35 (67.3)
Age	
Age, mean (sd)	36.8 (16.6)

Table 2. Incidence rate ratios estimated from univariate models and multivariate mixed effects Poisson regression model of tracheal dilation incidence

	Univariate Models		Multivariate model	
	IRR (95% CI)	p-value	IRR (95% CI)	p-value*
Immunosuppressants				
Rituximab	0.87 (0.64, 1.17)	0.343	0.57 (0.37, 0.96)	0.021
Methotrexate	0.73 (0.52, 1.04)	0.079	1.26 (0.78, 2.03)	0.350
Leflunomide	0.60 (0.37, 0.99)	0.047	0.32 (0.18, 0.66)	<0.001
Azathioprine	1.60 (1.12, 2.28)	0.009	0.70 (0.41, 1.20)	0.190
Cyclophosphamide †	1.16 (0.16, 8.27)	0.88	-	-
Mycophenolate mofetil †	0.57 (0.21, 1.54)	0.27	-	-
Additional Covariates				
Years from TBS diagnosis	0.93 (0.90, 0.95)	<0.001	0.94 (0.89, 0.96)	<0.001
Age over 40 at TBS diagnosis	0.50 (0.38, 0.66)	<0.001	0.45 (0.26, 0.95)	0.022
Female Sex	0.36 (0.14, 0.85)	0.03	0.85 (0.44, 1.68)	0.652
Severe Disease ‡	1.89 (1.43, 2.49)	<0.001	1.91 (0.90, 4.18)	0.121
ANCA status ¶	2.95 (1.85, 4.72)	<0.001	1.83 (0.73, 4.31)	0.205

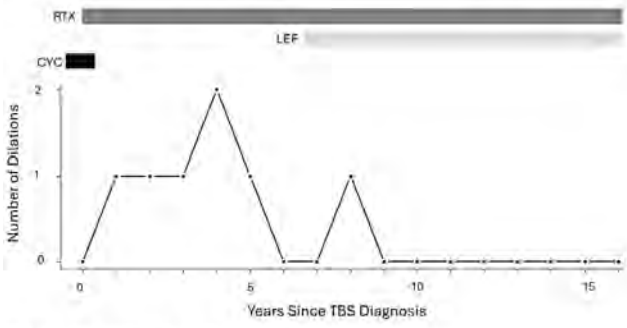
*P-value less than 0.0125 is significant after Bonferroni correction adjusting for multiple comparisons

† Cyclophosphamide and mycophenolate mofetil were not included in the final multivariate model due to limited use in our sample (fewer than 6 patients on each medication), and poorer model performance with their inclusion

‡ Severe GPA was defined by the presence of glomerulonephritis, diffuse alveolar hemorrhage, or mononeuritis. All other patients were non-severe.

¶ ANCA status was positive if c-ANCA, p-ANCA, anti-PR3 antibody, or anti-MPO antibody were positive at vasculitis diagnosis.

Figure 1. Example patient's annual dilation counts over time with corresponding immunosuppressant exposure data.



RTX = Rituximab, LEF = leflunomide, CYC = cyclophosphamide.

Conclusion: Leflunomide and rituximab (but not methotrexate or azathioprine) were associated with significantly fewer tracheal dilations in patients with tracheobronchial GPA. Older age and longer time since diagnosis were also associated with reduced dilation frequency.

Abstract Number: 1597

Effectiveness and Safety of Rituximab Biosimilars in Small Vessel Vasculitis: a Systematic Literature Review

Caitlyn Kanters[1], Joo Young Lee[2], Christian Pagnoux[3], Lillian Barra[4], Jean-Paul Makhzoum[5] and Arielle Mendel[6], [1]McGill University, Montreal, Canada, [2]Research institute of the McGill University Health Center, Montreal, QC, Canada, [3]Mount Sinai Hospital, University Health Network, Toronto, and Canadian Vasculitis Research Network (CanVasc), Toronto, ON, Canada, [4]Western University, London, ON, Canada, [5]University of Montreal, Montreal, [6]McGill University Health Centre, Montreal, Canada

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: To evaluate the safety and effectiveness of rituximab biosimilars in the treatment of small vessel vasculitis.

Methods: The Medline, CINAHL, Cochrane, Embase and Web of Science databases were searched from inception until May 7, 2025 to identify all studies (full-length manuscripts or abstracts) including $^{3}5$ adults diagnosed with any small vessel vasculitis treated with a rituximab biosimilar for induction or maintenance of remission, including switching from the originator to a biosimilar. Effectiveness outcomes were clinical remission (Birmingham Vasculitis Activity Score = 0) and relapse, while serious adverse events, serious infections, hypersensitivity reactions, late-onset neutropenia and hypogammaglobulinemia were safety outcomes.

Table 1. Rituximab biosimilars in small vessel vasculitis: study characteristics and outcomes

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Of 1,628 publications screened, 69 underwent full text review, and ten (5 full text articles, 5 abstracts) reporting on 566 patients treated with rituximab biosimilars were included (n=9 ANCA-associated vasculitis [AAV], n=1 cryoglobulinemic vasculitis [CV]). Seven studies were retrospective, while three were prospective. Most studies reported on the biosimilar Truxima (n=6), while Ruxience, Acelbia and Reditux were evaluated in one study each, and biosimilar type was not indicated in one abstract. Due to heterogeneous outcome reporting, we did not perform a meta-analysis. Follow-up ranged from 5-27 months after first rituximab biosimilar dose. Among studies evaluating a rituximab biosimilar for AAV induction (n=7), clinical remission at 6 months ranged from 60-93%, and relapses occurred in 0-23% of patients by 6 months (reported in 3 studies each). Among studies assessing a rituximab biosimilar for AAV maintenance (n=6), relapses occurred in 0-2% by 6 months (three studies). Of 3 studies evaluating outcomes after switching from originator to biosimilar in stable AAV, two reported sustained remission in 98-100% of patients at 6 months, while one observed relapses in 3/8 patients (timeframe undefined). In the CV study, renal parameters improved in 14/15 (93%) patients and peripheral neuropathy improved in 24/30 (80%) at 6 months. Three studies reported ≥1 serious infection in 0-7% of patients by 6 months. Five studies reported hypersensitivity reactions (2-14%). Hypogammaglobulinemia occurred in 4% and 31% of patients, and late-onset neutropenia in 2% and13% of patients (reported in two studies each). Four studies compared a rituximab biosimilar to the originator (3 AAV, 1 CV), with no significant differences found in terms of remission, relapse, serious adverse events, or infections.

Conclusion: We did not identify any randomized studies of biosimilar rituximab for small-vessel vasculitis, and observational data is limited. The biosimilars studied in AAV appear to have safety and effectiveness similar to historical randomized controlled trials and observational studies of the originator molecule.

Table. Demographic and clinical features of the 14 patients with small- to medium-sized vessel vasculitis treated with JAKi

Patient	Sex	Age at JAKi initiation (years)	Diagnosis	Disease duration (months)	Previous immuno-suppressants	JAKi	Clinical manifestations at JAKi initiation	JAKi treatment duration (months)	Clinical evaluation at last FU	JAK at last FU
1	F	50	IgA vasculitis	6.5	CYC, RTX, MTX, CysA, TAC, dapsone	TOFA	articular, cutaneous	8.7	active disease	stopped (VTE)
2	F	72	Cryoglo-bulinemic vasculitis	40.6	RTX	BARI	systemic, articular, cutaneous, PNS	45.6	complete remission	ongoing
3	F	80	GPA	0.9	MTX, CysA, TCZ, antiTNF, abatacept	TOFA	systemic, articular, ENT	35.1	complete remission	stopped (hepato-toxicity)
4	M	57	Cryoglo-bulinemic vasculitis	9.8	RTX, MTX, TCZ, anti-TNF, abatacept	UPA	systemic, articular	4.3	complete remission	ongoing
5	F	56	PAN	296.1	CYC, RTX, MTX, TCZ	UPA	systemic, articular, cutaneous, ocular, GI	2.3	active disease	stopped (inefficacy)
6	F	51	MPA	2.1	AZA, MTX, HCQ	UPA	articular, pulmonary, ENT	31.4	complete remission	ongoing
7	F	49	GPA	19.3	RTX, MTX, antiTNF, HCQ	UPA	articular, ocular, PNS, CNS	27.4	complete remission	ongoing
8	F	43	GPA	39.1	RTX, MTX	TOFA	systemic, ENT	4.6	partial remission	ongoing
9	F	33	GPA	45.5	RTX, AZA, TCZ, antiTNF	TOFA	systemic, articular, cutaneous, ocular	2.8	partial remission	ongoing
10	F	64	GPA	7.6	CYC, RTX,	TOFA	ocular	12.6	complete remission	ongoing
11	F	76	PAN	194.2	CYC, RTX, AZA, MTX, CysA, TCZ	TOFA	systemic, articular, cutaneous	2.6	active disease	ongoing
12	M	64	PAN	110.6	CYC, AZA, MTX, MMF, CysA, TCZ	UPA	systemic, articular, cutaneous	24.3	partial remission	ongoing
13	F	24	GPA	7.1	RTX	BARI	systemic, articular, cutaneous	4	partial remission	ongoing
14	M	69	MPA	68.9	CYC, RTX, AZA, MMF	UPA	systemic, articular, ENT, PNS	6	complete remission	ongoing

AZA= azathioprine; BARI= baricitinib; CNS= central nervous system; CYC= cyclophosphamide; CysA= cyclosporin A; ENT: ear, nose, throat; GI= gastro-intestinal; GPA= granulomatosis with polyangiitis; HCQ= hydroxychloroquine; JAKi= janus kinase inhibitors; MMF= mycophenolate mofetil; MPA= microscopic polyangiitis; MTX= methotrexate; PAN= polyarteritis nodosa; PNS= peripheral nervous system; RTX= rituximab; TAC=tacrolimus TCZ= tocilizumab; TNF= tumor necrosis factor; TOFA= tofacitinib; UPA= upadacitinib; VTE=venous thromboembolism

Background/Purpose: Medium- and small-vessel vasculitides (MVV and SVV) are a heterogeneous group of inflammatory diseases affecting the vascular wall. Current treatment strategies are based on a combination of glucocorticoids (GCs) and disease modifying anti-rheumatic drugs (DMARDs), but relapses, GC dependence and treatment-related toxicity remain major challenges. In preclinical studies, the Janus kinase/signal transducer and activator of transcription (JAK/STAT) pathway has emerged as a key regulator of chronic vascular inflammation. To date, data on the use of JAK inhibitors (JAKi) in clinical practice remains limited. This study aimed to evaluate the off-label use of JAKi in MVV and SVV, focusing on patient characteristics, therapeutic efficacy, and safety outcomes in multiple centers worldwide.

Methods: This was a retrospective, multicenter, observational study that collected real-world data on adult patients who met the classification criteria for MVV or SVV and were treated with JAKi. Data were extracted from electronic medical records. Complete response (CR) was defined as BVAS =0 and prednisone ≤5 mg/day, partial response (PR) as BVAS =0 and prednisone between 6 and 10 mg/day, and active vasculitis as BVAS≥1 regardless of prednisone dose.

Results: Fourteen patients (6 granulomatosis with polyangiitis, 2 microscopic polyangiitis, 3 polyarteritis nodosa, 2 cryoglobulinemic vasculitis, and 1 IgA vasculitis) from 8 different centers were included (Table). The median age was 57 (IQR 49-68) years. JAKi were prescribed for refractory disease in 12/14 (85.7%) and for GC sparing in 4/14 (28.6%). The median disease duration prior to JAKi initiation was 2.4 years (IQR 0.6-3.1). Among the JAKi, tofacitinib and upadactinib were used in 6/14 (42.85%) and baricitinib in 2/14 (14.3%) patients, respectively. At JAKi initiation, 13/14 (92.8%) patients were still receiving GCs at a median prednisone dose of 13.75 mg/day (IQR 7.5-20). JAKi were prescribed alone in 8/14 (47.1%) patients, in

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

combination with conventional synthetic DMARDs in 4/14 (28.6%) and with biologic DMARDs in 2/14 (14.3%). After a median follow-up of 7.4 months (IQR 4.1-26.6), JAKi achieved an overall response in 11/14 (78.6%) patients (7 CR and 4 PR). Three patients (21.4%) relapsed while on JAKi, including a major relapse that led to discontinuation of JAKi in one patient. Two other patients discontinued JAKi due to adverse events (1 hepatic toxicity and 1 venous thromboembolism). Twelve infections occurred in 5/14 (35.7%) patients, including 6 viral (among which 4 SARS-CoV-2 infections) and 6 bacterial infections. Of the 12 infections, 8 occurred with upadactinib, 3 with tofacitinib and 1 with baricitinib. At the last follow-up, 11/14 (78.6%) were still taking JAKi.

Conclusion: JAK inhibitors may offer a promising therapeutic alternative for refractory vasculitis. However, the risk of adverse events, especially infections, emphasizes the need for careful patient selection and prophylactic measures. Further prospective studies are needed to define the efficacy, safety and optimal role of JAKi in the treatment of MVV and SVV.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis include Granulomatosis with Polyangiitis (GPA), Microscopic Polyangiitis (MPA), and Eosinophilic Granulomatosis with Polyangiitis (EGPA). EGPA presents a different pathogenic, clinical, and therapeutic entity. However, international therapeutical recommendations (ACR, EULAR and KDIGO), epidemiological studies and clinical trials (RAVE and RITUXVAS) (1-4) include MPA and GPA as a combined group. Cyclophosphamide (CYC) and Rituximab (RTX) are considered the first-line therapeutic option in MPA and GPA. RAVE and RITUXVAS trials have demonstrated similar efficacy and safety with CYC and RTX. However, these studies are often limited in follow-up time, which may influence on the results.

Objectives: To compare safety and relapse rates between CYC and RTX.

Abbreviations. MACE: major cardiovascular event.

TABLE 2. Adverse Events and Relapse in 87 patients with ANCA associated Vasculitis treated with CYC and RTX.

Methods: Observational study of 196 patients diagnosed with ANCA-associated vasculitis at a referral hospital in northern Spain from January 1, 2000, to December 31, 2024. Classification of ANCA vasculitis was based on the 2022 ACR/EULAR criteria. Depending on the induction therapy administered, patients were divided into two groups: **i)** Patients treated exclusively with CYC and **ii)** with RTX. Patients who received both treatments at any time during follow-up were excluded. Rates of Adverse effects are expressed as the exposure-adjusted incidence rate (EAIR) per 100 person years (PY).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 87 patients were finally included (44 women/43 men); 48 received CYC and 30 received RTX, mean ages at diagnosis of 65.7±13.4 and 57.4±14.8 years, respectively. MPA was the most frequent vasculitis subtype in both groups. Most clinical and laboratory features were similar, except for renal and abdominal involvement that was more common in the CYC group (**Table 1**).

Despite a shorter mean follow-up in patients in the CYM group (17.4±23 vs 31.5±26.1 months), they present significantly more serious adverse events (83.3% vs. 56.4%; p= 0.0085) EAIR of 4.78 /100 PY Vs 1.78/100 PY. The most frequent adverse effect was severe infections (58% vs. 33.3%; p= 0.0304) with a EAIR of XX/100 PY on the CYP group Vs a EAIR of XX/ 100 PY on the RTX group. (**Table 2**).

No significant differences were found for other adverse events. During follow-up, relapses occurred more frequently in the CYC group (14% vs 5.1%; p= 0.178) with an EAIR of 0.8 and 0.16 respectively. (**Table 2**).

Conclusion: In our series, patients treated with CYC had statistically more frequently severe infections and a trend to higher relapse rates.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Benralizumab is approved for eosinophil-driven conditions, like eosinophilic asthma. Recently, the European Medicines Agency (EMA) and U.S. Food and Drug Administration (FDA) authorized its use for eosinophilic granulomatosis with polyangiitis (EGPA). However, real-world evidence remains limited. This study aims to evaluate the clinical effectiveness of benralizumab for EGPA in routine clinical practice on multiple centers.

Methods: We conducted an observational multicenter study with patients diagnosed with EGPA according to the 2022 EULAR/ACR classification criteria who received benralizumab treatment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Biologic treatment, n(%)	10 (43.4)
Azathioprine, n(%)	5 (21.7)
Methotrexate, n(%)	3 (13)
Mycophenolate mofetil, n(%)	2 (8.7)
Cyclophospharnide, n(%)	2 (8.7)

Abbreviations (in alphabetical order):
ANCA: Anti-neutrophil cytoplasmic antibodies; CNS: Central Nervous System; EGPA: Eosinophilic granulomatous polyangiitis; ENT: ears, nose and throat, n: number; PNS: Peripheral nervous System; SD: Standard Deviation

Effectiveness was assessed through clinical improvement, laboratory findings, pulmonary function, and corticosteroid-sparing effects. Clinical parameters were monitored throughout follow-up. Analytical outcomes included eosinophil count (>500 cells/μL) and IgE level improvement (>100 IU/L). Pulmonary function was evaluated using forced expiratory volume in the first second (FEV_1) and the FEV_1/FVC ratio.

Data were extracted from medical records up to April 30, 2025. Results were expressed as percentages, means ± standard deviation (SD), or medians [interquartile range, IQR]. Comparisons of continuous variables over time were conducted by Wilcoxon test.

Results: We included 23 patients (15 women/8 men); mean age of 58.5±13 years. Baseline clinical and laboratory characteristics before benralizumab initiation are summarized in Table 1. The most common manifestation was asthma (100%), followed by ENT involvement (91.3%), constitutional symptoms (76.1%), neurologic involvement (39.1%), cutaneous manifestations (21.7%), and renal (13% each).

Before treatment, all patients exhibited eosinophilia (median 865 [740-1100] eosinophils/mm^3). Elevated serum IgE in 56.5%; (median 225 [57-360.5] IU/L), and ANCA positivity in 69.5%. Previous immunosuppressive therapies included azathioprine (22%), methotrexate (13.6%), mycophenolate mofetil (9%), and cyclophosphamide (9%). Prior biologic therapies were used in 43.4%. Most commonly were Mepolizumab (50%), Omalizumab (40%), and Reslizumab (10%).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

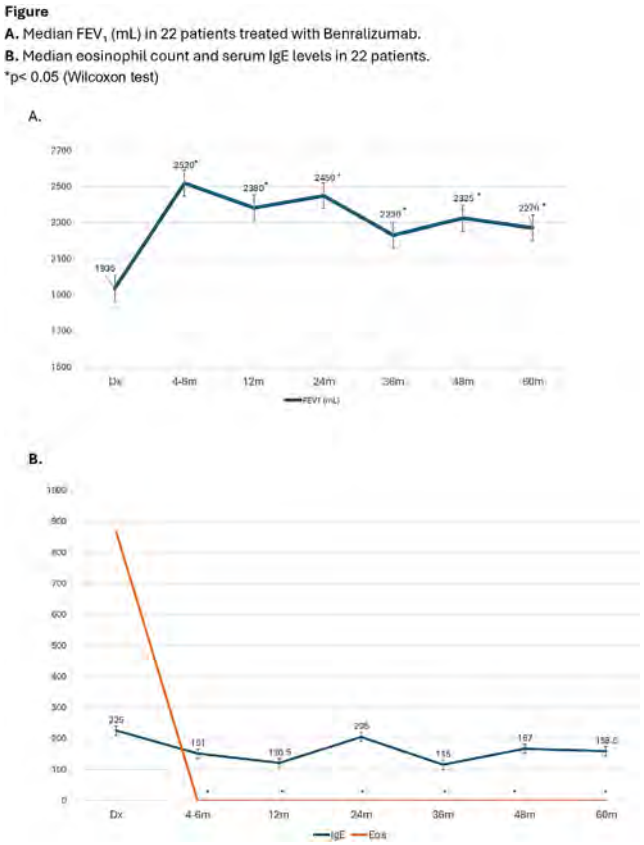

Figure A. Median FEV_1 (mL) in 22 patients treated with Benralizumab. B. Median eosinophil count and serum IgE levels in 22 patients. *p< 0.05 (Wilcoxon test)

Benralizumab was initiated a mean of 4.6±4 years post-EGPA diagnosis (30 mg subcutaneously every 4 weeks). Showed a rapid and sustained improvements over 60 months: **a)** FEV_1 increased from median 1935 [1545-2680] to 2270 [2192.5-2460] mL (p=0.0312), **b)** eosinophil counts dropped from 850 [740-1100]/mm^3 to 0 [0-0] (p< 0.0001), **c)** serum IgE levels decreased from 225 [57-360] (IU/mL) to 158.5 [115-217] IU/mL; (p=0.125) and, **d)** prednisone dose from 5 mg/day [2.5-10] to 0 [0-0]; (p=< 0.0001)

After a mean follow-up of 42.4±20.7 months 78.2% of patients remained in remission. Disease relapse occurred in 3 (13%) (2 respiratory, 1 systemic), while 2 patients discontinued therapy due to inadequate clinical response.

Conclusion: Benralizumab demonstrated rapid and sustained effectiveness, even in patients with severe and refractory EGPA, consistent with findings from clinical trials. These preliminary real-world data highlight its therapeutic potential, but further validation in larger cohorts with extended follow-up is necessary to establish its role in routine clinical practice.

Abstract Number: 1601

Obinutuzumab Induces and Maintains Remission in Refractory or Relapsing ANCA-Associated Vasculitis – A Case Series

Helen Au[1], Christian Löffler[2], Hartmut Mahrhofer[1], Bastian Walz[1] and Bernhard Hellmich[1], [1]Klinik für Innere Medizin, Rheumatologie und Immunologie, medius Klinik Kirchheim, Kirchheim unter Teck, Germany, [2]Medizinische Klinik V, Nephrology, Endocrinology, Hypertensiology and Rheumatology, Universitaetsmedizin Mannheim, University of Heidelberg, Mannheim, Germany

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: B-cell depletion with anti-CD20 therapy is the current cornerstone of management in organ- or life-threatening ANCA-associated vasculitis (AAV). Guidelines recommend the use of rituximab or cyclophosphamide for remission induction and rituximab for remission maintenance. Compared with rituximab, obinutuzumab is a newer humanized type 2 anti-CD20 monoclonal antibody and is postulated to result in deeper tissue B cell depletion. It has an emerging role in rituximab-intolerant patients and in rituximab-refractory disease. To date, only nine cases in two case series have been published on the use of obinutuzumab in rituximab-intolerant patients with AAV.

Methods: This single-centre case series reports the clinical outcomes of five patients who received obinutuzumab therapy for refractory or relapsing PR3+ granulomatosis with polyangiitis (GPA). All patients satisfied the 2022 ACR/EULAR classification criteria for GPA. Review of electronic health records was undertaken for patient demographics, disease manifestations, previous treatments, indication for obinutuzumab, clinical and laboratory outcomes, and potential complications.

Table 1: Patient demographics, disease manifestations, indications for obinutuzumab, and treatment history

Table 1: Patient demographics, disease manifestations, indications for obinutuzumab, and treatment history

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5

Results: One male and four female patients with refractory or relapsing GPA received obinutuzumab. Three had multi-system involvement while one had isolated episcleritis/scleritis and another, severe isolated ENT disease. All patients had refractory or relapsing disease despite guideline-directed induction therapy with rituximab and cyclophosphamide. For induction of disease remission, obinutuzumab was administered at one or two doses of 1000mg at week 0 and week 2. Maintenance treatment consisted of single 1000mg infusions at six- to twelve- monthly intervals. Obinutuzumab was effective in inducing and maintaining disease remission. Those patients with detectable ANCA titres at time of obinutuzumab treatment seroconverted from positive to negative. During a median follow-up of 14 months (range: 4-51 months), obinutuzumab was well tolerated with two infections noted (sinusitis and moderate SARS-CoV-2 infection requiring prolonged antiviral treatment).

Conclusion: This case series illustrating the use of obinutuzumab in five patients with GPA adds to the limited published literature. Obinutuzumab shows promise in the management of rituximab-refractory or relapsing AAV and appears to be efficacious and well tolerated. Results of use thereof in larger clinical studies are awaited.

Background/Purpose: Innate immune activation plays a key role in granulomatosis with polyangiitis (GPA), contributing to vascular inflammation via neutrophil extracellular traps, immune complexation (IC), and endothelial injury. Its role in response to rituximab (RTX) remains unclear. We aimed to evaluate changes in innate immune markers before and after RTX and assess their ability to predict remission and treatment response.

Methods: Ten plasma biomarkers reflecting neutrophil and platelet activation, endothelial injury, and IC were measured pre- and 6–12 months post-RTX. Skewed biomarkers were log-transformed or dichotomized. Changes over time were assessed using linear or generalized linear mixed-effects models. Confounders were selected systematically using iterative linear regression models, excluding aliased and collinear variables. Non-response was defined as < 50% BVAS/WG

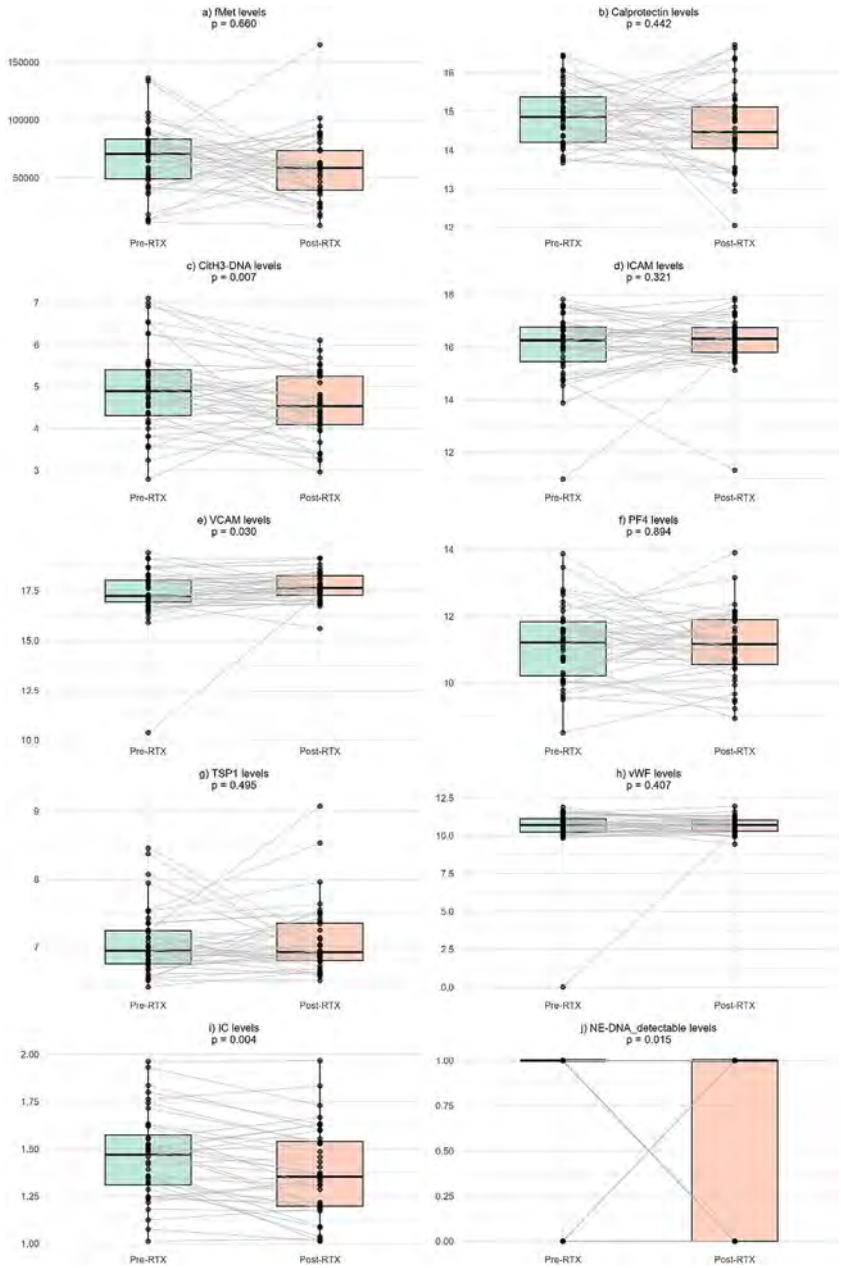

Figure 1: Comparison of the biomarker's levels pre- and post-RTX. fMet: N-Formylmethionine; CitH3-DNA: Citrullinated histone H3-DNA complex; ICAM: Intercellular adhesion molecule 1; VCAM: Vascular cell adhesion molecule 1 (VCAM-1); PF4: Platelet factor 4 complement; TSP1: Thrombospondin 1, vWF: Von Willebrand factor; IC: Immune complexation; NE-DNA: Neutrophil Elastase-DNA Complexes.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Receiving operating characteristics (ROC) curves and areas under the curve (AUC) of no remission (a), no response (b). Scores 1 to 4 refers to the number of biomarkers that are positive according to the thresholds and their direction specified in the figure. Numbers next to the biomarkers inside the square indicate logarithmic value (raw value, percentile). CitH3-DNA: Citrullinated histone H3-DNA complex; VCAM: Vascular cell adhesion molecule 1 (VCAM-1); IC: Immune complexation; NE-DNA: Neutrophil Elastase-DNA Complexes.

reduction without new symptoms; non-remission as BVAS/WG > 0. Wilcoxon and Fisher's tests compared trajectories by outcome. ROC curves and Youden index thresholds were used to evaluate predictive performance.

Combined biomarker scores we constructed to predict non-response/non-remission and calculated individual biomarker thresholds based on ROC-derived Youden index from pre-treatment samples. These thresholds were applied to generate a simple score (0–4), summing the number of positive biomarkers within those that significantly changed post-RTX. Areas under the curve (AUC) were calculated for each cutoff (score 0–4). A weighted score was derived from logistic regression, and DeLong's test was used to compare performance.

Results: Forty GPA patients were included (median age 53 [interquartile range 38–65], 58% female, 90% White). Thirty-four (85%) were PR3-ANCA+, 3 (7.5%) MPO-ANCA+ and 3 (7.5%) missing. Pre-RTX median BVAS/WG was 3.0, dropping to 0.0 post-RTX. Ten patients (25%) did not reach remission; 9 (23%) failed to respond.

Citrullinated histone H3-DNA complexes (CitH3-DNA), IC, and neutrophil elastase–DNA complexes (NE-DNA) levels decreased significantly post-RTX; vascular cell adhesion molecule 1 (VCAM) increased (**Figure 1**). Baseline biomarkers individually did not differentiate outcomes. However, a combined score of 4 positive biomarkers according to the thresholds and direction specified in **Figure 2** best identified non-responders across definitions: AUC ranged from 0.767 to 0.651. For lack of remission, score 4 had: sensitivity = 0.93, specificity = 0.60, positive predictive value (PPV) = 0.88, negative predictive value (NPV) = 0.75; for lack of response: sensitivity = 0.97, specificity = 0.33, PPV = 0.83, NPV = 0.75. Weighted scores did not significantly outperform the simple score.

Conclusion: A combined score of 4 innate immune biomarkers—CitH3-DNA, VCAM, IC, and NE-DNA—identifies patients who fail to achieve remission or response after RTX treatment. The simple additive score performed consistently across outcome definitions and was not improved by weighting. While promising for stratifying non-responders prior to B-cell–depleting therapy, this score requires external validation before clinical application.

Abstract Number: 1603

SGLT-2 Inhibitors are Associated with Lower Risk of End Stage Renal Disease (ESRD) and Lower Mortality in ANCA-associated Vasculitis With Kidney Involvement

Julia Foos[1], Naveed Shah[2] and Nezam Altorok[3], [1]Unversity of Toledo College of Medicine and Life Sciences, Toledo, [2]University of Toledo College of Medicine and Life Sciences, Toledo, [3]The University of Toledo, Toledo, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA-associated vasculitis encompasses three main conditions: Granulomatosis with Polyangiitis (GPA, previously called Wegener's granulomatosis), Eosinophilic Granulomatosis with Polyangiitis (EGPA, previously called Churg-Strauss), and microscopic polyangiitis. These three conditions are known to cause kidney issues. SGLT-2 inhibitors (SGLT-2i) have demonstrated the ability to protect some aspects of kidney function in patients with Type 2 diabetes. This study intends to investigate effects of SGLT-2 inhibitors on renal-related outcome measures in patients with ANCA-associated vasculitis and Type 2 diabetes.

Methods: This retrospective cohort study used TriNetX, a global, federated network of databases that provides de-identified data of over 113 million patients. We used all applicable ICD-10 codes to identify patients with GPA, EGPA, or microscopic polyangiitis and Type 2 diabetes, and if they take SLGT-2i for diabetes treatment. The participants in the study ranged from ages 18-80 years and were balanced based on age and sex. These cohorts filtered out patients who had received a previous diagnosis/procedure of Chronic Kidney Disease (CKD), End Stage Renal Disease (ESRD), unclassified kidney disorders, dialysis, and kidney transplant.

Results: We identified 219 patients who used SGLT-2i at time of diagnosis of ANCA-associated vasculitis with kidney involvement. Among these patients, we identified lower incidence of ESRD in patients who used SGLT-2i compared to age- and sex-matched controls. Age at index was 62.9 in the SGLT-2i group, and 64.1 in the control group. Specifically, we identified 33 patients who took SGLT-2i and were diagnosed with ESRD, compared to the 57 patients who did not take SGLT-2i (p=0.003). 10 patients on SGLT-2i received kidney transplants, and 0 became infected. 18 patients received kidney transplants but did not take SLGT-2 inhibitors, and 10 of their transplants became infected (p=0.001). We did not find

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

statistically significant difference in outcomes related to kidney transplant status (p=0.115) and dialysis services (p=0.062). Moreover, patients with ANCA-associated vasculitis who used SGLT2 inhibitors had a survival probability (outcomes: ESRD, stage 5 CKD, dialysis services, kidney transplant status, or kidney transplant infection) of 90% five years after meeting the selected criteria, as opposed to the 72% who did not take SGLT-2i (p=0.03).

Conclusion: Patients with ANCA-associated vasculitis who used SGLT-2i at time of diagnosis of ANCA-associated vasculitis had lower risk of ESRD and kidney transplant infection (p< 0.05). Also, significantly lower 5-year mortality was found in SGLT-2i users. These findings highlight a potential survival and nephroprotective role of SGLT-2i in ANCA-associated vasculitis.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Small vessel vasculitis mainly includes ANCA-associated vasculitis (AAV) and cryoglobulinemic vasculitis (CV), leading to significant organ damage. Rituximab (RTX), an anti-CD20 monoclonal antibody, has improved the prognosis by targeting B cells[1]. Anti-RTX antibodies (ARA) are detrimental in primary membranous glomerulonephritis[2] and rheumatoid arthritis but their impact in small vessel vasculitis remains unclear. We aimed to evaluate the impact of ARAs on disease progression, treatment response and prognosis in patients with AAV and CV.

Methods: We retrospectively identified patients with AAV or CV who developed ARA through two immunology laboratories and the French Vasculitis Study Group. ARA positivity was defined by an undetectable serum RTX level with high anti-RTX antibody titer (>20%). We evaluated demographic, clinical, and laboratory data; CD19+ B-cell counts at 6 months; and

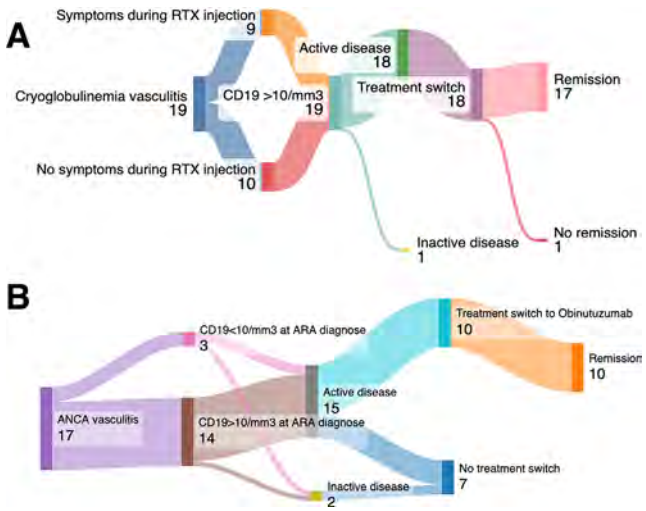

Figure 1. Sankey Diagram of Clinical Features, CD19 Reconstitution, and Treatment Outcomes in Cryoglobulinemic and ANCA-Associated Vasculitis Cohorts. A. Cyroglobulinemic vasculitis ARA's cohort: Among 19 patients with cryoglobulinemic vasculitis who developed anti-rituximab antibodies (ARA), half experienced infusion-related symptoms during rituximab (RTX) administration. All 19 showed CD19+ reconstitution (>10 cells/mm^3) at the time of ARA detection; 18 had active disease and were switched to an alternative therapy, leading to remission in 17 cases (1 remained with persistent disease). B. ANCA-associated vasculitis patients with ARA, 14 exhibited CD19+ reconstitution (>10 cells/mm^3) and 3 maintained depletion (<10 cells/mm^3). Fifteen had active disease, of whom 10 were switched to obinutuzumab—achieving remission in all—and 7 continued their previous regimen without switch (2 were inactive at ARA diagnosis).

Table 1 Baseline features, treatment regimens and follow-up outcomes of the study cohorts. A. Comparison between CV patients without anti-rituximab antibodies (CryoVas cohort, N = 321) versus those with detectable anti-rituximab antibodies (ARA cryoglobulinemia, N = 19). B. Comparison between patients with ANCA-associated ARA (N = 202) versus ARA-ANCA patients with detectable anti-rituximab antibodies (N = 17).

Table 2. Univariable and multivariable predictors of anti-rituximab antibody development in small-vessel vasculitis. A. illustrates the associations between key clinical factors and anti-rituximab antibody (ARA) positivity in cryoglobulinemic vasculitis (CV), using both univariable and multivariable Firth-penalized logistic regression. B. presents the same analyses for ANCA-associated vasculitis (AAV). Odds ratios and 95% confidence intervals were estimated via the logistf package; multivariable models adjust for all variables shown in each panel.

A

Cryoglobulinemic vasculitis

		Univariable			Multivariable		
Variable	N	Odd Ratio	95% CI	p-value	Odd Ratio	95% CI	p-value
Age ≤40 years	340	5.37	[1.84 - 14.5]	**0.003**	9.21	[1.29 - 65.8]	**0.027**
Sjogren disease	340	39.6	[9.79 – 362]	**<0.001**	31.2	[3.64– 268]	**<0.001**
Symptoms during RTX injection	340	116	[28.5 – 667]	**<0.001**	25.6	[3.30 – 198]	**0.002**
RTX 1g protocol (Day 1 and Day 15)	71	11.9	[3.68 - 43.4]	**<0.001**	10.1	[2.33 - 43.8]	**0.024**

Abbreviation: CI = Confidence Interval; RTX = Rituximab

Odds Ratio and 95% CI estimated via Firth's penalized logistic regression (logistf)

Abbreviation: CI = Confidence Interval; RTX = Rituximab

Odds Ratio and 95% CI estimated via Firth's penalized logistic regression (logistf).

outcomes including relapse or refractory disease. We also analyzed two control cohorts (one for AAV, one for CV) to assess risk factors for immunization.

Results: Thirty-six patients with ARA-positive vasculitis were included (median age 58 IQR [42-69]; 75% female), including 19 CV (all associated with Sjögren's syndrome) and 17 AAV. The most common organ involvement was skin (59%), peripheral nerve (42%), and kidney (41%). Patients received a median of five RTX infusions prior to ARA detection, with a median interval of 11 months (IQR [5-25]) from RTX initiation. Notably, 38% experienced serum sickness-like reactions during infusions prior to ARA identification. CD19+ B cells were detectable in 91% of patients at the time of ARA detection, and 91% had active disease at that time.

After ARA detection, 27 patients (75%) required a change in therapy, with obinutuzumab being the most common alternative (50%), while others received cyclophosphamide, belimumab or ofatumumab. Clinical remission was achieved in 96% of patients, with 92% achieving B-cell depletion after switching (**Figure 1**).

We next compared baseline and follow-up data between patients and controls (**Table 1**). In the CV group, variables independently associated with the detection of ARA were Sjogren's syndrome (adjusted OR 31.2; 95%CI 3.4-268; p=0.001), age ≤40 years (aOR 9.21; 95%CI 1.29–65.8; p=0.027), reactions during RTX infusions (aOR 25.6; 95%CI 3.30–198; p=0.002) and the use of RTX regimen 1 gram on days 1 and 15 (aOR 10.1; 95%CI 2.33–43.8; p=0.002). In the AAV group, variables independently associated with the detection of ARA were microscopic polyangiitis (aOR 3.7; 95%CI 1.21–10.0; p=0.021), renal involvement (aOR 3.36; 95%CI 1.01–11.2; p=0.048) and mononeuritis multiplex (aOR 3.58; 95% CI [1.19–10.8]; p=0.023), and the use of RTX regimen 1 gram on days 1 and 15 (aOR 4.87; 95%CI 1.59-14.9; p=0.006) (**Table 2**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In conclusion, ARA detection is associated with younger age, Sjogren's syndrome and infusion-related reactions in cryolgobulinemia vasculitis, and with microscopic polyangiitis, renal involvement, and mononeuritis multiplex in AAV, with the RTX regimen of 1 gram on days 1 and 15 being associated with ARA detection in both vasculitis. Monitoring and switching to obinutuzumab may improve outcomes.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a small-vessel vasculitis characterized by asthma, ear, nose, and throat (ENT) symptoms, eosinophilia, and systemic involvement. Despite the use of anti-interleukin (IL)-5/IL-5R therapies, asthma or primarily ENT symptoms may persist. Dupilumab (anti-IL-4Rα) is approved for severe asthma and chronic rhinosinusitis but has been associated with drug-induced eosinophilia and EGPA flares. Given their complementary mechanisms, the combination of anti-IL-5/IL-5R and dupilumab may improve disease control in patients with EGPA. We report the safety and efficacy of this off-label combination in relapsing/refractory EGPA.

Methods: This European, multicenter, retrospective study included EGPA patients fulfilling 2022 ACR/EULAR classification criteria treated with anti-IL-5/IL-5R in combination with dupilumab for relapsed or refractory disease. Complete response (CR) was defined as BVAS=0 and prednisone dose ≤4 mg/day, partial response (PR) as BVAS=0 and prednisone dose >4 mg/day. Failure was defined as inability to reduce GCs ≤7.5 mg/day due to persistently active disease, vasculitis relapse, and/or worsening of asthma or ENT symptoms, and requiring treatment escalation.

Results: Sixteen patients received the combination therapy, with mepolizumab or benralizumab in 8 cases each. Twelve patients (75%) received the addition of dupilumab to ongoing anti-IL-5/IL-5R, 6 for uncontrolled ENT symptoms, 5 for both uncontrolled ENT and asthma symptoms, and 1 for uncontrolled asthma. The remaining 4 patients (25%) received the

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

addition of anti-IL-5/IL-5R to dupilumab for drug-induced eosinophilia associated with vasculitis relapse in 3 and for uncontrolled ENT symptoms/asthma in 3.

Safety analysis showed no serious adverse events, with only two patients experiencing mild-to-moderate adverse events.

Thirteen patients with ≥3 months of follow-up were analyzed for efficacy (median follow-up 6 (3-12) months). At the start of combination therapy, the median prednisone dose was 5 mg/day (0-10), decreasing to 4.38 mg/day (0-6.25) at 3 months and 3.75 mg/day (1.25-5) at 6 months. In patients with dupilumab-induced eosinophilia, the addition of anti-IL-5/IL-5R reduced eosinophil counts from 1600/μL (1082-4000) to 170/μL (90-465) at 3 months and remained 170/μL (165-175) at 6 months. No eosinophilia occurred when dupilumab was added to anti-IL-5/IL-5R.

At 3 months, 4/13 (31%) and 1/13 (8%) achieved CR and PR, respectively, while 3/13 (23%) had treatment failure. At 6 months (data available for 11 patients), 5/11 (45%) and 3/11 (27%) achieved CR and PR, respectively, and at 9 months, CR was achieved in all patients with available follow-up, except for the 3 patients with initial treatment failure.

Conclusion: The combination of anti-IL-5/IL-5R and dupilumab in this small case series was safe and appeared to be an effective option in EGPA patients with uncontrolled ENT manifestations while on anti-IL-5/IL-5R or in patients with dupilumab-induced hypereosinophilia and EGPA manifestations, with optimal response requiring at least 6 months of treatment.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Avacopan has been approved for adjunctive use in adults with severe active granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) in the US. Here we describe 12-month effectiveness and safety outcomes for avacopan users in a large healthcare system.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Baseline Characteristics of Individuals Prescribed Avacopan for GPA/MPA

Characteristic at time of prescription	N=119
Age, years, mean (SD)	59.4 (16.2)
Female, n (%)	83 (69.8)
Race, n (%)	
Asian	7 (5.9)
Black	6 (5.0)
White	96 (80.6)
Other	9 (7.6)
Unknown	1 (0.8)
Hispanic ethnicity, n (%)	11 (9.2)
AAV status, n (%)	
Newly diagnosed	79 (66.4)
Relapsed	40 (33.6)
AAV phenotype, n (%)	
GPA	60 (50.4)
MPA	59 (49.6)
ANCA type, n (%)	
MPO-ANCA+	66 (55.5)
PR3-ANCA+	40 (33.6)
Dual positive	2 (1.7)
Negative	11 (9.2)
BVAS v3, median (IQR)	12 (8, 17)
Setting of avacopan prescription, n (%)	
Inpatient	37 (31.1)
Outpatient	82 (68.9)
Prescribing provider specialty, n (%)	
Rheumatology	60 (50.4)
Nephrology	59 (49.6)
Concomitant immunosuppression,* n (%)	
Rituximab ± csDMARD	65 (54.6)
Cyclophosphamide ± csDMARD	6 (5.0)
Rituximab and cyclophosphamide ± csDMARD	39 (32.8)
Other csDMARD	2 (1.7)
None	7 (5.9)
GPA/MPA-related cumulative GC exposure in the 3 months prior to prescription, prednisone-equivalent mg, median (IQR)	1252.6 (540.0, 3507.1)
GPA/MPA-related cumulative GC exposure in the 12 months prior to prescription, prednisone-equivalent mg, median (IQR)	2275.0 (970.0, 4100.0)

AAV, ANCA-associated vasculitis; ANCA, antineutrophil cytoplasmic antibody; BVAS v3, Birmingham Vasculitis Activity Score version 3; csDMARD, conventional synthetic disease modifying antirheumatic drug; GC, glucocorticoid; GPA, granulomatosis with polyangiitis; IQR, interquartile range; MPA, microscopic polyangiitis; MPO, myeloperoxidase; PR3, proteinase 3.
*Rituximab and cyclophosphamide use were considered to be baseline use if received within 5 weeks of avacopan initiation; other medications were considered if prescribed at baseline. csDMARDs included methotrexate (n=6), azathioprine (n=2), and mycophenolate (n=1).

Methods: This ongoing retrospective cohort study involves patients prescribed avacopan for GPA or MPA from 12/1/21-4/1/24. Data from 12 months pre- and post-avacopan prescription are reported. As in the ADVOCATE trial, sustained remission at month 12 is defined as a Birmingham Vasculitis Activity Score version 3 (BVAS v3) of 0 at months 6 and 12 with no glucocorticoid (GC) use for GPA/MPA for 1 month before months 6 and 12, and no relapse from months 6-12. Relapse is assessed after 1 month and is defined as: 1) ≥1 major BVAS v3 item, 2) ≥3 minor items, or 3) 1 or 2 minor items for ≥2 consecutive visits. Increase in BVAS v3 of < 3 and absence of major items defines a minor relapse; all others are defined as a major relapse. We also assessed other disease- and treatment-related outcomes, including the Glucocorticoid Toxicity Index-Metabolic Domains (GTI-MD).

Results: Among 119 patients prescribed avacopan, the mean age was 59.4 years; most were female (83, 70%), newly diagnosed (79, 66%), had GPA (60, 50%), and were MPO-ANCA+ (66, 55%) (**Table 1**). The median (IQR) baseline BVAS v3 was 12 (8, 17). Most patients received concomitant rituximab (65, 55%), cyclophosphamide (6, 5%), or both (39, 33%). Sixteen (13%) did not initiate avacopan, with the most common reasons being insurance denial (n=5) or high copay (n=3). Of the 103 (87%) initiating avacopan, organ involvement included the kidneys (58, 56%), lungs (50, 49%) and ear, nose, or throat (ENT) (43, 42%) (**Table 2**).

Table 2. Baseline Disease and Treatment-Related Characteristics of Individuals who Initiated Avacopan for GPA/MPA

Characteristic	N=103
Time from avacopan prescription to initiation, days, median (IQR)	10 (3, 22)
Initiated in ≤14 days of prescription, n (%)	68 (66.0)
Initiated in ≤21 days of prescription, n (%)	76 (73.8)
GPA/MPA-related GC use at baseline, n (%)	92 (89.3)
Prednisone-equivalent GC dose at time of initiation among those on GCs, mg, median (IQR)	40 (20, 60)
BVAS v3 at prescription, median (IQR)	12 (8, 17)
Organ involvement* at initiation, n (%)	
Kidney	58 (56.3)
Lung	50 (48.5)
Ear, nose, or throat	43 (41.8)
≥1 dialysis session at or within 30 days following initiation, n (%)	10 (9.7)
Baseline eGFR among those with kidney involvement and not on dialysis (n=49), ml/min/1.73m², median (IQR)	35 (20, 57)

BVAS v3, Birmingham Vasculitis Activity Score version 3; eGFR, estimated glomerular filtration rate; GC, glucocorticoid; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis
*Defined by presence of any BVAS v3 criterion for respective organ system

Major, n (%)	1 (1.1)
Minor, n (%)	2 (2.1)
Sustained remission at month 12#, n (%)	58 (61.1)
BVAS v3 of 0 at month 12, n (%)	90 (94.7)
GC-free at month 12, n (%)	83 (87.4)
Days to GC discontinuation among those off GCs at month 12, median (IQR) (n=72)	84 (56, 175)
≤5mg prednisone equivalent daily dose at month 12 among those on GCs for GPA/MPA at 12 months, n (%) (n=12)	3 (25)
Cumulative GC exposure between initiation and month 12, prednisone-equivalent mg, median (IQR)	1050 (280, 2030)
Remaining on avacopan at month 12, n (%)	38 (40.0)
Days to avacopan discontinuation among those off at month 12, median (IQR)	203 (140, 324)
Reasons for avacopan discontinuation (n=57)	
Completed provider's planned treatment course, n (%)	33 (57.9)
Days to discontinuation among those who completed planned course, median (IQR)	273 (181, 365)
Self-discontinued, n (%)	3 (5.3)
Aminotransferase elevation, n (%)	3 (5.3)
Other adverse event, n (%)	11 (19.3)
Other or unknown, n (%)	7 (12.3)
Glucocorticoid Toxicity	
GTI-MD Cumulative Worsening Score (CWS), median (IQR)	29.0 (19.0, 51.0)
GTI-MD Aggregate Improvement Score (AIS), median (IQR)§	0.0 (-19.0, 23.0)
Blood Pressure Domain AIS >0, n (%)	39 (41.1)
Body Mass Index Domain AIS >0, n (%)	20 (21.1)
Lipid Metabolism Domain AIS >0, n (%)	17 (17.9)
Glucose Tolerance Domain AIS >0, n (%)	5 (5.3)
Outcomes Among Those with Specific Baseline Organ Involvement	
Sustained remission among those with kidney involvement#, n (%) (n=54)	37 (68.5)
eGFR among those not on dialysis at month 12 (n=49), ml/min/1.73m², median (IQR)	44 (29, 71)
Sustained remission among those with ENT involvement#, n (%) (n=42)	25 (59.5)
Sustained remission among those with lung involvement#, n (%) (n=44)	26 (59.1)

BVAS v3, Birmingham Vasculitis Activity Score version 3; eGFR, estimated glomerular filtration rate; GC, glucocorticoid; GTI-MD, Glucocorticoid Toxicity Index-Metabolic Domains; ENT, ear, nose, or throat

*Table includes those with available data at month 12, excluding 4 people who died by month 12 (with causes of COVID-19 infection, diffuse alveolar hemorrhage due to AAV, necrotizing bacterial pneumonia, and decompensated heart failure) and 4 who were lost to follow-up

#Sustained remission defined as remission at months 6 and 12 (BVAS v3 of 0 and no GCs for GPA/MPA within 1 month before month 6 or month 12, respectively), without relapse between months 6 and 12. Relapse was defined as the return (after prior improvement) of vasculitis activity by 1 or 2 minor BVAS v3 items for ≥2 consecutive clinical visits, ≥1 major BVAS v3 item, ≥3 minor BVAS v3 items. Increase in the BVAS v3 of <3 and absence of major items defines a minor relapse; all others are defined as major.

§Aggregate Improvement Scores are the sum of scores from 0-3, 3-6, & 6-12 months; negative scores indicate improvement, zero indicates no change, and positive scores indicate net worsening over 12 months.

Among 95 with available 12-month follow-up data, 61 (64%) were in remission at month 6, while at month 12, 90 (95%) had a BVAS v3=0, 83 (87%) were GC-free, and 58 (61%) had sustained remission (**Table 3**). Three patients relapsed (1 major, 2 minor) between months 6 and 12. Overall, 38 (40%) were still on avacopan at 12 months and 57 (60%) discontinued therapy before 12 months mostly due to completion of the provider's planned treatment course (33/57, 58%) or adverse events (14/57, 25%). The median (IQR) cumulative prednisone-equivalent GC exposure over 12 months was 1050 (280, 2030) mg. Among 84 patients on GCs at baseline, 72 discontinued GCs after a median (IQR) of 84 (56, 175) days, and 12 remained on GCs at 12 months (range of 1.25-20 prednisone-equivalent mg daily). Sustained remission was similar in those with baseline kidney, lung, or ENT involvement.

The most common GTI-MD domain with net worsening (i.e., Aggregate Improvement Score [AIS] > 0) was Blood Pressure (41%), followed by Body Mass Index (21%), Lipid Metabolism (18%), & Glucose Tolerance (5%). The majority (53, 56%) had no net worsening of metabolic GC toxicity over 12 months (i.e., AIS ≤0), indicating either net improvement or no change.

Conclusion: In this real-world cohort of individuals with GPA or MPA, among those with 1-year follow-up, most avacopan users discontinued GCs within 3 months and had sustained remission at 12 months, and a minority had avacopan-related adverse events and/or worsening of GC toxicity.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Antibiotic prophylaxis is recommended during initial treatment of ANCA-associated vasculitis (AAV). We assessed characteristics associated with prophylaxis within a Canadian multicenter AAV cohort starting rituximab (RTX) for either induction or maintenance of remission.

Methods: We performed a secondary analysis of baseline characteristics from the Biosimilars in ANCA-associated Vasculitis compared to the Originator (BRAVO) cohort, including adults with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) who started RTX induction or maintenance (either the originator or a biosimilar) at cohort entry. We stratified characteristics (at time of starting RTX induction or maintenance, as applicable) according to concurrent antibiotic prophylaxis (e.g. trimethoprim sulfamethoxazole [TMP-SMX], dapsone, atovaquone), and compared groups using 95% confidence interval (CI) for the differences in mean or proportion, or the Mann Whitney *U* test as applicable. Characteristics of interest included demographics, current prednisone dose, disease activity, disease duration and prior relapse. Univariable and multivariable logistic regressions assessed the association of covariates of interest with prophylaxis.

Results: Of the 200 participants in BRAVO, 126 initiated induction and 58 initiated maintenance at baseline. [Table 1]. The proportion taking prophylaxis at the start of induction (81%) and maintenance (79%) was similar, whereas 98 (96%) of the induction group and 39 (85%) of the maintenance group were receiving prednisone at baseline. TMP-SMX was the most commonly used antibiotic during induction (95%) and maintenance (89%), with the remainder being primarily atovaquone (2% induction, 11% maintenance) and dapsone (2% in induction).

In the induction group, any prednisone use (OR 4.9; 95% CI 1.1-21.4), prednisone ≥20 mg/day (OR 6.5; CI 2.5-17.0) and baseline Birmingham Vasculitis Activity Score (BVAS) (OR for each point 1.2; 95 CI 1.1-1.3) were associated with antibiotic prophylaxis, while use of other concurrent immunosuppressants (OR 0.3; 95% CI 0.1-0.8) and having ≥1 prior relapse (0.3 OR; 95% CI 0.1-0.9) were negatively associated with prophylaxis. In multivariable analyses, daily prednisone dose ≥20 mg

Abbreviations: SD, standard deviation; IQR, interquartile range; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; RTX, rituximab; BVAS, Birmingham Vasculitis Activity Score; VDI, Vasculitis Damage Index

*the 95% CI for difference in mean or proportion excludes the null value

** p<0.05 (Mann-Whitney-U test)

(adjusted OR 3.4; 95% CI 1.2-10.0) and BVAS (aOR 1.1, 95% 1.0-1.2) remained associated with prophylaxis. In the maintenance group, prednisone use was also associated with prophylaxis in adjusted analyses (aOR 6.1, 95% CI 1.3-27.0).

Conclusion: In this multicenter cohort initiating RTX for induction or maintenance, 80% of the participants were taking antibiotic prophylaxis, which is higher than reported in other cohorts. During the induction and maintenance period, concurrent prednisone was associated with prophylaxis, as was higher disease activity during induction. Our findings provide additional insight into the patterns of antibiotic prophylaxis use in AAV.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Results from the 1-year double-blind period and first year of the open-label extension (OLE) of the MANDARA trial (NCT04157348) demonstrated that over 60% of patients with relapsing or refractory eosinophilic granulomatosis with polyangiitis (EGPA), with active non-severe disease at baseline, achieved remission. Additionally, more than 40% discontinued oral glucocorticoids after treatment with anti-interleukin-5/Receptor (anti-IL-5/R) therapies. This analysis focuses on changes in individual items of active disease and long-term damage in EGPA over the same two-year period.

Methods: Patients (without active life- or organ-threatening manifestations at the start of the trial) who completed the randomized double-blind period, could enter the OLE, during which they continued benralizumab (benra/benra n=66) or switched from mepolizumab to benralizumab (mepo/benra n=62). The protocol encouraged reduction in oral glucocorticoids. Disease activity was measured by the Birmingham Vasculitis Activity Score (BVAS), while items of damage were measured by the Vasculitis Damage Index (VDI) for the trial participants over two years (up to Week 104).

Results: In total, 128 patients entered the OLE. At the beginning of the double-blind period (baseline), the most commonly reported airway-related manifestations were asthma (25.8% of patients), paranasal sinus involvement (15.6%), and bloody nasal discharge/crusts/ulcers/granulomata (14.1%). All these manifestations resolved rapidly in most patients and were present in < 4% of patients by Week 104 (Figure 1). Sensory peripheral neuropathy (9.4%), arthralgia/arthritis (7.8%), and myalgia (6.3%) were the most reported non-airway manifestations at baseline, and their frequency also decreased rapidly to < 3% by Week 104. Cutaneous (3.9%) and renal manifestations (1.6%) were infrequent at baseline and either resolved

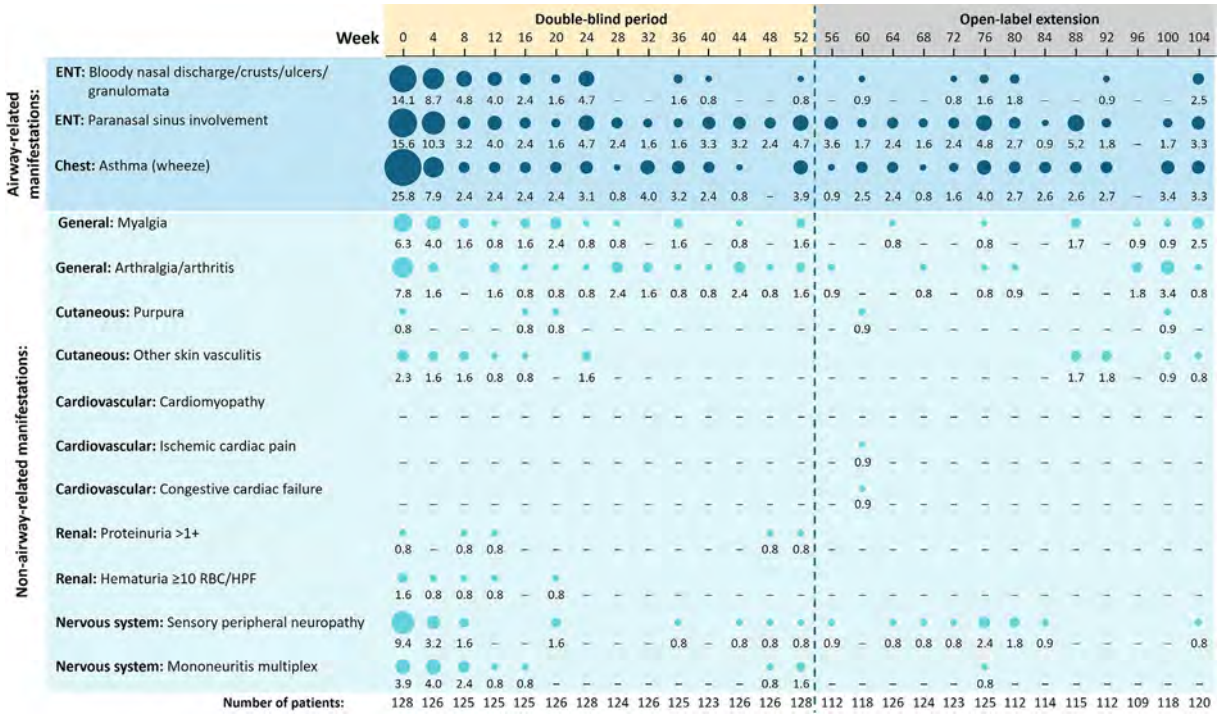

Figure 1. Summary of select manifestations of eosinophilic granulomatosis with polyangiitis up to Week 104 of the MANDARA trial Corresponding percentage of patients is shown beneath each bubble. Manifestations are categorized according to the BVAS. BVAS, Birmingham Vasculitis Activity Score; ENT, ear, nose, and throat; HPF, high power field; RBC, red blood cells.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

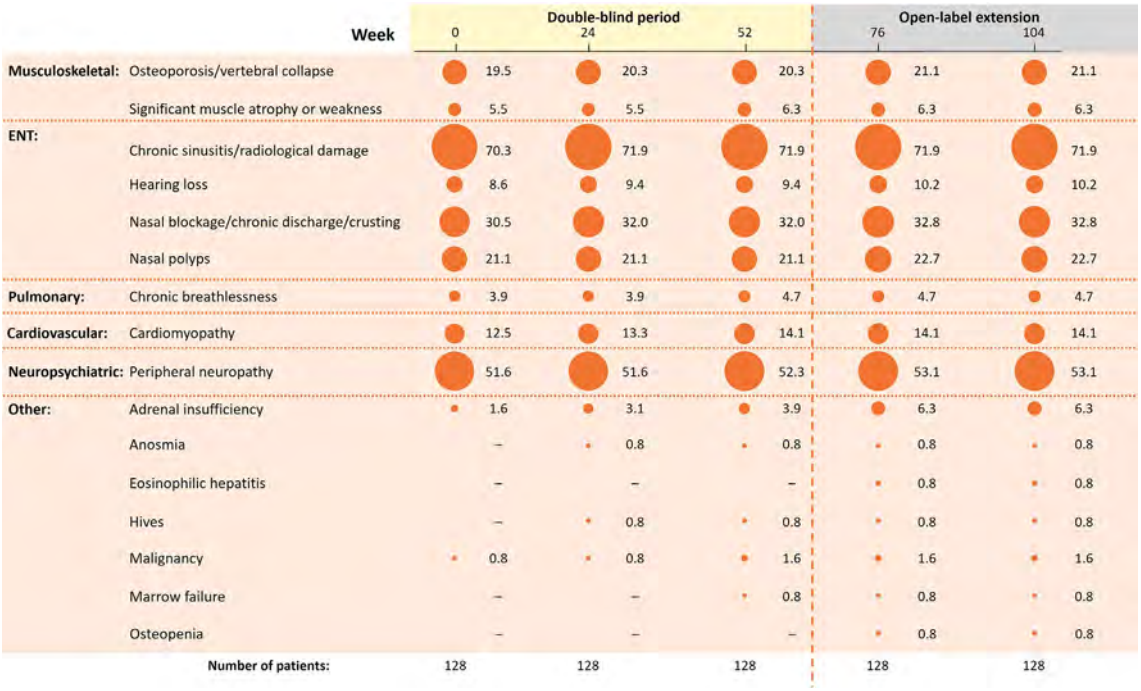

Figure 2. Summary of items of damage in patients with eosinophilic granulomatosis with polyangiitis up to Week 104 of the MANDARA trial Corresponding percentage of patients is shown beneath each bubble, as measured by VDI. ENT, ear, nose, and throat; VDI, Vasculitis Damage Index.

or affected < 1% of patients by Week 104. Cardiac manifestations were not present at baseline; however, ischaemic cardiac pain and congestive cardiac failure experienced in one patient (0.9%), were present at Week 60.

Overall, there were 29 new items of damage in 25 patients recorded up to Week 104, with 18 occurring in the double-blind period, and 11 during the first year of the OLE (Figure 2).

Conclusion: Among patients with EGPA, after two years of treatment with anti-IL-5/R therapies, mostly associated with substantial reductions in oral glucocorticoids, there is little disease progressive organ damage, suggesting a durable effect of treatment with mepolizumab and benralizumab for reducing both airway-and non-airway-related manifestations of disease.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Rituximab (RTX) has been shown to achieve high remission-induction and sustained maintenance rates across multiple studies and clinical trials in patients with AAV. The optimal dose and duration of rituximab for maintenance of remission in ANCA vasculitis (AAV) remains a matter of debate. In this interim analysis of an ongoing study, we aimed to compare the relapse rate, B cell depletion rate and hypogammaglobulinemia after receiving fixed protocol ultra-low dose (200mg, ULD biannually) and low dose (500mg, LD biannually) rituximab for maintenance of remission in patients with AAV.

Methods: Patients satisfying ACR / EULAR criteria for either Granulomatosis with polyangiitis (GPA) or Microscopic polyangiitis (MPA), in complete remission and receiving rituximab maintenance therapy for > 12 months, were recruited across 4 centres in India between 1st April 2023 - 1st February 2025. Based on the dose of maintenance rituximab used as per physician's discretion, the patients were subdivided into either LD or ULD group. Details of clinical presentation, disease activity as assessed by BVASvs3 and laboratory investigations were collected prospectively at recruitment (T0), 3 monthly follow up until the last follow up visit or relapse whichever occurred earlier. Remission was defined as Birmingham Vasculitis activity score (new/worsening) (BVAS) = 0 while relapses were defined as (BVAS) ≥ 1.

Figure-1: Flow chart depicting outcomes of patients with AAV treated with ULD and LD maintenance rituximab

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 35 patients (GPA= 30, MPA = 5) recruited, 18 and 17 patients received ULD and LD maintenance rituximab respectively. The clinical details at diagnosis and T0 visits are depicted in (Table-1). All the parameters at diagnosis except age and disease duration were similar in both groups (Table-1).

During median follow-up of 12 (IQR 9-15) months (Figure 1), 1 patient given LD rituximab had major flare with renal involvement (BVAS=11) at 6 months while another 1 patient developed sepsis at 15 months follow up and died. Among patients receiving ULD rituximab, one developed exacerbation of colitis and succumbed. None of the patients in either group developed hypogammaglobulinemia during follow up. The CD19 B cell count, and IgG levels at the last visit did not differ significantly between LD and ULD group.

Conclusion: In this proof-of-concept study, frequency of relapse, mortality, B cell depletion and adverse events were comparable between both LD and ULD rituximab group.

Early Mepolizumab Initiation Enables High Glucocorticoid and Immunosuppressant Discontinuation Rates in EGPA: A Retrospective Cohort Study of 35 Patients

Takashi Yamane[1], Ayaka Inoue[2], Noriaki Yasuda[2], Takahisa Ohnishi[3] and Akira Hashiramoto[4], [1]Kakogawa Central City Hospital, Kobe, Hyogo, Japan, [2]Kakogawa Central City Hospital, Kakogawa, Japan, [3]Kakogawa Central City Hospital, Kobe, Japan, [4]Department of Biophysics, Kobe University Graduate School of Health Sciences, Kobe, Japan

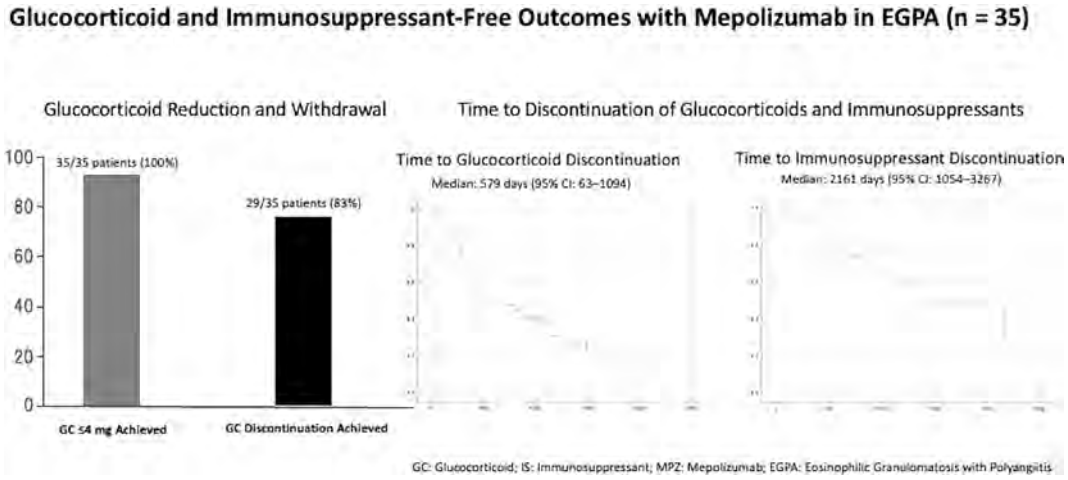
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

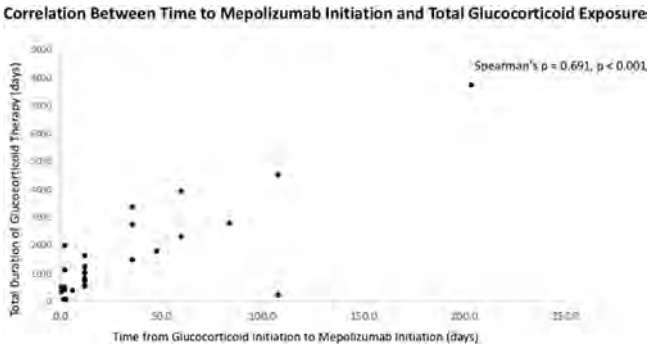
Background/Purpose: Mepolizumab (MPZ), an anti–interleukin-5 monoclonal antibody, has shown efficacy in reducing glucocorticoid (GC) dosage and sustaining remission in eosinophilic granulomatosis with polyangiitis (EGPA). This study investigated real-world outcomes of GC and immunosuppressant (IS) discontinuation, and the clinical predictors of successful shift to MPZ monotherapy.

Methods: We conducted a retrospective cohort study of 35 EGPA patients treated with MPZ and GC for ≥48 weeks. Patients were stratified by antineutrophil cytoplasmic antibody (ANCA) status and IS use. Outcomes included the proportion of patients achieving GC ≤4 mg/day and GC/IS discontinuation. GC exposure, time to withdrawal, and predictors were analyzed using Wilcoxon signed-rank, Mann–Whitney U, log-rank tests, and Cox proportional hazards models. Correlations were assessed by Spearman's coefficient.

Results: All patients (35/35) achieved GC tapering to ≤4 mg/day. GC was completely discontinued in 29 patients (83%), and 13 (37%) discontinued both GC and IS, achieving sustained MPZ monotherapy. The median time to GC-free status was 579 days (95% CI: 63–1094), while the median time to IS-free status was 2161 days (95% CI: 1054–3267). A significant

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License





negative correlation was observed between time from GC initiation to MPZ initiation and total GC duration (ρ = 0.691, p < 0.001), suggesting the benefit of early MPZ initiation. ANCA-negative patients achieved GC-free status more rapidly than ANCA-positive patients (p = 0.038). IS use did not significantly affect GC discontinuation time, though non-IS users tended to discontinue GC earlier (p = 0.040).

Predictors of Combined Glucocorticoid and Immunosuppressant Discontinuation Under Mepolizumab Monotherapy

At onset	Univariate HR (95%CI)	P	Multivariate HR (95%CI)	P
Sex(female)	**2.2(1.0-4.5)**	**0.007**	1.3(0.5-3.2)	0.553
Age	1.0(0.9-1.0)	0.486		
ANCA positive	0.7(0.3-1.6)	0.386		
Eos	1.0(1.0-1.0)	0.360		
CRP	0.9(0.8-1.0)	0.079		
FFS	0.7(0.4-1.1)	0.121		
Nasal	1.8(0.8-3.9)	0.155		
Asthma	2.0(0.5-8.9)	0.352		
Neurological	**0.3(0.1-0.8)**	**0.021**	0.3(0.12-0.9)	0.035
Cardiovasular	1.4(0.5-4.1)	0.533		
Renal	2.3(0.9-5.6)	0.078		

At MPZ initiation	Univariate HR (95%CI)	P	Multivariate HR (95%CI)	P
Onset to MPZ	0.9(0.9-1.0)	0.403		
History of relapse	**0.4(0.2-0.9)**	**0.036**	0.4(0.2-1.2)	0.101
Concomitant IS	**2.8(1.2-6.8)**	**0.023**	1.8(0.7-4.7)	0.254
GC dose	1.0(0.9-1.0)	0.449		

Cox Proportional Hazards Regression Analysis

HR: Hazard Ratio; CI: Confidence Interval; MPZ: Mepolizumab; IS: Immunosuppressants; GC: glucocorticoid

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Univariate Cox regression identified female sex (HR 2.2, 95% CI: 1.0–4.5, p = 0.007), absence of neurological involvement (HR 0.3, 95% CI: 0.1–0.8, p = 0.021), and no history of relapse (HR 0.4, 95% CI: 0.2–0.9, p = 0.036) as significant predictors of GC/IS discontinuation. In multivariate analysis, neurological involvement remained an independent predictor (HR 0.3, 95% CI: 0.12–0.9, p = 0.035).

Conclusion: MPZ facilitated tapering to low-dose GC in all patients and enabled complete GC discontinuation in the majority, with some patients achieving IS-free status. Early MPZ initiation significantly shortened GC exposure. ANCA-negative status and absence of neurological involvement were associated with more favorable outcomes. These findings support the treatment with MPZ monotherapy as a feasible long-term treatment strategy in selected EGPA patients.

Abstract Number: 1611

Effectiveness of Avacopan and Its Impact on Serum Calprotectin in MPA/GPA Patients Receiving Rituximab-Based Remission Induction: A Single-Center Study

Yusuke Ushio[1], Hiromi Shimada[2], Taichi Miyagi[3], Koichi Sugihara[2], Mao Mizusaki[2], Rina Mino[2], Kanako Chujo[3], Naoto Manabe[3], Mayuko Wada[2], Shusaku Nakashima[2] and Hiroaki Dobashi[2], [1]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Miki-cho, Kita District, Kagawa, Japan, [2]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Miki-cho, Kita-gun, Kagawa, Japan, [3]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Miki-cho, Kita-gun, Japan

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1592–1611) Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Avacopan, an oral C5a receptor antagonist, offers a promising glucocorticoid (GC)-sparing option for patients with microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA). Although randomized trials have demonstrated its efficacy, real-world data, particularly in combination with rituximab-based induction, remain limited. Moreover, reliable biomarkers for monitoring avacopan treatment response are yet to be established. This study aimed to evaluate the effectiveness of avacopan and its impact on serum biomarkers—especially calprotectin—in MPA/GPA patients receiving rituximab for remission induction.

Methods: We retrospectively analyzed MPA/GPA patients who received rituximab-based induction therapy between January 2019 and December 2024, followed for at least 12 months. Patients were divided into those who received avacopan (avacopan group) and those who did not (non-avacopan group) during induction therapy. The primary endpoint was GC-free remission (defined as BVAS = 0 with complete GC withdrawal). Cumulative GC dose by month 12 was also assessed. In the avacopan group, serum calprotectin (S100A8/A9) and C5a levels were measured at baseline and month 3. Statistical comparisons between two groups were performed using the Wilcoxon rank-sum test for continuous variables and Fisher's exact test for categorical variables. Paired t-tests were used to assess within-group changes in biomarkers. Pearson's correlation coefficient was used to examine the relationship between changes in biomarkers and BVAS.

ANCA: anti-neutrophil cytoplasmic antibody; PR3: proteinase 3; MPO: myeloperoxidase; GPA: granulomatosis with polyangiitis; MPA: microscopic polyangiitis; BVAS: Birmingham Vasculitis Activity Score; RTX: rituximab; GC: glucocorticoids.
† Organ involvement was based on the Birmingham Vasculitis Activity Score ≥ 1.
‡ An infusion of methylprednisolone was administered at a dose of 500 or 1000 mg per day for 3 consecutive days.
§ A single dose of rituximab (375 mg/m²) was administered when CD19+ B-lymphocytes reappeared in peripheral blood.
For statistical analyses, *p < 0.05, **p < 0.01. P-value: Wilcoxon rank sum test, Fisher's exact test.

Figure 1. Baseline characteristics of the patients.

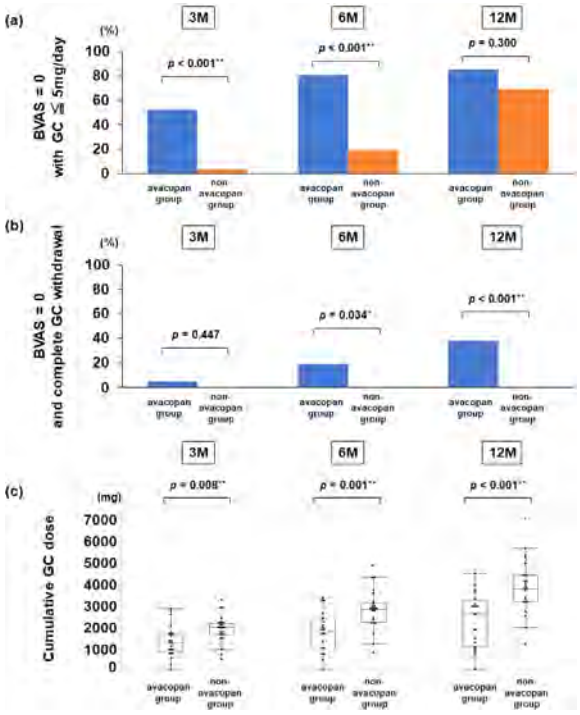

Figure 2. Comparison of remission status and cumulative GC dose between the two groups. (a) Proportion of patients achieving BVAS = 0 with GC ≦ 5 mg/day. (b) Proportion of patients achieving BVAS = 0 and complete GC withdrawal (GC-free remission). (c) Cumulative GC dose through month 12.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

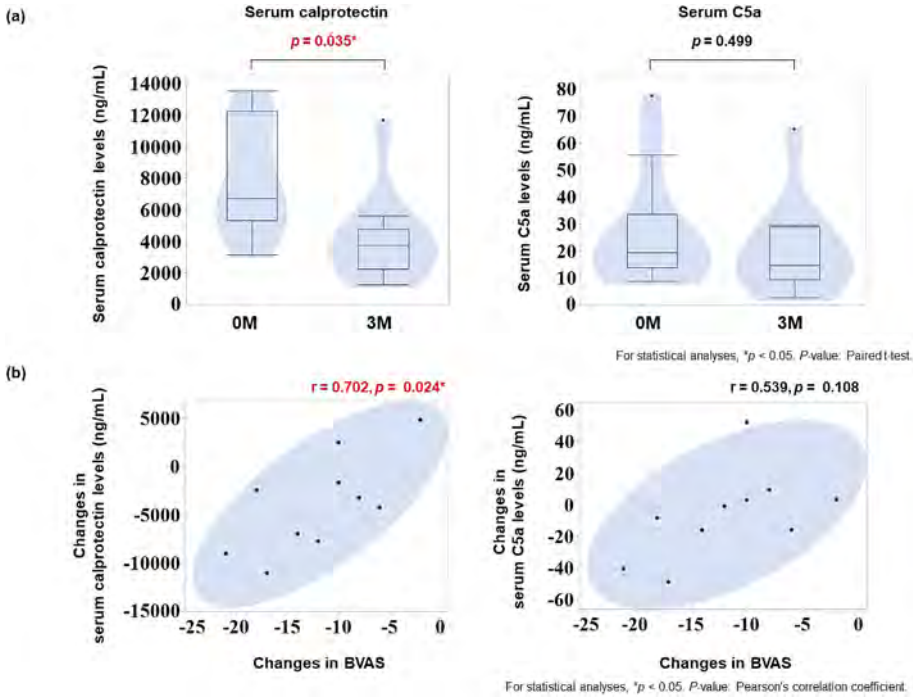

Figure 3. Serum biomarker changes and correlations with disease activity. (a) Changes in serum calprotectin and C5a levels from baseline to month 3. (b) Correlation between changes in BVAS and changes in serum calprotectin or C5a levels.

Results: A total of 47 patients were included (avacopan group: n = 21; non-avacopan group: n = 26). Baseline characteristics are shown in Figure 1. GC-free remission rate was significantly higher in the avacopan group at month 6 (19.1% vs. 0%, p = 0.034) and month 12 (38.1% vs. 0%, p < 0.001) (Figure 2). Cumulative GC dose at month 12 was significantly lower in the avacopan group (2343.2 ± 1242.3 mg vs. 4037.7 ± 1208.7 mg, p < 0.001). In the avacopan group, serum calprotectin levels significantly declined from 8082.1 ± 3624.6 ng/mL to 4170.5 ± 2975.8 ng/mL at month 3 (p = 0.035), and this change strongly correlated with BVAS improvement (r = 0.702, p = 0.024). In contrast, no significant change was observed in serum C5a levels (Figure 3).

Conclusion: Among MPA/GPA patients receiving rituximab-based induction therapy, avacopan enabled significant GC dose reduction while achieving clinical remission. Serum calprotectin decreased in response to treatment and correlated with disease activity, highlighting its potential as a real-world biomarker for monitoring avacopan efficacy.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Tocilizumab (TCZ) is the only biological drug currently approved for the treatment of giant cell arteritis (GCA), regardless of GCA duration. The "window of opportunity" is an increasingly widespread in different immune mediated inflammatory diseases, such as rheumatoid arthritis or psoriatic arthritis. Window of opportunity is usually defined as the chance of achieving remission depending on early treatment. Our aim was to assess the window of opportunity in a wide series of GCA patients treated with TCZ in clinical practice.

Table 1. Main clinical characteristics of GCA at initiation of tocilizumab.

Abbreviations: CRP: C-reactive protein; DMARDs: disease-modifying antirheumatic drugs; ESR: erythrocyte sedimentation rate; IQR: interquartile range; n: number; PMR: polymyalgia rheumatica; SD: standard deviation; TCZ: tocilizumab.
In this analysis, EULAR remission is the dependent variable.

Methods: Multicenter observational study of GCA patients treated with TCZ. Accordingly, to definitions of clinical trials in GCA, two groups of GCA were considered, "newly diagnosed GCA" and "relapsing GCA" depending on GCA diagnosis was made ≤6 or >6 weeks before initiation of TCZ, respectively. Window of opportunity in GCA was defined as the chance of achieving GCA-EULAR remission criteria (clinical and analytical remission). In addition, a multivariable study of associative factors with window of opportunity at 24 months of initiation of TCZ was conducted (logistic regression analysis).

Results: 471 patients (n=342; 72.6% female); mean age: 73.5±9 years were included. "Newly GCA" were 91 (19.3%) patients and "relapsing GCA", 380 (80.7%). In the newly diagnosed GCA, headache and visual impairment were statistically more frequent and median ESR and CRP were higher (**Table 1**).

After 52 weeks of treatment, EULAR remission was similar regardless of time to TCZ initiation (**Figure 1A,B&C**), and GCA phenotypes (**Figure 1D**). In the multivariable analysis there was a non-statistically higher trend to a EULAR remission when TCZ initiation was shorter from GCA diagnosis, OR 0.985 (0.970-1.000) (**Table 2**).

Conclusion: In contrast with the "window of opportunity" observed in other immune mediated inflammatory diseases, a delay in the initiation of TCZ therapy in GCA may not decrease its effectiveness (EULAR remission) in clinical practice.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: The cost of original biologics may limit treatment access. Biosimilars are biologics that are structurally highly similar and functionally equivalent to the approved reference product, providing the opportunity to improve access to treatment. Tocilizumab (TCZ)-biosimilar have showed therapeutic equivalence in rheumatoid arthritis. To date, there are no studies evaluating the effectiveness and safety of the switch to TCZ-biosimilar in GCA. The aim of this study is to assess the effectiveness and safety of switching from TCZ-reference product to TCZ-biosimilar in GCA patients in clinical practice.

Methods: Retrospective, multicentre, real-world clinical practice study of GCA patients who switched from TCZ-reference product to TCZ-biosimilar. We assessed a) effectiveness including clinical and laboratory parameters, and EULAR definition of remission (absence of signs and symptoms and normalization of acute phase reactants) (5), b) dose of prednisone, and c)

Feature	Value
Demographic features	
Age at TCZ biosimilar initiation, years (mean±SD)	74.1±9.0
Sex, women/men (% women)	26/12 (68.4)
GCA criteria, n (%)

side effects. Comparisons were performed between baseline and 3rd, and 6th months using McNeemar´s test for binary variables and T-student test for continuous variables

Results: A total of 38 patients (68.4% females, mean age 74.1 years) who were switched from TCZ-reference product to TCZ-biosimilar were included for analysis **(TABLE)**. The GCA phenotypes were: cranial (n=14; 36.8%), extracranial (n=14; 38.9%) and mixed (n=10; 26.3%). The patients had received TCZ-reference product for 36.1±27.7 months. Tyenne was prescribed in monotherapy in 34 (89.5%) patients, and combined with methotrexate in 4 (10.5%) patients. At the time of switching from TCZ-reference product to TCZ-biosimilar, 31 patients were in EULAR remission, the median (IQR) prednisone dose was 0 [0-5] mg/day, and the median ESR and CRP were 3 [2-8] mm/1st hour, and 0.4 [0.1-0.4] mg/dL, respectively. After a mean follow-up of 7.5±3.4 months from switching to TCZ biosimilar, there were no significant differences in EULAR remission, daily prednisone dose and CRP and ESR values **(Figure)**. Due to GCA remission TCZ administration interval was increased in 4 (10.5%) patients and discontinue in other. One patient developed herpes zoster one month after switching fromTCZ-reference product to TCZ-biosimilar

Conclusion: Our results suggest that TCZ-biosimilar is an effective and safe treatment for GCA patients when they were switched from the TCZ-reference product.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: European Alliance of Associations for Rheumatology (EULAR) recommendations for the management of Polymyalgia Rheumatica (PMR) and Large Vessel Vasculitis (LVV) date back to 2015 and 2020 respectively. Novel evidence about their management has emerged since then.

This study aims to systematically review the recent literature on the referral and diagnosis of PMR and LVV to inform the related EULAR recommendations.

Methods: A systematic review (PROSPERO CRD42024560403) focused on PMR, giant cell arteritis (GCA) and Takayasu arteritis (TAK) referral and diagnosis, was conducted across MEDLINE, Embase, and Cochrane databases with publications dating from May 2014 for PMR, and January 2018 for LVV, up to December 2024. No language restriction was applied. Age was limited to adults above 18 years. Randomised trials, observational studies (cohort, case-control, cross-sectional), systematic reviews and meta-analyses were included. Studies of single imaging modalities were outside the remit of the project. EULAR 2024 and American College of Rheumatology 2024 congress abstracts were additionally screened to identify relevant studies published after the end date of the search.

Relevant risk of bias tools were used to assess study quality.

Results: Forty-one studies (all observational) met the inclusion criteria (Figure 1).

Fast-track clinics (FTC) for suspected GCA (3 studies, n=682) reduced the risk of blindness from 19–27% to 12–13% and shortened the time to diagnosis from a median of 62 days to 33 days (p=0.04). FTC for suspected PMR (3 studies, n=662) reduced the diagnostic latency (7–53 days FTC vs 12–80 days controls, p=0.001) and the hospitalisation rate (3.5% FTC vs 20.4% controls, p=0.001).

Ten studies investigating the presence of subclinical LVV in patients with a PMR-like presentation have been retrieved (n=1229). The clinical presentation of isolated PMR and subclinical LVV was similar. However, subclinical LVV had a higher risk of relapse and greater need for immunosuppression (Table 1).

Ten studies (n=1047) confirmed similar or superior performance of imaging, namely temporal and axillary artery ultrasound (US) or positron emission tomography (PET) compared to temporal artery biopsy (TAB) alone for the diagnosis of GCA in terms of sensitivity and rapidity of diagnosis. Moreover, multimodal diagnostic pathways (9 studies, n=2470) integrating pre-test probability scores, imaging and/or TAB increased the accuracy of GCA diagnosis. A pathway based on US, followed by PET, and ultimately an expert clinician's opinion was more sensitive than TAB (92% vs 39%) and decreased the diagnostic delay (1.1 days US, 1.9 days PET, 10.8 days TAB).

Glucocorticoids (GC) rapidly reduced the sensitivity of TAB (5 studies): 23–74% GC < 1 week vs 20–52% GC > 1 week – OR 0.36, 95% CI 0.13–0.96 (p=0.04).

No new high-quality evidence emerged concerning the referral and diagnosis of TAK.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This systematic review provides new insights into the referral and diagnosis of PMR and LVV, including the value of multimodal FTC pathways, the use of US in the workup of PMR and LVV, and subclinical LVV in patients presenting with PMR-like symptoms. This evidence will inform the 2025 EULAR recommendations for the management of PMR and LVV.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) is a rare autosomal recessive autoinflammatory disorder first identified in 2014. Four major disease phenotypes have been described: vasculitic, hematologic, immunodeficient, asymptomatic. The mainstay treatment is TNF inhibitors (TNFi), especially in patients with the vasculitic phenotype. The prevalence of its various clinical and laboratory manifestations has not been previously reported in a meta-analysis.

We aimed to calculate the prevalence of the following clinical and laboratory manifestations: cutaneous involvement, polyarteritis nodosa (PAN)-like presentation, stroke (ischemic or hemorrhagic), ocular involvement, cytopenias, recurrent infections, hemophagocytic lymphohistiocytosis (HLH), fever and hepatosplenomegaly.

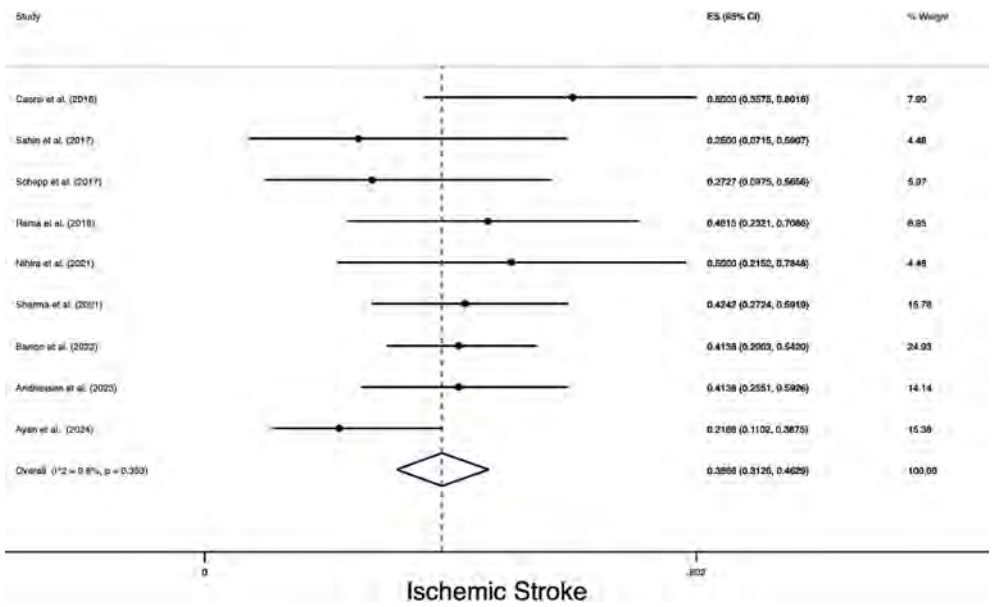

Figure 2. Pooled Prevalence of Ischemic Stroke with 95% Confidence Intervals. ES: Effect Size (Prevalence)

Methods: We searched PubMed and EMBASE for cohorts of patients with DADA2. In order to be considered eligible for our inclusion criteria, studies should have met the following criteria: (1) DADA2 diagnosis confirmed with genetic analysis, (2) reporting of clinical manifestations in both children and adults.

Results: Ten studies, 9 retrospective and 1 prospective, published between 2016 and 2025 provided data on 225 patients with DADA2. Cutaneous findings were the most common clinical manifestations with a prevalence of 80.82% (95% CI: 72.03-88.45%), while biopsy confirmed PAN was present in 28.94% (95% CI: 15.04-44.93%) of patients. Ischemic stroke was the manifestation with the lowest heterogeneity among included studies and yielded a prevalence of 38.66% (95% CI: 31.26-46.29%), while the prevalence of hemorrhagic stroke was lower at 9.86% (95% CI: 3.97-17.46%). Other common manifestations included fever 61.99% (95% CI: 48.72-74.49%), cytopenias 38.47% (95% CI: 23.60-54.40%), recurrent infections 35.72% (95% CI: 9.00-67.75%), hepatosplenomegaly 30.80% (95% CI: 16.63-46.82%), ocular involvement 13.85% (95% CI: 8.02-20.71%) and HLH 6.92% (95% CI: 1.69-14.50%). Finally, the majority (n=127, 56.4%) received TNFi; etanercept (79 patients) and adalimumab (31 patients) were the most commonly used.

Conclusion: In this meta-analysis of 225 patients with DADA2, cutaneous involvement, fever and ischemic stroke were the most common manifestations. Closer monitoring for cytopenia is needed to reduce the risk of recurrent infections. Both outcomes occurred in one third of patients included in this study. More than half of patients are receiving TNFi, leading to

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. prolongation of life-expectancy. Therefore, adult rheumatologists are expected to encounter patients with DADA2 more frequently and increased awareness of the disease and its manifestations is warranted for optimized patient care.

Short-Course Prednisone and Methotrexate in Polymyalgia Rheumatica: A Potential Therapeutic Approach

Edoardo Conticini[1], Silvia Grazzini[1], Raffaele Truscelli[2], Paolo Falsetti[3], Luca Cantarini[4] and Bruno Frediani[4], [1]Rheumatology Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, Italy, Siena, Italy, [2]University of Siena, Siena, Italy, [3]Siena University Hospital, Siena, Italy, [4]Rheumatology Unit, Department of Medicine, Surgery and Neurosciences, University Hospital of Siena, Siena, Italy, Siena, Italy

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Despite being considered an easy-to-diagnose and easy-to-treat condition, the optimal treatment of PMR is far from being fully elucidated. Three recently published trials have evidenced efficacy and safety of anti-IL6R agents, but their cost, as well as the high incidence and prevalence of PMR, make them unsuitable for extensive use as a first line treatment. At the same time, only a few, poorly designed, trials explored the role of cDMARDs. In addition, none of these studies adequately ruled out the presence of subclinical GCA, which, accounting for more than 20% of cases, may justify the poor response to MTX. In this regard, the aim of this prospective study was to assess whether the precocious administration of MTX, in association with a short course of GC, could be safe and effective in patients with recently diagnosed PMR, upon exclusion of subclinical GCA.

Methods: In this single arm, open label, prospective study, all patients with a recent diagnosis of PMR (< 4 weeks), fulfilling ACR/EULAR criteria with US were included. Patients with Southend pre-test score > 12 and OGUS > 1 were excluded beforehand. As a control group, an age and sex matched historical cohort of PMR treated with a monotherapy of GCs for at least 3 months from diagnosis was included.

At baseline, all patients were treated with 25 mg of PDN and 0,2 mg/kg/weekly MTX; PDN was gradually tapered to 0 within 20 weeks and, in case of flare, re-increased to the minimum effective dosage.

The primary endpoint of the study was PDN-free remission at 24 weeks. Secondary endpoints were sustained remission at 52 weeks (defined as clinical remission, absence of flares, CRP normalization), number of flares, PDN dosage, CRP and ESR at 24 and 52 weeks compared to historical cohort.

Results: Forty-one patients were prospectively included, while 63, age and sex matched, were included in the retrospective cohort.

	Baseline	6 months	12 months	p value 0-6 months	P value 0-12 months	P value 6-12 months
CRP (mg/dl)	6.28 ± 4.97	0.9 ± 0.47	1.13± 2.46	<0.001	<0.001	1.000
ESR (mm/h)	67.7 ± 26.7	18.13 ± 11.37	28.85± 30.91	<0.001	0.097	0.041
PDN dosage (mg/day)	25	3.42 ± 3.3	0.45± 0.11	<0.001	<0.001	<0.001
Patients in PDN-free remission (N/%)		24 (58%)	19 (59%)			
Patients dropping out for adverse events (N/%)		4 (9,7%)	2 (6,25%)			
Patients with flare (N/%)		7 (17%)	5 (15,3%)			

Legend: CRP: C-reactive protein; ESR: erythron sedimentation rate; PDN: prednisone. Values are expressed as mean

Values at baseline and during follow-up

In the MTX-cohort, at 6-months, 58% of patients were in steroid-free remission and therefore met the primary endpoint of the study. Eight, yet without any sign or symptom of PMR, were still taking a mean daily dosage of 3,88 mg of PDN.

Overall, a significant reduction of both CRP and ESR was observed. Similarly, mean daily PDN dosage dropped to 3,42 ± 3,3 mg. Seven patients (17,5%) suffered from disease flares, requiring a temporary increase of PDN dosage.

Thirty-two patients, upon the exclusion of those who dropped out due to the discontinuation of MTX and/or due to the administration of biological DMARDs, reached 52-weeks phase of the study and 59% of them maintained GCs-free remission.

A significantly higher number of relapses were reported within the first 12 months in the retrospective cohort (p = 0,036), in which up to 49 patients (77,8%) were still taking PDN, (4 > 7,5 mg).

Conclusion: In conclusion, upon a subclinical GCA is excluded, MTX, administered at adequate dosages, is a suitable option for the treatment of PMR, allowing a precocious discontinuation of oral GCs. The superiority of our findings can be explained by a higher dosage of MTX employed and by the exclusion of subclinical GCA, which is known to be associated with a higher relapse ratio. In this case, precocious administration of anti-IL6R agents should be warranted.

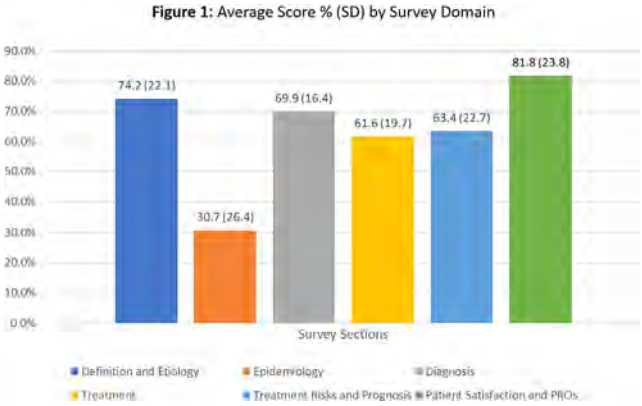

Figure 1: Average Score % (SD) by Survey Domain

Table 1: PMR Familiarity and Knowledge Assessment Participation Overview

Familiarity Category	n	% (of total respondents)
Total respondents asked about PMR	920	100%
Reported awareness of PMR	289	31.4%
Not aware or unsure about PMR	631	68.6%
...of whom recognized a condition with PMR-like symptoms	276	30.0%
Total invited to complete knowledge assessment	**565**	**61.4%**
Total completed knowledge assessment	**417**	**45.3%**

Background/Purpose: Polymyalgia rheumatica (PMR) is a commonly occurring inflammatory condition affecting older adults, primarily presenting with bilateral shoulder and hip stiffness. Despite its high prevalence in individuals over 50, there is a lack of evidence characterizing awareness or understanding of PMR among public health professionals (PHPs), defined as individuals working in disease diagnosis and treatment, health promotion, disease prevention, and health policy. This study assessed PHPs' familiarity with PMR and their knowledge across key clinical domains.

Methods: A cross-sectional knowledge assessment was administered to PHPs using convenience sampling via social media platforms and targeted outreach via the American Public Health Association email list. Participants were screened for prior familiarity of polymyalgia rheumatica (PMR) or familiarity with the hallmark symptoms of PMR. Those reporting familiarity were directed to complete a 31-item multiple-choice knowledge assessment across six domains: definition and etiology, epidemiology, diagnosis, treatment, treatment risks and prognosis, and patient satisfaction and reported outcomes. Those with no familiarity were excluded from the assessment to prevent bias but were included in descriptive reporting of awareness levels. Survey items were developed from a systematic literature review and validated by subject matter experts. Descriptive statistics were used to calculate mean scores and domain specific accuracy rates (**Figure 1**). Only fully completed responses from self-identified PHPs were analyzed. Duplicate entries were removed based on IP address, timestamps, and demographic data.

Results: Of 920 respondents asked about PMR, 289 (31.4%) reported prior awareness, while 631 (68.6%) had not heard of it or were unsure (**Table 1**). Among those not aware or unsure, 276 (43.7%) recognized a condition with symptoms consistent with PMR. In total, 565 participants familiar with PMR or its symptoms were invited to complete the full knowledge assessment; 417 provided complete responses and were included in the analysis. The average knowledge score was 64.7% (SD: 13.1%), with only 12.2% scoring 80% or higher. The largest knowledge gaps were in epidemiology, which had the lowest average score (30.7%); only 18.2% correctly identified estimated PMR prevalence, and 12.7% knew its estimated annual incidence. In the treatment domain, the mean score was 61.6% with 57.5% not knowing the proportion of patients who continue to experience symptoms with treatment, 50.9% not knowing appropriate visit frequency, and only 44.4% of respondents correctly identifying the first-line treatment for PMR.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Fewer than 40% of PHPs were familiar with PMR by name, and those with prior awareness showed notable gaps in epidemiology and treatment knowledge. Limited understanding of PMR's prevalence, diagnosis, and management among PHPs may contribute to under-recognition and delayed diagnosis. These findings underscore the need for targeted education to support earlier diagnosis, effective treatment, and better patient outcomes.

Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Glucocorticoids(GCs) are the mainstay of treatment in Takayasu arteritis (TAK). Conventional DMARDs(cDMARDs) and biologic DMARDS(bDMARDs) are often used as steroid sparing agents in TAK. Janus kinase inhibitors (JAKi), recently shown to be effective in giant-cell arteritis may be effective to treat TAK,but evidence to date has been limited to small, single-center studies.In this worldwide multi-center study, we aimed to assess the efficacy and safety of JAKi in patients with TAK.

Methods: Patients fullfilling the 1990 ACR Classification Criteria for TAK were eligible to participate in a retrospective observational cohort study. Each patient must have been treated with a JAKi at any point in the disease course. A standardized case report form was completed by investigators at each participating tertiary referral center. Physician global assessment (PGA) was used as the gold standard definition of active disease, and the Kerr et al(NIH definition) was also used, if available. Complete remission was defined as no new signs and symptoms of vascular disease assessed by a physician, normalized acute phase reactants (APR) and reduction of GC dose under 10 mg/d of prednisolone or its equivalent at the third month of treatment. Partial response was defined as at least 50% decrease in PGA score,APR and at least 50% reduction of initial GC dose at the third month.

Results: Data was collected from 25 patients with TAK (mean age:34.5±11 years; female/male: 24/1;mean disease duration: 8.1±6 years) from 8 centers. All patients were refractory to both cDMARDs and bDMARDs, except 2 patients who were refractory only to cDMARDs and given JAKi prior to a trial of bDMARDs. Before switching to JAKi (19 tofacitinib,

was increased in 1 patient (from 8 mg/d to 15 mg/d). GC was stopped in 3 (19%) patients. During follow-up 22%(4/18) of the patients experienced a relapse. Nine(36%) of the patients had a sustained remission.JAKi was discontinued in 11/23 (48%) patients.The main reason for discontinuation was disease activity in 7, infections in 2,unknown in 2 patients.Radiographic progression was observed in 4/21 (19%) patients during the follow-up.(Figure 1).

Conclusion: This study showed that JAKi achieved clinical remission in about half of patients with TAK refractory to DMARDs within a median 4 months of treatment. Complete remission was also achieved in 35% of the patients with a significant decrease in glucocorticoid dose in the 3rd month.Our results suggest that JAKi may be effective options for the treatment of patients with refractory TAK.

Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are chronic inflammatory disorders predominantly affecting patients over 50. Despite unclear etiopathogenesis, both conditions share central immunopathogenic pathways. Recent evidence indicates they might constitute a continuum of a single disease with diverse clinical manifestations, highlighting the importance of identifying reliable inflammatory biomarkers. Both disorders drive systemic inflammation, impair patient functionality, and potentially lead to severe complications like ischemic optic neuropathy or aneurysms from vascular involvement. Thus, accessible and cost-effective biomarkers for monitoring disease activity remain critical. This study evaluates the neutrophil-to-lymphocyte ratio (NLR) and the systemic immune-inflammation index (SII) as novel hematological indices for assessing inflammatory activity in PMR and GCA.

SII Outperforms NLR in ROC Analysis for Disease Activity Discrimination

Methods: We conducted a cross-sectional observational study including consecutive PMR and/or GCA patients fulfilling ACR-EULAR classification criteria. Patient demographics, clinical data (symptomatic systemic activity, treatment status), and laboratory parameters, including C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), NLR (neutrophils/lymphocytes), and SII (platelets × neutrophils/lymphocytes), were collected during a single assessment. Correlation analyses were performed using Spearman's test. Receiver operating characteristic (ROC) curves and Youden's index identified optimal diagnostic cut-offs. Sensitivity, specificity, positive (LR+) and negative (LR–) likelihood ratios, and odds ratios (OR) were calculated.

Results: A total of 68 patients were analyzed (mean age 76 ± 7 years; 53% female; PMR 85%, cranial GCA 19%, extracranial GCA 9%). Active systemic symptoms were present in 36 (53%) patients. Both NLR and SII were significantly higher in active compared to inactive patients (median NLR 2.63 vs. 1.84, $p = 0.002$; median SII 701 vs. 460, $p < 0.001$). Each index correlated moderately with CRP (NLR $\rho = 0.55$, SII $\rho = 0.62$; $p < 0.001$) but did not correlate significantly with ESR ($\rho \leq 0.19$; $p > 0.10$), nor were they affected by glucocorticoid therapy. ROC analysis showed SII had superior discriminatory power compared to NLR (AUC 0.76 vs. 0.72; $p < 0.05$). The optimal SII cut-off (≥560) demonstrated a sensitivity of 72%, specificity of 84%, LR+ of 4.6, LR– of 0.34, and OR of 14.0, significantly outperforming NLR ≥ 2.2 (sensitivity 67%, specificity 69%, LR + 2.1). Each 100-unit increase in SII was associated with a 28% increased odds of activity (OR 1.28, 95% CI 1.13–1.45), while each unit increase in NLR raised odds 1.6-fold (OR 1.63, 95% CI 1.11–2.39).

Conclusion: The SII emerges as a superior, glucocorticoid-independent marker of systemic disease activity in PMR/GCA compared to the NLR, providing additional clinical utility beyond ESR and complementing CRP. Its simple calculation from routine complete blood counts positions SII as an accessible and promising biomarker warranting prospective validation in longitudinal monitoring studies

Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Inflammatory aortitis is an uncommon condition that can be associated with rheumatologic, neoplastic, or infectious diseases. GCA and isolated aortitis are the most common causes.

Although diagnosis is typically based on a combination of clinical, laboratory, and imaging findings—with PET-CT being a key tool in evaluating active inflammatory processes—it is often underdiagnosed prior to surgery, and the diagnosis of aortitis is frequently made only after pathological confirmation.

Current literature includes few studies that specifically examine the relationship between preoperative PET-CT results and histopathological findings in patients with inflammatory aortitis.

Objective

To analyze the relationship between histopathological findings and preoperative PET-CT results in patients with biopsy-confirmed inflammatory aortitis or those under rheumatology follow-up.

Methods: Between 2020 and 2023, a total of 188 surgical procedures for aortic pathology were performed at our hospital. Cases were selected if they met at least one of the following criteria: (1) identification of an inflammatory pattern based on the standards of the Society for Cardiovascular Pathology and the Association for European Cardiovascular Pathology, or (2) active follow-up for a diagnosis of aortitis by the Rheumatology Department.

A total of 37 cases met the inclusion criteria. From this cohort, we selected patients who had undergone PET-CT prior to surgery and tissue sampling.

Table 1. Clinical and Demographic Characteristics

Age (years)	64.2 ± 10.2
Female/Male	3/2
Aortic aneurysm diameter (mm)	64.4 ± 12.8
Clinical presentation	
- Acute aortic syndrome	2 (40%)
- Aortic insufficiency	1 (20%)
- Incidental finding	2 (40%)
Time between PET-CT and surgery (months)	6 ± 6
Glucocorticoid treatment during PET-CT and surgery	0 (0%)
Immunosuppressive treatment during PET-CT and surgery	1 (20%) *
CRP levels prior to PET-CT	58.3 ± 97.7
CRP levels prior to surgery	28.3 ± 27.9
Reason for PET-CT request	
- Aortic aneurysm evaluation	3 (60%)
- Suspected neoplastic process	2 (40%)
PET-CT with signs suggestive of vasculitis	0 (0%)
Histology with inflammatory infiltrate	4 (80%)
- Granulomatous pattern	1 (20%)
- Lymphoplasmacytic pattern	2 (40%)
- - Suppurative pattern	1 (20%)
Rheumatology follow-up before histological confirmation of aortitis	1 (20%)

*Ustekinumab for Psoriasis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 2. Correlation Between PET-CT Findings, Histology, and Rheumatologic Diagnosis

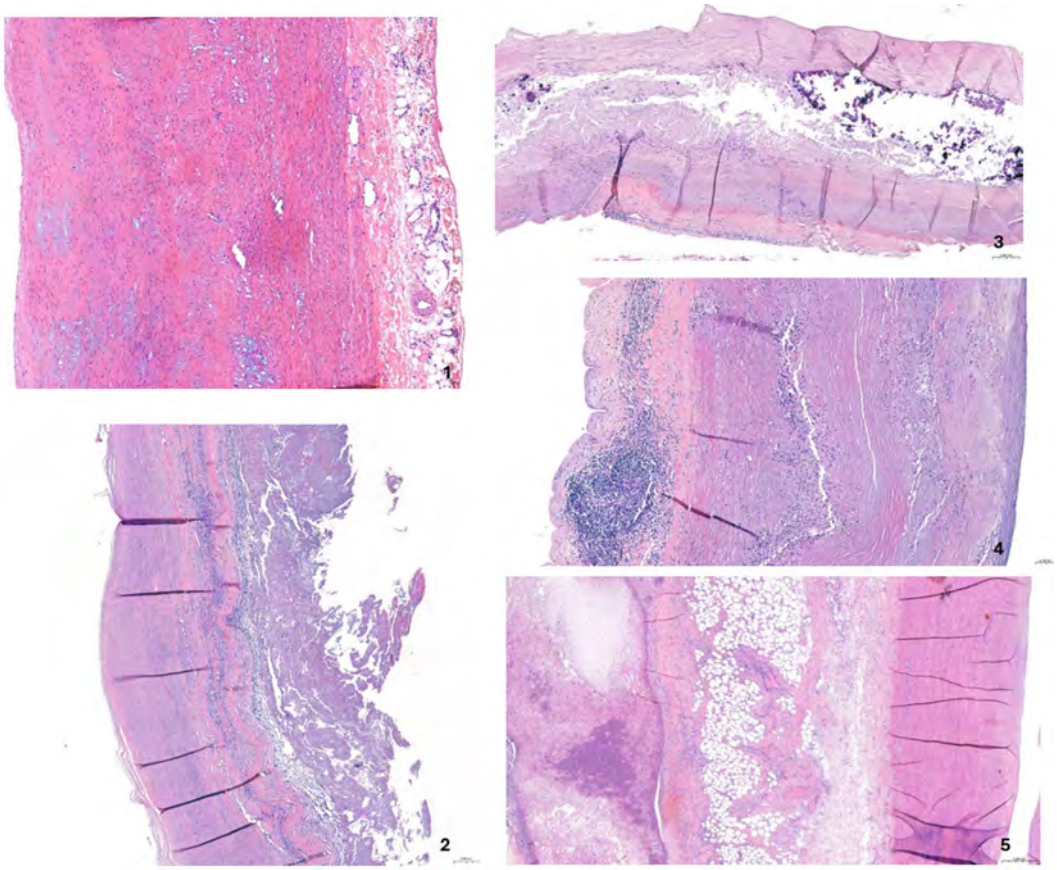
Patient	Increased Vascular Metabolism on PET-CT	Biopsy Histology	Rheumatologic Clinical Diagnosis	Image-Histology Correlation
1	No	Degenerative non-inflammatory	Peripheral spondyloarthropathy	Yes
2	No	Lymphoplasmacytic periaortitis associated with fibrosis	Isolated aortitis	No
3	No	Lymphoplasmacytic periaortitis associated with severe atherosclerosis	Inflammatory atherosclerotic aneurysm	No
4	No	Granulomatous aortitis with multinucleated giant cells	Giant cell arteritis	No
5	No	Acute aortitis with fibrino-leukocytic material and positive culture for *P. acnes*	Infectious aortitis	No

Results: Five patients with a confirmed diagnosis were included: one with GCA, one with peripheral SpA, one with isolated aortitis, one with inflammatory atherosclerotic aneurysm, and one with infectious aortitis. Clinical and demographic characteristics are shown in Table 1.

Two patients underwent emergency surgery for acute aortic syndrome. In one case, a PET-CT performed 4 months prior showed aortomegaly without inflammatory signs, and the biopsy confirmed a non-inflammatory degenerative process, despite elevated CRP at the time of both procedures. In the other case, PET-CT performed the day before surgery revealed

Histopathological sections corresponding to the patients in Table 2. (1) Non-inflammatory medial degeneration with diffuse extracellular mucinous matrix. (2) Lymphoplasmacytic infiltrate and stromal fibrosis in adventitia. (3) Severe calcified arteriosclerosis with chronic lymphoid infiltrate. (4) Non-necrotizing granulomatous inflammation with multinucleated giant cells. (5) Acute neutrophilic infiltrate with adventitial necrosis.



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

an aortic aneurysm without signs of vasculitis, while histological analysis showed a lymphoplasmacytic inflammatory infiltrate with associated fibrosis; this patient also had elevated CRP levels.

The remaining 3 patients underwent elective surgery for aortic aneurysm. In these cases, PET-CT also showed no signs of inflammation; however, histopathological analysis revealed inflammatory infiltrates in all specimens (Table 2 and Image).

In summary, among the cases analyzed, concordance between PET-CT and histopathological findings was observed in only 1 of 5 patients. In 4 patients, PET-CT results were negative, while biopsies demonstrated characteristic inflammatory patterns.

Conclusion: In this sample, a weak correlation was observed between PET-CT findings and histopathology. Some patients with negative PET-CT scans, showing no evidence of increased metabolic activity, exhibited inflammatory patterns on histological analysis. These findings suggest that a significant proportion of patients with negative PET-CT results may still have an underlying vasculitic process.

Abstract Number: 1621

Temporal Association Between Viral Positivity Rates and Kawasaki Disease Incidence at a Large Tertiary Center

Jessica Nguyen[1], Duc Nguyen[1], Ankona Banerjee[2], Kenneth Nobleza[2], Denver Niles[2] and Marietta De Guzman[1], [1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine, Houston

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Kawasaki disease (KD) is a systemic vasculitis associated with the development of coronary artery aneurysms predominantly affecting children less than 5 years of age. Prompt and accurate diagnosis remains challenging due to the unknown cause of this condition and the overlap of its clinical findings with other febrile illnesses in children. Viral infections have been proposed as a potential trigger for KD, particularly given the observed seasonal peaks in winter and spring across the continental United States. Previous studies have also suggested temporal associations between viral activity and KD incidence at certain centers. This study aims to characterize the seasonal distribution of KD and assess the temporal relationship between hospital viral positivity rates and KD incidence at a large tertiary center.

Methods: With IRB approval, we retrospectively reviewed patients diagnosed with KD at our institution from 2012 to 2019. We collected admission dates and demographic data. We obtained monthly viral positivity rates in hospitalized patients for 18 viruses (influenza A/B, respiratory syncytial virus, adenovirus, human metapneumovirus, rhinovirus, parainfluenza viruses

analysis assessing each virus independently; (2) a multivariable model for individual viral infection adjusting for month and year; and (3) a fully adjusted model including all viruses while controlling for month and year.

Results: From 2012-2019, 858 patients were diagnosed with KD at our institution. The median age was 2.6 years (IQR 1.2–4.5), with no significant difference in male-to-female ratio across the study period. A statistically significant difference in racial/ethnic distribution was observed in 2013 compared to 2012, 2014, 2015, and 2017 (Figure 1). KD cases were evenly distributed across winter (26%), spring (27%), and summer (26%) (Figure 2). For all regression models, no significant temporal association was found between viral positivity rates and KD incidence (Figure 3).

Conclusion: At our institution, KD cases were evenly distributed across winter, spring, and summer, a pattern that contrasts with prior studies reporting seasonal peaks. Additionally, we found no significant temporal associations between viral positivity rates and KD incidence. These negative findings suggest that common viruses may not be the primary triggers of KD and underscore the need for broader investigative approaches. Ongoing research is critical to elucidate the underlying causes of KD and to enhance timely diagnosis and treatment in young children.

Defective CD4+ regulatory T cells in active Takayasu arteritis patients can be improved by efficiency treatment of tofacitinib

Jing Luo[1] and Lan He[2], [1]the first affiliated hospital of xi'an jiaotong university, xi'an, China (People's Republic), [2]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: To investigate the efficacy of tofacitinib (TOF) in patients with active TAK, explore the effect on CD4+ regulatory T cells (Tregs) homeostasis and relationship with clinical outcomes.

Methods: This was a prospective, open-label cohort study. Thirty-four active TAK patients and 28 healthy controls (HCs) of comparable sex and age were recruited. All the patients were treated with glucocorticoids (GCs) and TOF. Complete response (CR) was assessed at the 6th month and relapse was recorded after CR, inflammatory parameter, GCs dose, vascular imaging, frequency and cytokine production of CD4+ regulatory T cells were evaluated for 24month follow-up. SPSS 22.0(SPSS, USA) was employed for data analysis. $P< 0.05$ indicated statistical significance.

Results: 1. CR was reached in 26/34 (76.47%) patients at 6th month. In responders group, the mean dosage of steroids and acute-phase reactants significantly decreased after 6 months TOF therapy.

2. In active TAK, the frequence of CD4+CD25+Foxp3+ Tregs and the percentage of Foxp3+ in CD4+CD25high T cells decreased, but IFN-γ+ and IL-17+ Tregs increased. Inflammatory Tregs correlated with disease activity parameters positively.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

3.After 6months TOF efficiency therapy, the percentage of IFN-γ+ and IL-17+Tregs decreased, but the frequence of CD4+-CD25+Foxp3+ Tregs and the percentage of Foxp3+ in CD4+CD25high T cells increased in CR group, and the alterations existed during 24 months follow up.

Conclusion: Decreased CD4+Tregs displaying reduced expression of FOXP3, increased expression of IFN-γ and IL-17 have been implicated in the pathogenesis of TAK.TOF therapy can be a promising treatment for active TAK patients and improving the Tregs defects.

The Association of Calprotectin with Vascular Injury and Remodeling in Clinically-Isolated Aortitis

Katarina Kmetova[1], Gavin Poppei[2], Kavya Sugur[3], Julia Ford[4], Wenying Liang[4], Emily Chong[4], Srilakshmi Yalavarthi[4], NaveenKumar Somanathapura[4], Nataliya Milman[5], Peter Merkel[6], Ora Singer[7] and Yu (Ray) Zuo[4], [1]Division of Rheumatology, University of Michigan, Ann Arbor, Michigan, USA, Ann Arbor, MI, [2]University of Michigan, Ann arbor, [3]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, Ann Arbor, MI, [4]University of Michigan, Ann Arbor, MI, [5]the Ottawa Hospital, Ottawa, ON, Canada, [6]University of Pennsylvania, Philadelphia, PA, [7]University of Michigan, Huntington Woods, MI

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Clinically-isolated aortitis (CIA), defined as inflammation of the aortic wall in the absence of extra-aortic arterial involvement, systemic vasculitis, or other associated autoimmune disease, is often discovered incidentally on surgical pathology after resection of an aortic aneurysm. The pathogenesis of CIA remains largely unknown, complicating both diagnosis and management. Neutrophil extracellular traps (NETs) have been implicated in the pathophysiology of various forms of vasculitis and vascular injury. Calprotectin, a circulating marker of NET formation, is a promising mechanistic biomarker in various NET-driven diseases. This study aimed to investigate the role of calprotectin in CIA pathogenesis, focusing on endothelial activation, vascular remodeling, and calcification (**Fig. 1A**).

Methods: A multicenter CIA cohort (n=28) with pathology- or imaging-confirmed cases was assembled, along with healthy controls (n=34) without systemic autoimmune disease. Plasma calprotectin and endothelial activation markers (ICAM-1, VCAM-1) were measured. In vitro, plasma-derived and recombinant calprotectin were tested on human aortic endothelial (HAOEC) and smooth muscle cells (HASMC) to assess activation, proliferation, migration, endothelial-to-mesenchymal transition (EndoMT), and calcification.

Results: Circulating calprotectin levels were significantly higher in CIA patients compared to controls (**Fig. 1B**). Using a threshold defined by the 99th percentile of control values, 68% of patients with CIA were classified as calprotectin-positive. Among 14 patients with longitudinal imaging, 3 had progression of aortic disease (i.e., worsening aortic dilatation or new aneurysm), 2 of whom were previously calprotectin-positive. Patients with CIA showed higher levels of ICAM-1 and VCAM-1 (**Fig. 1C-D**). Calprotectin levels correlated with CRP ($r=0.63$, $p< 0.001$). Mechanistic studies revealed that plasma from calprotectin-high CIA patients activated HAOECs, significantly increasing surface expression of ICAM-1 ($p< 0.01$) and

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Circulating calprotectin and endothelial activation in patients with clinically-isolated aortitis. (A) Study design. Plasma samples were obtained from 28 patients with clinically-isolated aortitis and 34 healthy controls. Circulating levels of (B) calprotectin, (C) ICAM-1, and (D) VCAM-1 were quantified by ELISA. Data presented with median value. Statistical comparisons were performed using the Kruskal-Wallis test. *** - p<0.001;

VCAM-1 ($p < 0.05$). Similarly, exposure to recombinant calprotectin upregulated expression of ICAM-1 and VCAM-1 transcripts ($p < 0.05$ for both). Calprotectin exposure resulted in i) increased expression of mesenchymal markers, including α-SMA and Transgelin (**Fig. 2A–E**), consistent with the induction of EndoMT and ii) promotion of endothelial cell proliferation and migration (**Fig. 2F–I**). In HASMCs, the addition of recombinant calprotectin significantly increased intracellular calcium deposition (**Fig. 3**), suggesting a role in promoting microcalcification and vascular stiffening.

Conclusion: Calprotectin is elevated in most patients with CIA and may contribute to disease pathogenesis by activating aortic endothelial cells, triggering proliferation, migration, and EndoMT, while also driving microcalcification in smooth muscle cells. Together, these changes suggest a role for calprotectin in vascular remodeling. Our findings suggest a neutrophil-driven pathway of aortic injury in CIA, supporting further investigation of calprotectin as a potential biomarker and therapeutic target.

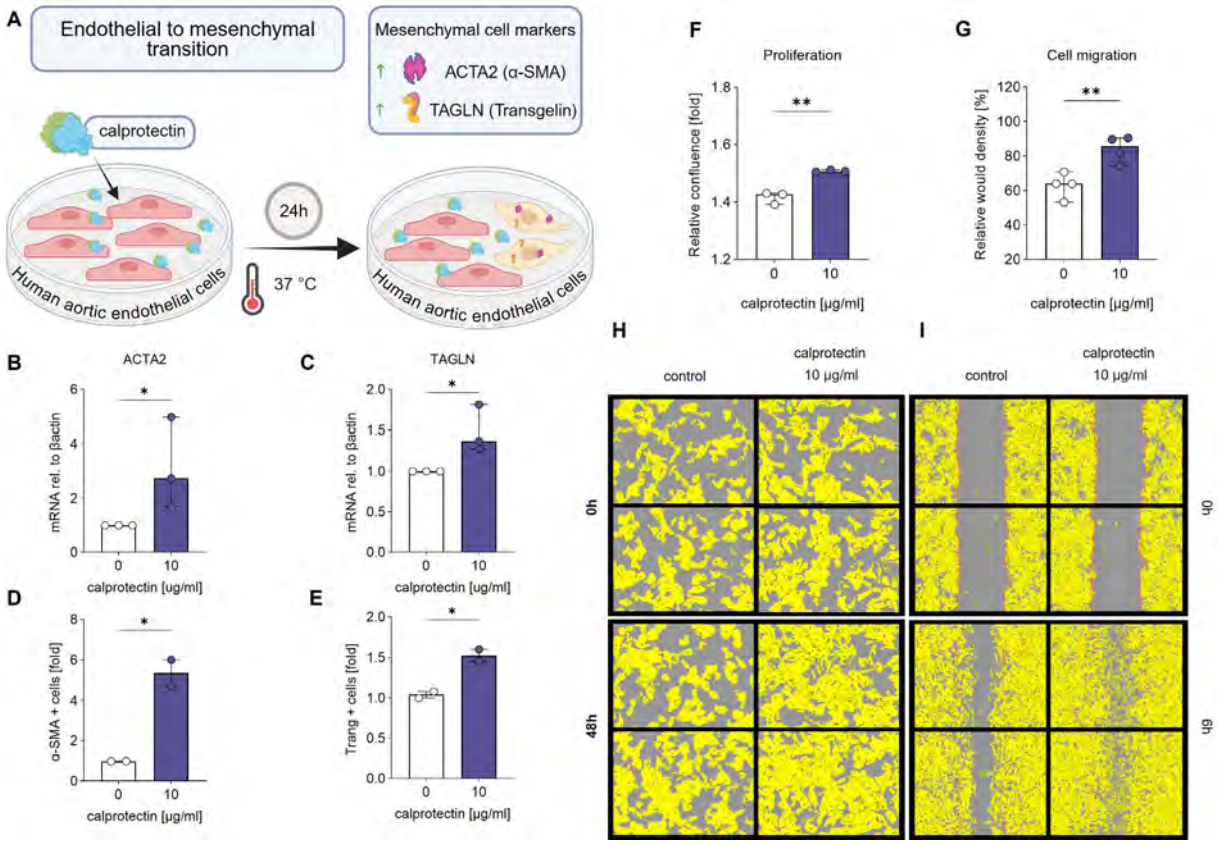

Figure 2: Calprotectin triggers endothelial-to-mesenchymal transition (EndoMT) in human aortic endothelial cells (HAOECs). (A) HAOECs were cultured with 10 µg/mL recombinant calprotectin for 24 h. (B, C) Calprotectin-treated cells showed an increased expression of markers of EndoMT: ACTA2 and TAGLN (D, E) further validated by flow cytometry. Calprotectin also altered behavior of HAOECs, promoting (F, H) proliferation and (G, I) migration. Images were captured and analyzed using the Incucyte® Live-Cell Analysis System. Data presented with median ± 95% CI. Statistical analysis was performed using the Kruskal-Wallis test. * - p<0.05; ** - p<0.01

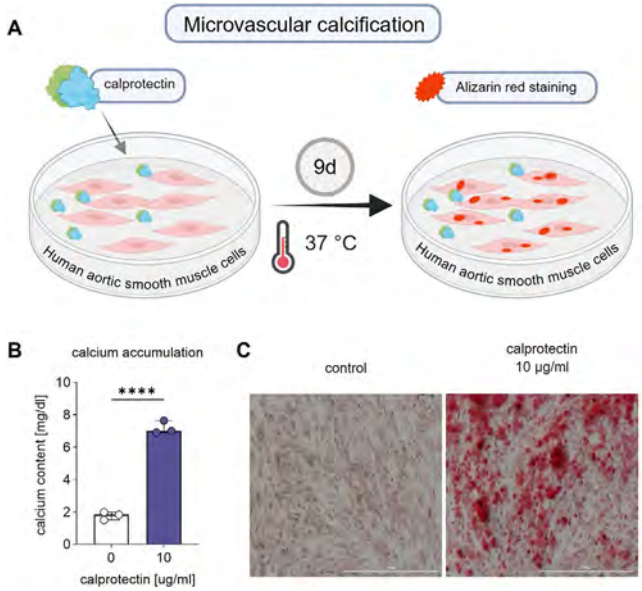

Figure 3: Calprotectin-induced microvascular Ca2+ accumulation in human aortic smooth muscle cells (HASMC). (A) HASMCs were treated with 10 µg/mL calprotectin for 9 days. (B) Following treatment, cells were washed and incubated with 1 M HCl to dissolve intracellular calcium. Calcium content was quantified using the QuantiChrom™ Calcium Assay Kit. (C) Calcium accumulation was visualized by staining with 1% Alizarin Red for 45 min, with calcified areas appearing as red deposits. Data presented with median ± 95% CI. Statistical analysis was performed using the Kruskal-Wallis test. **** - p<0.0001

Disease activity status in Takayasu's arteritis influences the angiogenic potential of patient-derived endothelial cells

Luciana Yamamoto de Almeida[1], Kaitlin Quinn[2], James Simone[2], Lily Dai[2], Benjamin Turturice[2], Urvashi Kaundal[2], Chloe Palmer[2], Karyssa Stonick[3], davide Randazzo[4], Carmelo Carmona-Rivera[5] and Peter Grayson[6], [1]National Institutes of Health, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [3]National Insitute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [4]Light Imaging Section, Office of Science and Technology, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, Bethesda, [5]Systemic Autoimmunity Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, Bethesda, MD, [6]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Chevy Chase, MD

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Takayasu's arteritis (TAK) is a rare, systemic, chronic large vessel vasculitis of unknown etiology primarily affecting the aorta and its branches. Arterial damage, with stenosis or occlusion of the large arteries, may occur as a result of vascular inflammation. In response, collateral circulation is known to develop in some patients and helps overcome vascular damage by providing alternative blood flow to areas where major vessels are blocked or narrowed. Therapeutic targeting of tumor necrosis factor-alpha (TNF-α) and interleukin-6 (IL-6) can lead to clinical improvement in subsets of patients with TAK. However, it remains unclear which components are more likely to be effective targets for the treatment of TAK and whether they may impact collateral vessel formation. The aim of this study is to investigate whether and how inflammation affects angiogenic outcomes in the context of TAK.

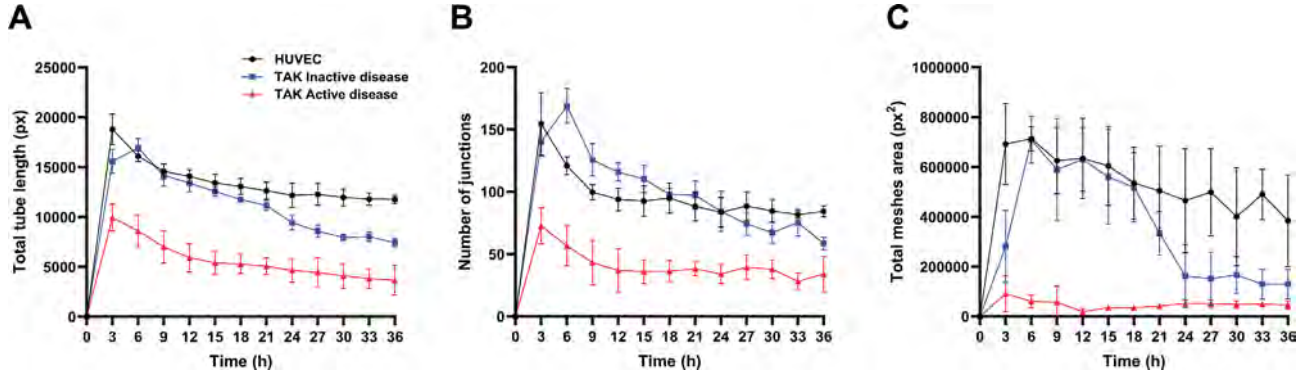

Figure 1: Matrigel tube formation assay in an Incucyte® Live-Cell Analysis System. TAK-derived CECs from active and inactive disease states, as well as HUVECs, were cultured in endothelial growth media (EGM-2) for 36 h in 96-well plates coated with a semi-solid Matrigel. The total tube lengths (A), number of junctions (B), and total meshes area (C) formed in the assay were measured. Data are presented as the mean ± standard error of the mean.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: To understand the molecular players involved in TAK disease activity and blood vessel formation, we utilized flow cytometry to analyze the frequency of peripheral blood-derived circulating endothelial progenitor (EPCs) and $CD31^+$ terminally differentiated endothelial cells (CECs), Luminex assays to measure plasma-derived cytokines and growth factors, and live cell imaging of Matrigel-based tube formation assays to test the angiogenic potential of CECs and endothelial cell lines *in vitro* (Figure 1). As TNF-α and IL-6 have an important role in driving TAK-related inflammation, we investigated their effect on angiogenesis.

Results: Neither the frequency of EPCs nor CECs among TAK patients was significantly correlated with disease activity in our cohort TAK patients (n = 9). Additionally, there were no striking differences in the overall profile of plasma-derived cytokines and growth factors in these patients (n= 64). However, CECs isolated from TAK patients in remission exhibited a robust angiogenic potential that was similar to that of endothelial cell lines, while those from TAK patients with active disease showed diminished capacity to form tubular structures. Finally, TNF-α but not IL-6 or the IL6/sIL6R complex showed an apparent anti-angiogenic effect *in vitro*.

Conclusion: We established an efficient *in vitro* assay capable of confirming that chronic inflammation in TAK can lead to endothelial dysfunction, since the disease activity state influences the angiogenic capabilities of patient-derived CECs. In addition, we identified TNF-α as a dominant cytokine that contributes to vascular pathology. Overall, our experimental framework provides useful insights into the basic mechanisms of TAK pathogenesis. Future research integrating clinical response with effective therapy to reduce inflammation and promote collateral vessel formation may be potentially beneficial for patients with TAK.

Abstract Number: 1625

Factor VIII as a Potential Biomarker of Disease Activity in Relapsing Polychondritis

Ashika Ajitumar[1], Eric Robbins[2], Yusuf Mastoor[2] and **Marcela ferrada**[3], [1]University of Maryland, baltimore, MD, [2]University of Maryland, baltimore, [3]University of Maryland, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Relapsing polychondritis (RP) is a rare autoimmune disease marked by episodic inflammation of cartilaginous tissues. A major challenge in its clinical management is the absence of reliable biomarkers to track disease activity. Conventional inflammatory markers such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) often fail to correlate with clinical disease flares. As part of a prospective cohort study of patients with relapsing polychondritis we evaluated the utility of Factor VIII levels as a potential biomarker for disease activity in patients with RP.

Methods: Patients older than 18 years old with a confirm diagnosis of RP were included in this study. All patients were evaluated prospectively as part of a dedicated relapsing polychondritis cohort at the University of Maryland. Each patient underwent standardized assessment for disease activity and organ damage using clinical evaluations at the time of laboratory

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

testing. Serum levels of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and Factor VIII were measured in all participants. Statistical analysis was performed using t-tests for categorical variables to evaluate associations between biomarkers and disease activity.

Results: Of the 50 patients included, the majority were female (87%). Factor VIII levels ranged from 70% to 400%, with a median value of 172%. Laboratory values were collected at the time of clinical evaluation. Elevated Factor VIII was identified in 27 patients; of these, 22 (81%) had clinically active disease, a statistically significant association ($p = 0.02$). In contrast, ESR was elevated in only 2 patients and CRP in just 1, demonstrating poor correlation with disease activity. LDH, measured in a subset, also correlated with both elevated Factor VIII and clinical activity.

Conclusion: Factor VIII appears to be a promising biomarker for disease activity in relapsing polychondritis, showing a statistically significant correlation with active disease. In contrast, traditional inflammatory markers like ESR and CRP were elevated in very few patients and did not reflect disease status. These findings support the need for further investigation of Factor VIII as a more reliable tool for monitoring RP, and highlight the limitations of relying solely on ESR and CRP in clinical assessment

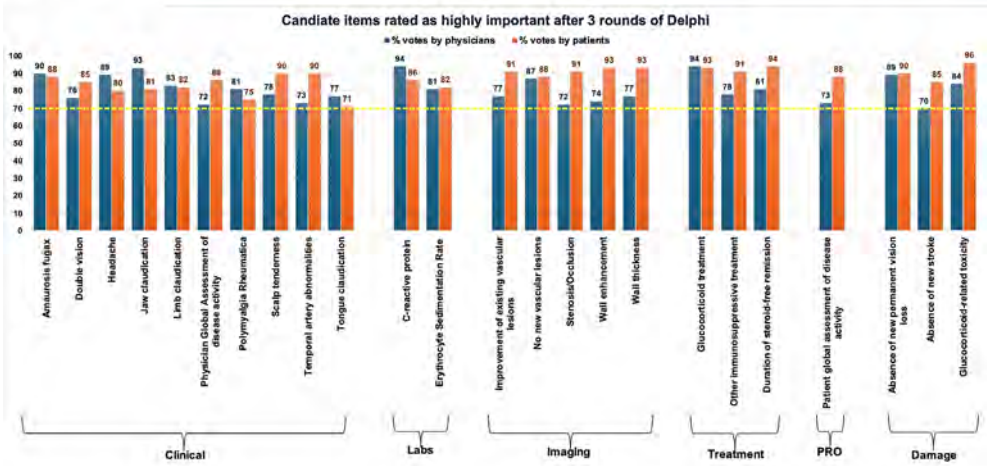
Figure 1. Twenty-four items regarding response to treatment in giant cell arteritis that reached consensus after 3 Delphi rounds



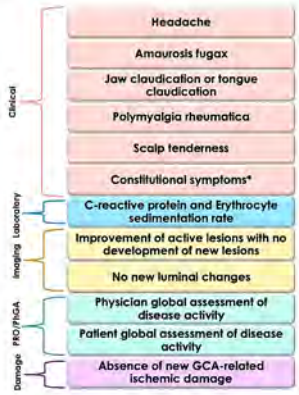
Legend: Labs: laboratory parameters; PRO: patient-reported outcome; yellow dotted line: cut-off for consensus (consensus: Items obtaining a score 7-9 by at least 70% of physicians and 70% of patients); Items shown here reached consensus in the last round each item was included.

Background/Purpose: The therapeutic landscape of giant cell arteritis (GCA) is growing rapidly but there are currently no internationally standardized criteria for assessing response to treatment in GCA. To address this issue, there is an ongoing project to develop response criteria for GCA, supported by European Alliance of Associations for Rheumatology (EULAR) and the American College of Rheumatology (ACR). Following a systematic literature review (SLR), a Delphi exercise was conducted to determine items that might be included in the future response criteria.

The goal of this Delphi exercise was to identify the most important and relevant items to consider when developing criteria to measure response to treatment in GCA.

Methods: A four-round web-based Delphi exercise was conducted. Participants from 38 countries included patients with GCA and physicians with expertise in GCA. They rated the importance (1=lowest, 9=highest) of 51 items from a prior SLR, grouped into six domains, and suggested additional items. Items obtaining a score of 7-9 by at least 70% of physicians

Figure 2. The 12 items selected for the next step in developing criteria for response in giant cell arteritis: preliminary criteria and item weighting



Legend: PRO: patient-reported outcome; PhGA: physician global assessment of disease activity; Colors are reflective of the categories of items selected.

*Items selected by the task force, despite not reaching consensus in the Delphi exercise.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and 70% of patients were considered critically important and to have reached consensus for inclusion. Items which scored 1-3 by 70% of physicians and patients were considered not important and excluded from subsequent rounds. In a 4th round of the Delphi (ranking round), participants selected and ranked the 10 most relevant items from those deemed most important in the previous three rounds. A task force (n=32 members) meeting followed to review the Delphi results, discuss rankings, and finalize the selection of items.

Results: A total of 187 physicians and 85 patients participated in the Delphi exercise. Thirteen new items were proposed in round 1. Twenty-four items were rated as critically important (18 in round 1, 5 in round 2, 1 in round 3) by ≥70% of patients and ≥70% of physicians **(Figure 1)**. These items covered the six domains of the Delphi **(Figure 1)**: 10 for clinical, 2 for laboratory, 5 for imaging, 3 for treatment, 1 for patient-reported outcomes and 3 for damage. No items were excluded during any round, and consensus was not reached for 40 items.

The top three highest-rated items by both patients and physicians were headache (ranked highest by 52% of patients and physicians), amaurosis fugax (ranked highest by 10%), and jaw claudication (ranked highest by 7%).

Of the task force members, 24/32 (75%) participated in the virtual task force meeting. Among the items discussed by the task force **(Figure 1)**, glucocorticoid-related parameters were excluded as they were considered indirect indicators of response to treatment. Constitutional symptoms were added by the task force as they are important constellation of symptoms seen in GCA. The task force also decided to cluster items with similar constructs to capture the spectrum of the disease more concisely. 12 items were selected for the next phase of the project **(Figure 2)**.

Conclusion: This Delphi exercise identified a set of 12 items within 6 domains as being relevant towards measuring response in GCA. These 12 items will be used in a subsequent group conjoint analysis to further prioritize and weigh potential items for inclusion in a draft set of criteria to measure treatment response in GCA.

*Studies published since 1st April 2014 (for PMR) or 31st December 2017 (for GCA)

Background/Purpose: EULAR recommendations informing the management of Polymyalgia Rheumatica (PMR) and Large Vessel Vasculitis (LVV) were previously published separately in 2015 [1] and 2020 [2] respectively. Newly-emerging evidence has necessitated a comprehensive update. We aimed to conduct a systematic literature review (SLR) to inform the 2025 EULAR recommendations for PMR and LVV.

Methods: An SLR (PROSPERO registration: CRD42024560403), performed on 31st December 2024 on MEDLINE, EMBASE and CENTRAL searched for literature on adult patients with PMR, Giant Cell Arteritis (GCA) or Takayasu arteritis (TAK), using MeSH terms for pharmacological and non-pharmacological management. Eligible studies included randomized controlled trials (RCTs) and observational studies, published since 1st April 2014 (for PMR) or 31st December 2017 (for LVV), without language limitations. Abstracts presented at EULAR 2024 and ACR 2024 were additionally hand-searched. Studies were assessed for their quality using relevant Risk of Bias (RoB) tools for RCTs/observational studies (Cochrane Risk of Bias 2/Newcastle Ottawa Scale).

Results: After deduplication and full-text screening, 141 articles were included (30 RCTs) (Figure 1). RCTs of GCA (low RoB) reported superiority of secukinumab (Phase-2, n=1), mavrilimumab (Phase-2, n=1) and upadacitinib (Phase-3, n=1) vs placebo; Phase-2 trials of sarilumab (n=1) and sirukumab (n=1) were prematurely terminated (high RoB). The two RCTs of sariliumab and sirukumab in GCA were at high risk of bias due to their premature termination due to which no inferences could be drawn about their effectiveness. Secondary analyses from the GiACTA trial reported similar efficacy of tocilizumab versus placebo in those with cranial symptoms, PMR symptoms, or both cranial & PMR symptoms, and better improvements in SF-36 and fatigue scores with tocilizumab than placebo. RCTs of TAK reported similar effectiveness of methotrexate or mycophenolate (unclear RoB), and superiority of adalimumab vs tocilizumab (high RoB). Phase-3 RCTs in PMR revealed superiority of tocilizumab and sarilumab (low RoB) vs. placebo while smaller phase-2 studies provided initial evidence for efficacy of rituximab (low RoB) and abatacept (unclear RoB) vs placebo (Table 1). A RCT showed similar efficacy of tofacitinib or glucocorticoids in PMR although this study was at high risk of bias.

Conclusion: The SLR identified several new Phase-2 and Phase-3 RCTs about the efficacy and safety of IL-6i, IL-17i, Janus kinase inhibitors and B-cell depletion therapies in GCA and PMR. High quality adequately sized RCTs in TAK are still lacking. This evidence was used to inform the 2025 EULAR recommendations for management of Polymyalgia Rheumatica and Large Vessel Vasculitis.

Abstract Number: 1628

Characterization of non-GCA, non-Takayasu Aortitis in a Single Health System Cohort

Nuzhat Batool[1], Zuha Anwar[1], Sharika Hasan[2], Miltiadis Tembelis[2], Jason Hoffmann[1], Nihan Gencerliler[2], justeena Joseph[3], Steven Carsons[4] and Elise Belilos[1], [1]NYU Grossman LI School of Medicine, Queens, NY, [2]NYU Grossman LI School of Medicine, Queens, [3]Long Island Community Hospital, Long Island, NY, [4]NYU Long Island School of Medicine, Mineola, NY

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Advances in imaging modalities has led to increased diagnosis of aortitis. While aortitis occurring in the setting of giant cell arteritis (GCA) and Takayasu arteritis (TAK) is well characterized, other forms of aortitis are less well characterized and can be associated with a variety of other etiologies or may be idiopathic. We sought to identify the demographic, clinical and imaging characteristics of non-GCA/TAK aortitis.

Methods: In this retrospective cross-sectional study, the study population was identified using ICD 10 codes for aortitis from 1/1/12-12/31/22, across NYU Health system. Eligibility criteria were age between 18-90 years and a diagnosis of aortitis. 300 subjects were identified by using EMR diagnoses of aortitis, GCA, TAK. All charts were reviewed by rheumatology and radiology teams. 52 cases met the inclusion criteria. For data analysis used Wilcoxon rank sum test for continuous variables and Fisher's exact test for categorical variables. A p-value of < 0.05 was considered statistically significant. All analyses were performed using R (R Core Team) version 4.4.0.

Table 1

Characteristic	N	Overall, N=52	GCA/TAK aortitis (N=16)	Other Aortitis Cases (N=36)	P Value

Periaortic fat stranding and inflammatory changes	46	24 (52%)	7 (54%)	17 (52%)	>0.9

Results:

36 cases of non-GCA/TAK aortitis and 16 cases of TAK/GCA aortitis were identified. Of the TAK/GCA group, 44% were identified as GCA and 56% were identified as TAK. Of the non-GCA/TAK aortitis cases, 25% were associated with other autoimmune diseases such as ANCA-related disease, Bechet's, RA, Sarcoid and SPA. In addition, 39% of the non-GCA/TAK cases were associated with infection and 36% were idiopathic.

The median age for the non-GCA/TAK and GCA/TAK groups was 69 years and 45 years, respectively (p=0.002). 45% of aortitis cases were incidental findings. When patients did present with symptoms, 42% of non-GCA/TAK patients presented with abdominal pain and 33% with back pain (p=0.05).

CTA/ CT was the most frequently utilized imaging modality in both groups. MRA/ MRI was utilized in 48% of cases for follow up purposes. Common imaging findings associated with aortitis included periaortic fat stranding and inflammatory changes which were seen in more than 54% of GCA/TAK aortitis and 52% of non-GCA/TAK aortitis cases (p=NS). Aortic wall thickening, which was seen in 77% of GCA/TAK aortitis cases and 64% of non-GCA/TAK aortitis p=NS. Aortic wall enhancement was seen in 54% of GCA/TAK aortitis cases vs 37% of non-GCA/TAK cases p=NS. Aortic stenosis was seen in 25% in GCA/TAK patients vs 2.8% non-GCA/TAK patients p=0.03.

70% of study participants received medical treatment for aortitis (85% of GCA/TAK cases and 69% of non-GCA/TAK cases). Steroids were used to treat over 66% of study participants; 87% in the GCA/TAK group and 55% in the non-GCA/TAK group (p=0.054).

Table 3

Characteristic	N	Overall N=52	GCA/TAK Aortitis N=16	Other Aortitis Cases N=36	P value
Did the patient receive treatment?	46	3 (70%)	11 (85%)	21 (64%)	0.3
Steroids used for treatment	44				0.05

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In our health system cohort of aortitis cases, 45% were incidental findings. In non-GCA/TAK aortitis, 39% were attributed to infection, 25% to autoimmune conditions and 36% were idiopathic. Steroids, when employed for treatment of aortitis, were more commonly used in GCA/TAK aortitis vs non-GCA/ TAK aortitis. The difference may reflect caution regarding steroids use in cases of infectious aortitis as well some uncertainty regarding approach to treatment for non-GCA/TAK aortitis.

Abstract Number: 1629

Real-World Effectiveness of Interleukin-6 Receptor Inhibitors Compared to Methotrexate in Steroid-Refractory Frail Patients with Polymyalgia Rheumatica

Sebastian E Sattui[1], Christian Dejaco[2], Kerri Ford[3], **Stefano Fiore**[4], Sebastian H Unizony[5], Fenglong Xie[6] and Jeffrey Curtis[7], [1]Division of Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh, PA, [2]Medical University of Graz, Department of Rheumatology, Graz, Austria; Department of Rheumatology, Hospital of Brunico (SABES-ASDAA), Brunico, Italy, [3]Sanofi, Cambridge, MA, [4]Sanofi, Morristown, NJ, [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [6]The University of Alabama at Birmingham, Birmingham, AL, [7]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: A previous post hoc analysis of frail (defined by claims-based frailty index [CFI] ≥0.2) patients with PMR on second line (2L) and 3L treatment showed that those on IL-6 receptor inhibitors (IL-6Ri) were more than twice (HR 2.32) as likely to discontinue GC vs. those on conventional synthetic immunomodulators (csIM: methotrexate [MTX], azathioprine, and leflunomide), nearly 2 times the effect size in overall PMR cohort (HR 1.28). This study builds on prior analysis by comparing IL-6Ri to MTX as 2L treatment, with frailty as inclusion criteria and level of frailty as PS match covariate. Frailty was defined as CFI ≥0.25 (validated threshold in the general population), minimizing inclusion of patients with pre-frailty. This study compared effectiveness of IL-6Ri to MTX in GC-refractory frail patients with PMR.

Methods: This observational retrospective comparative cohort study compared effectiveness of IL-6Ri to MTX using US Medicare claims data (10/2016-12/2022). Inclusion criteria were age ≥50 years, ≥1 inpatient or ≥2 outpatient PMR diagnosis codes ≥30 days apart, ≤25 mg prednisone equivalent dose (PED), CFI ≥0.25, initiation of IL-6Ri or MTX (index date) with no prior IL-6Ri/csIM and continuous enrollment 180 days prior (baseline) to 1 day. Patients initiating IL-6Ri and csIM on same day and patients with seropositive RA, other systemic rheumatic disease (except giant cell arteritis), organ transplant, multiple sclerosis or active malignancy treatment during baseline were excluded. MTX initiators were direct matched on select characteristics and then PS matched on demographic, treatment and clinical characteristics. Primary and key secondary outcomes were time to GC discontinuation (>60-day gap) and time to minimal (≤2 mg/day PED) or no GC, respectively.

Results: Overall, 29% and 18.3% of patients in IL-6Ri and MTX groups, respectively, had CFI ≥0.25. Of these, 86 matched pairs receiving 2L treatment with no prior IL-6Ri were identified. Patient characteristics were generally balanced, though the mean time from first PMR diagnosis to index date (1025 vs. 799 days) and occurrence of seronegative RA (32.6%

CI, confidence interval; GC, glucocorticoids; HR, hazard ratio; IL-6, interleukin-6; IL-6Ri, IL-6 receptor inhibitors; MTX, methotrexate.

Figure 1.

vs. 22.1%) were higher in IL-6Ri vs. MTX groups. About 1/4th of the patients were moderately-severely frail (CFI ≥0.35, 20.9% vs. 26.7%) **(Table 1)**. Time to GC discontinuation **(Figure 1A)** and time to minimal or no GC **(Figure 1B)** up to 1 year were significantly shorter for IL-6Ri vs. MTX-treated patients (HR [95% CI] 1.75 [1.05, 2.93]; p=0.033) and (HR [95% CI] 1.86 [1.15, 3.00]; p=0.011), respectively.

Conclusion: IL-6Ri therapy led to a more rapid GC discontinuation or to achieving minimal GC dose in frail patients with PMR, suggesting that this vulnerable population may benefit more from IL-6Ri vs. MTX.

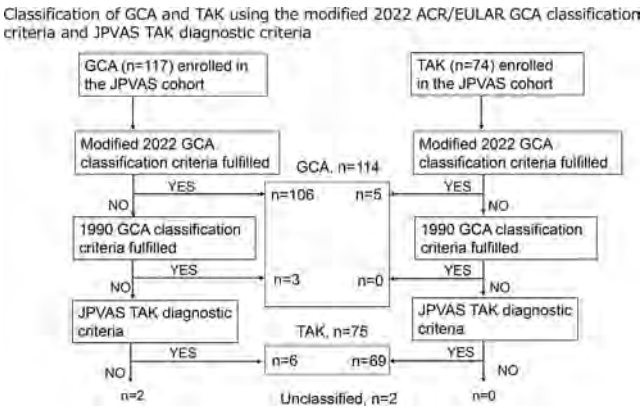
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: Given the increasing number of patients with giant cell arteritis (GCA) in Japan and the higher incidence of Takayasu arteritis (TAK) compared to Europe and the U.S., our aim is to validate the discriminability of the modified 2022 ACR/EULAR GCA classification criteria for TAK and GCA and to compare the clinical profiles of GCA and TAK reclassified by the classification criteria for large-vessel vasculitis (LVV).



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1 Clinical features of GCA and TAK after classification according to the algorithm*

	GCA (n=114)	TAK (n=75)	*P*-value
Age at onset, mean (SD)	72.7 (8.2)	37.5 (20.3)	<0.001
50 years old and more, %	99.1	29.3	<0.001
Female, %	68.4	70.7	0.743
New headache, %	63.2	6.7	<0.001
Scalp tenderness, %	28.1	0	<0.001
Abnormal examination of the temporal artery, %	58.8	0	<0.001
Visual disturbance, %	14.9	2.7	0.004
Sudden visual loss, %	2.6	0	0.217
Jaw claudication, %	33.3	9.3	<0.001
Polymyalgia rheumatica, %	37.7	0.0	<0.001
Arthralgia/arthritis/myalgia, %	49.1	21.3	<0.001
Definitive vasculitis on temporal artery biopsy, %	83.3 (70 / 84)	0	–
Large-vessel involvement, %	65.8	100	–

* We applied the modified 2022 ACR/EULAR GCA classification criteria (1) first to our cohort, followed by the 1990 ACR GCA classification criteria and the JPVAS diagnostic criteria for TAK (2). According to the JPVAS diagnostic criteria for TAK, patients are diagnosed with TAK if they exhibit at least one clinical symptom along with diffuse or multiple arterial lesions including wall thickening, while GCA is excluded.

Aneurysm of ascending aorta, %	0.0	8.0	0.014
Aortic arch lesion, %	57.9	65.3	0.347
Descending thoracic aorta lesion, %	65.8	50.7	0.060
Abdominal aorta lesion, %	67.1	40.0	0.001
Descending thoracic aorta-abdominal aorta lesions, %	57.9	33.3	0.002
Stenosis of mesenteric artery, %	1.3	6.7	0.102
Renal artery lesion, %	11.8	6.7	0.273
Stenosis of renal arteries, %	3.9	5.3	0.493

LV-GCA: large-vessel GCA with or without cranial lesions

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: The Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS) prospective study included 117 incidental GCA and 74 TAK diagnosed by attending physicians at participating JPVAS facilities from 2015 to 2019. In the modified 2022 ACR/EULAR GCA classification criteria, shoulder or neck stiffness was changed to polymyalgia rheumatica (PMR), and fluorodeoxyglucose (FDG)-positron emission tomography (PET) activity to wall thickening, stenosis, or aneurysm of the descending thoracic to abdominal aorta. We applied the GCA criteria first to our cohort, followed by the JPVAS diagnostic criteria for TAK, in which patients are classified as TAK if they exhibit at least one clinical symptom along with diffuse or multiple arterial lesions including wall thickening.

Results: The modified GCA classification criteria had sensitivities of 91.5% for overall GCA, 90.9% for large-vessel GCA (LV-GCA), and 36.3% for isolated LV-GCA without cranial lesions. The specificity was 93.2%. Discrimination between GCA and TAK using the modified criteria excluding age was high, with a C statistic of 0.945 (95% CI: 0.916–0.975). Combining PMR, bilateral axillary arteries, descending thoracic to abdominal aortic lesions, and inflammatory markers (i.e., using only these four items out of original 11 items) yielded a C statistic of 0.730 (95% CI: 0.661–0.799). Excluding PMR from this combination resulted in poor discrimination of 0.598 (95% CI: 0.530–0.667); adding age 50 years or older improved the discrimination to 0.898 (95% CI: 0.847–0.949).

Out of 117 GCA and 74 TAK patients enrolled in the JPVAS, 106 and five were classified as GCA based on the modified 2022 GCA classification criteria, followed by the 1990 ACR classification criteria and the JPVAS criteria, and overall, 114, 75, and two were classified as GCA, TAK, and unclassified, respectively (Figure 1). A comparison of GCA and TAK after the classification revealed notable differences in age and clinical features (Table 1). Bilateral axillary artery and descending thoracic to abdominal aorta were more common lesions in LV-GCA than in TAK. Arterial stenosis was significantly more prevalent in TAK than in LV-GCA (Table 2). Among the five patients with TAK classified as GCA, two were under 60, one had carotid artery tenderness, three had bilateral axillary artery lesions, and two were HLA-B52 positive.

Conclusion: The discriminability of the modified 2022 ACR/EULAR GCA classification criteria for TAK and GCA was good, and the classification utilizing the modified GCA criteria and the JPVAS TAK criteria was seen as beneficial. However, the 1990 ACR classification criteria was needed for a few cases, and classification of late-onset TAK and LV-GCA was difficult in some cases.

Abstract Number: 1631

New Arterial Damage in Takayasu's Arteritis

Tanaz Kermani[1], Sema Kaymaz-Tahra[2], Aysegul Avcu[3], Fatma Alibaz-Oner[4], Haner Direskeneli[3], Peter Merkel[5] and Vasculitis Clinical Research Consortium, [1]University of California Los Angeles, Santa Monica, CA, [2]Bahcesehir University Faculty of Medicine Department of Internal Medicine Division of Rheumatology, Istanbul, Turkey, [3]Marmara University, Istanbul, Turkey, [4]MARMARA UNIVERSITY, SCHOOL OF MEDICINE, DEPARTMENT OF INTERNAL MEDICINE, DIVISION OF RHEUMATOLOGY, Istanbul, Turkey, [5]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 10:30AM–12:30PM

Background/Purpose: Damage is one of the consequences of disease and is often considered irreversible. This study aimed to evaluate new arterial damage in Takayasu's arteritis (TAK).

Methods: Patients with TAK were included in this analysis if they were enrolled in a multicenter, prospective, observational cohort from North America, or seen at a single-center in Turkey, and had available data on vascular imaging. Baseline imaging and imaging at last visit were compared to identify new lesions (stenosis, occlusions, aneurysms) in previously unaffected territories. Variables associated with new arterial damage were evaluated.

Results: The study included 305 patients with TAK: 92% female; mean±SD age 40.9 (13.5) years; median (25^{th}, 75^{th} percentile) disease duration from diagnosis 1.2 (0, 4.9) years; median (25^{th}, 75^{th} percentile) time from symptom onset to diagnosis 54.1 (16.6, 178.2) weeks; median duration of follow-up 5.8 (2.0, 9.4) years. 128 patients (42%) were enrolled ≤ 180 days from time of diagnosis (the "recently diagnosed" group).

Table 1: Frequency and type of vascular lesions in 305 patients with Takayasu's arteritis

	Entire cohort, N = 305			Recently diagnosed, N = 128		
Vessel	Stenosis	Occlusion	Aneurysm	Stenosis	Occlusion	Aneurysm
Ascending aorta	2	1	16	0	1	4
Aortic arch	7	1	6	1	1	2
Descending aorta	22	1	11	3	1	3
Abdominal aorta	40	1	7	16	5	1
Innominate	12	6	3	4	4	0

Left iliac	3	0	2
Right iliac	5	0	0
Left femoral	1	0	0
Right femoral	1	1	0

Table 3: New arterial lesions in previously unaffected arterial regions in 204 patients with Takayasu's arteritis

Variable	New lesion N=72	No new lesion N=132	p-value
Mean age, years (SD)	40.6 (13.4)	41.5 (13.4)	0.64
Female sex, N (%)	65 (90)	123 (93)	0.59
Mean disease duration, years (SD)	3.3 (4.4)	2.7 (4.5)	0.36
Recently diagnosed, N (%)	31 (43)	64 (49)	0.47
Mean time between first and last imaging, years (SD)	4.9 (4.5)	6.5 (5.5)	0.04
Glucocorticoid ever, N (%)	69 (96)	121 (92)	0.39
DMARDs ever, N (%)	64 (89)	121 (92)	0.62
Biologic drugs ever, N (%)	29 (40)	40 (30)	0.17

SD: standard deviation; % = percentage, DMARDs: non-biologic disease-modifying anti-rheumatic drugs

The lesions on imaging at first visit in all 305 patients are outlined in **Table 1**. Aneurysmal disease was more frequently observed in the ascending aorta and aortic arch, while stenotic disease was more frequent in the abdominal aorta.

204 patients (67%) had at least 1 follow-up imaging study. Median (25^{th}, 75^{th} percentile) time from first available imaging study to last available imaging study was 4.1 (1.6, 8.4) years. 72 patients (35%) had at least 1 new arterial lesion in a previously unaffected territory. Among 95 patients recently diagnosed, 31 patients (32%) had new arterial lesions. The distribution of new vascular lesions is outlined in **Table 2**. The majority of new lesions were stenoses and occurred in the left carotid artery, abdominal aorta, and superior mesenteric artery. Of the 72 patients with new lesions, 36 patients (50%) had ≥ 2 new lesions (range 2-9).

When characteristics were compared between patients with and without new arterial lesions (**Table 3**), no differences were found in age, sex, time between imaging studies, recent diagnosis, or treatment.

Conclusion: Nearly one-third of patients with TAK develop *new*, often multiple, arterial lesions during follow-up, indicating significant burden of disease despite treatment. The majority of the new lesions are stenotic or occlusive. Given the frequency of new lesions, serial imaging remains important in the monitoring of TAK. To better capture the longitudinal arterial damage that occurs in this disease, indices of damage in TAK should include data derived from vascular imaging.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: (1612–1632) Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 10:30AM–12:30PM

Background/Purpose: PET/CT enables assessment of active vascular inflammation in Takayasu arteritis (TAK), which is often difficult to evaluate with conventional imaging. Although the distribution of affected arteries has been classified into patterns by both conventional imaging and PET/CT, its relationship with clinical outcomes remains unclear. This study aimed to evaluate the significance of PET/CT-based arterial involvement in treatment-naïve TAK and its association with relapse and cardiovascular events.

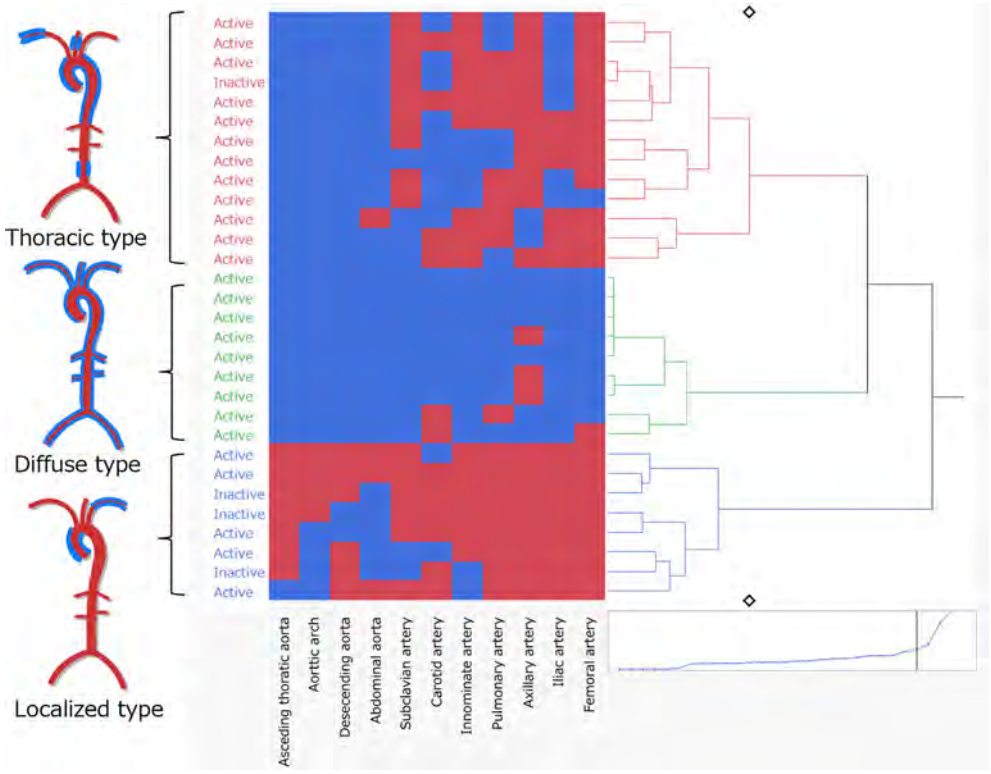

Figure 1. Hierarchical clustering based on the distribution of affected arteries revealed three distinct patterns.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

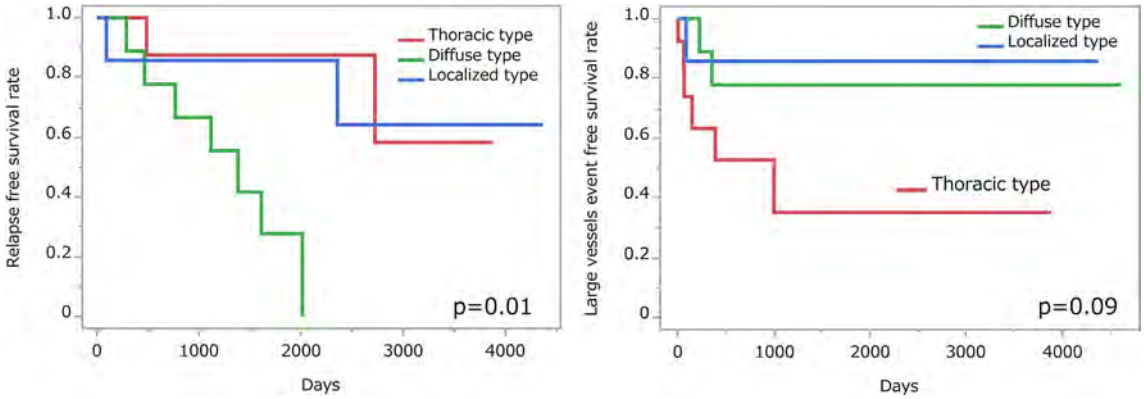

Figure 2. Survival curve analysis showed higher relapse rates in the diffuse type and a trend toward more large vessel events in the thoracic type.

Methods: We conducted a retrospective study of patients with TAK who underwent PET/CT before treatment between 2010 and 2024. Hierarchical clustering was performed based on the distribution of affected arteries, with 18F-fluorodeoxyglucose uptake assessed by a four-grade visual scale; the score ≥1 was considered positive. Clinical characteristics and outcomes were compared across clusters. Relapse and large vessel events were defined according to the 2018 EULAR recommendations and analyzed using survival analysis. Longitudinal changes in PET/CT and clinical activity were evaluated in patients with post-treatment PET/CT. Continuous variables were expressed as medians with interquartile ranges.

Results: Thirty patients were included, with a follow-up of 4.8 years (1.4–9.9), age at diagnosis of 48 years (28–58), and 90% female. All met Japanese diagnostic criteria; 80% met the 2022 ACR/EULAR criteria. Numano's classification based on CT was as follows; I, 2; II, 10; III, 3; V, 15. Relapse occurred in 12 patients (40%) with one major relapse; and large vessel events in nine patients (30%); aortic regurgitation, 2; aortic aneurysm, 5; aortic stenosis. 4; cardiovascular death, 1. Hierarchical clustering revealed three distinct patterns: (A) thoracic type (mainly thoracic aorta with less frequent branch involvement; 43%), (B) diffuse type (extensive involvement of the aorta and its branches; 30%), and (C) localized type (mainly branch lesions; 27%) (Figure 1). The proportion of type V was 78% in A, 38% in B, and 38% in C (p=0.35), indicating inconsistency between PET/CT and angiographic classifications. PET vascular activity scores were significantly different among clusters: 9 (7–13) in A, 15 (12–21) in B, and 3 (1–5) in C (p< 0.01). CRP levels were as follows; 3.1 (1.7–3.8), 3.4 (1.4–5.6), and 0.7 (0.1–7.1) mg/dL (p=0.28). Relapse rates were the highest in B (23%, 78%, and 25%, p=0.04), whereas large vessel events tended to occur more in A (46%, 22%, and 13%; p=0.09) (Figure 2). Numano's classification was not associated with relapse or large vessel events. Among 17 patients with repeated scans, PET/CT activity was observed despite clinical inactivity, indicating a risk of relapse in such patients. Meanwhile, a relapse was also observed in a patient whose PET/CT activity had normalized (Figure 3).

Conclusion: PET/CT-based arterial pattern in TAK was classified into three clusters with distinct prognostic profiles. Diffuse type was associated with higher relapse, whereas thoracic type tended to present vascular complications. Conventional angiographic classification failed to predict these outcomes, and thus PET/CT would provide superior risk stratification in TAK.

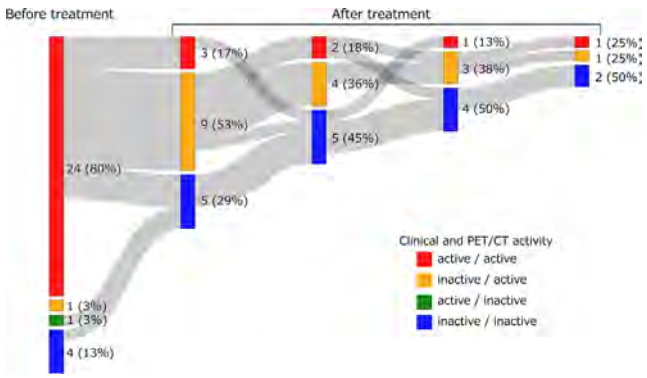

Figure 3. Sankey diagram illustrating temporal changes in clinical and PET/CT disease activity.

Malondialdehyde-Acetaldehyde and Citrulline Modified Proteins are Overexpressed in Cardiac Tissues in Rheumatoid Arthritis-Associated Heart Failure and Mediate Endothelial Cell Dysfunction

Hannah Johnson[1], Wenxian Zhou[2], Michael Duryee[1], Engle Sharp[1], Kimberley Sinanan[1], Carlos Hunter[1], Tate Johnson[1], Mabruka Alfaidi[1], Daniel Anderson[3], Geoffrey Thiele[1] and Ted Mikuls[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Bellevue, NE, [3]0587964, Durham, NC

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Cytokines & Cell Trafficking (1650–1655)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Previous reports show that malondialdehyde-acetaldehyde (MAA) adducts are overexpressed in RA, especially in joint/lung tissues, and that they colocalize with citrulline (CIT). This is relevant as MAA and CIT act synergistically through p38- and NF-κB-dependent pathways to activate macrophages, producing proinflammatory and profibrotic effects mediated through crosstalk with tissue resident cells. Heart failure (HF) is a highly overrepresented cause of death

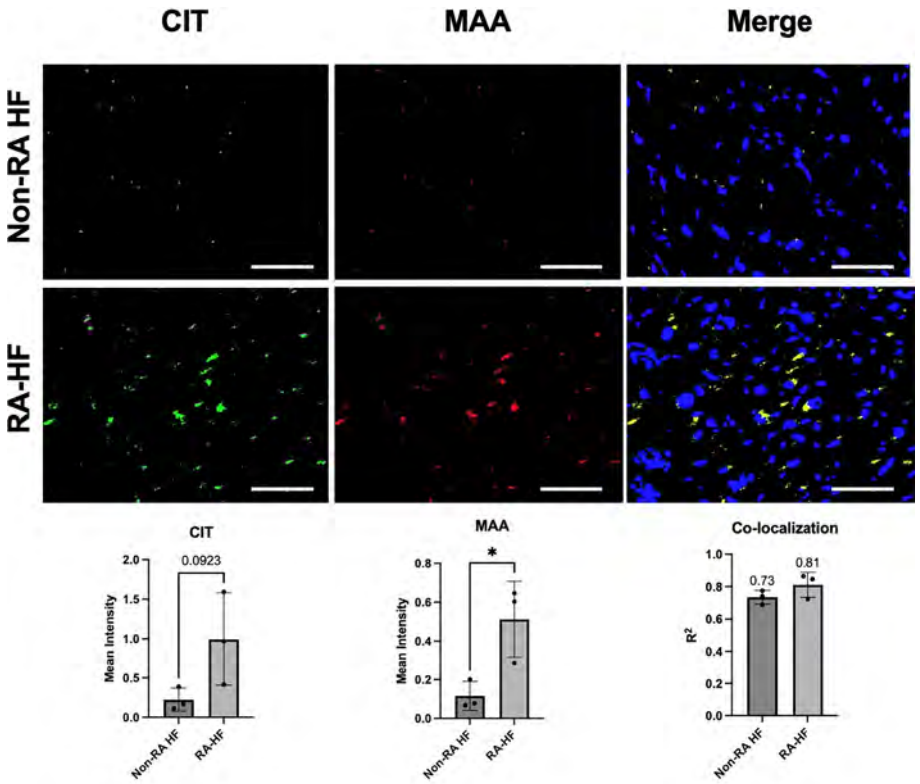

Figure 1. Immunohistochemistry Reveals CIT and MAA Expression and Colocalization in the Heart of RA-HF Patients. Representative image of 20X frame at apex of left ventricle is shown. White scale bar = 200 μm. Data shown on graphs are mean ± standard deviation. Student's T test was performed and the statistical differences between groups are shown in *: * p<0.05.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. RT-PCR Demonstrating Attenuated HCAEC Inflammatory Gene Expression Following Incubation with Supernatants from Macrophages Stimulated with FIB-MAA-CIT in the Presence or Absence of p38 and NF-κB Inhibitors. 24-hr mRNA expression was measured for; A) IL-6, B) MCP-1, C) ICAM-1, and D) VCAM-1. Relative quotient (RQ) compared to media-cultured negative control cells were calculated and shown in the y-axis. One-way ANOVA was performed and the statistical differences between groups are shown in *: * p<0.05; *** p<0.001; **** p<0.0001.

in RA patients, characterized by tissue inflammation, fibrosis, and vascular endothelial dysfunction. Herein, we sought to examine whether MAA has increased expression and colocalization with CIT in heart tissues from patients with RA-HF. We also examined whether inhibition of macrophage signaling pathways limits endothelial cell (EC) activation and inflammation mediated by MAA-CIT stimulation.

Methods: Left ventricular (LV) apex tissue from RA-HF patients and age/sex matched non-RA HF controls were examined (n=3/group). LV tissues were stained with anti-CIT and anti-MAA antibodies. Quantification and co-localization were done using ImageJ and FIJI Coloc2. Separately, human U-937 macrophages were pre-incubated with either media, 1 μM of BIRB-796 (p38 inhibitor), or 50 μM of BAY-11-7085 (NF-κB inhibitor) for 1-hr before stimulation with unmodified fibrinogen (FIB) or FIB co-modified with MAA+CIT (FIB-MAA-CIT) for 48-hrs. To assess the crosstalk between macrophages and ECs, macrophage supernatants were collected and used to indirectly stimulate human coronary artery endothelial cells (HCAECs) for 24-hrs. HCAEC supernatants were then analyzed for IL-6, MCP-1, ICAM-1, and VCAM-1 by ELISA, while RNA was analyzed by RT-PCR. Analyses were performed using a Student's T test or one-way ANOVA with Tukey's post hoc test.

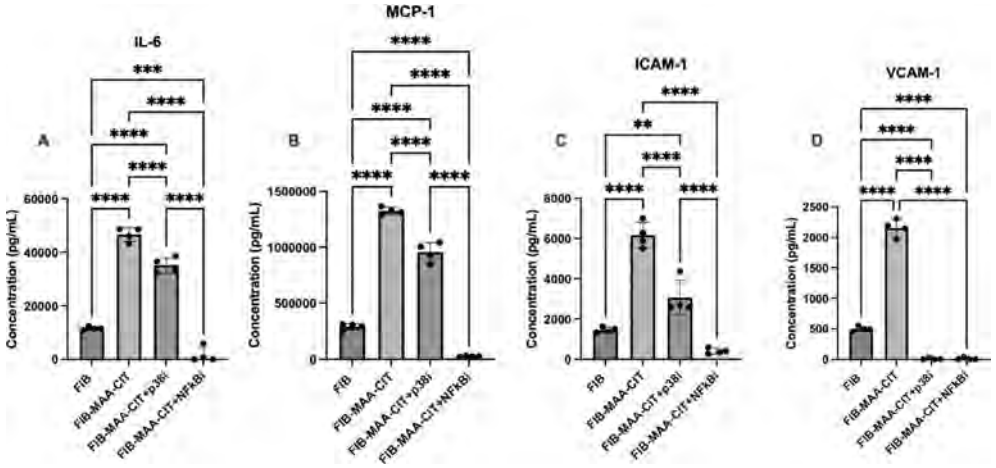

Figure 3. ELISA Demonstrating Attenuated HCAEC Inflammatory Protein Release Following Incubation with Supernatants from Macrophages Stimulated with FIB-MAA-CIT in the Presence or Absence of p38 and NF-κB Inhibitors. 24-hr cytokine concentrations in supernatants were measured for; A) IL-6, B) MCP-1, C) ICAM-1, and D) VCAM-1. One-way ANOVA was performed and the statistical differences between inhibitory groups are shown in *: ** p<0.01; *** p<0.001; **** p<0.0001.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: LV tissues from RA-HF patients demonstrated trends towards increased CIT deposition (p=0.09) and significantly increased MAA deposition (p< 0.05) vs. non-RA HF controls, with strong co-localization (R2=0.81) (Fig 1). HCAECs stimulated with supernatants from macrophages treated with FIB-MAA-CIT showed significantly increased expression of IL-6, MCP-1, ICAM-1, and VCAM-1 compared to FIB control, validating prior observations. Interestingly, direct stimulation of HCAECs with FIB-MAA-CIT yielded diminished effects (not shown). HCAECs stimulated with supernatants from macrophages pre-treated with p38 or NF-κB inhibitors and FIB-MAA-CIT showed significantly attenuated mRNA expression and soluble cytokine/chemokine production (Figs 2,3).

Conclusion: This study is the first to demonstrate increased MAA expression and MAA-CIT co-localization in cardiac tissues of RA-HF patients compared to non-RA HF patients. We also demonstrated that macrophages activated with FIB-MAA-CIT mediate coronary EC inflammation through their supernatants, an effect that is attenuated following inhibition of p38 and NF-κB. Further research will validate these findings using patient-derived monocytes and explore whether agents targeting MAA, CIT, or downstream signaling pathways have the potential to attenuate cardiac dysfunction that occurs in mouse models of RA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Cytokines & Cell Trafficking (1650–1655)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Familial Mediterranean fever (FMF) is an autoinflammatory disease associated with biallelic pathogenic variants in the *MEFV* gene encoding the myeloid-restricted inflammasome sensor pyrin. The majority of FMF-associated missense variants reside in exon 10 of *MEFV within the B30.2/SPRY domain*, with M680I, M694V, and V726A being the most common disease-associated variants in Eastern Mediterranean populations. The Ile692del (rs104895093) variant has been reported in Arab patients with recessively inherited FMF, Patients who are compound heterozygous for the I692del and V726A variants presented with a severe inflammatory phenotype including transfusion-dependent anemia and neutrophilic dermatoses. Several patients had a history of cytokine storm, which is not reported in patients with classical FMF. To study the impact of the Ile692del variant, we analyzed the clinical histories, biomarker testing, and response to

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

therapy of 53 individuals who have at least one copy of the Ile692del variant. We then examined the inflammatory signature associated with this phenotype in the primary cells of patients who are compound heterozygotes for I692del/Val726Ala. We have designated this condition as CHIVE-18 syndrome.

Methods: We designed analogous panels to measure the response to cytokine stimulation in whole blood and cryopreserved PBMCs. Phospho-STAT staining was carried out on whole blood (n=2) or frozen PBMCs (n=2) of compound heterozygotes for I692del/Val726Ala with controls. Samples were stained with fluorochrome-conjugated antibodies for myeloid and lymphoid markers, stimulated with IFN-a, IFN-g, or IL-10 and then stained with intracellular antibodies for pSTAT1 and pSTAT3. Stained cells were acquired on a 5-laser Cytek® Aurora Spectral Cytometer.

Results: All patients with CHIVE-18 had significantly elevated levels of serum total IL-18, IL-18 BP, and free IL-18. Given high serum levels of the IL-18 cytokine, a known inducer of IFN-g, we measured phosphorylation of STAT1 and STAT3 in stimulated patients' cells. CHIVE-18 patients had enhanced STAT1 phosphorylation after stimulation with IFN-g compared to age-matched controls, while pSTAT3 was not higher. Interferon-induced STAT1 phosphorylation was more pronounced in cellular populations from the myeloid lineage, confirming the role of these cells in mediating FMF pathology.

Conclusion: CHIVE-18 syndrome is a severe inflammatory disease distinct from classic FMF. Our data show that IFN-induced pSTAT1 was more pronounced in cellular populations from the myeloid lineage, consistent with observations in patients with pyogenic arthritis, pyoderma gangrenosum and acne (PAPA) syndrome, another pyrin-related autoinflammatory disease, and confirms the role of these cells in mediating FMF pathology. Although IFN-γ is not a major driver of a pyrin-mediated inflammatory disease, it is a contributing factor to disease pathophysiology and could make patients with high-impact mutations prone to episodes of cytokine storm. Such hyperinflammatory episodes increase mortality risk and should be treated aggressively. Affected patients usually require treatment with high-dose of IL-1 inhibitors or with combination of cytokine inhibitors.

Abstract Number: 1652

The Hidden Impact of Hyperuricemia on Immune Cell Dysfunction

Isabella Yi, Henry Ping and **Qian Wang**, iLab Research Institute, Mountain View, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Cytokines & Cell Trafficking (1650–1655)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Background: Hyperuricemia, characterized by elevated serum uric acid levels, is often asymptomatic yet poses serious health risks. This study investigates how soluble monosodium urate (MSU) influences immune cell dynamics, uncovering potential immunological consequences of high uric acid levels.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Methods: Leukocyte Reduction System (LRS) cells were cultured with or without soluble MSU at 100 μg/mL for 24 hours. Single-cell and bulk RNA sequencing was conducted to assess changes in immune cell populations, and enzyme-linked immunosorbent assays (ELISA) were utilized to measure cytokine production.

Results: Results: MSU exposure led to significant alterations in immune cell profiles, decreasing CD8+ T cells including CD8+ TCM (T central memory), CD8+ TEM (T effector memory), and effective CD8+ T cells, monocytes and dendritic cells while increasing CD4+ T cells, Tregs, macrophages, mast cells. Importantly, MSU markedly elevated proinflammatory cytokines, including TNF-α, IL-1β. Additionally, upregulation of inhibitory immune checkpoint molecules such as CD274, PDCD1LG2, CD276, PDCD1, and ELISA showed the increased protein levels CD274 and CD276. These results indicated a shift toward an immunosuppressive state.

Conclusion: Conclusions: These findings reveal that MSU profoundly alters immune cell behavior, driving inflammation and activating immunosuppressive pathways. Asymptomatic hyperuricemia may compromise immune function, potentially diminishing cancer surveillance or inducing autoimmune conditions such as lupus. Proactive management of elevated uric acid levels is crucial for maintaining immune balance. Moreover, LRS cells serve as a valuable model for investigating immune interactions under stress, paving the way for future research into the health impacts of hyperuricemia.

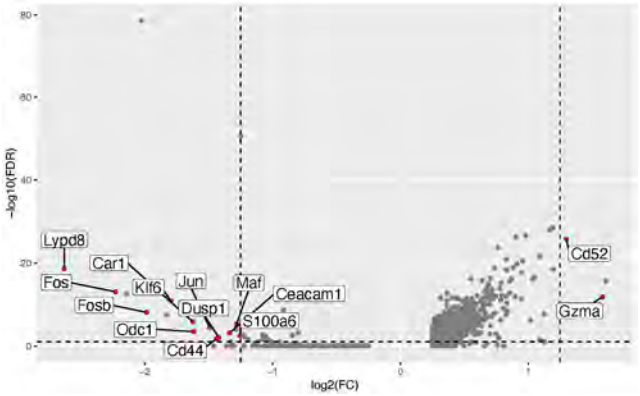
Gut-joint lymphocyte trafficking functions to regulate systemic immunity

Sarah Danielson[1], Sucai Liu[2] and Kristine Kuhn[3], [1]University of Colorado Anschutz Medical Campus, Aurora, [2]University of Colorado School of Medicine, Aurora, CO, [3]2022 - 2023 / Adult/ University of Colorado, Aurora, CO

SESSION INFORMATION

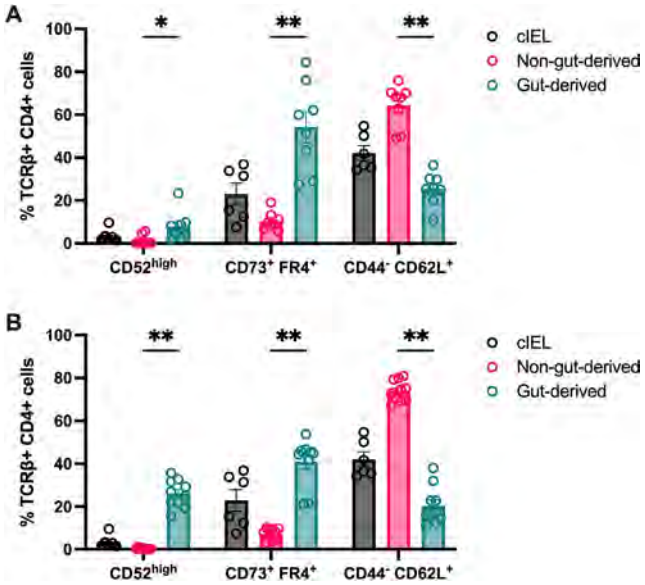
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Cytokines & Cell Trafficking (1650–1655)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: The gut-joint and mucosal origins hypotheses postulate that immune alterations in mucosal sites may precede and impact the development of rheumatoid arthritis and spondyloarthritis. However, the mechanisms behind these connections remain unknown. Our prior work using KikGR transgenic mice, in which we performed colonoscopy-



Volcano plot of differentially expressed genes in gut-derived CD4+ splenocytes after RNA sequencing.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



cIELs and cells from spleen (A) or joint-draining lymph nodes (B) were isolated from colonoscopy-guided photoconverted KikGR mice and expression of the indicated markers was evaluated CD4+ TCRαβ+ T cells from each tissue by flow cytometry. Non-gut-derived and gut-derived cells were compared using multiple Wilcoxon tests. *, p<0.05; **, p<0.01.

guided green-to-red photoconversion, demonstrated that colon intraepithelial lymphocytes (cIELs) constitutively traffic. The trafficking cIELs, referred to as gut-derived T cells, were characterized as TCRαβ^{+} CD4^{+} and found in extraintestinal tissues including the spleen, liver, lungs, and joints. In this study, we aimed to further elucidate the functions of gut-derived T cells and the intestinal signals that influence their systemic function.

Methods: Using colonoscopy-guided photoconverted KikGR mice, we performed single cell RNA sequencing of sorted KikGreen^{+} (non-gut-derived) and KikRed^{+} (gut-derived) splenocytes, then validated results by flow cytometry. We used an MHCII tetramer containing the flagellin peptide Cbir1, a common T cell antigenic target, to evaluate broad commensal reactivity. We then generated KikGR^{+} I-Ab$^{fl/fl}$ Villin-Cre (MHCII$^{\Delta IEC}$) mice, which lack expression of MHCII on intestinal epithelial cells, and performed single cell ATAC sequencing on cIELs from MHCII$^{\Delta IEC}$ and MHCII^{WT} mice followed by flow cytometry on trafficking cells.

Results: Differential gene expression analysis of our RNA sequencing data revealed increased transcription of *Cd52*, a marker of regulatory function, and decreased transcription of the AP-1 transcription factor family members *Fos*, *Jun*, and *Maf* in gut-derived CD4^{+} T cells, suggesting either antigen inexperience or anergy. Flow cytometry of lamina propria, spleen, mesenteric lymph nodes, and joint-draining lymph nodes confirmed significantly higher numbers of gut-derived regulatory CD52^{high} and anergic CD73^{+} FR4^{+} CD4^{+} T cells and significantly lower numbers of gut-derived naïve CD62L^{+} CD44^{-} T cells. Cbir1-reactive CD4^{+} T cells, representative of microbiome reactivity, were more frequent in gut-derived than non-gut-derived cells, and gut-derived Cbir1-reactive T cells expressed more CD73 and FR4 as well as CD52 than non-gut-derived Cbir1-reactive cells. We then hypothesized that epithelial antigen presentation to commensal-reactive cIELs induced anergy. Single cell ATAC sequencing of MHCII$^{\Delta IEC}$ cIELs revealed modest decreases in accessibility of NFAT binding sites compared to cIELs from littermate controls. However, we did not see significant differences in expression of regulatory markers (Foxp3, CD73 and FR4, CD52) or antigen experience markers (CD62L, CD44) by flow cytometry.

Conclusion: Our analysis of gut-derived CD4^{+} T cells suggest that these cells are commensal-reactive and may play a role in peripheral tolerance through induction of anergy or expression of the regulatory marker CD52. These data are in line with our previous work demonstrating that gut-derived T cells help resolve joint inflammation. Ongoing studies will now assess the role of intestinal inflammation on gut-derived T cell function as well as interrogate how these cells gain their function.

Abstract Number: 1654

A Dual Inhibitor of TAK1 and MAP4K2, NG25, Suppresses Cytokine-driven Inflammation in Juvenile Idiopathic Arthritis Synovial Fibroblasts

Meena Afroze Shanta[1] and Salahuddin Ahmed[2], [1]College of Pharmacy and Pharmaceutical Science, Washington State University, Spokane, WA, [2]Washington State University, Spokane, WA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Cytokines & Cell Trafficking (1650–1655)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Chronic synovitis is a hallmark of juvenile idiopathic arthritis (JIA), and synovial fibroblasts are major perpetrators of inflammation and tissue destruction. Thus, we tested the efficacy of NG25, a dual TAK1 and MAP4K2 inhibitor, on IL-1β- or cytokine cocktail-activated JIA synovial fibroblasts (JIASFs) *in vitro*.

Methods: JIASFs were isolated from the synovial fluid aspirated from the knees of de-identified JIA patients. JIASFs (n=3-4) were pretreated with NG25 (0.01–1 μM) followed by IL-1β (10 ng/ml) stimulation for 15 minutes to study the impact on signaling pathways or 24 hours to account for inflammatory or invasive proteins or gene expression. To study the involvement of TAK1 in inducing JIASF aggressive and inflammatory phenotype, the expression of COX-2, podoplanin, IL-6, IL-8, CXCL5, and CCL5 following NG25 treatment was determined by ELISA or Western blotting. The inhibitory potential of NG25 against IL-1β activation was further extended to cytokine cocktail [IL-1β (1 ng/ml), TNF-α (5 ng/ml), and IFN-γ (10 ng/ml)] driven activation of JIASFs. The efficacy of NG25 was further compared with different TAK1 inhibitors (5Z-7-oxozeaenol (5Z), takinib, or HS-276). The statistical value of $p< 0.05$ was considered statistically significant.

Results: NG25 (0.01–1 μM) dose-dependently inhibited IL-1β-induced p-TAK1 at $Thr^{184/187}$ in JIASFs with IC_{50} of 531 nM (n=3, $p< 0.01$), which resulted in downstream inhibition of p-JNK, p-p38, and p-NF-kBp65, but no effect on p-ERK. Western blot analysis showed that NG25 selectively inhibits IL-1β-induced COX-2 expression in a dose-dependent manner (n=4; $p< 0.001$), with no effect on the markers of cell adhesion and invasion (ICAM-1, VCAM-1, and Podoplanin). Evaluation of the conditioned media by ELISA showed a significant and selective inhibitory effect of NG25 on CXC chemokines (ENA-78 and IL-8), IL-6, and MMP-3 production (n=4; $p< 0.001$ at 250 nM). In a wash-out experiment where fresh low-serum media was replaced after 24 h of IL-1β +/- NG25 (1 μM) treatment, the inhibitory actions of NG25 on IL-6, IL-8, and MMP-3 production were sustained for up to 7 days in JIASFs and were superior compared to 5Z (0.25 μM), takinib (10 μM) or HS-276 (10 μM) (n=3; $p< 0.01$). Furthermore, NG25 inhibited the cytokine cocktail (TNFα/IL-1β/IFN-γ)-induced IL-6 (85%), IL-8 (86%), ENA-78 (100%), and MMP-3 (100%) production in JIASFs more efficiently when compared to the other TAK1 inhibitors (5Z, takinib, and HS-276) (n=3-4; $p< 0.01$-0.001). Similarly, NG25 was most effective in the selective inhibition of COX-2 expression, without affecting the expression of VCAM-1, Cadherin-11, or Podoplanin in cytokine cocktail-activated JIASFs *in vitro* (n=4; $p< 0.05$).

Conclusion: Our preliminary findings delineate NG25's potential anti-inflammatory and anti-chemotactic activities in JIASFs. These findings lay a foundation for testing the efficacy of NG25 in animal models of JIA.

Abstract Number: 1655

Aberrant Noncoding RNAs Are Enriched in Extracellular Vesicles and Implicated in Interferon Activation

Sandra Williams[1], Soyeong Sim[2] and Sandra Wolin[2], [1]National Institute of Arthritis, Musculoskeletal and Skin Diseases; National Cancer Institute, Bethesda, MD, [2]National Cancer Institute, Frederick, MD

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Cytokines & Cell Trafficking (1650–1655)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Extracellular vesicles (EVs) are small structures that enclose a variety of nucleic acids. While much of the published work on EV RNA has focused on the role of mRNAs and microRNAs in intercellular communication, these RNAs are a small fraction of the RNA cargoes of EVs (1). RNA surveillance pathways eliminate defective RNAs and are also implicated in maintaining immunological tolerance to host RNA (2). We hypothesized that EVs package defective noncoding RNAs (ncRNAs) as part of a novel RNA surveillance pathway, which may prevent these RNAs from being recognized as foreign and activating an interferon response.

Methods: We generated mouse macrophage RAW 264.7 cell lines that stably express doxycycline-inducible shRNAs against Dis3l2 as well as control nonsilencing shRNAs. Dis3l2 is a ribonuclease that degrades aberrant structured ncRNAs in cytosol. We purified EVs from these cell lines and used a thermostable group II intron reverse transcriptase to make cDNA libraries and sequence RNA from whole cells and EVs, which allowed us to characterize highly structured RNAs that are missed by conventional RNA-Seq.

We also performed conventional RNA-Seq on Dis3l2-depleted cells. To determine effects of preventing exosome packaging, we treated RAW 264.7 cells with pharmacological EV inhibitors and performed Northern blots and qPCR on cellular RNA after drug treatment.

Results: Across multiple classes of RNAs, including small ncRNAs, repeat RNAs, mRNAs, and microRNAs, EVs are enriched for aberrant transcripts. Many aberrant transcripts are further enriched in EVs purified from cells depleted of Dis3l2. We confirmed our sequencing results with Northern blots.

Transcriptomic analysis of Dis3l2-depleted RAW 264.7 cells show a striking Type I interferon signature. Treating cells with an EV inhibitor was associated with cellular accumulation of some of the aberrant RNAs found in EVs, as well as upregulation of interferon-stimulated genes.

Conclusion: Our data implicate EVs in a novel RNA surveillance pathway that competes with other surveillance pathways to purge cells of RNAs that may otherwise activate an interferon response. Thus, EVs may be involved in protecting cells from aberrant activation of innate immune sensors. Such pathways may be important for diseases like systemic lupus erythematosus, where aberrant nucleic acid sensing and an interferon response are implicated in pathogenesis.

Risk of Serious Infection associated with non-TNF biologic initiation after Anti-TNF Use in Older Adults with Rheumatoid Arthritis

Jiha Lee[1], Sofia Pedro[2] and Kaleb Michaud[3], [1]University of Michigan, Ann Arbor, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Health Services Research (1656–1661)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: In older adults with rheumatoid arthritis (RA), anti-TNF therapies are typically used as first-line biologic treatment. However, many patients require a switch to non-TNF biologics due to inadequate response or adverse effects. While the infection risk associated with initial anti-TNF therapy is well-established, less is known about the safety of non-TNF therapies initiated after anti-TNF exposure in this population. This uncertainty is particularly relevant for late-onset RA (LORA), where age-related immune changes and distinct disease characteristics may increase infection risk. This study examines the risk of serious infection (SI) associated with initiating non-TNF biologics after anti-TNF therapy in older adults with RA, comparing outcomes between those with LORA and younger-onset RA (YORA).

Methods: Using data from FORWARD—The National Databank for Rheumatic Diseases (2001–2019), we identified RA patients aged ≥60 years who initiated a non–TNF b/tsDMARD (anakinra, abatacept, JAK inhibitors, tocilizumab, rituximab) following anti-TNF therapy. Patients were categorized as LORA or YORA based on RA diagnosis age (≥60 vs < 60) and propensity score–matched on age at treatment, sex, race/ethnicity, and comorbidities. Those with other rheumatic diseases, cancer, or HIV before the first SI event were excluded. The index date was the first report of subsequent treatment after anti-TNF use. SI was defined as infection requiring IV antibiotics, hospitalization, or resulting in death within 12 months of

Table 1: Baseline characteristics of propensity-score matched older adults with RA and anti-NTNF initiation following anti-TNF therapy use by age of RA diagnosis

	LORA (N=198)	YORA (N=675)	P-value
Age at anti-TNF initiation	74.3 (5.6)	74.2 (6.3)	0.837
Female, %	80.3	79.8	0.900
Non-Hispanic White race/ethnicity, %	96.0	98.5	0.127
Medicare coverage, %	93.9	87.9	0.036
Educational level, years	13.4 (2.3)	14.0 (2.3)	0.011
Annual income, US$1,000	45.8 (29.2)	43.6 (29.2)	0.479
Urban community, %	27.9	20.8	0.100
Disease duration, years	8.9 (4.5)	27.9 (13.0)	<0.01
Past Smoking habits	45.5	50.5	0.3112
RDCI (0-9)	2.0 (1.5)	2.0 (1.5)	1.000
HAQ (0-3)	1.3 (0.7)	1.3 (0.7)	0.780
Pain VAS (0-10)	4.7 (2.4)	4.8 (2.7)	0.673
Global seventy VAS (0-10)	4.7 (2.4)	4.2 (2.4)	0.053
PAS (0-10)	4.4 (2.2)	4.6 (2.1)	0.469
Prior serious infections, %	14.6	25.8	0.006
Ever glucocorticoid use, %	87.4	85.9	0.659
Current glucocorticoid use, %	42.6	39.4	0.513
Long-term GC use pre-index, %	25.8	30.3	0.252
Concurrent methotrexate use, %	60.1	48.5	0.020

Note: Each LORA patient was matched to YORA patients based on age at NTNF initiation, sex, race/ethnicity, and comorbidity burden
*The values are presented as mean (SD) unless indicated otherwise.
Abbreviations: NTNF = non-TNF biologic or targeted synthetic DMARD, LORA = Late Onset Rheumatoid Arthritis; YORA = Young Onset Rheumatoid Arthritis; RDCI = Rheumatic Disease Comorbidity Index, HAQ = Health Assessment Questionnaire; VAS = Visual Analog Scale; PAS = Patient Activity Scale

Table 2: Adjusted HR for risk of serious infection related to subsequent non-TNF b/tsDMARD use after exposure to anti-TNF in older adults with RA

Variable	Adjusted HR	95% (CI)	
LORA	1.26	0.44	3.60
Age group at non-TNF therapy initiation			
60-70	Reference		
70-80	2.11	0.68	6.54
80+	3.83	1.01	14.4
Prior Infections	3.24	1.19	8.85
HAQ disability	6.24	2.45	15.9
Concurrent MTX use	1.17	0.48	2.84
Long-term GC use (time-varying)*	2.62	1.04	6.62
Other NTNF vs ABA	1.33	0.48	3.72

GC = glucocorticoid, NTNF = non-TNF therapy, ABA = Abatacept
*long-term GC use (time-varying) defined as at least 5mg/day prednisone equivalent for 90 consecutive days prior to SI

the index date and was attributed to subsequent therapy if it occurred during treatment or within three months of discontinuation (extended to 12 months for rituximab). SI risk differences were estimated using kernel-weighted, propensity score–adjusted survival models, stratified by RA onset group.

Results: 198 LORA patients were matched to 675 weighted YORA patients. Baseline characteristics after kernel propensity-score matching are summarized in Table 1. Abatacept was the most commonly used non-TNF b/tsDMARD in both groups (49.1% in YORA, 47.7% in LORA), followed by rituximab (22.6% in YORA, 22.2% in LORA). A greater proportion of LORA patients initiated subsequent therapy after only one prior anti-TNF agent compared to YORA (81.5% vs. 68.2%). The crude incidence of SI was 1.4 per 1,000 patient-years in YORA and 2.0 per 1,000 patient-years in LORA. In Cox regression models, the risk of SI was higher with older age groups at non-TNF therapy initiation, prior infection, higher HAQ disability score, and recent long-term GC use (Table 2). The risk of SI did not differ significantly between abatacept and other non-TNF therapies.

Conclusion: Among older adults with RA who initiated a non-TNF b/tsDMARD after anti-TNF therapy, the risk of SI did not differ by RA onset age or by specific treatment regimen (abatacept vs. other non-TNF therapies). However, prior SI, recent long-term GC use, and higher HAQ disability scores were independently associated with increased SI risk. These findings highlight the importance of individualized infection risk assessment when selecting second-line therapies in older adults.

Table 1. Patient characteristics and TNF inhibitor (TNFi) switch counts, n=2112	
Mean age, First TNFi (SD)	36.3 (18.4)
Mean follow-up time, years (SD)	7.1 (5.6)
Female (%)	1275 (60.5)
First documented TNFi (%)	
Etanercept	671 (31.8)
Adalimumab	668 (31.6)
Infliximab- biooriginator	530 (25.1)
Infliximab -biosimilar	140 (6.6)
Certolizumab	67 (3.2)
Golimumab	36 (1.7)
Number of switches between TNFi drugs (%)	
1	1,481 (70.1)
2	418 (19.8)
>2	150 (7.1)

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are cornerstones of autoimmune-disease therapy, yet many patients switch agents because of loss of effectiveness, adverse events, or insurance barriers. Unstructured clinical notes contain the rationale for switching but are costly to review manually. Our objective was to determine whether large language models (LLMs) can automatically identify TNFi-to-TNFi switching and the reasons for switching in real-world practice.

Methods: We conducted a retrospective observational study of de-identified electronic health records (2012-2023) from a single academic center. We defined TNFi-to-TNFi switching as a change from one TNFi to a different TNFi at consecutive encounters and include patients with a TNFi-to-TNFi switch and ≥6 months follow-up. Using a zero-shot prompt, GPT-4-turbo-128k and eight open-source LLMs extracted (1) TNFi stopped, (2) TNFi started, and (3) reason category between: adverse event, anti-drug antibodies, insurance/cost, lack of effectiveness, patient preference, other, or unknown. Performance was assessed on a subset of manually expert-annotated notes with micro-F1 scores.

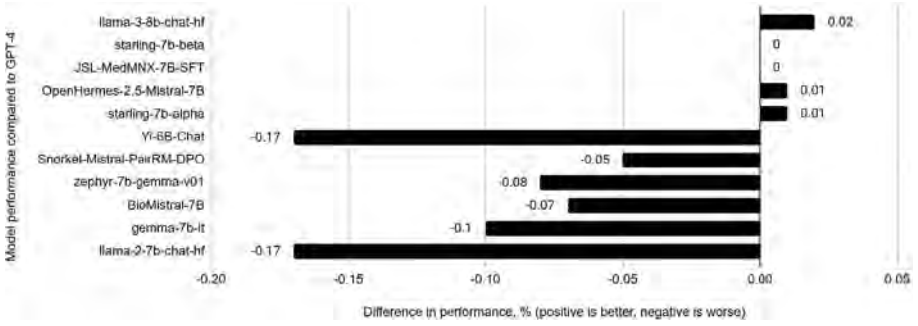

Figure 1. Average win minus loss percentage rates of open-source large language models compared to GPT-4 in identifying started and stopped medication on the manually reviewed note subset. Positive numbers indicate the model is superior to GPT-4 (the model correctly identified a started or stopped medication where GPT-4 did not), negative numbers indicate the contrary.

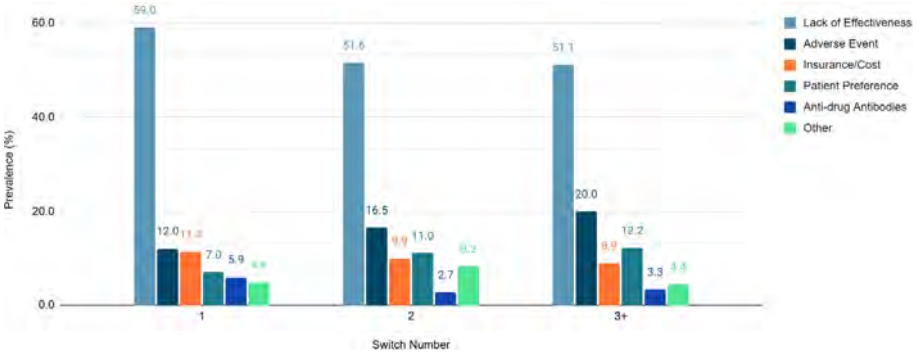

Figure 2. Percentage of identified reasons for switching.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: 2,112 patients met inclusion criteria (Table 1). On the manually annotated subset (n=146), GPT-4 achieved micro-F1 scores of 0.75 for stopped TNFi, 0.80 for started TNFi, and 0.83 for reason extraction. The best open-source models approached GPT-4 for medication identification: Starling-7B-beta (0.88 stopped, 0.79 started) and Llama-3-8B-Instruct (0.82 stopped, 0.75 started). Only Llama-3-8B-Instruct matched GPT-4 for reason identification with F1=0.83. Figure 1 depicts a direct comparison between models. In the first switch, the leading reasons were lack of effectiveness (59%), adverse events (12%), and insurance/cost issues (11%). Subsequent switches showed a higher share of adverse events and patient preference and fewer effectiveness and cost-driven changes (Figure 2).

Conclusion: GPT-4 can extract complex TNFi switching patterns from clinical notes with high accuracy, substantially reducing the need for manual chart review. Several local models offer comparable performance. This capability enables scalable pharmacoepidemiologic studies of treatment lines and could power point-of-care tools that summarize medication histories for clinicians. Further work should evaluate generalizability to other biologic classes and multi-institution datasets.

Cardiovascular Disease Risk and Risk Calculator Performance in Rheumatoid Arthritis-Associated Interstitial Lung Disease

Omair Khan[1], Halie Frideres[2], Punyasha Roul[3], Grant Cannon[4], Gary Kunkel[5], Brian Sauer[6], Joshua Baker[7], Ted Mikuls[1], Bryant England[1] and Tate Johnson[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]UNMC Department of Rheumatology, Omaha, NE, [3]UNMC, Omaha, NE, [4]University of Utah and Salt Lake City VA, Salt Lake City, UT, [5]University of Utah and George E Wahlen VAMC, Salt Lake City, UT, [6]Salt Lake City VA/University of Utah, Salt Lake City, UT, [7]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Health Services Research (1656–1661)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Existing cardiovascular disease (CVD) risk stratification strategies underperform in RA. Lung disease is an established CVD risk factor, and RA-interstitial lung disease (RA-ILD) clinically affects 1 in 10 RA patients. As RA-ILD is not captured by current CVD risk calculators, we evaluated RA-ILD as a risk factor for major adverse cardiovascular events (MACE) and heart failure (HF) in RA, and assessed the performance of the Predicting Risk of cardiovascular disease EVENTs (PREVENT) calculator in RA-ILD.

Methods: We performed a retrospective cohort study of patients with RA and RA-ILD using national Veterans Administration (VA) data (2000-2021). RA patients were identified using ≥2 diagnostic codes, a rheumatologist diagnosis, plus a positive autoantibody or DMARD dispense. RA-ILD was defined at baseline and in follow up, using a validated RA-ILD administrative algorithm (PPV >80%). Cohort entry was the date the RA algorithm was fulfilled or the date of RA-ILD diagnosis (if ILD developed in follow up). Overall CVD, MACE (myocardial infarction, stroke), and HF were identified in VA, Medicare, and National Death Index data. Those with pre-existing MACE or HF were excluded. Cox regression was used to estimate the risk of CVD related to RA-ILD status, adjusted for age, sex, race, BMI, smoking status, CVD risk factors, rurality, and

Table 2. Baseline 10-year CVD risk in RA and RA-ILD according to Predicting Risk of cardiovascular EVENTs (PREVENT) calculator

	RA (N=66,295)	RA-ILD (N=3,620)	p-value
Overall CVD			
Low/Borderline risk (<7.5%)	18,352 (34.3%)	525 (22.2%)	
Intermediate risk (7.5-20%)	24,998 (46.7%)	984 (41.5%)	
High risk (≥20 %)	1,0209 (19.1%)	860 (36.3%)	<0.001
MACE			
Low/Borderline risk (<7.5%)	31,536 (58.9%)	1,045 (44.3%)	
Intermediate risk (7.5-20%)	20,225 (37.8%)	1,047 (44.4%)	
High risk (≥20 %)	1,798 (3.4%)	268 (11.4%)	<0.001
Heart Failure			
Low/Borderline risk (<7.5%)	33,736 (63.0%)	1,060 (44.7%)	
Intermediate risk (7.5-20%)	16,915 (31.6%)	968 (40.9%)	
High risk (≥20 %)	2,908 (5.4%)	341 (14.4%)	<0.001

Abbreviations: RA, rheumatoid arthritis; RA-ILD, rheumatoid arthritis associated interstitial lung disease; CVD, cardiovascular disease; MACE, major adverse cardiovascular events

healthcare utilization. PREVENT variables were queried in the 12 months prior to cohort entry. Estimated 10-year risk of overall CVD, MACE and HF was calculated and PREVENT categories (low/borderline, intermediate, high risk) were described. Calibration (standardized incidence ratios [SIR = observed:predicted event rate]) and discrimination (Harrell's C statistic, sensitivity using cutoff of 7.5%) of PREVENT were compared between those with and without RA-ILD.

Results: We studied 69,915 RA patients (mean age 63, 87% male). Patients with RA-ILD (N=3,620) were more frequently smokers, seropositive, with more traditional CVD risk factors and healthcare utilization. Over 613,200 person-years, 17,713 overall CVD events occurred. The incidence of all CVD outcomes was higher in RA-ILD, as were unadjusted hazards for overall CVD (HR 1.93 [1.81-2.07]), MACE (1.49 [1.37-1.63]), and HF (2.46 [2.26-2.68], **Table 1)**. In adjusted models, the risk of overall CVD (aHR 1.19 [1.11, 1.28]) and HF (1.44 [1.31, 1.58]) persisted, while MACE risk was null in RA-ILD vs. RA without ILD (0.98 [0.90, 1.07], **Table 1)**. A greater percentage of patients with RA-ILD were categorized as high risk (overall

Table 3. Performance of the PREVENT CVD risk calculator in RA-ILD vs. RA without ILD

Table 3. Performance of the PREVENT CVD risk calculator in RA-ILD vs. RA without ILD *

	RA (N=66,295)	RA-ILD (N=3,620)
Overall CVD **		
SIR (95% CI)	2.07 (2.04-2.11)	1.49 (1.37-1.61)
Sensitivity	82.61%	93.09%
Harrel's C statistic	0.64	0.64
MACE		
SIR (95% CI)	2.60 (2.55-2.65)	1.50 (1.35-1.66)
Sensitivity	60.00%	75.88%
Harrel's C statistic	0.62	0.62
Heart Failure		
SIR (95% CI)	1.61 (1.57-1.65)	1.41 (1.27-1.56)
Sensitivity	59.93%	73.24%
Harrel's C statistic	0.67	0.67

*Standardized incidence ratios (SIR) calculated as observed to expected CVD events, based on estimated CVD risk in the PREVENT calculator (SIR > 1 reflecting an underestimation of CVD risk). Measures of discrimination (sensitivity and Harrel's C) calculated using an estimated risk cutoff of 7.5%.

**Overall CVD = Composite of MACE and HF

Abbreviations: RA, rheumatoid arthritis; RA-ILD, rheumatoid arthritis associated interstitial lung disease; SIR, Standardized incidence rate; CI, confidence interval; CVD, cardiovascular disease; MACE, major adverse cardiovascular events; HF, heart failure

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. CVD: 36.3% vs 19.1%; **Table 2**) using PREVENT, which demonstrated improved calibration (overall CVD SIR 1.49 vs. 2.07) and sensitivity (93.1 vs. 82.6%) in RA-ILD vs. RA without ILD (**Table 3**). Harrel's C was similar regardless of RA-ILD.

Conclusion: RA-ILD was associated with higher CVD risk in RA, driven by increased HF risk, possibly due to the effect of pulmonary hypertension and chronic hypoxia on cardiac function. Reflecting a high comorbidity burden, RA-ILD patients were more frequently categorized as high risk by PREVENT, which may in turn improve calibration of PREVENT in RA-ILD. Whether early identification and management of RA-ILD may help mitigate the elevated HF risk observed in RA requires continued research.

Prevalence and Progression of Multimorbidity in Rheumatoid Arthritis-Associated Interstitial Lung Disease

James Fagerland[1], Yangyuna Yang[1], Punyasha Roul[2], Tate Johnson[1], Scott Matson[3], Grant Cannon[4], Brian Sauer[5], Jeffrey Curtis[6], Joshua Baker[7], Ted Mikuls[1] and Bryant England[1], [1]University of Nebraska Medical Center, OMAHA, NE, [2]UNMC, Omaha, NE, [3]University of Kansas, Kansas City, MO, [4]University of Utah and Salt Lake City VA, Salt Lake City, UT, [5]Salt Lake City VA/University of Utah, Salt Lake City, UT, [6]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL, [7]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Health Services Research (1656–1661)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Multimorbidity, the presence of multiple chronic conditions, is common in RA, and the progression of multimorbidity in RA is associated with poor long-term outcomes. However, the burden and progression of multimorbidity in high-risk RA populations, such as those with the extra-articular manifestation of RA-associated interstitial lung disease (RA-ILD), is not well understood. Thus, we evaluated the prevalence and progression of multimorbidity in RA-ILD within the Veterans Health Administration (VA).

Methods: We performed a cohort study of RA-ILD patients using national VA data between 1999 and 2021. RA-ILD patients were identified with validated RA and ILD administrative algorithms (>80% PPV), then followed from the date the RA-ILD algorithm was fulfilled (index date) until death or end of study period. Multimorbidity burden was quantified as the number of conditions present among 43 chronic conditions (based on prior published multimorbidity studies in RA), using diagnostic codes from inpatient and outpatient encounters prior to the index date and throughout follow-up. The prevalence of individual morbidities at baseline and newly developing annually through the end of follow-up was descriptively summarized. Group based trajectory modeling was utilized to derive unique longitudinal trajectories of multimorbidity burden, stratified by tertile of baseline multimorbidity burden (low, moderate, and high). Multimorbidity trajectory group membership was then used to predict respiratory-related hospitalizations (respiratory-related discharge diagnosis in primary position from VA administrative data) in Cox regression models that adjusted for age, sex, race, smoking status, baseline multimorbidity burden, and calendar year.

Table 2: Adjusted hazard ratios for respiratory-related hospitalization among RA-ILD patients by multimorbidity trajectory groups.

Model	aHR (95% CI)
Tertile 1 – low baseline multimorbidity	
Group 3. Rapid multimorbidity progression	1.24 (0.98, 1.57)
Group 2. Moderate multimorbidity progression	1.23 (1.03, 1.48)
Group 1. Slow multimorbidity progression	1 (referent)
Tertile 2 – moderate baseline multimorbidity	
Group 3. Rapid multimorbidity progression	1.60 (1.29, 1.98)
Group 2. Moderate multimorbidity progression	1.30 (1.11, 1.52)
Group 1. Slow multimorbidity progression	1 (referent)
Tertile 3 – high baseline multimorbidity	
Group 3. Rapid multimorbidity progression	1.58 (1.12, 2.24)
Group 2. Moderate multimorbidity progression	1.27 (1.07, 1.51)
Group 1. Slow multimorbidity progression	1 (referent)

Values adjusted hazard ratio and 95% confidence interval from Cox model adjusting for age, sex, race, smoking status, baseline multimorbidity burden, and calendar year. Base rate of respiratory hospitalizations in the slow multimorbidity progression groups were: 10.4/100PY in Tertile 1, 11.8/100PY in Tertile 2, and 16.1/100PY in Tertile 3.

Group numbering corresponds to numbering in **Figure 1**.

Abbreviations: aHR, adjusted hazard ratio; CI, confidence interval

Adjusted hazard ratios for respiratory-related hospitalization among RA-ILD patients by multimorbidity trajectory groups.

Results: We studied 6,232 RA-ILD patients (92.6% male, mean age 69 years) with a mean (SD) of 11.2 (5.3) morbidities at baseline that increased to 13.5 (5.5) over a median follow-up of 5 years. Cardiometabolic, respiratory, and musculoskeletal morbidities were the most frequent and present in most RA-ILD patients by the end of follow-up (**Table 1**). All morbidities increased in prevalence over follow-up, with cardiometabolic and cancer morbidities among those with the greatest increase in prevalence. Trajectory modeling identified 3 multimorbidity trajectories within each tertile of baseline multimorbidity burden representing slow, moderate, and rapid multimorbidity progression during follow-up (**Figure 1**). Within each baseline multimorbidity burden tertile, the rapid (group 3; aHR range 1.24 to 1.60) and moderate (group 2; aHR range 1.23 to 1.30) multimorbidity progression trajectory groups were associated with a higher risk of respiratory-related hospitalization compared to the slow progression group (group 1) (**Table 2**).

Conclusion: Multimorbidity was highly prevalent and progressive throughout the RA-ILD disease course in this national VA RA-ILD cohort. More rapidly progressive multimorbidity trajectories predicted higher risk of respiratory-related hospitalization independent of baseline multimorbidity burden. Together, these findings emphasize the need to monitor and manage multimorbidity in RA-ILD patients to optimize long-term outcomes.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Health Services Research (1656–1661)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Patients with inflammatory rheumatic diseases (IRDs) frequently experience psychological distress, however access to psychological support remains limited. The aim of this trial (DRKS identifier: DRKS00032862) was to investigate the effectiveness of a digital psychological intervention for individuals with IRDs.

Methods: Participants aged 18 years or older were recruited across Germany between February 22, 2024 and June 4, 2024 if they had been diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (PsA), or systemic lupus erythematosus (SLE) and reported psychological distress and reduced quality of life. Participants were randomized to either a self-guided digital psychological intervention or a treatment as usual control condition. The primary outcomes were change in psychological distress (Hospital Anxiety and Depression Scale [HADS]) and quality of life (Assessment of Quality of Life [AQoL-8D]) from baseline to three months. Secondary outcomes included changes in self-efficacy, health literacy, perceived stress, functional impairment, depression and anxiety.

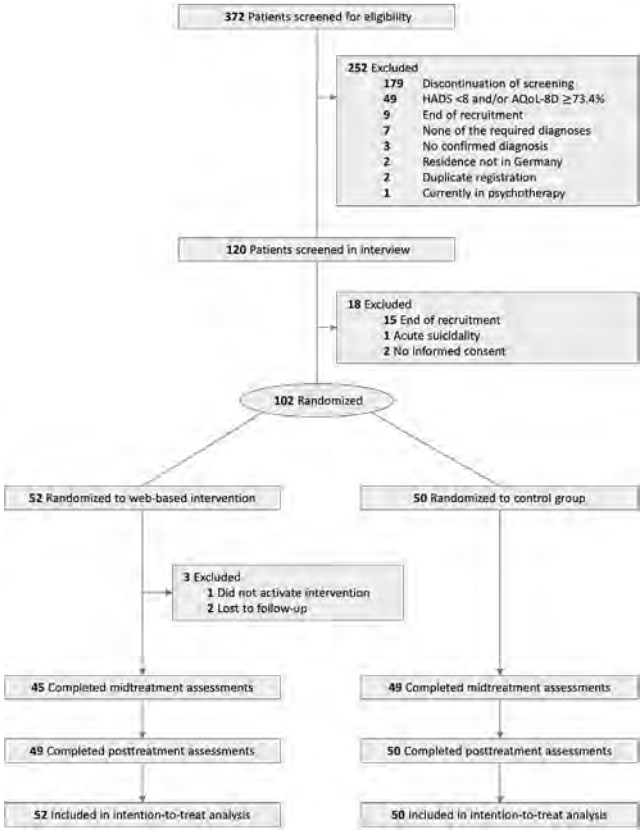

Figure 1. Trial Participant Flow Diagram

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

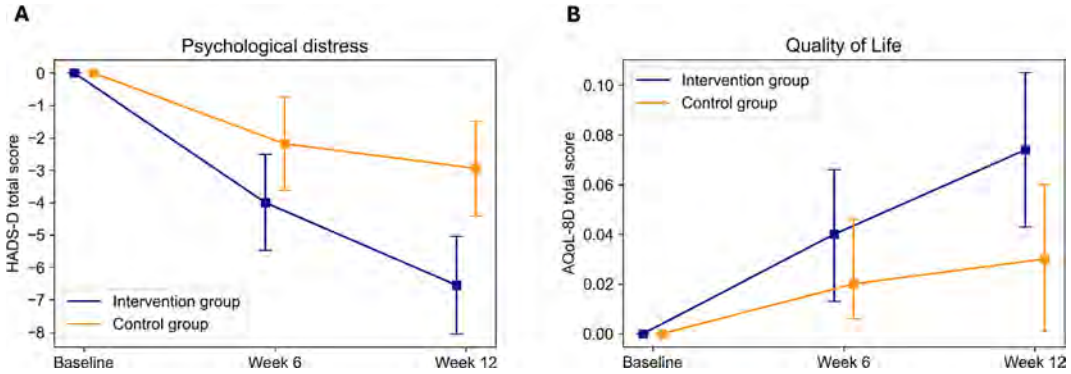

Figure 2. Least-squares Mean Changes of Primary Outcome Measures

Results: A total of 102 participants (mean [SD] age, 47.2 [12.9] years; 92 [90.2%] female; see Table 1) were randomized to the intervention group (n = 52) and the control group (n = 50) (Fig.1). The intervention group showed a significantly greater reduction in psychological distress at the 3-month follow-up (least squares mean difference, −3.60; 95% CI, −5.73 to −1.47; $P < .001$; Cohen's d = -0.71), and a greater improvement of quality of life (least squares mean difference, 0.04; 95% CI, 0.00 to 0.09; $P = .047$; Cohen's $d = 0.49$) (Fig.2). A significantly greater proportion of participants in the intervention group experienced a clinically meaningful improvement in psychological distress (59.2% vs. 34.0%, $P = .016$) and quality of life (55.1% vs 32.0%, $P = .026$) compared to the control group. Secondary outcomes measures showed a similar pattern of improvement, except for functional impairment. No adverse events related to the intervention were reported.

Table 1. Baseline Characteristics (Intention-to-Treat Sample)

Characteristic	Participants, No. (%)		
	Total (N = 102)	Intervention group (n = 52)	Control group (n = 50)
Age, mean (SD), y	47.2 (12.9)	52.4 (12.5)	41.8 (11.2)
Gender			
Female	92 (90.2)	47 (90.4)	45 (90.0)

Conclusion: This randomized clinical trial supports the effectiveness and safety of a digital psychological intervention in individuals with IRDs. These findings suggest that such digital interventions could be a valuable, scalable approach to addressing mental health needs in rheumatology.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Health Services Research (1656–1661)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Remote therapeutic monitoring (RTM) and remote physiologic monitoring (RPM) programs have the potential to capture data between clinical visits and provide information back to providers about the health status of their patients. We evaluated the ability of patient reported outcome (PRO) data coupled with passive biosensor data streams to classify RA low disease activity (LDA).

Methods: We recruited 150 RA patients to a prospective study that captured PRO data and among a subgroup (n=96), wear a Fitbit Versa2 device for approximately 3-4 months at the time that they initiated adalimumab or upadacitinib. Clinical Disease Activity Index (CDAI) was collected at baseline and follow-up. A variety of PROs and passive biosensor activity data were captured at various frequencies.

Various machine learning methods (Distributed RandomForests [DRF], Gradiant Boosting, Generalized Linear Models, Ensemble) were used to classify LDA using only the baseline clinical data plus longitudinal PROs and biosensor data. Models were trained on a random split sample (training/testing) in a 2/3:1/3 ratio. Model building prioritized parsimonious models that minimized the number of PROs that patients were asked to provide (allowing for 3 PROs, at most), de-prioritizing more frequently collected PROs (e.g. daily) and favoring less frequently collected PROs (e.g. weekly, monthly). A scenario that simulated PRO data collection with at half the frequency was modeled to evaluate ML model performance under these conditions, intended to reduce participant burden. The best models were selected based on the F1 statistic (harmonic mean of sensitivity and positive predictive value), and separately, the F1 statistic, requiring a PPV of ≥80%. Confidence intervals were estimated using 1000 bootstrap samples.

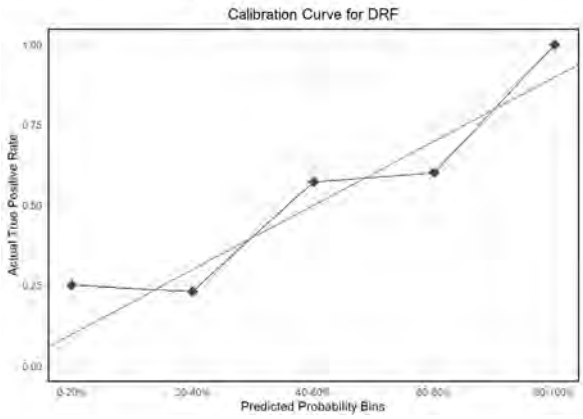
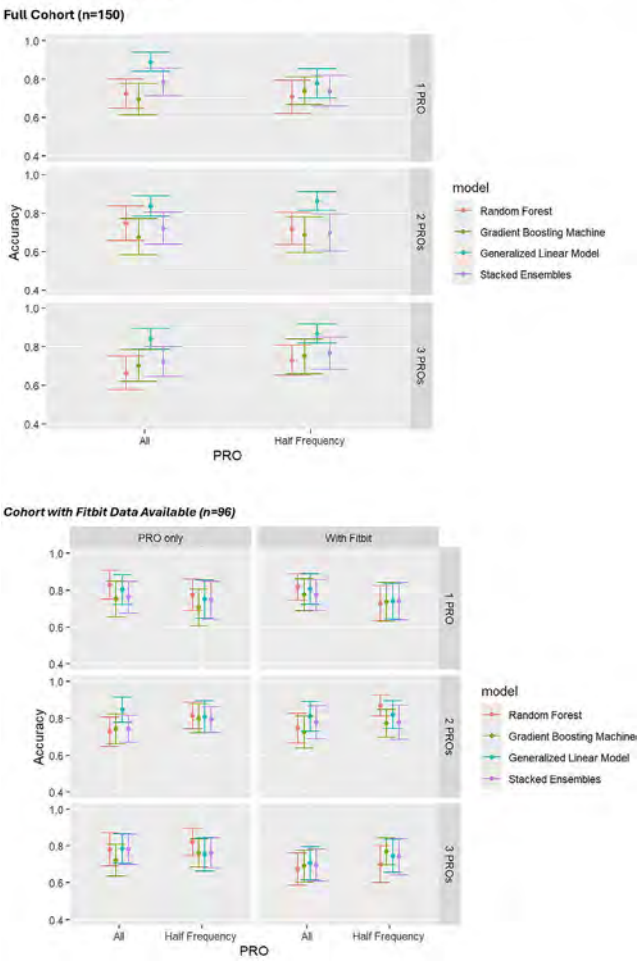
Figure 1: Model Calibration Showing Predicted Likelihood of Low Disease Activity or Remission (CDAI <=10) at Month 3-4 among RA Patients Initiating Upadatacinib and Adalimumab (results shown from testing sample) from Distributed RandomForests machine learning model



23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2: Model Performance to Classify RA Low Disease Activity or Remission at 3 months following Adalimumab or Upadacitinib, Varying the Machine Learning Method, Number of PROs, and Use of Biosensor Data



Results: Characteristics of the RA cohort (Table 1) were: mean (SD) age 52.1(12.0) years, 79.3% female, mean (SD) BMI 31.5 (7.7), mean (SD) baseline CDAI 29.9 (16.4), 64.7% seropositive. Concomitant therapies included NSAIDs (40.7%), glucocorticoids (32.7%), opioids (24.7%) opioids. Prior treatment history: 36.7% were biologic naïve, and 27.3% used exactly 1 biologic. Mean (SD) step count was 6299 (3815) steps and mean (SD) sleep was 6.5 (2.9) hours of sleep.

The most important longitudinal PRO variables included weekly PROMIS Fatigue, PROMIS Pain Interference, and RADAI5. Model accuracy (predicted vs. observed LDA) is shown (Figure 1) and indicated that model calibration was reasonable. Model accuracy exceeded 80% with 1, 2, or 3 PROs, with or without Fitbit biosensor data (Figure 2). Using only half-frequency PRO data capture (e.g. every 2 weeks) did not substantially impair model accuracy. Performance was modestly better if daily PROs plus Fitbit data were used (not shown), albeit at the expense of greater participant burden.

Conclusion: Machine learning can accurately identify RA patients in LDA or remission measured 3-4 months after starting adalimumab or upadacitinib using as few as 1 longitudinal PRO measures collected as infrequently as every 2 weeks. Only small increases in performance were observed when actigraphy biosensor data was added.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II: Models and Mechanisms (1662–1667)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Nerandomilast is a preferential inhibitor of phosphodiesterase 4B with antifibrotic and immunomodulatory properties. The Phase III FIBRONEER-ILD trial in patients with progressive pulmonary fibrosis (PPF) showed that nerandomilast significantly reduced the decline in forced vital capacity (FVC) and had an acceptable safety profile. We explored the efficacy and safety of nerandomilast in the subgroup of patients with autoimmune disease-related interstitial lung diseases (ILDs) (autoimmune ILDs) in the FIBRONEER-ILD trial.

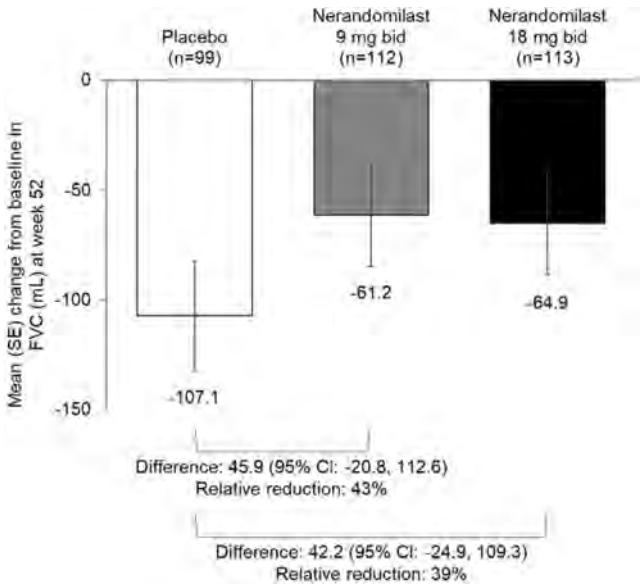

Figure. Change from baseline in FVC (mL) at week 52 among patients with autoimmune ILDs in the FIBRONEER-ILD trial.

Nasopharyngitis	7 (7.0)	15 (13.4)	11 (9.7)
COVID-19	11 (11.0)	8 (7.1)	12 (10.6)
Pneumonia	12 (12.0)	8 (7.1)	9 (8.0)
Condition aggravated	14 (14.0)	6 (5.4)	8 (7.1)
Weight decreased	4 (4.0)	8 (7.1)	15 (13.3)
Decreased appetite	6 (6.0)	4 (3.6)	13 (11.5)
Nausea	4 (4.0)	5 (4.5)	12 (10.6)
Serious adverse event(s)	31 (31.0)	27 (24.1)	41 (36.3)
Adverse event(s) leading to treatment discontinuation	8 (8.0)	5 (4.5)	11 (9.7)

Data are n (%) of patients with ≥1 such adverse event reported over 52-week treatment period or until 7 days after the last dose in patients who discontinued treatment before week 52. *Adverse events (coded based on preferred terms in the Medical Dictionary for Regulatory Activities) reported in >10% of patients in any treatment group in patients with autoimmune ILDs.

Methods: Patients with PPF (excluding idiopathic pulmonary fibrosis) were randomized 1:1:1 to receive nerandomilast 9 mg bid, nerandomilast 18 mg bid, or placebo. PPF was defined using the same criteria as in the INBUILD trial (Flaherty KR et al. N Engl J Med 2019;381:1718-27). Patients taking nintedanib (at a stable dose for ≥12 weeks) or not taking nintedanib (for ≥8 weeks) were eligible to participate. Cyclophosphamide, tocilizumab, mycophenolate, or rituximab were not permitted at enrolment but could be initiated after 6 months to manage worsening systemic disease. Prednisone >15 mg/day (or equivalent) was not permitted at enrolment but could be prescribed during the trial for acute exacerbation of ILD or after 6 months to manage worsening systemic disease. In the subgroup with autoimmune ILDs, we evaluated absolute change from baseline in FVC (mL) at week 52 and adverse events up to week 52. Analyses were pre-specified.

Results: Among 1176 treated patients, 325 (27.6%) had autoimmune ILDs (100 placebo, 112 nerandomilast 9 mg bid, 113 nerandomilast 18 mg bid). At baseline, among patients with autoimmune ILDs, 212 (65.2%) were female, mean (SD) age was 63.4 (11.2) years, FVC was 71.5 (15.0) % predicted, diffusing capacity for carbon monoxide (DLco) was 51.5 (16.8) % predicted; 111 (34.2%) patients were taking nintedanib. The most frequent autoimmune disease diagnoses were rheumatoid arthritis (118 patients [36.3%]), systemic sclerosis (75 [23.1%]), and mixed connective tissue disease (47 [14.5%]). Among patients with autoimmune ILDs, adjusted mean changes in FVC (mL) at week 52 were -107.1 (95% CI: -156.1, -58.0) in the placebo group, -61.2 (-106.9, -15.5) in the nerandomilast 9 mg bid group (difference vs placebo: 45.9 [95% CI: -20.8, 112.6]), and -64.9 (-111.0, -18.7) in the nerandomilast 18 mg bid group (difference vs placebo: 42.2 [-24.9, 109.3]) (Figure). The most frequent adverse event was diarrhea (Table). Adverse events leading to treatment discontinuation were similar across treatment groups.

Conclusion: In the FIBRONEER-ILD trial, the efficacy of nerandomilast on slowing decline in FVC in patients with autoimmune ILDs was consistent with that observed in the overall trial population. Nerandomilast had an acceptable safety and tolerability profile.

Abstract Number: 1663

Tocilizumab for acute exacerbation of rheumatic disease-related interstitial lung disease: A prospective real-world study

Wenwen Xu[1], Yiyangzi Ma[2], Shuang Ye[3] and Qiong Fu[2], [1]Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China (People's Republic), [2]Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, Shanghai, China (People's Republic), [3]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, Shanghai, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II: Models and Mechanisms (1662–1667)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Acute exacerbation (AE) of rheumatic disease-related interstitial lung disease (RD-ILD) is a severe and potentially life-threatening condition, while there remains no clear consensus of evidence-based therapy guidelines. Conventional treatments rely on high-dose corticosteroids and broad immunosuppressants, which carry significant toxicity and variable efficacy. This study aims to evaluate the effectiveness and safety of the interleukin-6 (IL-6) receptor inhibitor tocilizumab in managing AE-RD-ILD.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This prospective observational study enrolled hospitalized AE-RD-ILD patients treated with tocilizumab between January 2023 and May 2024. Retrospective controls were selected from the same institution and period, receiving corticosteroids with or without conventional immunosuppressants (e.g., cyclophosphamide, mycophenolate mofetil). All patients met diagnostic criteria for AE-RD-ILD, including: acute worsening of respiratory distress requiring additional oxygen supply within 1-month, High-resolution computed tomography (HRCT) demonstrating new bilateral ground-glass opacities and/or consolidations superimposed on pre-existing ILD patterns, and confirmed underlying rheumatic disease by clinical and serological criteria. Exclusion criteria included active infections, severe comorbidities (e.g., heart failure), or recent use of interleukin-6 inhibitors. Primary outcome was complete response (CR) at 24 weeks, defined by resolution of dyspnea, radiographic improvement, steroid reduction (≤15 mg/day prednisone equivalent), and survival without severe adverse events or lung transplantation.

Results: A total of 45 patients were included in the analysis (tocilizumab group: n=26; control group: n=19). Baseline characteristics were comparable with no significant differences in median age (62 vs. 63 years, P=0.918) or ILD duration (16 vs. 15 months, P=0.991). Among enrolled patients, 39 (86.6%) met American College of Rheumatology (ACR) classification criteria for defined rheumatic diseases (dermatomyositis: 33, rheumatoid arthritis: 3, systemic sclerosis: 2, ANCA associated vasculitis: 1), while the remaining 6 (13.3%) were diagnosed as undifferentiated connective tissue disease. The tocilizumab group achieved a significantly higher 24-week CR rate of 80.8% (21/26) compared to 10.5% (2/19) in the control group (P< 0.001), with 26% lower cumulative prednisone use (3955 vs. 5375 mg, P=0.017), reduced maintenance doses by 50% (10 vs. 20 mg/day, P< 0.001), fewer new acute exacerbations (3 vs. 8 events, P=0.045), and higher oxygen discontinuation rates (76.9% vs. 5.3%, P< 0.001). Safety outcomes favored tocilizumab, with significantly fewer infections (7 vs. 21 events, P< 0.001) and lower composite mortality/lung transplantation rates (3.8% vs. 31.6%, P=0.034). Subgroup analyses showed consistent benefits across demographics (P for interaction >0.05).

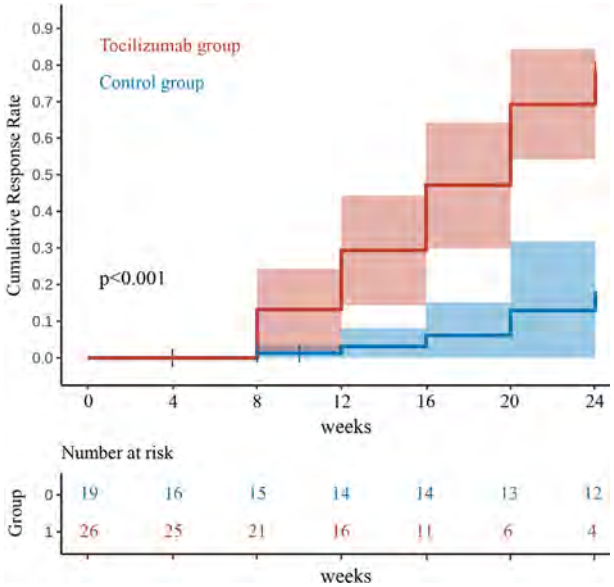

Figure 1. Cumulative response curve for the tocilizumab and control groups within 24 weeks. Direct Standardization adjusted by variables of sex, age, course, PaO2/FiO2, forced vital capacity predicted, baseline immunosuppressive therapy, the maximum daily dose of steroids after AE, anti-fibrotic drugs, B cells, and ILD field. One death and five deaths were censored in the tocilizumab group and control group respectively. The complete response rate was 80.8% (21/26) compared to 10.5% (2/19) (p<0.001). The difference between the response rates for two groups after 8, 12, 16, 20 and 24 weeks were 11.9% (95% CI 0.6-23.3), 26.2% (10.4-42.0), 41.0% (21.5-60.5), 56.3% (32.2-80.5) and 60.3% (31.1-89.5), all P<0.05.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Respiratory Support Parameters & CT Images: Pre-Post Treatment Comparison. B: A 45-year-old male with anti-Jo-1 syndrome ILD. Baseline HRCT showed non-specific interstitial pneumonia (NSIP) pattern with homogeneous ground-glass opacities and spared subpleural parenchyma. After 6 months, acute exacerbation led to respiratory failure with increased ground-glass opacities and diffuse lung involvement without volume loss. After high-dose prednisone and tocilizumab treatment, significant absorption and improvement of pulmonary lesions were observed. C: A 41-year-old female with anti-synthetase syndrome ILD. Baseline HRCT showed NSIP pattern. After 5 months, acute respiratory failure occurred with diffuse ground-glass opacities, consolidation, increased subpleural reticulation, and traction bronchiectasis severity, with volume loss. One-month post-treatment, pulmonary lesions improved.

Conclusion: AE-RD-ILD patients treated with the tocilizumab demonstrated higher CR rate at 24 weeks, reduced steroid requirement, with a favorable safety profile, which support the potential for tocilizumab to addresses the critical unmet need in managing AE-RD-ILD.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Abstract Number: 1664

Cardiac Sarcoidosis Response to Steroid-Sparing Immunosuppression

Alexia Zagouras[1], Sammy Pickell[1], Yuhan Liu[1], Ronald Witteles[1] and **Matthew Charles Baker**[2], [1]Stanford University, Stanford, CA, [2]Stanford University, Menlo Park, CA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II: Models and Mechanisms (1662–1667)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: There are no FDA-approved therapies for cardiac sarcoidosis (CS), a disease associated with high morbidity and mortality. Treatment typically consists of glucocorticoids and off-label use of steroid-sparing immunosuppressive therapies. For over a decade, we have implemented a consistent treatment approach for patients with CS at our institution. Here we report the treatment outcomes of this approach and explore disease-related characteristics associated with first-line treatment failure.

Methods: This retrospective cohort study was conducted utilizing a registry of adult cardiac sarcoidosis patients seen in the Stanford University Cardiology and Rheumatology clinics between 1/1/2011 and 12/31/2024. All patients met the Heart Rhythm Society diagnostic criteria for CS or the Japanese Circulation Society criteria for isolated CS and were treated with a standard protocol (**Figure 1**), consisting of prednisone (20mg-60mg daily) and methotrexate (up to 25mg weekly), followed by the addition of a tumor necrosis factor (TNF) inhibitor for patients who did not have complete resolution of ^{18}F-fluorodeoxyglucose (FDG) uptake on cardiac FDG-positron emission tomography/computed tomography (FDG-PET/CT) on methotrexate alone. Patients were excluded if they did not have at least one follow-up cardiac FDG-PET/CT after treatment initiation. Through manual chart review, we extracted demographics and clinical variables and determined treatment response. Comparisons between methotrexate responders and non-responders were made using Fisher's exact test.

Hispanic	1 (1.8)	0 (0.0)	1 (2.6)
White	46 (80.7)	14 (77.8)	32 (82.1)
Other	1 (1.8%)	0 (0.0)	1 (2.6)
Body mass index, mean (SD), kg/m^2	29.0 (5.2)	29.2 (4.9)	28.9 (5.4)
Other organ involvement, n (%)			
Lungs	25 (43.9)	7 (38.9)	18 (46.2)
Lymph nodes	36 (63.2)	8 (44.4)	28 (71.8)
Eyes	5 (8.8)	2 (11.1)	3 (7.7)
Skin	3 (5.3)	0 (0.0)	3 (7.7)
Liver	7 (12.3)	1 (5.6)	6 (15.4)
Neurological	1 (1.8)	0 (0.0)	1 (2.6)
Other	16 (28.1)	3 (16.7)	13 (33.3)
Number of organs involved, mean (SD)	2.7 (1.5)	2.2 (1.2)	2.9 (1.6)
Baseline LVEF, %			
Mean (SD)	45.4 (14.6)	39.9 (15.9)	47.9 (13.4)
Median [Min, Max]	45.0 [20.0, 70.0]	33.0 [20.0, 70.0]	50.0 [20.0, 70.0]
Baseline PET/CT pattern, n (%)			
Diffuse	4 (7.0)	1 (5.6)	3 (7.7)
Focal	45 (78.9)	17 (94.4)	28 (71.8)
Focal on diffuse	8 (14.0)	0 (0.0)	8 (20.5)
Area of FDG uptake			
Septum	41 (71.9)	13 (72.2)	28 (71.8)
Right ventricle	14 (24.6)	1 (5.6)	13 (33.3)

SD = standard deviation, y = year, kg = kilogram, m = meter, LVEF = left ventricular ejection fraction.

Table 2. Cardiac sarcoidosis treatment characteristics and outcomes.

	Total Cohort (*n* = 57)	Methotrexate Non-Responders (*n* = 39)
Prednisone max dose, mean (SD), mg	42.2 (14.4)	-
Prednisone duration, mean (SD), y	1.4 (3.7)	-
Methotrexate max dose, mean (SD), mg	23.5 (3.0)	-
Methotrexate duration before PET/CT, mean (SD), y	0.6 (0.9)	-
Methotrexate responders, n (%)	18 (31.6)	-
TNF inhibitor, n (%)	-	37 (94.9)
Infliximab	-	28 (71.8)
Adalimumab	-	9 (23.1)
Lost to follow-up	-	2 (5.1)
TNF inhibitor duration before PET/CT, mean (SD), y	-	0.5 (0.7)
TNF inhibitor responders, n (%)	-	36 (97.3)

SD = standard deviation, mg = milligrams, y = year, PET/CT = positron emission tomography/computed tomography, TNF = tumor necrosis factor.

Results: Fifty-seven CS patients were followed for a mean (standard deviation [SD]) of 3.8 (3.0) years. After stopping prednisone, 18 patients (31.6%) on methotrexate monotherapy had complete resolution of FDG uptake on cardiac FDG-PET/CT, and 39 patients (68.4%) had ongoing disease activity. Methotrexate responders were older (66 years vs 62 years), more likely to be female (44% vs 26%), had fewer organs involved by their sarcoidosis (2.2 vs 2.9), and had a lower baseline left ventricular ejection fraction (40% vs 48%) (**Table 1**). Right ventricular involvement was present in only 1 of 18 (5%) methotrexate responders vs 13 of 39 (33%) methotrexate non-responders (p = 0.037). Of the methotrexate non-responders, 37 (95%) were treated with a TNF inhibitor, and all but one patient had a complete response to therapy (**Table 2**).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Treating cardiac sarcoidosis with upfront initiation of methotrexate and a relatively rapid prednisone taper over 28 weeks resulted in complete resolution of FDG uptake in roughly one-third of patients, with two-thirds requiring the addition of a TNF inhibitor; RV involvement was associated with more difficult to treat disease. Our results support the use of methotrexate as a first-line steroid-sparing medication for the treatment of CS, demonstrate the efficacy of TNF inhibitors in methotrexate non-responders, and highlight the need for future studies to further define risk factors for inadequate response to methotrexate.

Comparative Effectiveness of Biologic Versus Conventional Therapy in Uveitis with Systemic Rheumatic Diseases: Real-World Evidence from a Propensity-Matched Cohort

Hanieh Akbari[1] and shahrzad Abdollahi[2], [1]Jefferson Einstein Montgomery Medical Center, Norristown, PA, [2]Jefferson Einstein Philadelpha, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II: Models and Mechanisms (1662–1667)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Uveitis is a vision-threatening manifestation of systemic rheumatic diseases. While conventional immunosuppressants are typically first-line, biologics are often reserved for refractory cases. Long-term real-world data comparing these approaches remain limited.

Methods: We performed a retrospective cohort study using TriNetX, a global database of de-identified electronic health records from 146 healthcare organizations. Adults with non-infectious uveitis and a systemic rheumatic disease were identified using ICD-10-CM codes. Patients were grouped into:

Table 1. Baseline Demographic, Clinical, and Treatment Characteristics of Patients with Rheumatic Disease–Associated Uveitis Before and After Propensity Score Matching

Characteristic	Conventional (Pre-match)	Biologic (Pre-match)	Conventional (Post-match)	Biologic (Post-match)	p-value (Post-match)

Table 2. Comparative Ocular, Procedural, Systemic, and Cardiovascular Outcomes at 1 and 5 Years in Patients with Rheumatic Disease–Associated Uveitis Treated with Biologic versus Conventional Therapy After Propensity Score Matching

Outcome	Conventional (n=2,985)	Biologic (n=2,985)	Risk Ratio (95% CI)	p-value
1-Year Outcomes				
Blindness	2.0%	0.8%	2.57 (1.57–4.20)	<0.001
5-Year Ocular Outcomes				
Blindness	3.8%	2.0%	1.85 (1.39–2.47)	<0.001
Glaucoma	8.3%	4.2%	1.96 (1.58–2.43)	<0.001
Cataracts	8.2%	5.3%	1.53 (1.26–1.86)	<0.001
Macular Edema	3.0%	0.9%	3.46 (2.27–5.27)	<0.001
Uveitis Flares	5.2%	4.1%	0.78 (0.58–1.06)	0.47
5-Year Procedural Outcomes				
Optical Coherence Tomography (OCT)	11.0%	7.2%	1.54 (1.30–1.83)	<0.001
Intravitreal Injection	3.1%	0.9%	3.69 (2.40–5.69)	<0.001
5-Year Systemic Outcomes				
Sepsis	4.1%	1.6%	2.63 (1.84–3.75)	<0.001
Pneumonia	5.5%	3.5%	1.55 (1.20–2.01)	<0.001
Heart Failure	4.3%	1.8%	2.34 (1.66–3.31)	<0.001
Myocardial Infarction	1.8%	1.0%	1.84 (1.17–2.89)	0.008
Major Adverse Cardiovascular Events (MACE)	14.6%	12.3%	1.19 (1.02–1.39)	0.031
All-Cause Mortality	5.8%	2.4%	2.40 (1.84–3.13)	<0.001

Table 3. Subgroup Comparison of Major Adverse Cardiovascular Events and Other Clinical Outcomes Between TNF and JAK Inhibitors in Biologic-Treated Patients with Rheumatic Disease–Associated Uveitis

Outcome	TNF Inhibitors (n=317)	JAK Inhibitors (n=317)	Risk Ratio (95% CI)	p-value
Major Adverse Cardiovascular Events (MAC	3.1%	9.0%	0.34 (0.13–0.86)	0.017
All-Cause Mortality	1.9%	2.5%	0.76 (0.26–2.21)	0.61
Sepsis	1.3%	2.2%	0.59 (0.17–2.05)	0.41
Pneumonia	3.8%	4.4%	0.86 (0.40–1.87)	0.71
Blindness	2.2%	2.8%	0.78 (0.29–2.11)	0.63

(1) a conventional therapy cohort (corticosteroids plus methotrexate, azathioprine, or mycophenolate), and

(2) a biologic therapy cohort (TNF, IL-17/23, or JAK inhibitors).

Patients with infectious uveitis or concurrent use of both therapies were excluded. Among 11,432 eligible patients (6,661 in the conventional cohort; 4,771 in the biologic cohort), 2,985 from each group were matched 1:1 using propensity scores based on demographics, comorbidities, and baseline corticosteroid use. Outcomes were assessed at 1 and 5 years following the index treatment. Primary endpoints included ocular complications, ophthalmic procedures, systemic infections, cardiovascular events, and all-cause mortality. Risk ratios (RRs), 95% confidence intervals (CIs), and p-values were reported. A subgroup analysis compared TNF vs. JAK inhibitors.

Results: The matched cohort had a mean age of 49.7 ± 15.9 years; 59.3% were female. Racial distribution included White (57.2%), Black (22.2%), Asian (6.2%), and Hispanic/Latino (5.6%).

At 1 year, biologics were associated with reduced blindness (0.8% vs. 2.0%; RR 2.57, 95% CI 1.57–4.20; $p< 0.001$), with similar uveitis flare rates (3.2% vs. 2.5%; $p=0.19$).

At 5 years, biologics significantly reduced glaucoma (4.2% vs. 8.3%; RR 1.96), cataracts (5.3% vs. 8.2%; RR 1.53), macular edema (0.9% vs. 3.0%; RR 3.46), and blindness (2.0% vs. 3.8%; RR 1.85) ($p< 0.001$ for all). Procedural use was also lower: optical coherence tomography (7.2% vs. 11.0%; RR 1.54) and intravitreal injections (0.9% vs. 3.1%; RR 3.69) ($p< 0.001$).

Systemic complications favored biologics, including sepsis (1.6% vs. 4.1%; RR 2.63), pneumonia (3.5% vs. 5.5%; RR 1.55), heart failure (1.8% vs. 4.3%; RR 2.34), and all-cause mortality (2.4% vs. 5.8%; RR 2.40) ($p< 0.001$ for all). Cardiovascular

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

events were also reduced: myocardial infarction (1.0% vs. 1.8%; RR 1.84; p=0.008) and major adverse cardiovascular events (MACE) (12.3% vs. 14.6%; RR 1.19; p=0.031).

In a matched subgroup analysis (n=317 per group), TNF inhibitors were associated with fewer MACE events than JAK inhibitors (3.1% vs. 9.0%; RR 0.34, 95% CI 0.13–0.86; p=0.017).

Conclusion: Biologic therapy was associated with significantly improved ocular, systemic, cardiovascular, and survival outcomes in patients with rheumatic disease–associated uveitis, without compromising inflammatory control. These findings support earlier use of biologics in this population. Future prospective studies are needed to validate these associations, refine treatment strategies, and identify subgroups most likely to benefit from targeted biologic therapy.

Abstract Number: 1666

Treatment with Rilzabrutinib was associated with Rapid and Sustained Reduction in Disease Activity in Patients with IgG4-RD Previously Treated or Naïve to B cell Depletion

John Stone[1], Mollie Carruthers[2], Alireza Meysami[3], Matthew Charles Baker[4], Daniela Ghetie[5], Lindsay Lally[6], Fernando Martinez-Valle[7], Lorenzo Dagna[8], nicolas schleinitz[9], Jeea Choi[10], Leda Mannent[11] and Owen Hagino[10], [1]Massachusetts General Hospital , Harvard Medical School, Concord, MA, [2]Vancouver General Hospital, Vancouver, BC, Canada, [3]Henry Ford Health, Detroit, MI, [4]Stanford University, Menlo Park, CA, [5]Oregon Health and Science University, Portland, OR, [6]Hospital for Special Surgery, NEW YORK, NY, [7]Vall d'Hebron Hospital, Barcelona, Spain, [8]IIRCCS San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy, [9]Aix Marseille university, AP-HM, Marseille, France, [10]Sanofi, Morristown, NJ, [11]Sanofi, Gentilly, France

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II: Models and Mechanisms (1662–1667)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: IgG4-RD is a progressive, immune-mediated fibrotic disease with limited treatment options. Rilzabrutinib is a reversible, orally available inhibitor of Bruton's tyrosine kinase (BTKi). Here, we conducted an open label proof-of-concept safety and efficacy study of rilzabrutinib in adult patients with IgG4-RD, stratified by prior rituximab treatment history.

Methods: The study (NCT04520451) included patients with active IgG4-RD whose last dose of rituximab was >6 months prior to screening (or with evidence of B cell reconstitution)[rituximab-experienced] or naïve to rituximab [rituximab-naïve]. During the 4-week screening period, prednisone (20 mg/day to 40 mg/day) was prescribed according to the investigator's assessment of organ(s) involved and level of disease activity . Over the first 4 weeks of rilzabrutinib treatment, prednisone was tapered off and rilzabrutinib continued for up to 52 weeks. Disease activity was tracked with the IgG4-RD Responder Index (RI). Efficacy endpoints included proportion of participants without disease flare (defined as an increase in RI >2 or initiation of rescue treatment with glucocorticoid or immunomodulator), RI Total Activity score (observed and change from baseline) at each visit, and proportion of participants with a reduction in RI Total Activity score ≥2 at each visit.

Results: A total of 27 participants (15 rituximab-experienced, 12 rituximab-naïve) were enrolled. At baseline, 10/15 (67%) rituximab-experienced participants had a history of flaring on treatment, 1 (7%) without response to rituximab, 3 (20%) with adverse reaction to rituximab, and 1 (7%) with prior response to rituximab.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The proportion of participants on rilzabrutinib monotherapy without a disease flare at the end of treatment was 19/27 (70%), and was similar in both the rituximab-experienced subgroup (73%) and the rituximab-naïve subgroup (67%). Rituximab-naïve participants had a higher total activity score at baseline vs rituximab-experienced participants (mean±SD: 15.7±7.6 vs. 10.1±5.7), By Week 12 the total activity scores were 3.0±2.0 (77% reduction from baseline) and 4.3±3.4 (52% reduction from baseline) in the rituximab-naïve and rituximab-experienced groups, respectively. At Week 52, the total activity score (mean±SD) in the rituximab-naïve subgroup was 1.7±1.5 (an 88% reduction from baseline) and 3.1±3.7 (71% reduction from baseline) in rituximab-experienced group. At Week 52, all participants in the rituximab naïve-subgroup and 88% in the rituximab-experienced subgroup had a reduction of >2 points in IgG4-RD RI Total Activity score.

Conclusion: Following withdrawal of oral prednisone, disease activity as measured by the RI Total Activity score declined rapidly, substantially, and was sustained during the 52-week treatment period. Although comparisons are limited by the small sample size, and differences in disease characteristics at baseline, the proportions without flare or rescue and reductions in disease activity were substantial in both the participants who were previously treated with rituximab (including those refractory to rituximab) and naïve to rituximab.

Abstract Number: 1667

Recurrent or Incident Pericarditis With Concurrent Autoimmune Disease: Stable Control With Rilonacept Interleukin-1 Pathway Inhibition

Zachary Daniel[1], Summia Afridi[1], Michael Allen[2] and Khoa Ngo[1], [1]Albany Medical College, Albany, NY, [2]Albany Med, Albany, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II: Models and Mechanisms (1662–1667)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Up to 30% of patients with incident pericarditis will develop recurrent pericarditis (RP), with severe impact on quality of life. More than 20% of these patients have concurrent autoimmune disease, and this subgroup is at particularly high risk for recurrence. RHAPSODY established that IL-1 pathway inhibition with rilonacept is highly effective in preventing episodes of RP for idiopathic or post-pericardiotomy etiologies. This study aimed to investigate the efficacy and safety of rilonacept in the autoimmune RP subgroup.

Methods: This is a single-center retrospective case series of consecutive patients with incident or RP and underlying autoimmune disease who initiated rilonacept at any time between 7/2022 to 1/2024 at an academic tertiary referral center. Patients were included if they met ESC criteria for recurrent, incessant, or incident pericarditis at the time of rilonacept initiation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Patient Characteristics at Rilonacept Initiation

Characteristic	Value
Total number of patients	16
Incessant/incident, n (%)	4 (25.0)
Recurrent, n (%)	12 (75.0)
Demographics	
Age, years old, mean +/-SD	49.6 +/-18.4
Gender	
Females, n (%)	9 (56.3)
Males, n (%)	7 (43.8)
ESC Pericarditis Diagnostic Criteria	
Chest pain, n (%)	16 (100)
Friction rub, n (%)	1 (6.3)
TTE w/ pericardial effusion, n (%)	14 (87.5)
EKG findings, n (% of pts with EKG obtained)	9/12 (75.0)
Cardiac MRI findings, n (% of pts with Cardiac MRI obtained)	1/2 (50.0)
Elevated CRP prior, n (%)	16 (100)
Medications Prescribed	
Aspirin, n (%)	1 (6.3)
NSAIDs, n (%)	7 (43.8)
Colchicine, n (%)	13 (81.3)
Corticosteroids, n (%)	12 (75.0)
Dose in prednisone equiv. (mg/d)	28.2 +/- 24.6
Hydroxychloroquine, n (%)	5 (31.3)
Mycophenolate, n (%)	2 (12.5)

Results: A total of 16 patients were followed for 1.6 (IQR 1.2-2.2) years after rilonacept initiation. Time elapsed from first pericarditis episode to rilonacept initiation was 8.8 (IQR 0.1-19.5) months, with 2.5 (IQR 1-4) prior flares. Sjogren's syndrome was diagnosed in 14 patients, SLE in 2, and sarcoidosis/Sjogren's in 1. Out of 16 patients, 4 had preceding autoimmune disease, diagnosed a median 15 months prior to their first pericarditis episode.

During the RP episode that led to rilonacept initiation, CRP was elevated in 100% of patients to a mean 173.8 +/- 120.4 mg/L. Corticosteroids were used for RP in 12 (75%), and 13 (81%) were treated with colchicine. Additional patient characteristics are described in Table 1. Both patients with SLE were prescribed HCQ and mycophenolate throughout the follow-up period.

The duration of rilonacept treatment was 1.5 (IQR 0.8-2.2) years. No recurrences were observed in patients while on treatment. There were no adverse events related to rilonacept reported to providers during the follow-up period. All 12 patients treated previously with corticosteroids for RP were able to taper entirely off.

A total of 2 patients withdrew from rilonacept prior to data cutoff, one with SLE and one with Sjogren's (range 8.3-9.0 months post-initiation), both due to patient preference. These patients remained recurrence free over a mean 1.2 years of follow-up after discontinuation of rilonacept.

Conclusion: IL-1 pathway inhibition with rilonacept in the autoimmune RP subgroup was associated with complete abrogation of RP episodes. Further research should establish the optimum duration of treatment in the high-risk autoimmune RP cohort, evaluate the safety profile of rilonacept with concomitant DMARD therapy, and assess the efficacy of treatment in a broader spectrum of autoimmune conditions.

Abstract Number: 1668

A Clinically Validated Assay for Rapid Determination of Type I and Type II Interferon Activity in Pediatric Inflammatory Diseases

Evan Hsu[1], Courtney Leson[2], Amrita Basu[3], Michael Lam[4], Jian Yue[4], Casey Rimland[5], Rachel Weng[4], Lauren Henderson[6], Joyce Chang[2], Mary Beth Son[4], Fatma Dedeoglu[4], roshini Abraham[3] and **Pui Lee[1]**, [1]Boston Children's Hospital, Newton, MA, [2]Boston Children's Hospital, Boston, [3]Nationwide Children's Hospital, Columbus, OH, [4]Boston Children's Hospital, Boston, MA, [5]Brigham and Women's Hospital, Boston, [6]Boston Children's Hospital, Watertown, MA

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Pediatric Rheumatology – Clinical I (1668–1673)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Type I interferons (IFN-I) and type II interferon (IFN-g) are essential to host defense but dysregulated production of these cytokines is increasingly recognized in inflammatory diseases. Aberrant IFN-I production is associated with autoimmunity and excess IFN-g is linked to cytokine storm syndromes with T lymphocyte activation. Assays to measure IFN-I and IFN-g are not available in most institutions. We aimed to develop a clinical flow cytometry assay that rapidly captures the activity of IFN-I and IFN-g.

Methods: We compared bulk RNA sequencing data from healthy controls and patients with macrophage activation syndrome (MAS), multisystem inflammatory syndrome in children (MIS-C), and systemic lupus erythematosus (SLE) to identify biomarkers of IFN-I and IFN-g signaling. We developed a flow cytometry assay to measure IFN-inducible markers on

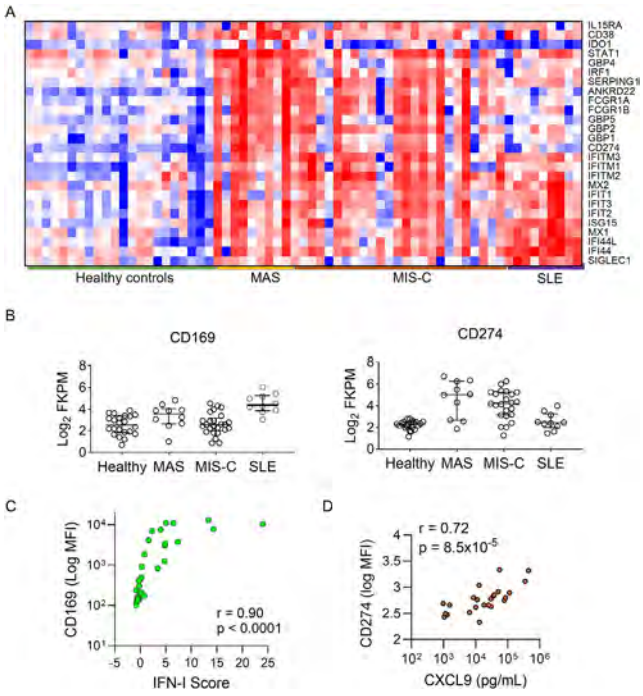

Figure 1. Bulk RNA sequencing data of peripheral blood mononuclear cells from healthy controls and patients with MAS, MIS-C, or SLE. A) Heat map comparing the expression of genes preferentially induced by IFN- (top half) and by IFN-I (bottom half). B) Comparison of CD169 (SIGLEC-1) and CD274 (PD-L1) expression among healthy controls and patient groups. C) Spearman's correlation between CD169 expression and the 28-gene composite IFN-I score in healthy controls and patients with SLE. D) Spearman's correlation between CD274 expression and plasma CXCL9 levels in patients with MAS.

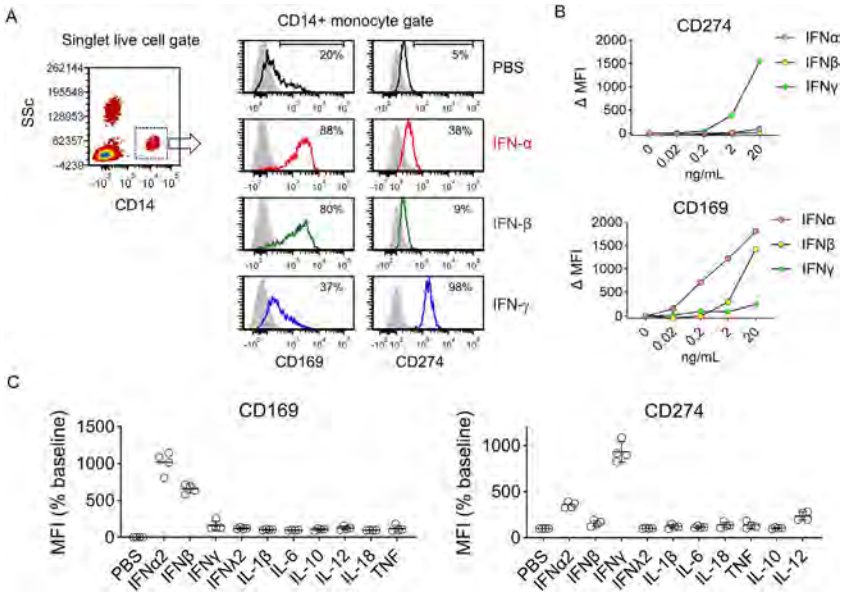

Figure 2. Development of a flow cytometry assay to evaluate IFN activation. A) Gating strategy and representative histograms for evaluation of CD169 and CD274 expression in peripheral blood CD14+ monocytes from a healthy donor with and without IFN stimulation. B) Change in mean fluorescence intensity of CD274 and CD169 expression in response to IFN stimulation at different concentrations. C) Changes in CD169 and CD274 expression on CD14+ monocytes from 4 healthy donors in response to stimulation by different cytokines.

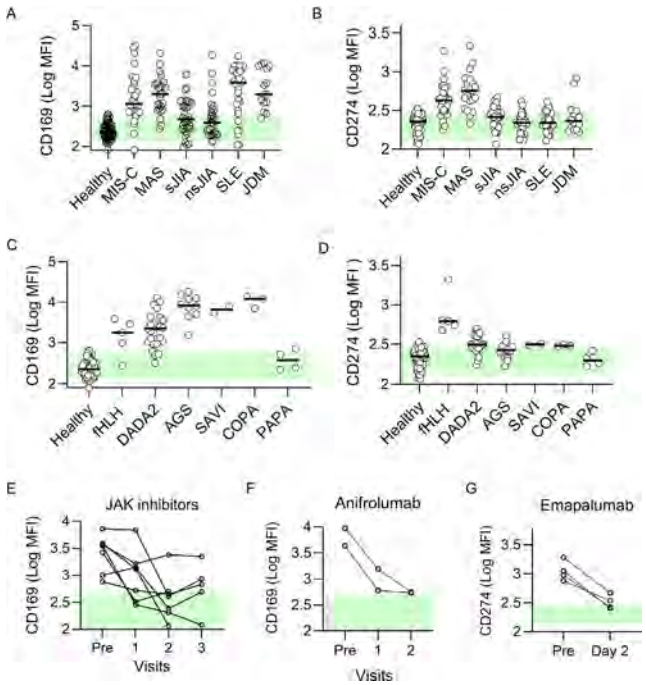
peripheral blood monocytes and acquired data across different pediatric inflammatory diseases. The findings were verified by a clinical laboratory that independently developed and validated this assay for clinical use.



Quantifying IFN-I and IFN- activity in pediatric inflammatory diseases. A) CD169 and B) CD274 expression in healthy controls compared to patients with different inflammatory diseases. C) CD169 and D) CD274 expression in healthy controls compared to patients with familial hemophagocytic lymphohistiocytosis and monogenic autoinflammatory diseases. E) Changes in CD169 expression in patients with Aicardi-Goutières syndrome after treatment with JAK inhibitors. F) Changes in CD169 expression in a patient with SLE and a patient with Singleton-Merten syndrome after anifrolumab treatment. G) Changes in CD274 expression in patients with MAS after initiation of emapalumab. Green area indicates normal range (mean +/- 2 standard deviations) established by the healthy control group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Consistent with previous studies, RNA sequencing data from peripheral blood mononuclear cells identified a strong IFN-I signature in patients with SLE and a strong IFN-g signature in patients with MAS and MIS-C. We found that CD169 (SIGLEC-1) transcript levels positively correlated with the IFN-I signature while CD274 (PD-L1) expression reflected the IFN-g signature (Figure 1). Flow cytometry confirmed that surface expression of CD169 and CD274 on $CD14^+$ monocytes are specific readouts of IFN-I and IFN-g activity, respectively (Figure 2). Based on these findings, we developed a flow cytometry assay to capture CD169 and CD274 expression, which requires 50 μL of whole blood and 30 minutes of hands-on time. We demonstrated the utility of this method for rapid screening of IFN dysregulation in >200 patients with a variety of pediatric inflammatory diseases including MAS, MIS-C, SLE, juvenile idiopathic arthritis, juvenile dermatomyositis, and monogenic autoinflammatory diseases (Figure 3A-D). We further illustrated the use of this test for therapeutic monitoring of recently approved medications that target the IFN pathways including Janus kinase inhibitors, emapalumab (anti-IFN-g), and anifrolumab (anti-IFN α/β receptor; Figure 3E-G). Finally, we outlined the steps of validating this assay for clinical use and summarize the findings during test validation and post-clinical implementation.

Conclusion: We developed a clinically validated flow cytometry test to rapidly assess type I IFN and IFN-g activity. This test is useful for evaluation and monitoring of pediatric inflammatory diseases and can be readily implemented in clinical laboratories.

Provider and Patient/Caregiver Family Priorities in Defining Minimal Disease Activity and Flare in CNO Delphi Survey Results

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is an inflammatory bone disease that can result in bone destruction/deformity, persistent bone pain and pathological fractures. Due to the lack of randomized control trials, treatment is empirical and based on physician experience. Clinical studies to compare treatments require validated definitions of minimal disease activity (MDA) and disease flare. This study aims to develop and validate definitions of MDA and flare in patients with CNO.

Methods: A Delphi survey on priorities for defining MDA and flare was sent to CNO patient/caregivers and CARRA's CNO Workgroup. Based on responses, key parameters from our multisite prospective registry (CHronic nonbacterial Osteomyelitis International Registry, CHOIR) were extracted to create 2 cohorts to define MDA and flare (Table 1). Missing variables

Table 1. Characteristics of Cohorts Used to Develop Definitions of Minimal Disease Activity and Flare in CNO

	MDA Cohort (n=600)	Flare Cohort (n=573)
Age: in years, median [IQR]	12.7 [10.2, 15.1]	12.8 [10.3, 15.1]
Sex (n, %)	Female: 320 (55) Male: 261 (45)	Female: 309 (56) Male: 248 (45)

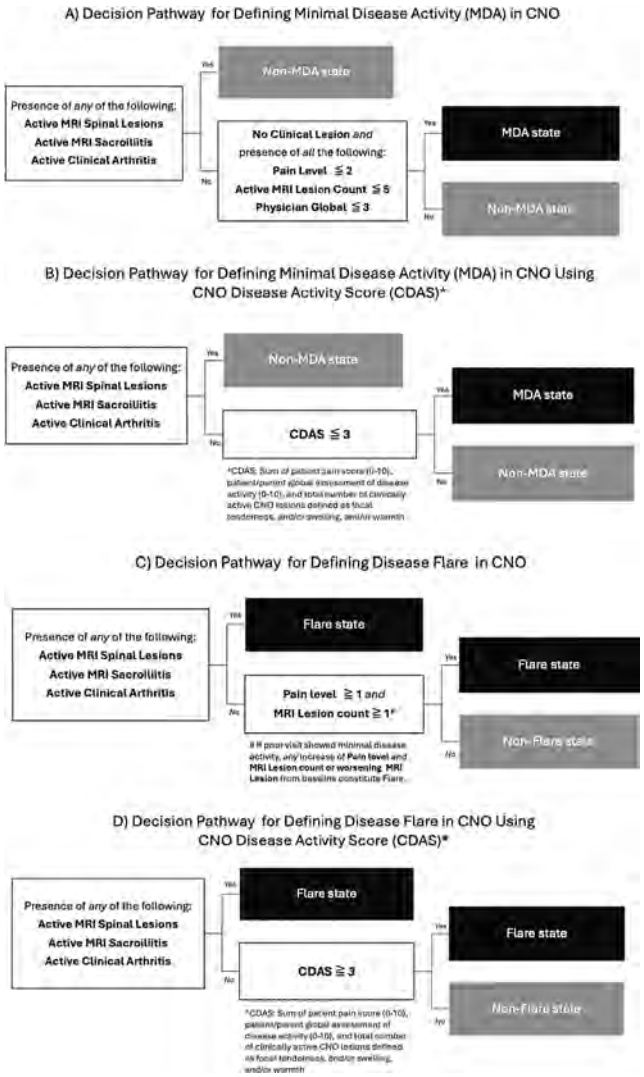

Figure 2. Decision Pathways for Defining Minimal Disease Activity and Disease Flare in CNO

were imputed. A global expert panel of 13 pediatric rheumatologists and 7 patient/caregivers voted on whether a clinical scenario was considered MDA (a single time point assessment) or flare (worsening disease compared to prior visit). Consensus was defined as ≥80% agreement using nominal group technique. A decision tree or ROC analysis were used to determine the cutoff points. The model was validated using 10-fold cross-validation to ensure generalizability.

Results: Results: A total of 252 participants (172 patients/caregivers and 80 providers) completed the survey from 5 continents. Most providers (90%) had >5 years of experience treating children with CNO with ≥5 patients/year. Among patients, 91% were diagnosed within 10 years, 98% had taken medications for CNO and 85% had experienced a flare. Discrepancy was noted among items deemed important for MDA and flare between the 2 groups (Figure 1). Of the MDA cohort, 253 cases were classified by consensus as MDA, 324 as non-MDA, and 23 as inconclusive. Pain level ($p< 0.001$), physician global ($p=0.012$), patient global ($p=0.005$), clinical lesion count ($p=0.001$) and MRI lesion count (< 0.001) were significantly associated with MDA classification. Of the flare cohort, 404 were classified by consensus as flare, 159 as non-flare and 10 were inconclusive. Pain level ($p< 0.001$) and MRI lesion count ($p=0.049$) were associated with flare designation. Cases with presence of either sacroiliitis or spinal lesions on MRI or active clinical arthritis were consistently voted as flare and as non-MDA ($p< 0.001$). The median [IQR] clinical disease activity score (CDAS) was 0 [0,2] in cases with MDA compared to 10 [6, 12] in those without MDA ($p< 0.001$) with a threshold CDAS ≤ 3 for being categorized as MDA. The accuracy of the MDA model without CDAS and with CDAS was 0.77 and 0.89, respectively. The median [IQR] CDAS was 8 [4, 12] in cases

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

with flare, compared to 0 [0, 2] in those without flare (p< 0.001) with a threshold CDAS ≥3 for being categorized as flare.The accuracy of the flare model without CDAS and with CDAS was 0.78 and 0.87 respectively. Decision pathways were developed (Figure 2).

Conclusion: Through Delphi survey and formal consensus techniques, we developed definitions and decision pathways of MDA and flare in patients with CNO proposed as useful targets for future clinical trials.

Abstract Number: 1670

Large Retrospective Cohort Study Of Chronic Recurrent Multifocal Osteomyelitis: Disease Presentation, Clinical, And Laboratory Features

Shima Yasin[1], Shima Yasin[2] and Polly Ferguson[3], [1]King Abdullah Specialized Children's Hospital,Ministry of National Guard Health Affairs, Jeddah, Saudi Arabia, [2]Univeristy of Iowa, Iowa City, [3]University of Iowa Carver College of Medicine, Iowa City, IA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical I (1668–1673)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory bone disease that affects children and adolescents. The disease typically presents with bone pain with or without systemic features. Treatment options for CRMO include non-steroidal anti-inflammatory drugs (NSAIDs), methotrexate, bisphosphonates and TNF inhibitors. To date all presented cohorts were of very small numbers and lack generalizability. We are presenting one of the largest CRMO cohorts, aiming to provide more detailed and generalizable clinical and laboratory features.

Methods: This study was approved by Institutional Review Board. Using retrospective chart review we identified more than 200 subjects with confirmed CRMO seen at our center. Descriptive statistics were used for clinical and laboratory features and chi^2 test for comparison of subgroups.

Results: This cohort consisted of 204 patients, of those 141 (69%) were females, and 63 (31%) were males. Age at onset of symptoms ranged from 3 to 17 years of age. Mean age at onset of symptoms was 8 years and 10 years at diagnosis. This demographic and clinical characteristics of the whole cohort is shown in Table (1). The clinical history of the subjects in this study varied between individuals but many of the characteristic symptoms for CRMO were very similar. All patients presented with bone pain at onset. The average number of sites of bone pain was three, and pain was bilateral in 39%. Pain at night was evident in 43% of patients, and 46% of patients had objective swelling at onset. In total, there were

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Chronic Recurrent Multifocal Osteomyelitis site of involvement in the total cohort and in male and female subgroups.

type of NSAID at some point in their treatment. Most patients were prescribed approximately two medications during their treatment regimen. Each of the medications prescribed for CRMO were divided into groups based on drug class and reported in (Table1).

When assessing location, 170 patients (84%) had evidence of CRMO in the lower body long bones, 29% of patients had spine disease, and 21% had sacroiliac (SI) disease (Figure 1). When comparing males and females, there was not statistically significant difference between males and females in clinical features or site/location (Table 1). Females had a higher percentage of spine, mandible, and clavicle lesions, compared to the males. In contrast, SI disease was more common in males and the difference approached significance at p=0.08, when compared to females (Tabel 1).

Conclusion: CRMO is more likely to be present in females than males and the average age of diagnosis is at approximately 10 years of age. In our study population, lower body CRMO involvement was the most common, and least common in the mandible. Males had higher percentage of sacroiliac disease. There was no significant difference between females and males in demographics or clinical features. Substantial number of patients in the study who had a milder form of CRMO were able to mitigate symptoms with the use of NSAIDs only.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Pediatric Rheumatology – Clinical I (1668–1673)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: MAS is a life-threatening complication of Still's disease characterized by systemic IFNg-driven hyperinflammation. Patients with Still's disease may present with MAS at any disease stage, including at the time of initial diagnosis. MAS episodes may also recur. Emapalumab, an anti-IFNg antibody, achieved sustained control of MAS and facilitated rapid tapering of glucocorticoids (GCs) in a phase 2 pilot study (NCT03311854). This analysis presents data by MAS presentation from an expanded population of patients treated with emapalumab for MAS in Still's disease.

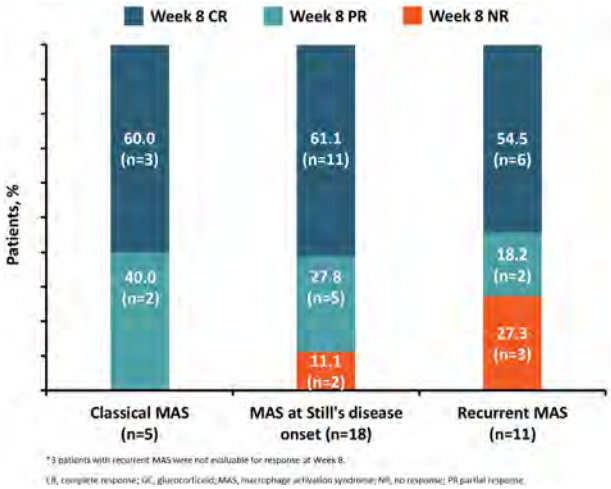

Figure 1. Week 8 responder status* by presentation subgroup amongst patients with MAS in Still's disease with an inadequate response to high-dose GCs

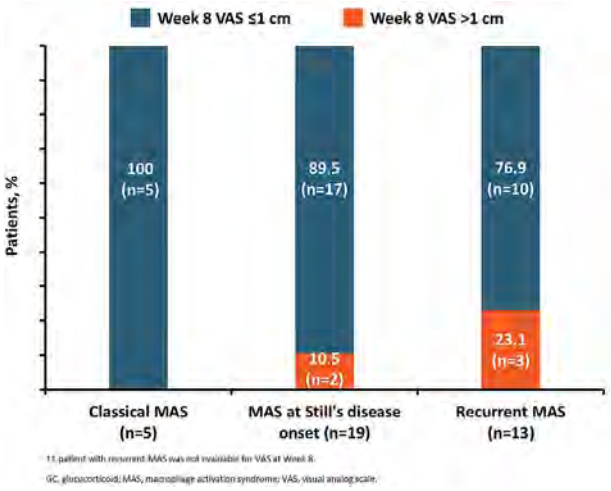

Figure 2. Prevalence of VAS ≤1 cm† at Week 8 by presentation subgroup amongst patients with MAS in Still's disease with an inadequate response to high-dose GCs

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

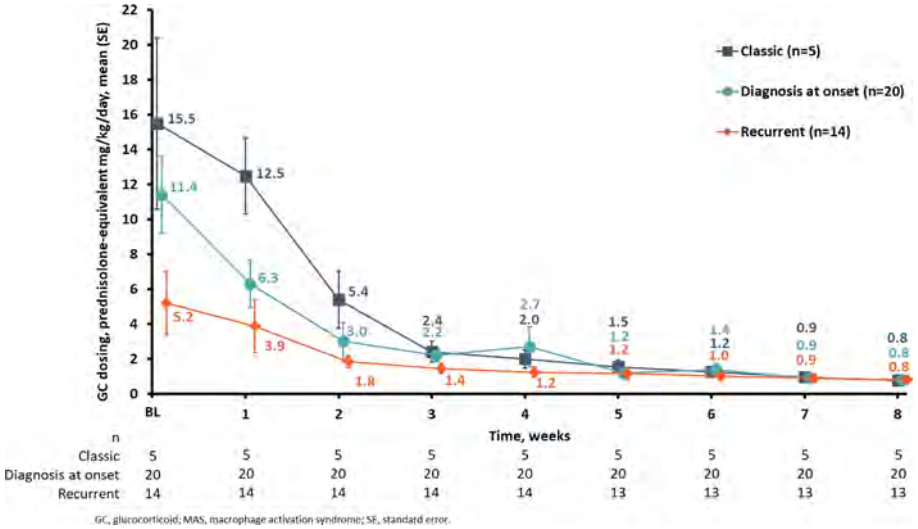

Figure 3. Change in GC dosing over time in patients treated with emapalumab from different MAS subgroups who had an inadequate response to high-dose GCs

Methods: Data were pooled from 2 open-label, single-arm interventional studies (NI-0501-06 [NCT03311854] and NI-0501-14 [EMERALD; NCT05001737]) in patients with MAS in Still's disease who had an inadequate response to high-dose GCs or investigator-assessed rapid worsening of clinical condition and/or laboratory parameters. All patients were administered a loading dose of emapalumab 6 mg/kg via intravenous infusion on Day 1; emapalumab 3 mg/kg was then administered every 3 days from Days 4–16 and twice weekly from Days 17–28 (or longer for insufficient clinical response). The primary efficacy endpoint was complete response (CR) at Week 8 (MAS clinical activity score measured on a 10 cm visual analog scale [VAS] ≤1/10 cm) and normalization of 7 MAS-related laboratory parameters. Partial response (PR) was defined as VAS < 4 cm and normalization of ≥3 abnormal baseline laboratory parameters included in the composite primary endpoint. MAS was classified as classic (first MAS diagnosis secondary to an earlier Still's diagnosis), diagnosed at onset of Still's disease or recurrent. MAS subgroup data was collected prospectively in EMERALD and retrospectively using patient narratives for NCT03311854.

Results: 39 patients were enrolled (31 [79.5%] females), with a median age of 12 years (range, 9 months–64 years). 84.6% of patients received concomitant biologics alone or in combination, mainly anti-interleukin-1 (66.6%) and cyclosporine A (43.6%). Twenty patients (51.3%) had MAS at Still's disease onset, 5 (12.8%) patients had classical MAS, and 14 (35.9%) had recurrent MAS. A higher proportion of patients in EMERALD had recurrent MAS compared with NI-0501-06 (10/25 [40.0%] vs 4/14 [28.7%]) and a lesser proportion had classical MAS (2/25 [8.0%] vs 3/14 [21.4%]). CR (54.5–60.0%) and VAS ≤1 cm (76.9–100%) rates were similar across groups (**Figures 1 and 2**). While the recurrent group had the highest rates of non-responders at Week 8, overall response (OR) rates were still high with 8/11 patients (72.7%) achieving an OR at Week 8 and 10/13 (76.9%) achieving VAS ≤1 cm at Week 8. Changes in GC dosing from baseline to Week 8 were similar across MAS subgroups (**Figure 3**). Emapalumab was well tolerated. One patient with MAS at diagnosis of Still's disease and one patient with recurrent MAS died during the study.

Conclusion: Emapalumab treatment was associated with consistent CR rates of approximately 55–60% among patients with different MAS presentations, who had an inadequate response to high-dose GCs, including patients with recurrent disease. Patients achieving VAS ≤1 cm, changes in GC dosing and safety were also similar across MAS subgroups.

Abstract Number: 1672

Classification criteria, disease phenotypes and long-term outcomes of childhood Sjögren's Disease into adulthood

Coziana Ciurtin[1], Ruby Gotch[2], Hannah Peckham[1], Robert Wilson[2], Muthana AlObaidi[3] and Elizabeth C Jury[1], [1]University College London, London, United Kingdom, [2]University College London Hospital NHS Trust, London, United Kingdom, [3]Great Ormond Street Hospital, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical I (1668–1673)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Childhood Sjögren Disease (cSjD) is a rare clinical phenotype lacking research on long-term outcomes and impact on the quality of life of young people (YP). This study aimed to characterise the natural history of cSjD into adulthood mapped onto the available classification criteria, the adult SjD clinical phenotypes (1) and the Florida Scoring System (FSS)-derived classification for cSjD (2).

Methods: Detailed patient and disease characteristics were collected retrospectively from a single centre, including assessment of disease activity, symptoms severity and damage using validated scores (ESSDAI, ESSPRI and SSDDI). Two paediatric diagnosis criteria, Bartunkova et al.,1999 (3) and Tomiita et al., 2019 (4), as well as the 2016 ACR/EULAR adult classification criteria (5) were tested at disease onset vs. last assessment.

Results: We identified 30 YP with cSjD (F:M=14:1, 60% White), aged 25.8+/-5.2 years, with symptoms onset at age 12.7+/-3.3 years, follow-up 1-25 years (mean 10.5+/-5.4 years), and diagnosis delay of 3 weeks-5 years (**Table**). Manifestations at cSjD onset included: fatigue (73.3%), arthralgia (70%), dryness (56.6%), glandular swelling (33.6%), and skin rashes (30%). All 9 patients with >3 years diagnostic delay had dryness (100% vs. 38% of the ones diagnosed within 3 years, $p< 0.001$). All by one were ANA positive, while 83.3%, 40% and 43.3% were anti-Ro, anti-La and rheumatoid factor positive, respectively. All YP had ultrasound features of sialadenitis at diagnosis and 40% had salivary/lachrymal gland diagnostic biopsies. Three patients were diagnosed with lymphoma (10%), all within 3 years from diagnosis. All patients were treated with hydroxychloroquine, 19 with various cDMARDs, 7 with rituximab, one with belimumab and 3 with cyclophosphamide. At the last assessment, the median ESSDAI was 2 (IQR 2-8), median ESSPRI was 5.33 (IQR 3-7); 17 (56.6%) cSjD patients had damage due to decreased saliva/tear secretion, and 3 (10%) experienced teeth loss. At the time of diagnosis compared to last assessment, 12(40%) vs. 20(66.6%) fulfilled the ACR/EULAR criteria, 9(29%) vs. 14(46.6%) fulfilled the paediatric Bartunkova criteria and 12(40%) vs. 19(61.2%) had at least a 'probable' diagnosis of cSjD based on Tomiita criteria. At the last assessment, 36.6% had 'high' vs. 30% 'low symptoms burden', while 26.6% had 'dominant pain' and 6.66% 'dominant dryness with fatigue' symptoms. At presentation, 56.6% patients could not be mapped onto any of the FSS-derived clusters as they presented with either 'high' or 'low symptoms and positive tests', reflecting their longer diagnosis delay compared to the cSjD cohort used for the FSS classification.

'Definite' or 'Probable' diagnosis (Tomlits algorithm, 2021)	12 (40%)	19 (61.2%)
Mapping onto the paediatric FSS-derived categories at diagnosis N (%)		
Dryness with positive tests	8 (26.6%)	Not applicable
High symptoms with negative tests	5 (16.6%)	
Low symptoms with negative tests	1 (3.33%)	
Unclassifiable as presented with either 'high' or 'low symptoms', but found with 'positive tests'	17 (56.6%)	
Mapping onto the NSST-derived adult clinical phenotypes N (%)		
High symptom burden	Data not available at diagnosis	11 (36.6%)
Low symptom burden		9 (30%)
Pain dominant with fatigue		8 (26.6%)
Dryness dominant with fatigue		2 (6.66%)

Legend: ACR – American College of Rheumatology; AZT – azathioprine; cSjD – Childhood onset Sjögren Disease; EULAR – European Alliance of Associations for Rheumatology; F – females; FSS – Florida Scoring System; H – hydroxychloroquine; M – males; MMF – mycophenolate mofetil; MTX – methotrexate; N – number; NSST – Newcastle Sjögren Stratification Tool.

Conclusion: This unique longitudinal cohort analysis revealed differences between cSjD and adult SjD clinical phenotypes, and poor performance of the FSS for cSjD classification at presentation. Almost 2/3 patients could not be initially classified/diagnosed by any of the available criteria, and 1/3 still could not be classified even after 10 years of follow-up. These findings highlight the critical need for adequate classification/research in cSjD, characterised by early damage accrual and 10% risk of lymphoma in this unique adult cohort.

Is Transient Synovitis of the Hip preclinical Juvenile SpA ? A follow-up study

Anirudh Bandu[1], Michal Cidon[2] and Michael Weisman[3], [1]CHLA, Los Angeles, NJ, [2]Children's Hospital of Los Angeles, Los Angeles, CA, [3]Cedars-Sinai Medical Center, LOS ANGELES, CA

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Pediatric Rheumatology – Clinical I (1668–1673)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Transient synovitis (TS) of the hip is considered a common, self-limited condition in the pediatric population. However, recurrences can occur; these may signal an early manifestation of enthesitis-related arthritis (ERA) or

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Juvenile Spondylarthritis (SpA). We conducted a retrospective chart review study that identified the initial visit of all coded transient synovitis cases from 2002 to 2022 and attempted to contact these patients by telephone. The study goal was to determine, through direct interview, whether these patients had recurrent disease and subsequent clinical features indicative of early juvenile spondylarthritis (SpA) or enthesitis-related arthritis (ERA).

Methods: Data collected from the initial chart review included demographics and details from the initial ED visit. A follow-up by telephone interview obtained data on the recurrence of transient synovitis, chronic back pain (lasting > 6 weeks), joint pain, and physician diagnoses such as Enthesitis Related Arthritis, Juvenile SpA, or related conditions after obtaining consent.

Results: A Total of 184 charts were analyzed after review to determine the accurate diagnosis of transient synovitis; 74 patients (40%) were successfully contacted. The demographics and clinical features of the 74 contacted were no different from those of the 110 who were unable to be contacted. [Refer to Figure 1] One third of the contacted patients reported recurrent transient synovitis; these subjects exhibited significantly higher rates of musculoskeletal pain compared to those with non-recurrent transient synovitis. Chronic back pain was reported in 41.7% of the recurrent transient synovitis group vs. 0% of the non-recurrent group ($p < 0.001$). Chronic peripheral pain was present in 66.7% in the recurrent group vs. 8.0% in the non-recurrent group (OR 21.6, 95% CI: 5.3–113.0, $p < 0.001$). Combined chronic peripheral and back pain was present in 75.0% in the recurrent group vs. 8.0% in the non-recurrent group (OR 31.8, 95% CI: 7.5–176.9, $p < 0.01$). Pain localized to hips, knees, and ankles was significantly more common in recurrent cases ($p < 0.005$). Absence of pain was strongly associated with the non-recurrent group (92.0% vs. 33.3%, $p < 0.001$). [Refer to Figure 2]

Conclusion: Recurrent transient synovitis may be an early indicator of Juvenile SpA or Enthesitis Related Arthritis. In our retrospective cohort, one-third of transient synovitis cases reported recurrence of transient synovitis. Of those who reported

No TS Recurrence versus TS Recurrence

recurrences, a substantial number of participants also indicated additional symptoms that are concerning for a developing enthesitis related arthritis or Juvenile SpA such as chronic back pain and lower extremity pain. Recurrent transient synovitis may signify an important precursor to Juvenile SpA or enthesitis related arthritis and potentially be considered a risk factor. These findings support the need for ongoing follow-up with pediatric rheumatology. A future prospective study would be necessary to establish a diagnosis of Enthesitis Related Arthritis or Juvenile SpA in individuals who experienced recurrent transient synovitis.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Treatment I: Preventative and Novel Treatments (1674–1679)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Individuals with elevations of serum anti-cyclic citrullinated peptide (anti-CCP) antibodies are at-risk for rheumatoid arthritis (RA). Identification of interventions to prevent RA in anti-CCP-positive individuals is a current priority. Hydroxychloroquine (HCQ) has been used in such individuals without supporting clinical trial data. We conducted a phase 2, randomized, double-masked, placebo-controlled, parallel group trial to evaluate the efficacy and safety of a 12-month course of HCQ to prevent clinically apparent RA (clinical RA) by 36 months. We previously reported results from interim analyses (ACR Convergence abstract 1604); this current report presents the final clinical trial results.

Methods: Individuals at-risk for RA with anti-CCP3 ≥2 times the upper limit of normal (ULN) were assigned to receive HCQ or placebo for 12 months, with up to 24 months of post-drug follow-up. The primary outcome was the development of clinical RA at 36 months. Clinical RA was defined using the 2010 ACR/EULAR RA Classification Criteria with a score of ≥6, or a joint examination with RA-like synovitis with ≥1 erosion identified via x-ray imaging of the hands, wrists, and feet. Evaluation for clinical RA was triggered by the presence on physical examination of ≥1 joint with RA-like synovitis. Secondary outcomes included safety, development of inflammatory arthritis (IA)(≥1 joint with RA-like synovitis), and participant-reported joint symptoms.

Results: Of 144 randomized participants, 71 were assigned to HCQ and 73 to placebo (Table 1). In the modified intent-to-treat population, clinical RA occurred in 21 of 69 (30.4%) participants in the HCQ group and 24 of 73 (32.9%) in the

CI=Confidence Interval; HCQ=Hydroxychloroquine; max=Maximum; min=Minimum

Note: Percentages are based on the number of participants with evaluable data

[1] Participant-reported joints assessed were hand (proximal interphalangeal joints and metacarpal phalangeal joints), wrist, elbow, shoulder, hip, knee, ankle (including subtalar joint and calcaneonavicular joint) and foot (metatarsal phalangeal joints) joints on both sides

[2] Participant-reported joints assessed were hand (proximal interphalangeal joints and metacarpal phalangeal joints), wrist and foot (metatarsal phalangeal joints) joints on both sides.

[3] Difference in medians is calculated as HCQ - Placebo. Confidence intervals (CIs) for the differences in medians were calculated using bootstrap resampling.

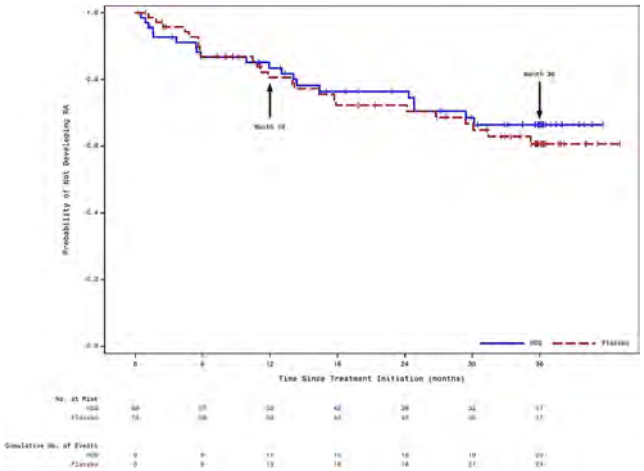

Figure. Development of clinical rheumatoid arthritis. Shown is the Kaplan-Meier based survival estimates of not developing clinical rheumatoid arthritis (clinical RA) in the modified intention-to-treat population. Tick marks indicate censored data. The number of participants at risk for development of clinical RA and the cumulative number of events in each group at each time point is given below the graph. Arrows indicate Month 12 and Month 36. In the modified intent-to-treat population, clinical RA occurred in 21 of 69 (30.4%) participants in the HCQ group and 24 of 73 (32.9%) in the placebo group. The Kaplan-Meier derived risk of clinical RA at 36 months was 0.336 with HCQ and 0.394 with placebo (difference -0.058; 95% confidence interval -0.336 to 0.220; P=0.52).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

placebo group. The Kaplan-Meier derived risk of clinical RA at 36 months was 0.336 with HCQ and 0.394 with placebo (difference -0.058; 95% confidence interval -0.336 to 0.220; P=0.52) (Figure). Results for IA were similar. The occurrence and severity of joint symptoms were not observed to differ between groups (Table 2). Adverse event incidence was similar between groups.

Conclusion: In this randomized, placebo-controlled trial involving individuals with anti-CCP3 levels ≥2 times the ULN, a 12-month course of HCQ was not effective in reducing rates of clinical RA at 36 months. No differences were observed between groups in the development of IA or symptoms. These findings demonstrate that this duration of HCQ is not beneficial to prevent clinical RA in similar populations. Moreover, given that there are costs and potential toxicities of HCQ the findings of this trial should inform the care of similar populations. Funded by the National Institute of Allergy and Infectious Diseases; ClinicalTrials.gov NCT02603146.

Session Title: Abstracts: Rheumatoid Arthritis – Treatment I: Preventative and Novel Treatments (1674–1679)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: A substantial number of patients with rheumatoid arthritis (RA) experience treatment failure, incomplete response, or intolerance to TNFis (TNFi-IR). Neuroimmune modulation using an implantable neurostimulator device to

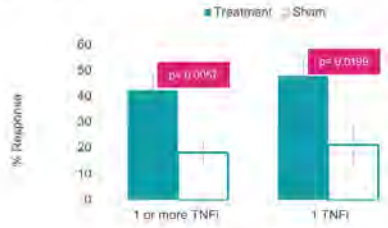
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

electrically stimulate the left cervical vagus nerve is an emerging therapeutic approach for such patients. We present a TNFi-IR subgroup analysis from the RESET-RA study (ClinicalTrials.gov, NCT04539964).

Methods: RESET-RA is a randomized, double-blind, sham-controlled study that enrolled 242 patients at 41 sites in the U.S. with moderate to severe RA, and an inadequate response or intolerance to at least 1 prior biological or targeted-synthetic DMARD. All patients were implanted with an integrated neurostimulator device and randomized 1:1 to receive either active stimulation (treatment) or sham. The primary endpoint of ACR20 response was assessed at 3 months. After 3 months, all patients crossed over to receive active stimulation during an open-label follow-up period, with results reported through 12 months. A subgroup analysis for patients only having prior exposure to TNFi therapies was performed to assess efficacy outcomes, including ACR20/50/70 response, improvement in disease activity, and adjunctive drug use in combination with stimulation.

Results: 124 patients (67 treatment; 57 sham) had exposure solely to TNFi therapies prior to enrolling. 83 (67%) had inadequate response or intolerance to 1 prior TNFi, 31 (25%) to 2 prior TNFis, and 10 (8%) to ≥3 prior TNFis. Baseline characteristics were well-balanced with mean age 55.5 years, 85.5% female, RA duration 11.7 years, 14.4 tender joints, 9.9 swollen joints (28 joint count), 5.3 DAS28-CRP, and 36.5 CDAI. ACR20 response at 3 months showed a statistically significant difference between treatment 42.4% (28/66) vs. sham 18.2% (10/55) (p=0.0057). ACR20 response at 3 months for patients with prior exposure to just 1 TNFi was even higher, with treatment 48.0% and sham 21.2% (p=0.0199) (**Figure 1**). ACR responses improved further through 12 months (**Table 1**). Other endpoints such as mean change in tender and swollen joint counts, DAS28-CRP and CDAI LDA/remission rates also favored the treatment group at 3 months and further improved through 12 months (**Figure 2**). Augmentation of therapy with a b/tsDMARD in combination with stimulation was allowed without restriction following the 3-month, controlled portion of participation. Therapy augmentation with a b/tsDMARD occurred in 7%, 11%, and 13% of all patients at months 6, 9, and 12, respectively. For treatment patients only receiving

Figure 1: ACR20 Response Rates at Month 3



ACR20 response rates for treatment and sham groups for patients exposed to 1 or more TNFi therapies (left) and exposure to 1 TNFi therapy (right) at 3 months. Patients were imputed as non-responders if missing or rescued with high-dose steroids or b/tsDMARDs.

Table 1: ACR Response Rates from 3-12 Months

	Month 3		Month 6			Month 9			Month 12		
	Treatment	Sham	Treatment	Sham - Crossover	All	Treatment	Sham - Crossover	All	Treatment	Sham - Crossover	All
ACR20	42.4% (28/66)	18.2% (10/55)	54.7% (29/53)	50.0% (25/50)	52.4% (54/103)	51.9% (28/54)	60.0% (27/45)	55.6% (55/99)	60.0% (27/45)	51.2% (22/43)	56.7% (49/88)
ACR50	16.7% (11/66)	7.3% (4/55)	28.3% (15/53)	24.0% (12/50)	26.2% (27/103)	27.8% (15/54)	28.9% (13/45)	28.3% (28/99)	37.8% (17/45)	34.9% (15/43)	36.4% (32/88)
ACR70	6.0% (4/66)	1.8% (1/55)	17.0% (9/53)	6.0% (3/50)	11.7% (12/103)	13.0% (7/54)	13.3% (6/45)	13.1% (13/99)	15.6% (7/45)	14.0% (6/43)	14.8% (13/88)

ACR response rates for treatment group for patients exposed to 1 or more TNFi therapies at 3, 6, 9, and 12 months. Patients were imputed as non-responders if missing or rescued with high-dose steroids or b/tsDMARDs up to 3 months. Month 6, 9, and 12 results exclude patients that augmented stimulation therapy with high-dose steroids or b/tsDMARD.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2: Disease Activity and Mean Change in Joint Counts through Month 12

DAS28-CRP LDA/remission rates (A), CDAI LDA/remission rates (B), mean change in the number of tender joints (C), and mean change in the number of swollen joints (D) shown at 3, 6, 9, and 12 months. Patients imputed as non-responders if missing or rescued with high-dose steroids or b/tsDMARDs up to 3 months. Month 6, 9, and 12 results exclude patients that augmented stimulation therapy with high-dose steroid or b/tsDMARD.

stimulation (i.e., non-augmented), ACR20/50/70 response rates at 12 months were 60%, 38% and 16% respectively, with 52% and 49% achieving LDA or remission per DAS28-CRP and CDAI scores, respectively.

Conclusion: In a population of RA patients previously treated with only TNFi therapies, neuroimmune modulation using an implantable device to stimulate the left vagus nerve had statistically significant and clinically meaningful improvements in efficacy at 3 months, with durable improvements through 12 months. Neuroimmune modulation provides a differentiated, non-pharmaceutical treatment option for RA in patients with inadequate response to TNFi therapy.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Treatment I: Preventative and Novel Treatments (1674–1679)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: We assessed the safety and efficacy of UPA versus ADA from SELECT-COMPARE through 7-years.

Methods: Patients with RA and an inadequate response to MTX were randomized 2:2:1 to UPA 15 mg once daily, placebo(PBO), or ADA 40 mg every other week, with patients receiving background MTX. For < 20% improvement in tender or swollen joint counts at weeks 14, 18, or 22, or failure to achieve CDAI low disease activity (LDA) by week 26, patients were switched from PBO or ADA to UPA, or from UPA to ADA. All remaining on PBO switched to UPA at week 26. Safety was evaluated by exposure-adjusted event rates of treatment-emergent adverse events (TEAEs) per 100 patient-years up to 7 years (cutoff: September 19, 2024) for all patients receiving ≥1 dose of UPA or ADA. Efficacy through ∼7 years was evaluated based on as observed data by treatment sequence on achievement of low disease activity (CDAI≤10) and remission (CDAI≤2.8), and DAS28(CRP) ≤3.2 and < 2.6.

Results: 1,629 patients (PBO, N=651;UPA, N=651; ADA, N=327) were randomized and treated. At 7 years, 820 patients remained on UPA or ADA (continuous UPA,n=216; PBO to UPA,n=338; continuous ADA, n=82; ADA to UPA, n=80;UPA toADA, n=104). UPA was generally well tolerated, displaying similar rates of overall TEAEs and most adverse events of special interest when compared to ADA (Figure 1). Most adverse events of special interest, such as MACE, VTE, and malignancies excluding nonmelanoma skin cancer (NMSC) occurred at similar rates for both treatments; UPA showed numerically higher rates of herpes zoster, creatine phosphokinase elevation, NMSC, lymphopenia, and hepatic disorders than ADA. Disease activity targets showed consistent achievement over 7 years, with >88% of patients receiving continuous UPA or ADA achieving CDAI LDA and/or DAS28(CRP) ≤ 3.2 at week 372. Generally similar proportions of patients receiving continuous UPA vs continuous ADA achieved CDAI remission and DAS28(CRP) < 2.6 over time. Numerically greater proportions of patients who switched from ADA to UPA after inadequate initial response achieved CDAI and DAS28(CRP) targets compared to those who switched from UPA to ADA. Evaluating efficacy responses by NRI, recognizing the limitation of applying NRI over long-term, randomized UPA showed greater efficacy than ADA at week 372 with higher rates of CDAI LDA (31.2% vs 23.5%), CDAI remission (21.8% vs 13.1%), DAS28(CRP) ≤ 3.2 (28.7% vs 20.8%), and DAS28(CRP) < 2.6 (26.4% vs 16.8%) (all comparisons, nominal P < .05).

Conclusion: The UPA safety profile at 7 years remained consistent to previous findings with no new safety concerns. Treatment with continuous UPA and ADA resulted in stable maintenance of disease activity targets over 7 years. In patients with an early insufficient response to their original treatment who switched to the alternate therapy, those who were switched from ADA to UPA showed numerically greater efficacy than those who switched from UPA to ADA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Treatment I: Preventative and Novel Treatments (1674–1679)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose:

While conventional synthetic DMARDs (csDMARDs) remain first line therapy in early RA, most patients do not achieve sustained remission, and a subgroup develop difficult-to-treat RA (D2TRA). More effective remission induction is achieved with first line biologic DMARDs (bDMARDs), which have a comparable safety profile to csDMARDs in clinical trials. Falling treatment costs through biosimilar use further support the health economic argument for first line bDMARD, particularly for anti-TNF drugs. Beyond early remission induction, it is important to assess whether first-line bDMARDs improve long-term outcomes compared with csDMARD treat-to-target approach.

Methods:

An Inflammatory Arthritis cohort was used to identify DMARD-naive early RA patients treated with an anti-TNF as first-line induction therapy for 12 months as part of a clinical trial. Early RA patients who received usual care with treat-to-target csDMARDs were used as controls. All patients had ≥5 years follow-up. Outcomes at 5 and 10 years were categorized as: 1) drug free remission, 2) csDMARDs only, 3) single bDMARD, 4) failure of bDMARD class or 5) failure of ≥2 mechanisms of actions (MoA) of b/tsDMARDs (EULAR D2TRA criterion #1 [1]). Rates of sustained remission (DAS28 or clinician-documented remission for ≥6 months) and time to first bDMARD were evaluated. Analyses used multinomial and binary logistic regression and Wilcoxon rank-sum test.

Results: 114 anti-TNF induction patients and 228 matched controls with RA, diagnosed between 2007-2015, were included. Baseline characteristics were similar between groups (Table 1). All cases that satisfied "failure of ≥2 MoA b/tsDMARDs" also fulfilled all three criteria of the EULAR definition for D2TRA. At 5 years, only 0.9% were D2T in the anti-TNF group compared to 7% in the controls (OR 0.11, p=0.033) (Table 2). Rates of drug free remission were also significantly higher in the anti-TNF group compared to the controls at 5 years (13.2% vs 6.1%, OR 2.25, p=0.049). Eighty-eight percent of all patients had 10-year follow-up data available. The differences in rates of D2TRA and drug free remission at 10 years were no longer apparent. However, a significantly higher proportion of patients who received anti-TNF induction therapy were on single bDMARD at 10 years compared to the csDMARD controls (27.7% vs 12.5%, OR 2.64, p=0.006). Sustained remission was more frequent in the anti-TNF group compared with controls at 10 years (62% vs 45%, adjusted OR 1.91, p=0.014). The median adjusted time to require escalation to biologic therapy was 52.5 months in the anti-TNF group compared to 39.3 months in the control group (p=0.019).

Table 1. Baseline characteristics

	csDMARD (n=228)	Anti-TNF (n=114)	p-value
Female n (%)	176 (77%)	78 (68%)	0.106
Age (years) Median (IQR)	51.0 (44.0-63.0)	50.0 (40.2-62.0)	0.073
Seropositivity* n (%)	180 (79%)	86 (75%)	0.550
Symptom Duration (months) Median (IQR)	6.0 (5.0-9.0)	6.0 (4.0-8.0)	0.103
Baseline DAS28-ESR Median (IQR)	4.48 (3.77-5.25)	4.52 (4.01-5.50)	0.221

csDMARD: conventional synthetic disease modifying anti-rheumatic drug, TNF: tumour necrosis factor, IQR: interquartile range, DAS28-ESR: disease activity score in 28 joints using erythrocyte sedimentation rate
*Anti-cyclic citrullinated peptide antibody and/or rheumatoid factor positive

Table 2. Clinical outcomes at 5 and 10 years

	5 Years				10 Years			
Clinical Outcome	csDMARD n=228 % (n)	Anti-TNF n=114 % (n)	OR (95% CI)	p-value	csDMARD n=208 % (n)	Anti-TNF n=94 % (n)	OR (95% CI)	p-value
Drug Free	6.1% (14)	13.2% (15)	2.25 (1.00–5.07)	***0.049***	10.1% (21)	12.8% (12)	1.39 (0.60–3.21)	0.441
csDMARD only	66.2% (151)	57.9% (66)	-	-	52.9% (110)	43.6% (41)	-	-
Single bDMARD	15.4% (35)	22.8% (26)	1.73 (0.94–3.18)	0.080	12.5% (26)	27.7% (26)	2.64 (1.33–5.24)	***0.006***
Failure of single bDMARD	5.3% (12)	5.3% (6)	1.08 (0.38–3.07)	0.885	13.9% (29)	9.6% (9)	0.68 (0.28–1.62)	0.381
Difficult to treat RA	7% (16)	0.9% (1)	0.11 (0.01–0.84)	***0.033***	10.6% (22)	6.4% (6)	0.72 (0.27–1.97)	0.527
Sustained Remission	54.4% (124)	64.0% (73)	1.54 (0.96-2.50)	0.079	45.2% (94)	61.7% (58)	1.91 (1.15-3.22)	***0.014***

csDMARD; conventional synthetic disease modifying anti-rheumatic drug, TNF; tumour necrosis factor, OR; odds ratio, CI; confidence interval, bDMARD; biological disease modifying anti-rheumatic drug, RA; rheumatoid arthritis

Conclusion: These data suggest first line anti-TNF induction therapy in RA is associated with better long-term outcomes compared with treat-to-target csDMARD approach with favourable health economic data. Fewer than 1% of anti-TNF treated patients were D2T at 5 years. Furthermore, fewer anti-TNF treated patients required ≥2 bDMARDs at 10 years and a higher proportion achieved sustained remission. This real-world study further highlights the potential benefits, including costs, to be realised from adopting routine first line bDMARD use in early RA.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Treatment I: Preventative and Novel Treatments (1674–1679)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Clinical trials aimed at delaying or preventing rheumatoid arthritis (RA) in individuals at risk have been published with variable results. In the APIPPRA study, 52 weeks of treatment with abatacept reduced rates of progression to RA, effects sustained beyond the treatment period. The aim of this study was to capture long term outcomes in the ALTO study to establish whether one year of abatacept treatment prevents or delays the onset of RA in subsequent years.

Methods: APIPPRA was a phase IIB randomised, controlled trial recruiting 213 ACPA+$^{-}$ individuals with inflammatory arthralgia but no clinical synovitis. Participants were randomised to receive 52 weekly subcutaneous injections of placebo (n=103) or 125mg abatacept (n=110) and followed up for a further 52 weeks. All study participants deemed eligible and randomised to the APIPPRA study were invited to participate in the follow up study. The primary endpoint was the time to development of either clinical synovitis in ^{3} 3 joints, RA according to ACR/EULAR 2010 criteria, or time to first treatment with disease modifying anti-rheumatic drugs, whichever was met first. Primary endpoints were evaluated after stratifying for serum autoantibodies defined at the APIPPRA baseline visit. Secondary endpoints included multiple disease activity assessments. Severe adverse events and events of special interest were recorded.

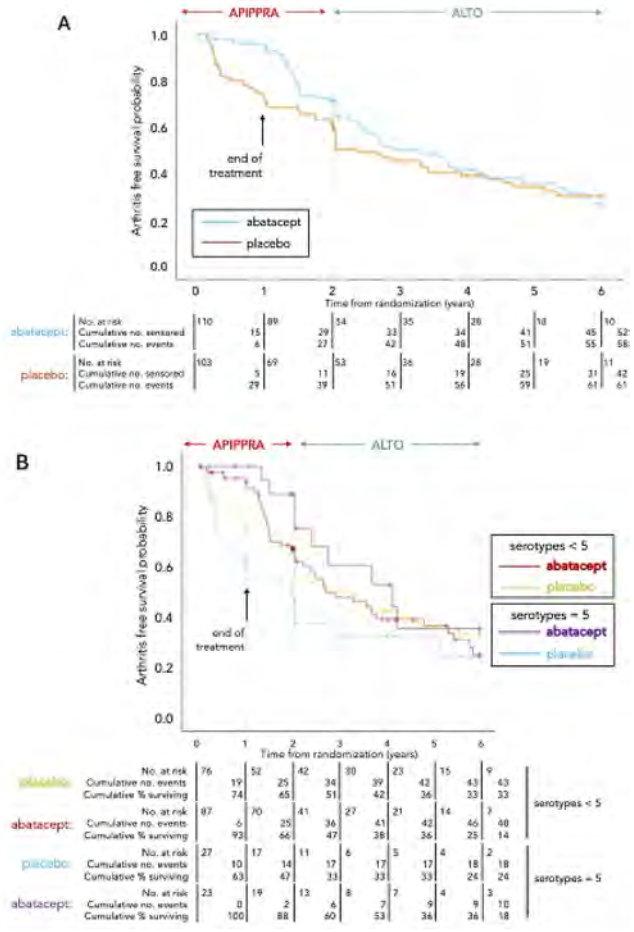

Figure 1: Kaplan-Meier arthritis-free survival curves by study arm for the combined APIPPRA and ALTO study periods for the intention to treat population (A) and stratified by baseline autoantibody status (B).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Between 26th April 2021 and 31st January 2023, 143 enrolled in ALTO; 71 randomised to abatacept and 72 to placebo. Median follow up time was 66 months (Q25-Q75: 54 – 78). At the end of follow up, there were 119 primary outcome events. By the end of the first year after randomisation, the cumulative Kaplan-Meier proportion with arthritis was 29% in the placebo arm and 6% in the abatacept arm. At the end of 2 years these were 40% and 30%, and at the end of the third and fourth years, differences between arms were 4% and 2% respectively (Figure 1A). Differences in restricted mean arthritis-free survival time up to 2 years were 3.3 months (95% CI 1.4 – 5.3; p=0.001), up to 3 years 4.4 months (95% CI 1.1 – 7.8; p=0.008), and up to 4 years 5.0 months (95% CI 0.38 – 9.8; p=0.039). Differences were no longer sustained at 5 years. Stratifying by baseline IgG ACPA levels the cumulative proportion with arthritis after 2 years was 49% in the placebo arm compared to 27% in the abatacept arm in those with levels □ 340 IU/ml; by 4 years it was 67% and 59% for placebo and abatacept, respectively. For those with an extended serotype (IgG and IgA ACPA, anti-carbamylated protein antibodies, anti-acetylated protein antibodies and RF, designated 5 serotypes), the cumulative proportion with arthritis was 53% for placebo and 12% for abatacept after 2 years, and 67% and 47% by the end of 4 years of follow up, differences sustained to 6 years (Figure 1B). There were 5 SAEs in those randomised to the abatacept arm and one in the placebo arm; none were deemed related to study drug.

Conclusion: Interception with abatacept for one year delays progression to RA for up to 4 years. Those at highest risk of progression have a more mature autoantibody response and are sensitive to T cell co-stimulation modulation. RA interception with abatacept is well tolerated, with no new safety signals emerging during follow up.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Rheumatoid Arthritis – Treatment I: Preventative and Novel Treatments (1674–1679)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: The management of Rheumatoid Arthritis (RA) has markedly advanced, enabling the achievement of disease control and remission. Nevertheless, a proportion of patients remains refractory to multiple therapies. These individuals have recently been included in the newly proposed Difficult-to-Treat (D2T) RA classification. As this concept gains traction, ongoing research is increasingly aimed at identifying the determinants of treatment resistance across bDMARDs mechanisms of action, including patient characteristics and treatment trajectories. In this study, we aimed to estimate the probability of progressing to D2T RA within our RA UCLouvain cohort and assess whether the initial choice of b- or ts-DMARDs influences this risk.

Methods: Retrospective analysis recording clinical, laboratory, radiologic, and treatment data from the first consultation available through all b/tsDMARD treatments until the last and at becoming D2T visit. Kaplan-Meier analyses and subgroup comparisons were performed based on diagnosis era and treatment strategies.

Table 1A-B. A) Comparisons of Demographic and Clinical Characteristics Between D2T and Non-D2T RA Groups B) Comparison of Clinical Characteristics in D2T RA Patients Diagnosed Before and After 2000 Legend: Values are presented as mean ± SD or % (n), unless otherwise indicated. Abbreviations: ACPA, anti-citrullinated protein antibody; RF, rheumatoid factor; DAS28, 28-joint Disease Activity Score; HAQ, Health Assessment Questionnaire; D2T RA, difficult-to-treat rheumatoid arthritis; csDMARD, conventional synthetic disease-modifying antirheumatic drug; b/tsDMARD, biological or targeted synthetic DMARD; SD, standard deviation; ns, non specified.

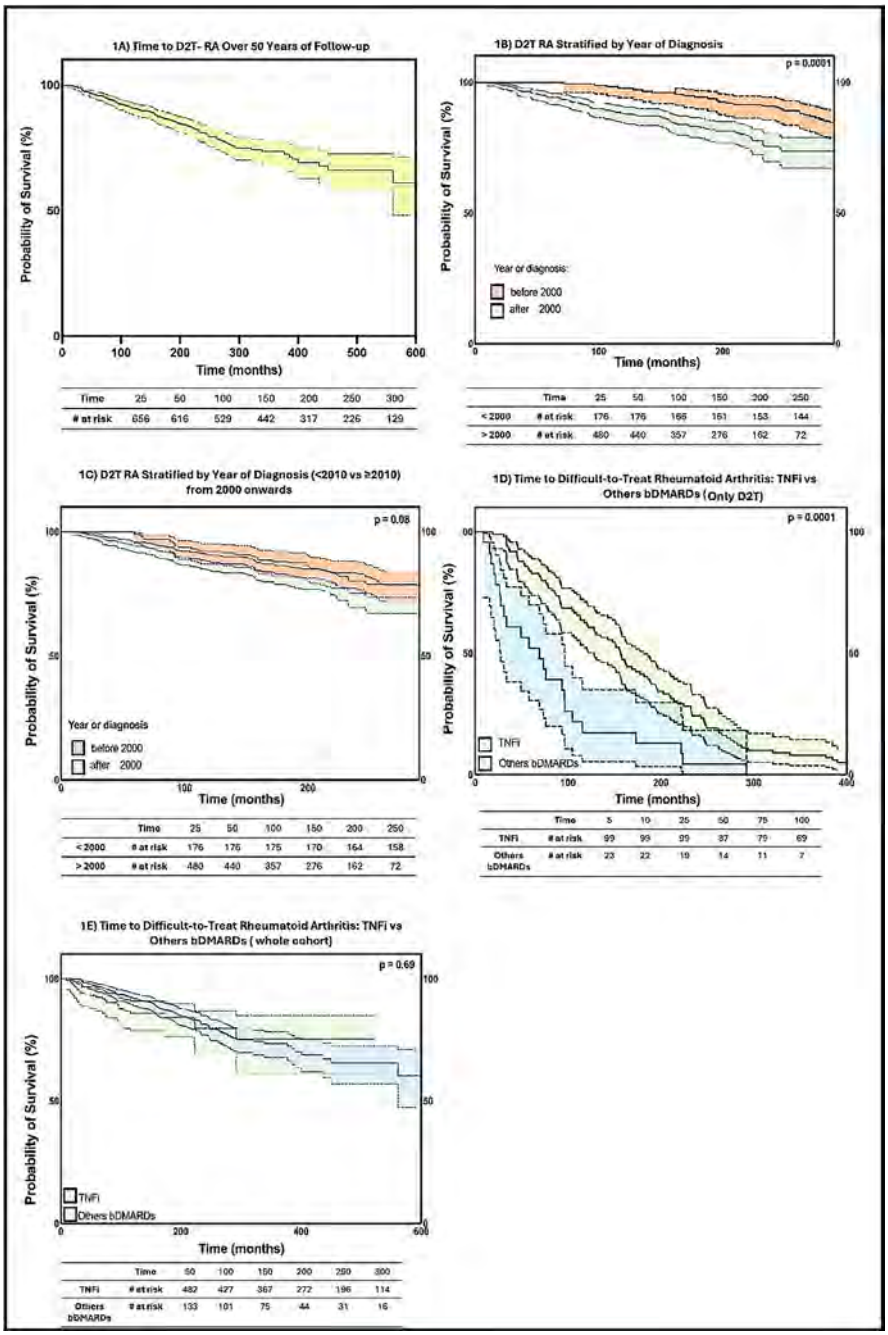

Figure 1. Progression to D2T Rheumatoid Arthritis Over Time (Kaplan–Meier Curve) Legend: Keplen – Meier curve analysis (Outcome = Becoming D2T) for: 1A) Whole cohort up to 50 years of follow up; B) Whole cohort stratified for years of diagnosis (before or after 2000); C) Whole cohort stratified for years of diagnosis (before or after 2000) without considering medical history before year 2000; D) Time to difficult to treat stratified for first line of therapy only including D2T patients; E) Time to difficult to treat stratified for first line of therapy (whole cohort).

Results: We included 675 RA patients [M/F, 158/517], with a median duration of follow-up of 217.1 ±9.8. months. 126 (18.7%) RA patients fulfilled the D2T RA definition. As shown in Table 1A, compared to non-D2T patients, the D2T group was diagnosed at a younger age (p=0.032) and had higher functional impairment (HAQ: 1.60 ± 0.12 vs. 1.30 ± 0.04; p = 0.004), and were more frequently exposed to corticosteroids before b or tsDMARD initiation (82.8% vs. 63.8% ;p< 0.001). Kaplan-Meier curves (Figure 1A-E) showed a progressive decline in D2T-free survival. Patients diagnosed after 2000 had earlier access to b or tsDMARDs (p < 0.001) (Table 1B), but D2T rates remained similar, suggesting that earlier treatment did not fully mitigate risk (Figure 1C). Treatment pathway (Figure 2A) revealed frequent transitions between mechanisms of action, particularly from anti-TNF to IL-6 and JAK inhibitors, reflecting a pattern of therapeutic escalation typical of D2T RA. A heatmap

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

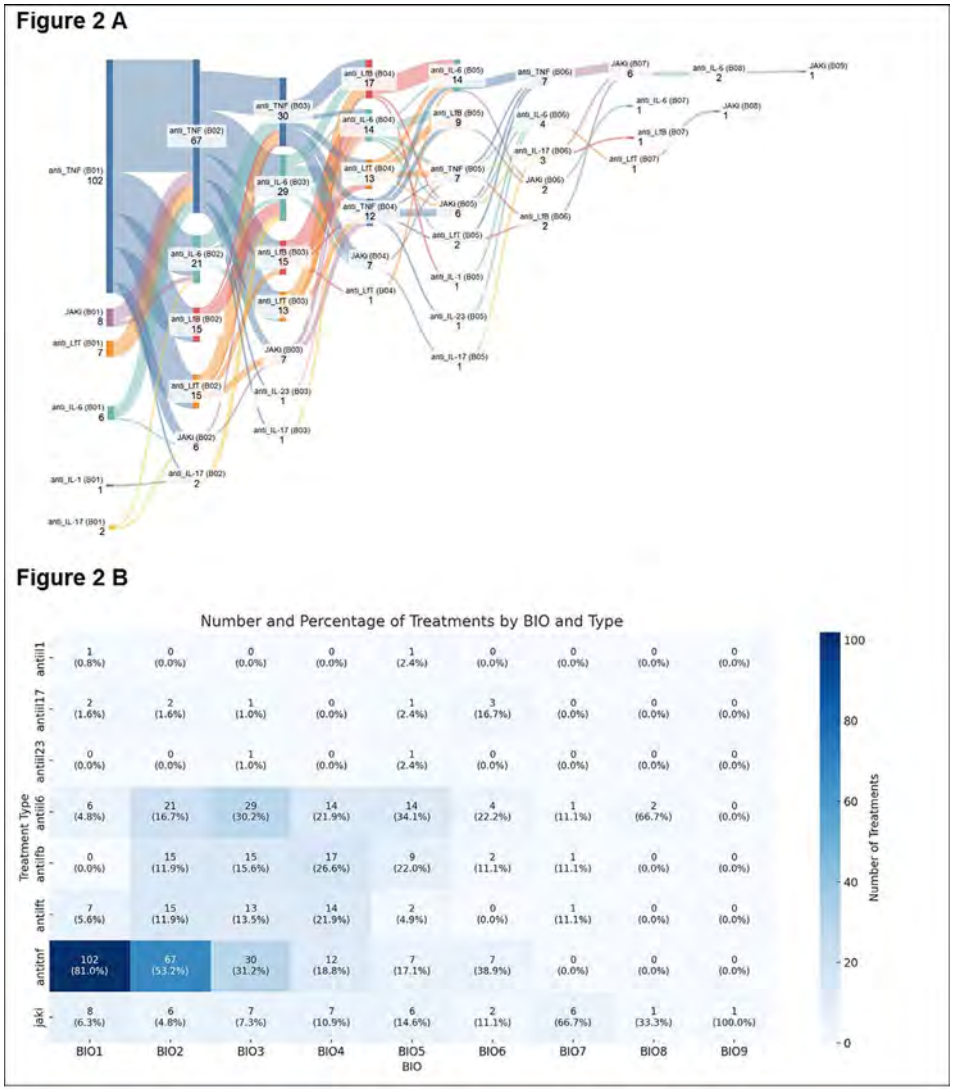

Figure 2 A-B. A) Sankey diagram of biologic transitions in D2T RA patients B) Heatmap of treatment classes by biologic line (BIO1-BIO9) Legend: A) Sankey-Plot showing b/tsDMARDs progression from the first (BIO1) to the ninth (BIO9) line of therapy. B) Heatmap for b/ts DMARDs prescription. Each cell represents the absolute (and relative, %) number of prescriptions for each treatment line

(Figure 2B) confirmed that while anti-TNFs dominated the first biologic line (81%), their use dropped markedly in later lines treatments. Analysis of reasons for treatment discontinuation showed that from the third biologic line, inefficacy—either primary or secondary—was by far the most common driver of therapeutic switches (over 80%), outweighing adverse events or other causes, underscoring the refractory nature of the disease in these patients. Importantly, D2T-free survival did not differ significantly based on the class of initial b/tsDMARD (Figure 1D-E) or whether csDMARDs were used in combination.

Conclusion: In this large cohort of 675 RA patients with a longterm follow-up, 127 RA patients developed D2T RA (18.8%). D2T patients are younger and have more functional impairment. Corticosteroid use prior to the first bDMARD was more frequent in the D2T group We did not identify a difference in the outcome (D2T) when comparing different treatment strategies comparing TNFi or other as the first line. Disease severity and persistent inflammation appears to be the primary drivers of D2T progression, rather than specific treatment strategies. Further analyses are ongoing to better define the concept of D2T RA.

Background/Purpose: Sjögren's disease (SjD) is burdened by significant lymphoproliferative risk. Up to date there is no established consensus on the salivary gland ultrasonographic (SGUS) features of lymphoma or of high lymphoproliferative risk (HLR) lesions (e.g., LELs, GCs, MESA/LESA). The aim is to systematically review existing literature on SGUS features of SjD patients complicated by SG Lymphoma or HLR lesions.

Methods: A systematic review of existing literature (SLR) (January 1988 – January 2025) was conducted according to PRISMA 2020 guidelines (Prospero registration: CRD420251008467).

Results: 15 studies (13 full text articles, 2 international conference abstracts) were included, with a predominantly moderate-low risk of bias (Figure 1). 13/15 described SGUS features of lymphoma, considering 121 total cases. 11/13 described the presence of focal lesions in lymphomas (8/11 quantitatively), identifying 45 focal lesions on 117 cases. These lesions were described with variable features, but commonly presented as a dominant glandular hypo- to anechoic mass on SGUS (Table 1). In 3/11 studies, the parenchyma surrounding the focal lesion was also assessed, with quantitative or inferable SGUS scores indicating moderate to severe involvement in all cases (Table 1). 10/13 studies described a diffuse glandular involvement (presence of SGUS abnormalities) in lymphoma cases (7/10 quantitatively), identifying 32 cases on 105 lymphomas. 4/10 studies quantitatively reported SGUS scores, with moderate-severe involvement in most cases (Table 2). 9/15 studies described HLR lesions, with a total of 161 quantifiable cases. In 4/9 a focal lesion in HLR cases was described, resulting in 11 focal lesions on 16 HLR cases considered, with descriptions and features as heterogeneous as lymphomas. Only 1/4 studies addressed SGUS features of the surrounding parenchyma, reporting a severe grade (Tab.2). 5/9 studies

reported a diffuse involvement in the absence of mention of focal lesions in HLR lesions (only 3 quantitatively), identifying 77 cases on 149 HLR lesions. 2/5 of these studies address SGUS scores reporting quantitative measures, more frequently a moderate-severe involvement (Table 2). No prospective studies define SGUS's role in detecting or predicting lymphoproliferative evolution.

Conclusion: The SLR confirms that both major salivary gland lymphoma and HLR lesions in SjD can appear as a dominant focal lesion (mostly hypo-anechoic lesion/mass), or as a diffuse involvement (mostly moderate-severe SGUS scores). SGUS features are described with highly heterogenous methodology and terminology, thus highlighting the necessity of a standardization in the reporting measures.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Sjögren's Disease – Basic & Clinical Science (1680–1685)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: The association between Sjögren's disease (SjD) and non-Hodgkin lymphoma (NHL) is well established, although reported standardized incidence ratios (SIRs) vary considerably across studies. In contrast, the risk of solid tumors in SjD remains controversial, with conflicting evidence in the literature. This study aimed to determine the SIRs for lymphoma and other malignancies (both hematologic and solid tumors) in patients with SjD, identify independent predictors of cancer development, and assess the impact of malignancies on overall mortality.

Methods: We conducted a prospective, multicenter observational study including 314 patients with SjD who met the 2002 American-European Consensus Group criteria. Clinical, demographic, and serological data, as well as malignancy incidence and survival outcomes, were prospectively collected over a median follow-up of 9.5 years [IQR 9.2–9.9]. SIRs were calculated using data from the GLOBOCAN project. Independent predictors of lymphoma and other malignancies were identified through multivariate Cox regression analysis. Cancer-related mortality and its impact on overall survival were assessed using relative risk (RR) estimates.

Results: Among the 314 patients, 22 incident malignancies (7.01%) were identified: 11 hematologic (all NHL) and 11 solid tumors. The overall cancer risk was elevated (SIR: 1.68; 95% CI: 1.68–1.69). A markedly increased risk was observed for NHL (SIR: 15.36; 95% CI: 15.32–15.40) and hematologic malignancies overall (SIR: 3.55; 95% CI: 3.54–3.56), while a modest increase was seen for solid tumors (SIR: 1.54; 95% CI: 1.53–1.55). Multivariate analysis identified older age (HR: 1.06; 95% CI: 1.01–1.11), smoking (HR: 3.56; 95% CI: 1.24–10.24), lymphadenopathy (HR: 3.34; 95% CI: 1.33–8.37), splenomegaly (HR: 14.04; 95% CI: 1.36–144.51), and cryoglobulinemia (HR: 9.12; 95% CI: 1.93–43.07) as independent predictors of malignancy. Cryoglobulinemia emerged as the strongest predictor of lymphoma (HR: 11.07; 95% CI: 1.18–103.75). A prior history of cancer significantly differentiated hematologic malignancies from solid tumors (HR: 26.97; 95% CI: 1.26–418.46). Malignancies accounted for 23.8% of all deaths in the cohort (RR: 2.21; 95% CI: 1.18–4.12).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Patients with Sjögren's disease are at increased risk of developing hematologic malignancies—particularly non-Hodgkin lymphoma—and, to a lesser extent, solid tumors. Cryoglobulinemia emerged as the strongest independent predictor of lymphoma. Malignancies significantly contribute to mortality, highlighting the need for targeted surveillance and timely intervention in high-risk patients. Further research is needed to validate findings and guide personalized approaches to improve outcomes.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Sjögren's Disease – Basic & Clinical Science (1680–1685)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Fibroblasts (fb) are increasingly recognized as dynamic signaling hubs in rheumatic disease, yet their contribution to Sjögren Disease (SjD) remains poorly defined. We dissect fb subpopulations, uncovering pathways by which fbs orchestrate the immunopathology of SjD.

Methods: We analyzed 3'-scRNAseq from freshly dissociated salivary gland (SG) biopsies of SjD^{SSA+} (n=15; 60,873 cells) and nonSjD^{SSA-} control subjects (n=19; 36,467 cells), using informatic approaches to predict cellular interactions (Fig 1a-b). We used 5000 plex spatial transcriptomics to corroborate the SjD enriched cell subsets and signaling hubs in a representative SjD^{SSA+} SG (FS:3). We used immunofluorescence microscopy of human SGs, murine dorsal root ganglion sensory neurons, and a pre-clinical model to quantitatively assess tactile allodynia.

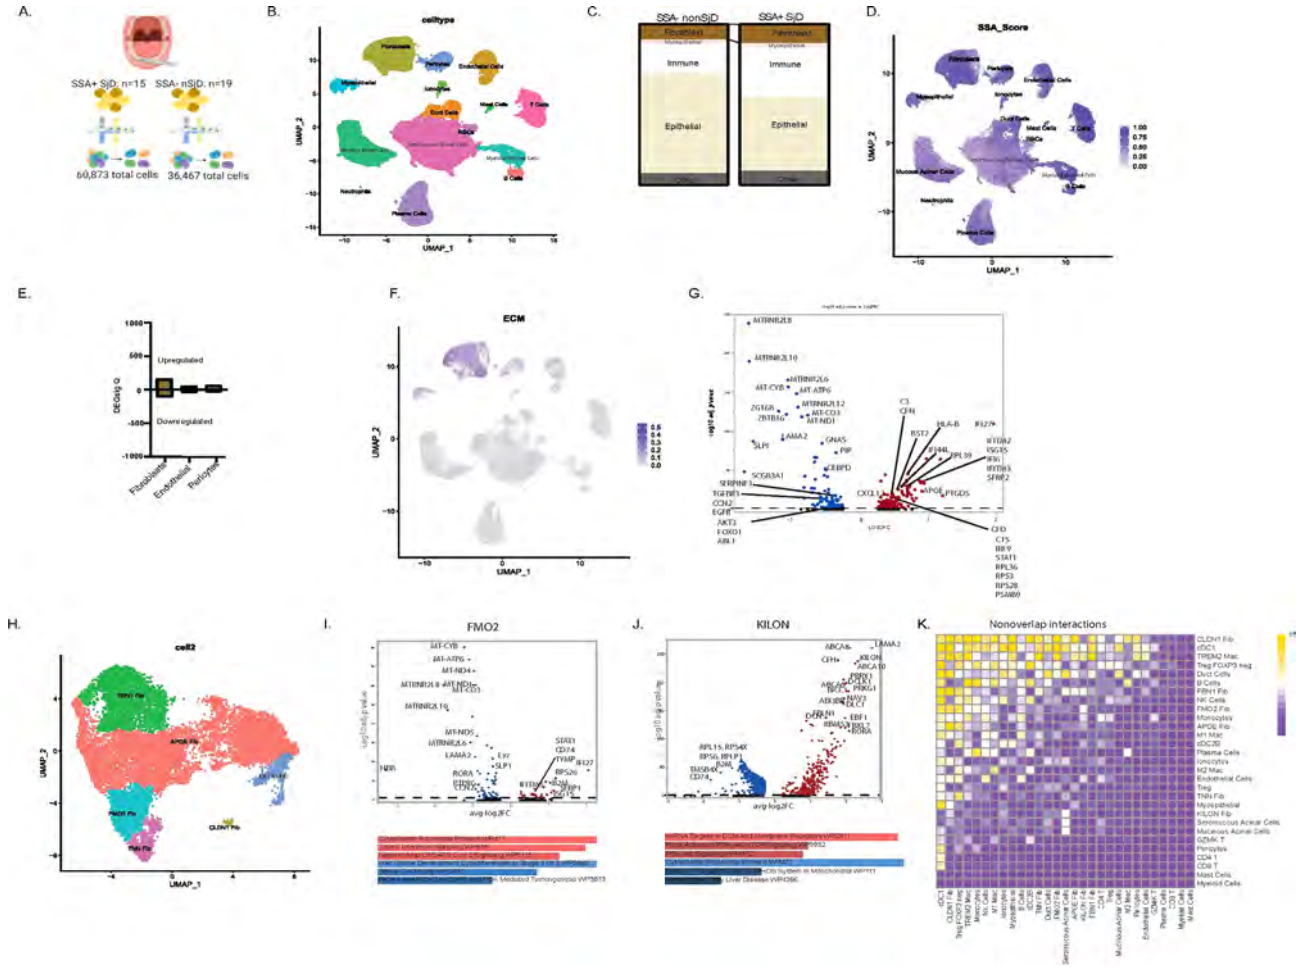

Figure 1. SSA+ SjD salivary glands fb populations with aberrant transcriptional signaling and cellular interactions. A) Schematic of our single cell analysis pipeline; B) UMAP plot of 97,340 cells colored by cell type; C) Number of cells in each population comparing SSA+ SjD to nonSjD controls; D) UMAP plot of differentially expressed transcripts in each cell subset between SSA+ SjD and nonSjD controls; E) Number of differentially expressed transcripts between SSA+ SjD and non SjD control participants by stromal cell populations (q-value ≤0.05); F) UMAP plot of differentially expressed ECM-related transcripts of each cell subset; G) Volcano plot showing top up and down regulated transcripts in SSA+ SjD fbs compared to control fbs subsets; H) Sub clustering identified six fb subsets: 1) APOE+; 2) CLDN1+; 3) FBN1+; 4) FMO2+; 5) KILON+; and 6) TNN+. I) FMO2+ fbs display greater ribosomal proteins, Type-II IFN response, and viral infection-related pathways; J) KILON+ fbs express transcripts related to axon and nerve growth and have pathways related to miRNA targets in the ECM/membrane receptors and PI3K Akt mTOR signaling. Top five upregulated (red) and downregulated (blue) pathways shown wikipathways darker and longer=more significant, corrected for sex. Pathways were selected from transcripts with q value <= 0.05; K) Based on ligand-receptor (L-R) signaling, FMO2+ fbs are predicted to signal with dendritic cells, Treg cells, monocytes, and TREM2+ macrophages more in SjD. KILON+ fbs exclusively interact with seromucous acinar more in SjD – key target cells in SjD.

Results: SG fbs are numerically expanded (Fig. 1c) in SjD^{SSA+} and exhibit more differentially expressed genes (DEGs) than control fbs (Fig. 1d–e). SjD^{SSA+} fbs upregulate extracellular matrix related transcripts (i.e., fibrosis; Fig. 1f), with pathways enriched in ribosomal proteins and interferon (IFN) signatures (Fig. 1g). Given these aberrant transcriptional profiles, we hypothesized that distinct fb subsets drive these changes. We identify six fb subsets: 1) *APOE*$^{+}$; 2) *CLDN1*$^{+}$; 3) *FBN1*$^{+}$; 4) *FMO2*$^{+}$; 5) *KILON*$^{+}$; and 6) *TNN*$^{+}$ (Fig 1h). We focus on the *FMO2*$^{+}$ fbs, with a strong IFN signature (Fig 1i), and *KILON*$^{+}$ fbs, with multiple nerve/axon related transcripts (Fig 1j). Ligand-receptor analysis predict SjD interactions between *FMO2*$^{+}$ fbs and dendritic cells, Treg cells, and macrophages/monocytes (Fig 1k), while *KILON1*$^{+}$ fbs engage with seromucous acinar cells (Fig 1k). Upstream regulator analysis of *FMO2*$^{+}$ fbs includes IFN regulatory factors and STAT1 (Fig. 2a) and signaling with *TREM2*$^{+}$ macrophages via predicted interactions such as CSF1–CSF1R (Fig. 2b). Spatial transcriptomics confirms

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

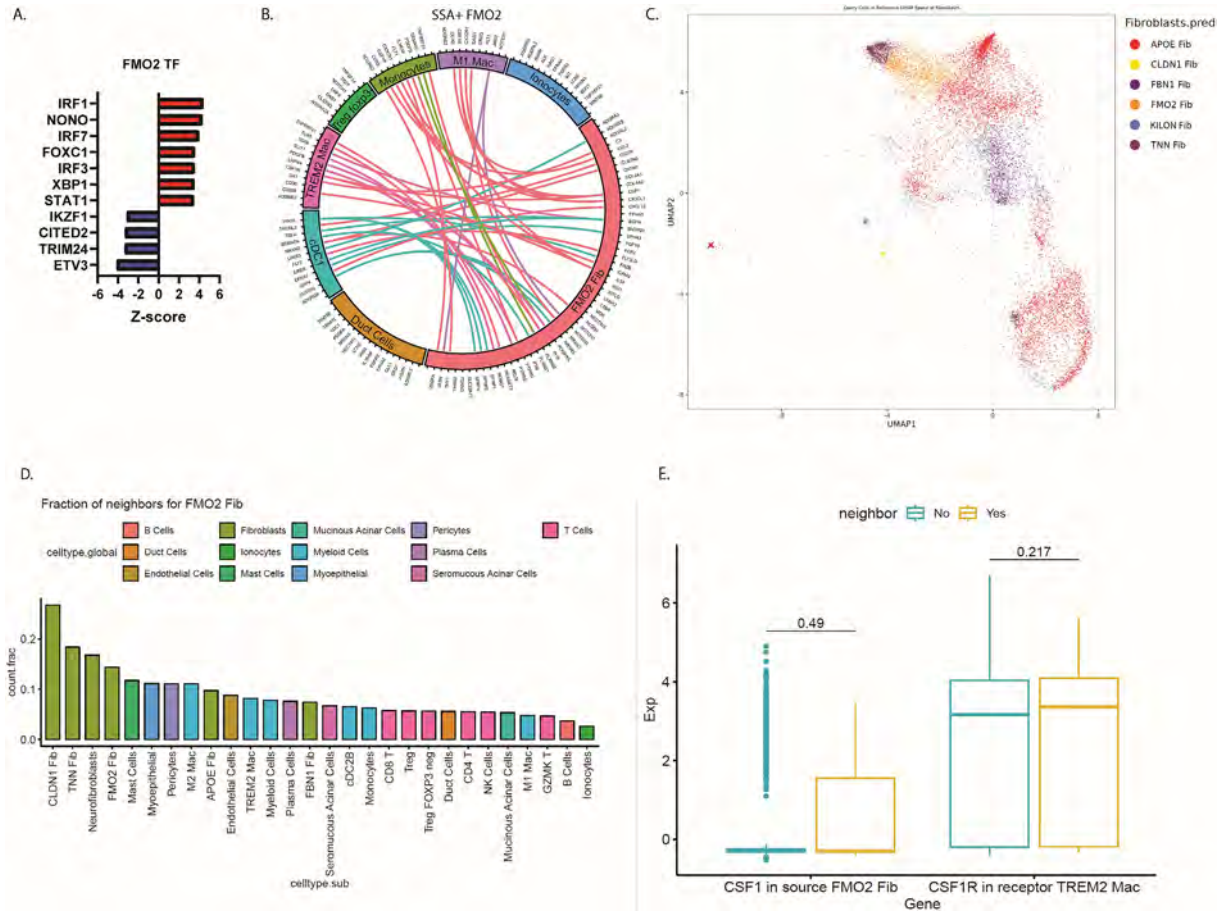

Figure 2. FMO2+ fb clusters are regulated by interferon-related transcription factors and interact with monocytes through unique ligand-receptor interactions. A) Upstream transcription factors of FMO2+ fbs involve interferon regulatory factors (IRF) and STAT1; B) FMO2+ fb interactions with TREM2 macrophages that uniquely occur in SSA+ SjD include CSF1R/CSF1; C) UMAP of fb clusters identified in a SSA+ SjD salivary gland using xenium spatial transcriptomics; D) Using xenium spatial transcriptomics, we showed that FMO2+ fb co-localize with TREM2 macrophages; E) FMO2+ fbs that co-localize with TREM2 macrophages trend toward expressing more CSF1R/CSF1.

FMO2^{+} Fbs and *TREM2*$^{+}$ macrophages colocalize in SjD SGs (Fig. 2c–d), with a trend of CSF1–CSF1R enrichment (Fig. 2e). In contrast, *KILON*$^{+}$ fbs are transcriptionally regulated by MLXIPL and MYC (Fig. 3a) and are increased in SjD^{SSA+}. Injection of recombinant human KILON increases the depolarization of mouse dorsal root ganglia neurons (Fig. 3b–e) and induces mechanical allodynia (Fig. 3f–g).

Conclusion: We characterize fb heterogeneity in SjD^{SSA+} and uncover disease-associated subsets with divergent functionality. *FMO2*$^{+}$ fbs align with previously described "immune-fbs," exhibiting IFN signaling and predicted crosstalk with *TREM2*$^{+}$ macrophages via CSF1–CSF1R, supporting macrophage survival, migration, and expansion. We identify a novel *KILON*$^{+}$ fb subset enriched for neuron/axon guidance transcripts, that causes allodynia *in vivo*. We propose two hypotheses: *KILON*$^{+}$ fbs innervate functional epithelium or contribute to neuroimmune dysregulation driving glandular dysfunction. We expand paradigms of fb function beyond structural support, positioning fbs as drivers of immune modulation and maladaptive transformation of SGs innervated by the primary afferents of sensory neurons. These findings suggest a potential molecular mechanism that underlies pain amplification in SjD patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

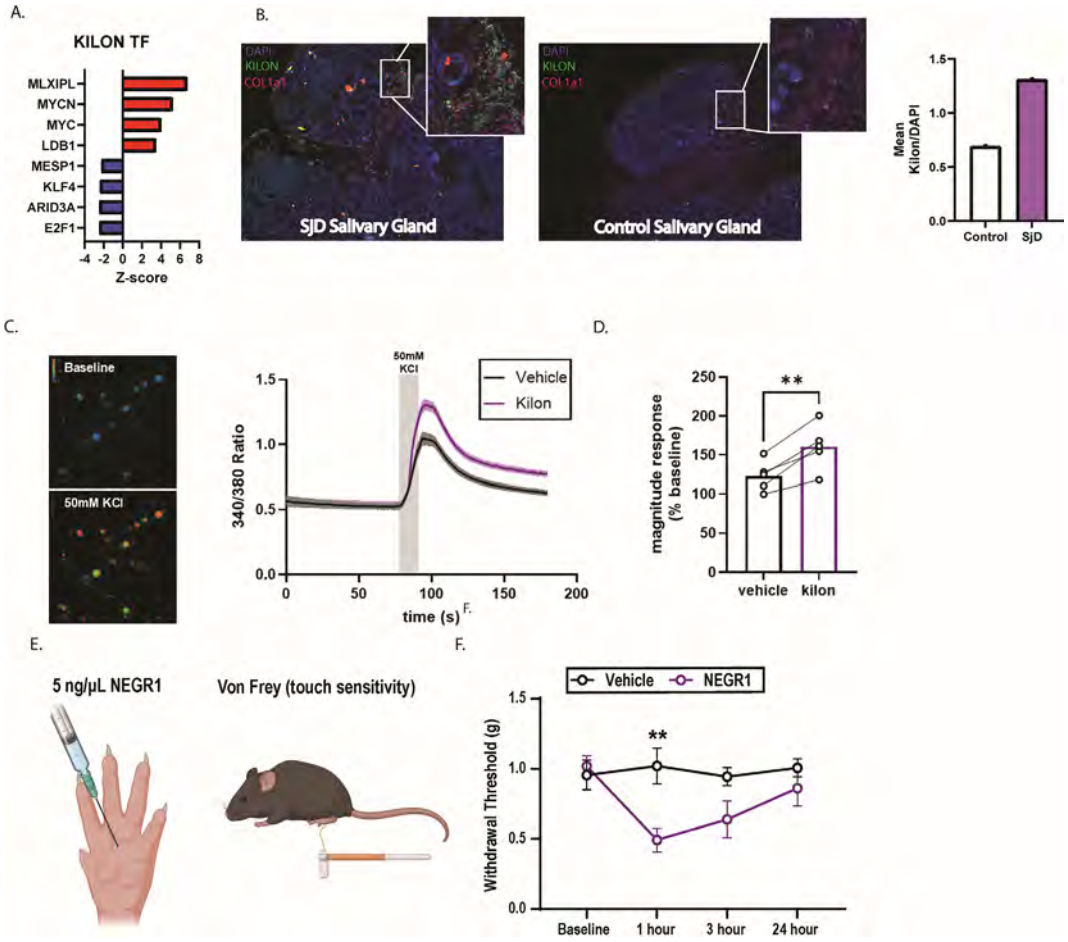

Figure 3. KILON+ fb clusters are uniquely regulated and enriched in SjD, and KILON increases pain sensitization in mice. A) Upstream transcription factors of KILON+ fbs involve and MLXIPL and MYC; B) SSA+ SjD (n=3) and control salivary glands (n=3) were stained with KILON, COL1A1 (fbs) and DAPI (nuclei). KILON was significantly higher in SjD fbs (*= p-value <0.05, determined by student's t-test); C) Dorsal root ganglion from mice were stimulated with KCl in the presence or absence of human recombinant KILON. Mouse dorsal root ganglion (cells from n=3 mice combined for analyses) were cultured in the presence of 200 ng/mL of human recombinant KILON or vehicle for two hours before proceeding to Fura Calcium imaging. Blue shows low calcium influx compared to high red calcium influx. Treatment with recombinant human KILON increases calcium influx in neurons; D) The average response of cells to depolarization increases in each animal treated with KILON (p-value determined using paired t-test); E) Representative figure of intraplantar injection of 5 ng/µL KILON and the von Frey pain test; F) Mice (n=9 animals per group; n=6 male and n=3 female) were injected with recombinant human KILON or with vehicle into the paw. At one hour, mice treated with KILON had a significantly lower withdrawal threshold than mice treated with vehicle (p-value **= ≤0.01 as determined by the repeated measures two-way ANOVA).

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Sjögren's Disease – Basic & Clinical Science (1680–1685)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Sjögren disease (SD) is a B cell driven systemic auto-immune disease, with a need for biomarkers to better assess disease activity, risk of lymphoma and finding new therapeutic targets. While BAFF, a key B cell survival cytokine involved in precoce steps of B cell ontogeny, has been previously associated with systemic manifestations and lymphomagenesis in SD, data on a proliferation-inducing ligand (APRIL), another B cell cytokine acting in later stages of B cell ontogeny (e.g., plasmablasts and plasma cells via BCMA and TACI receptors), remain limited. This study aimed to investigate associations between APRIL, B cell biomarkers, disease activity and risk of lymphoma in SD.

Methods: Serum APRIL levels (ELISA, Invitrogen°) were assessed in 337 patients with SD from the French ASSESS cohort (17-year follow-up) and 40 healthy donors (HD). All patients met 2016 ACR/EULAR classification criteria. Patients were stratified according to the validated clustering of the ASSESS cohort: (C1) biologically active without systemic manifestations; (C2) systemic manifestations; (C3) low activity/high symptom burden; and SD-related lymphoma (incident n=9, prevalent n=16). The association between SD-related lymphoma, APRIL and lymphoma predictors at enrollment (clinESSDAI, ESSDAI, lymphocytopenia < 0.5 G/L, CD4/CD8 T cell ratio≤0.8, RF positivity, cryoglobulinemia, monoclonal component, and low C4) and other potential biomarkers (IgG levels, total gammaglobulins, immune-complexes, beta2microglobulin, kappa and lambda free light chains, quantitative [q] anti- SSA/SSB autoantibodies, digital interferon [IFN] alpha, s-FLT3, CXCL10, CCL19, CXCL13, BAFF), were analyzed in univariate and multivariate models. Multivariate analyses took into account APRIL and variables significantly associated with lymphoma in univariate analyses selected by a stepwise procedure. Estimation of incident lymphoma risk was assessed in a separate multivariate model.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: APRIL levels increased across subgroups: HD (0.36 ng/mL), cluster 3 (0.34), cluster 1 (0.97), cluster 2 (1.2), lymphoma (2.33), with highest levels in incident lymphoma (2.8; p< 0.0001). In multivariate analysis, including only markers significantly associated with lymphoma in univariate analyses, APRIL expression at enrollment remained significantly associated with lymphoma (OR 1.1; 95% CI [1- 1.17] p=0.045), along with BAFF levels (mean [SD]: 1085.1 pg/ml [742.4]; per 1000 BAFF units, OR 1.75; 95% CI [1.11-2.71]; p=0.0012), CD4/CD8 ratio ≤ 0.8 (OR 4.7 95% CI [1.13-18.03]; p=0.027), low C4 (OR 5.38 95% CI [1.89-16.04]; p=0.002), lymphopenia < 0.5 G/L (OR 51.02 95% CI [4.65-611.01]; p=0.001), glandular (OR 4.95 95% CI [1.49-15.97]; p=0.007), and adenopathy (OR 6.43 95% CI [1.1-31.8]; p=0.027) domains of the ESSDAI. In a separate multivariate model, APRIL (OR 1.1 95% CI [1.01-1.21]; p=0.02) and CXCL13 (OR 1.0 95% CI [1.0-1.0]; p=0.01) were found independently associated with the risk of developing incident lymphoma.

Conclusion: These results suggest the interest of APRIL, a B-cell cytokine easily measurable in patients' sera, as a potential biomarker of SD-related lymphoma, and as a potentially relevant therapeutic target in SD.

Integration of Multiple Spatial Transcriptomics Reveals Novel Insights into Sjogren Disease Salivary Gland Fibroblast by Peripheral Serostatus

Zhou Fang[1], Ahmet Coskun[1] and **Sara McCoy**[2], [1]Georgia Tech, Atlanta, [2]University of Wisconsin–Madison, Madison, WI

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Sjögren's Disease – Basic & Clinical Science (1680–1685)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Anti-SSA antibody positive (SSA+ [Ro52 or Ro60]) and negative (SSA-) Sjögren disease (SjD) have differing clinical phenotypes and prognostic features; however, the pathogenesis driving these two endotypes remains unclear. We define a novel pathogenic SjD cell, fibroblasts (fbs), and shed new light on traditional pathogenic processes (Ro52/60) using integrated spatial sequencing techniques. Our objective is to define the salivary gland (SG) fibroblasts (fb) cellular neighborhoods and interactions driving pathology in SSA+ compared to SSA- SjD with a focus on Ro52/60

Methods: We performed spatial analyses with Xenium and CosMx of human SG tissue derived from 2 SSA+ and 2 SSA- patients fulfilling 2016 ACR/EULAR criteria for SjD. After data integration, we labeled cell types and proceeded to neighborhood analyses using graph attention neural networks. We performed immunofluorescence for Ro52 and Ro60 in SSA+ and SSA- SjD SG (n=9).

Results: Our data integration and analyses using Xenium and CosMX yielded nine major cell types. Next, we performed neighborhood analyses, comparing SSA+ and SSA- SjD neighborhoods and found SSA+ fbs interact most with ductal epithelial and T cells. In contrast, SSA- fbs interact with ductal epithelial cells alone. We compared neighborhoods that

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

predominate in SSA+ or SSA- SjD SGs and that had similar cell subset composition. For example, neighborhood clusters 1 and 7 show plasma cells and seromucous acini neighboring with fbs; yet cluster 1 is found nearly exclusively in SSA+ samples and cluster 7 is found in SSA- SjD SGs, respectively. In the SSA+ predominant cluster 1, fb transcripts include JAK1, IRF4, and STAT6, whereas the SSA- cluster 7 fbs have important transcripts that include CXCL12/14 and IFITM3. Analyses of top differential transcripts show SSA+ fbs expressed CSF1R and CD40, whereas SSA- fbs express CCL28, IL10, and IFI6.

We used seqFISH to orthogonally identify 12 cell subsets in SSA+ and SSA- SjD SGs. We labeled our glands with Ro52 and Ro60. Ro52 expression is lower in SSA- compared to SSA+ SjD cell subsets except in T-cells, ki67 high B-cells, and follicular dendritic cells. In contrast, Ro60 expression is lower in SSA- compared to SSA+ SjD cell subsets except for basal and luminal ductal cells. Both Ro52 and Ro60 are most differentially expressed by serostatus in myoepithelial cells. SSA+ non-lymphocytes express more Ro52 than lymphocytes. This pattern is reversed in SSA- SGs. Akin to Ro52, SSA+ non-lymphocytes express more Ro60 than lymphocytes. In contrast to Ro52, SSA- non-lymphocytes express more Ro60 than lymphocytes.

Conclusion: By integrating multiple spatial profiling techniques, we identify unique fb subsets driving cellular interactions in SSA+ and SSA- SjD. Ro52/Ro60 have long been hypothesized to be central to SjD pathogenesis. For the first time, we determine cell-specific Ro52/60 expression in SSA+ compared to SSA- SGs. Ro52/Ro60 expression differs by cell subsets in SSA+ and SSA- SjD, with myoepithelial cells showing the most divergent Ro52/Ro60 expression by serostatus, a potential nidus for autoantibody formation. These findings provide new pathogenic insight into SjD fb by serostatus and gain new perspectives on Ro52 and Ro60 in a cell-specific manner.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: Sjögren's Disease – Basic & Clinical Science (1680–1685)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Performance of the recently developed composite responder index STAR is highly awaited.

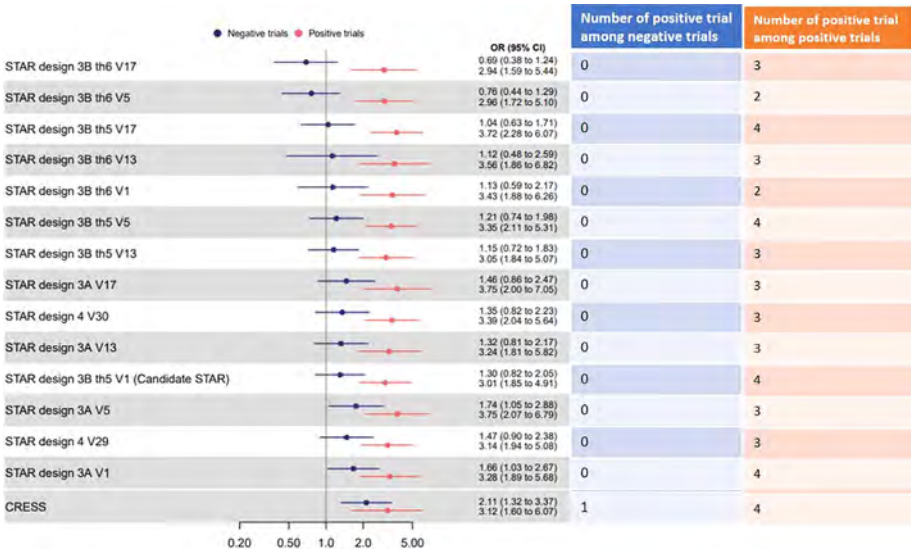
We conduscted this study to evaluate the performance of STAR in previously completed clinical trials shared within the NECESSITY consortium.

Methods: Data from 9 trials used for STAR development (Abatacept (ASAP-III), leflunomide+hydroxychloroquine (REPURP-SS) and rituximab (TEARS and TRACTISS), the iscalimab and ianalumab phase 2 trials, Baminercept, hydroxychloroquine (JOQUER), tocilizumab (ETAP)) and two other independent clinical trials (GSK (NCT02631538), Belimumab + Rituximab, Belimumab, Rituximab versus placebo and BMS Abatacept (NCT02915159). Trials were classified, by an expert panel, as positive, negative or "in between", in regards to primary and key secondary endpoints.

The STAR candidate, and its 14 alternate binary option (including the recently developed CRESS) responses were calculated retrospectively at the timing of the primary endpoint of the corresponding trial.

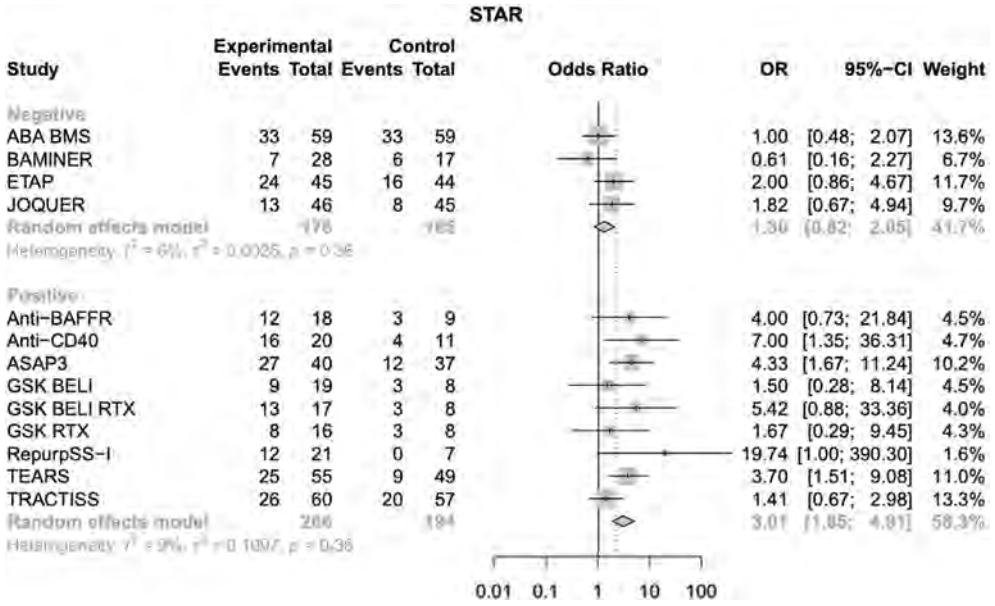
To better appraise sensitivity to change of the STAR options, meta-analyses of the 11 RCTs were run for each option, separately for positive and "in between" trials together, where positive results were expected, and negative trials, where no difference between groups was expected.

Meta-analyses were run using the Mantel-Haenszel method with Paule-Mandel estimator for τ2, Q-profile method for confidence interval of τ2and τ and continuity correction of 0.5 in studies with zero cell frequencies. Treatment effect was expressed as an odds ratio (OR): 1 or below indicates the absence of any effect, above 1 favors the experimental treatment. Consequently, a STAR option that is sensitive and specific to change should have a treatment effect close to the null effect for the negative trials, and as far from the null effect for the positive trials.



Summary of results of the meta-analyses of negative and positive trials, using as endpoint, the STAR candidate and alternate binary options

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Meta-analyses of the 4 negative and 7 positive trials using the STAR candidate as endpoint

Results: Of the 11 trials, 7 were classified as positive by the expert panel. Among these positive trials, when using STAR candidate and the 14 alternate binary options, OR ranged from 2.85 to 3.75, and the number of trials actually positive (ie, having significant between arm difference with the STAR option) ranged from 2 to 4 (figure 1 in red).

Among the 4 negative trials, when using the STAR candidate and the 14 alternate binary options, OR ranged from 0.69 to 2.11. OR was statistically significant (in favor of an effect of the treatment) in 3 STAR alternate option, which wrongly detect a difference in trial were no efficacy was observed (figure 1 in blue).

The STAR candidate displays an OR of 3.01 (1.85 - 4.91) in positive trials and 1.30 (0.82 – 2.05) in negative trials and detects significant differences in 4 of the 7 positive trials (figure 2). The CRESS displays an OR of 3.12 (1.60 – 6.07) in positive trials and 2.11 (1.32 – 3.37) in negative trials and detects significant differences in 4 of the 7 positive trials, and one of the negative trials.

Conclusion: In this analysis based on 11 trials, the STAR appears to detect treatment response accurately, with a high sensitivity to change for treatments showing a beneficial effect. Additionally, it exhibits specificity to change by not falsely detecting improvement in negative trials.

Abstract Number: 1686

The Prevalence of Depressive Symptoms and Persistent Depression among Older Adults with Systemic Lupus Erythematosus (SLE)

Patti Katz[1], Sofia Pedro[2] and Kaleb Michaud[3], [1]UCSF, San Rafael, CA, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: ARP I: Multidimensional Influences on Health in SLE (1686–1691)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Depression is reported to be common in SLE, but little is known about depressive symptoms among older adults with SLE. While the burden of comorbid conditions and the cumulative effects of SLE may be heightened in this group,[1] odds of depression are higher in younger age groups in the general population.[2] Screening for depression appears to be uncommon in rheumatology settings. We compared depressive symptom levels and the self-reported awareness of depression among older adults with SLE to those with RA and OA.

Methods: Data were from FORWARD, The National Databank for Rheumatic Diseases, a longitudinal observational cohort. Data are collected semiannually. Individuals with diagnosed SLE, rheumatoid arthritis (RA), and osteoarthritis (OA) were included in analyses; those with concurrent fibromyalgia were excluded. Depressive symptoms were assessed with the Patient Heath Questionnaire (PHQ)-8 over 4 survey periods. PHQ-8 scores were classified as ≥mild (≥5) or ≥moderate (≥10) levels of depressive symptoms. Persistent depression was defined as mild/moderate symptoms at ≥2 time points. Generalized estimating equation (GEE) regression analyses (unadjusted and adjusted for age, sex, education, disease duration, physical function, and pain) compared scores among the 3 groups. The proportion of individuals with notable levels of depressive symptoms who did not self-report with depression was examined.

Results: Data from 3770 participants (12,896 observations) were included (SLE n=179, obs=663; RA n=2088, obs=7792; OA n=1503, obs=4441). Mean age was 69±8 years (Table 1). Across years, with only one exception, older adults with SLE had higher PHQ-8 scores and higher frequencies of scores ≥5, and ≥10. Any occurrence of PHQ-8 scores ≥10 was seen in 21.0%, 18.2%, and 11.0% of those with SLE, RA, and OA, respectively. Persistent PHQ-8 scores ≥10 were found in 11.4%, 11.6%, and 8.2% of those with SLE, RA, and OA. GEE analyses (unadjusted and adjusted) showed significantly higher PHQ-8 scores and significantly higher prevalence of mild depressive symptoms in SLE compared to RA and OA (Table 2). Prevalence of moderate symptoms were significantly higher in SLE compared to OA in unadjusted analyses, but differences were attenuated after adjustment. In each year, at least 2/3 of those with ≥mild and about half of those with ≥moderate depressive symptoms did not self-report having depression (Table 3).

Conclusion:

Older adults with SLE appear to carry a greater burden of depressive symptoms than individuals of similar age with RA or OA, and large portions of individuals seem to be unaware of having depressive symptoms. Given this lack of awareness,

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: ARP I: Multidimensional Influences on Health in SLE (1686–1691)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: SLE predominantly affects women and is often accompanied by physical changes and psychological distress. Although both body image dissatisfaction and sexual dysfunction are reported in SLE, their relationship remains

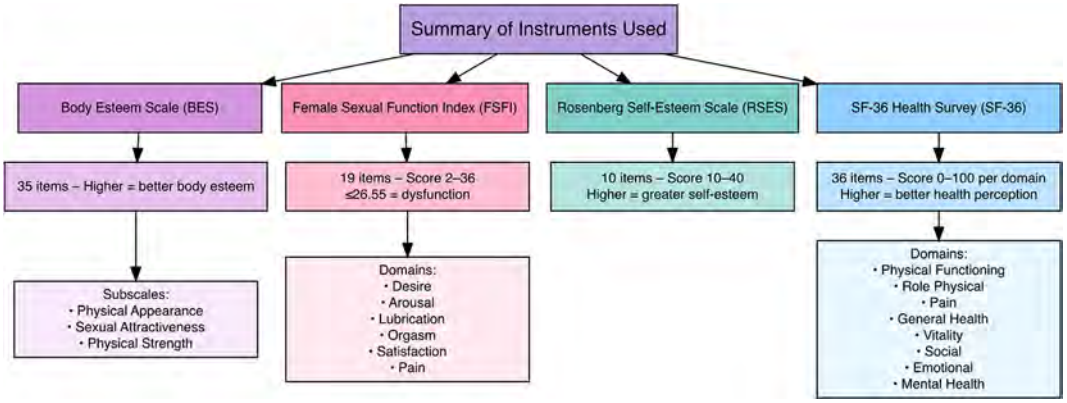

Figure 1: Flowchart detailing the instruments used (BES, FSFI, RSES, SF-36), including the number of items, score interpretation, and corresponding domains assessed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

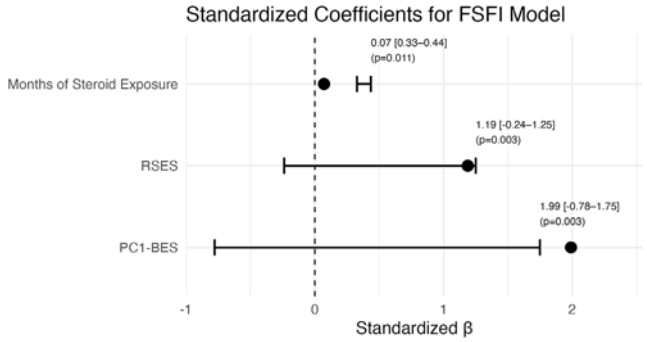

Figure 2: Forest plot of standardized regression coefficients (β) ± 95% confidence intervals for PC1-BES, RSES, and months of steroid exposure in the multivariable model predicting FSFI total score.

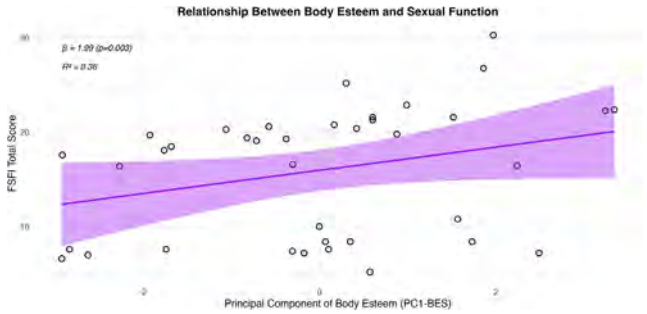

Figure 3: Scatterplot of PC1-BES versus FSFI total score with fitted regression line (β = 1.99, p = 0.003) and 95% confidence ribbon (R^2 = 0.36).

unclear. We sought to determine whether body esteem is independently associated with overall sexual function in women with SLE.

Methods: In this cross-sectional observational study, we analyzed data from 38 adult women who all met the 2019 EULAR/ACR classification criteria for SLE. Participants completed the Body Esteem Scale (BES), the Rosenberg Self-Esteem Scale (RSES), the Female Sexual Function Index (FSFI), and the SF-36 v2 questionnaire (Figure 1). Steroid exposure was measured as the total number of months the patient had received steroid treatment, from initiation to the most recent use. Principal component analysis summarized the three BES subscales into a single component: PC1-BES. We used linear regression to predict the FSFI total score and assessed interactions, nonlinearity, outliers, and subdomain effects. Statistical significance was set at α = 0.05.

Results: The mean±SD age was 35.8±12.6 years, disease duration was 7.5±6.8 years, and months of steroid exposure were 29.3±36.5 months. In the adjusted model, greater body esteem (PC1-BES) was significantly associated with higher FSFI scores (β = 1.990; 95% CI, 0.730 to 3.250; p = 0.003), independent of self-esteem (RSES; β = 1.190; 95% CI, 0.440 to 1.930; p = 0.003) and months of steroid exposure (β = 0.070; 95% CI, 0.020 to 0.130; p = 0.011). The model explained 27% of the variance in sexual function (R^2 = 0.270), with overall fit significant (F(3,34) = 6.470; p = 0.001) (Figures 2 and 3).

The interaction and non-linearity tests did not yield significant findings. Subdomain analyses revealed consistent positive associations between PC1-BES and FSFI domains of arousal, lubrication, orgasm, satisfaction, and pain (all p < 0.05). Adding the eight SF-36 subscales did not improve model performance.

Conclusion: Among 38 women with SLE, higher body esteem is independently and positively associated with overall sexual function (FSFI), independent of self-esteem (RSES) and steroid exposure. This relationship was consistent across the FSFI subdomains. Addressing concerns about body image should be considered in comprehensive SLE care to improve sexual health and quality of life. Interventions targeting body image, such as cognitive-behavioral therapy, may improve sexual health. The independent positive link observed with months of steroid exposure warrants longitudinal investigation to clarify its role.

Impact of Stress, Anxiety, and Depression on Fatigue as moderated by Resilience and Exposure to Trauma in Rheumatology Patients

Akhila Veeravalli[1], Sankeerthana gajjala[2] and Sarath Chandra Mouli Veeravalli[3], [1]Department of Rheumatology, KIMS Hospitals, Secuderabad, India, Hyderabad, Telangana, India, [2]KIMS Hospitals, Secunderabad, India, Hyderabad, Telangana, India, [3]Dept. of Rheumatology and Clinical Immunology, KIMS Hospitals, Secunderabad, India, Hyderabad, Telangana, India

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: ARP I: Multidimensional Influences on Health in SLE (1686–1691)

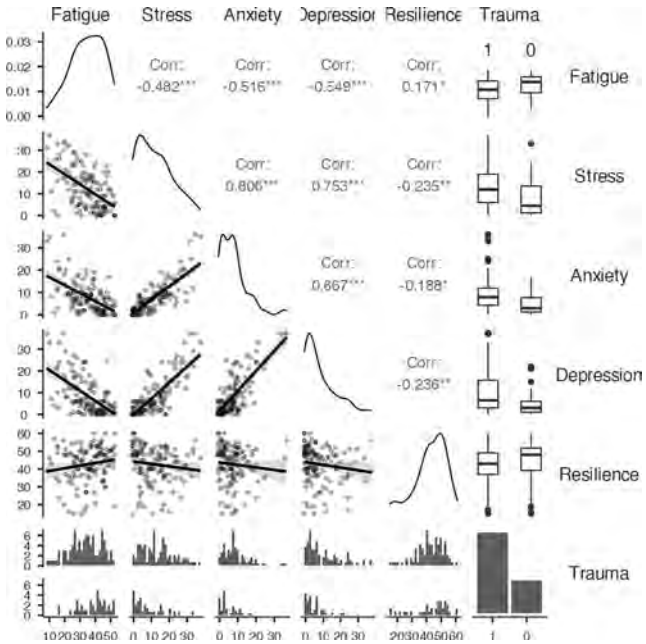
Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose:

This study aimed to examine the impact of psychological distress—specifically stress, anxiety, and depression—on fatigue in rheumatology patients, and explored how this relationship is moderated by trauma exposure and resilience. Understanding these dynamics is essential for developing holistic psychosocial interventions for individuals with chronic autoimmune disorders.

Methods: A quantitative, non-experimental comparative design with a between-groups approach was employed using convenience sampling. The sample comprised 132 participants recruited from the outpatient departments of KIMS Hospitals, Secunderabad, and HRC Hospital, Begumpet. Participants included 95 females and 37 males, aged 19 to 78 years



Spearman's Correlation Matrix among the variables.

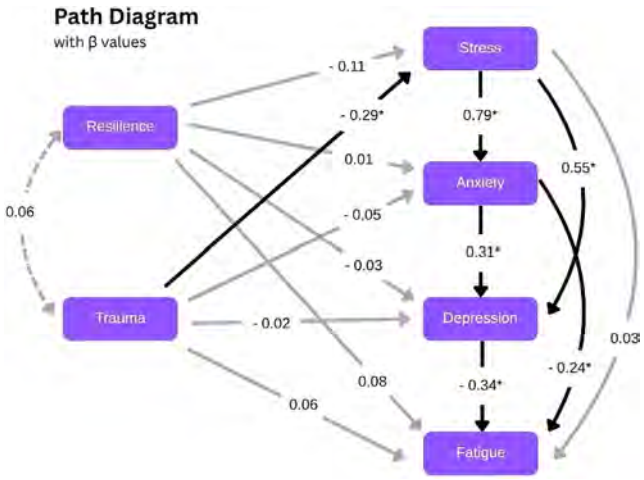
Mediation Analysis (indirect effects) of the hypothesied Path Model

(M = 42.7), diagnosed with Rheumatoid Arthritis (n = 36), Spondyloarthritis (n = 32), Psoriatic Arthritis (n = 26), or Systemic Lupus Erythematosus (n = 38). A General Information Schedule was used to collect demographic data. Disease activity was assessed using DAS-28, ASDAS, cDAPSA, or SLEDAI as appropriate. Fatigue was measured using the FACIT-Fatigue Scale (Version 4). Depression, Anxiety, and Stress were assessed using the DASS-42. Trauma exposure was measured using the Brief Trauma Questionnaire (BTQ), which included items on emotional abuse, familial illness, and pregnancy-related issues. Resilience was assessed using the abbreviated Nicholson McBride Resilience Questionnaire.

Data were analyzed using JAMOVI. Descriptive statistics were calculated, and normality tested with the Shapiro-Wilk test. Inferential analyses included the Mann-Whitney U test, Kruskal-Wallis test, Spearman's correlation matrix, and path analysis using the SEMLj module.

Results: While no significant group differences were found, Spearman's correlation revealed that higher psychological distress is linked to greater fatigue, while resilience showed a protective effect, implying complex, non-linear relationships, supporting the use of structural equation modeling to clarify how resilience may buffer the impact of trauma-related distress on fatigue. The path model demonstrated excellent fit (CFI = 1.000; RMSEA = 0.000). Depression was the strongest direct predictor of fatigue (β = -0.34, p = 0.006); anxiety had a marginal effect; stress influenced fatigue only indirectly. Resilience did



The Hypothesized Path Model showing the direct and indirect effects of the studied variables

23652203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

not significantly mediate or moderate these paths, potentially due to the small, non-normally distributed sample, which may have limited power to detect subtle effects.

Conclusion: The findings underscore the critical role of psychological factors—particularly stress, anxiety, and depression—in the experience of fatigue among patients with rheumatological conditions. Trauma exerts an indirect effect, while resilience showed no significant buffering, possibly due to sample size and distribution limitations. Results support the need for integrated care. Interventions could be two-pronged: one path reducing psychological distress, the other bolstering resilience, thereby addressing fatigue from two converging angles. Future research will expand the sample and test the effectiveness of such interventions.

Addressing Perceived Discrimination in Lupus Care: Enhancing Patient Empowerment and Health Equity Through Education and Support

Kimberly Cabrera[1], Priscilla Calvache[2], Lillian Mendez[3], Giselle Morales[4] and Jillian Rose-Smith[2], [1]Hospital for Special Surgery, New York, [2]Hospital for Special Surgery, New York, NY, [3]Patient Advocate, Carteret, NJ, [4]Hospital for Special Surgery, Glendale, NY

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: ARP I: Multidimensional Influences on Health in SLE (1686–1691)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: SLE is a life-threatening autoimmune disease that disproportionately affects African American (AA), Hispanic/Latino, & Asian populations. These communities experience serious health disparities, including more severe illness & poorer health outcomes. Research highlights that perceived racial discrimination in healthcare is a major concern among SLE patients, particularly among AA patients, contributes to lower trust in physicians, treatment adherence, & worsened health outcomes. A hospital-based support & education program conducted a survey to identify lupus patients' self-reported experiences with perceived discrimination & healthcare navigation.

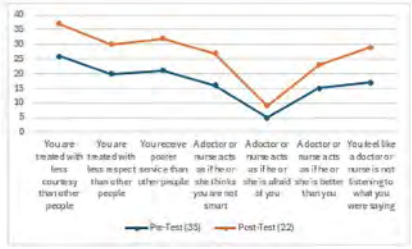

Figure 2

Methods: A pre/post-test survey, including validated scales such as the Everyday Discrimination Scale (EDS) was disseminated online to lupus patients participating in monthly support group sessions. The survey assessed key areas, including disease activity, experiences of discrimination, & patient-provider communication. A pre-test was administered at the beginning of the year, followed by 6 virtual support group meetings that provided education on recognizing & intervening when discrimination occurs in healthcare settings.

Results: A total of 37 participants completed the pre-test, and 23 completed the post-test (n=56). Most respondents (82%) identified as female. The racial breakdown included 44% Black/AA, 21% White, 57% identifying as Hispanic/Latino, 27% identifying as other races, and 8% Asian. There was a notable concentration of respondents aged 30–39 (35%). (See Figure 1)

Using the criteria that responses other than "Never" indicate a discriminatory experience, analysis of the EDS revealed a decrease () in reported discrimination experiences from pre-test to post-test. Participants who reported being treated with less courtesy by 24.3%, while reports of being treated with less respect by 11.6%. Perceived poorer service by 10% and reports of feeling that a doctor or nurse acted superior by 6.5%.

However, some areas saw slight increase (): participants reporting that a doctor or nurse did not listen by 5.9%, and those perceiving that a healthcare provider believed they were not smart by 4.3%. (See figure 2)

Conclusion: Despite limitations, this study affirms that tailored education & peer support can meaningfully reduce perceived discrimination and strengthen patient empowerment in lupus. Participants reported greater awareness, improved communication with providers, & enhanced healthcare navigation skills. These findings highlight the benefit of incorporating equity-driven, patient-centered programs into clinical & community settings to build trust, promote self-advocacy, & advance health equity for individuals living with SLE.

Environmental Heat Exposure and Risk of Systemic Lupus Erythematosus

Jennifer Woo[1], Kaitlyn Lawrence[2] and Dale Sandler[1], [1]National Institute of Environmental Health Sciences, Durham, NC, [2]DLH, Corp., Durham, NC

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: ARP I: Multidimensional Influences on Health in SLE (1686–1691)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Environmental heat exposures have been linked to increased morbidity and mortality. Individuals with systemic lupus erythematous (SLE) often have heat- and photo- sensitivity, which may make them particularly vulnerable to environmental heat exposure. While exposure to heat has been associated with disease flares and hospitalization among individuals with SLE, it is unknown whether exposure to extreme heat is associated with incident SLE and how socioeconomic factors may impact the association.

Methods: We use data from 48,934 eligible participants in the Sister Study, a prospective breast cancer cohort in the US aged 35 to 74 (enrollment: 2003-2009). Eligible participants had no prior history of SLE and had heat exposure data linked to their residential address at enrollment. Incident SLE was self-reported during follow-up through October 2022. PRISM weather data were obtained at 4km resolution and linked to participant baseline residence to estimate single year and 3-year average estimates of average daily maximum apparent temperature (i.e., heat index) and the total number of hot days where the apparent temperature exceeded 85 degrees Fahrenheit (F). Hazard ratios (HR) and 95% confidence intervals (CI) for SLE associated with quartile differences in heat measures were estimated using Cox proportional hazards regression. Models were adjusted for age, enrollment year, race and ethnicity, age at menarche, smoking status, alcohol status, and body mass index. We explored effect measure modification, stratifying by educational attainment—a proxy for resource availability to potentially mitigate heat exposure.

Results: Over follow-up (672,477 person years), 395 participants reported incident SLE after enrollment (mean age at diagnosis: 61±10 years) with an average time to diagnosis of 6.4 years. Increasing quartiles of environmental residential heat were associated with greater SLE. Individuals living in areas of the highest quartile of 3-year average daily apparent temperature had 1.35 (CI:1.00, 1.82) times greater SLE hazard than those living in the lowest quartile. Similarly, SLE hazard was also elevated for individuals living in areas in the highest quartile of 3-year average number of annual days over 85F compared to participants living in the lowest quartile (HR:1.40; CI:1.04, 1.89). Single year associations were similar in magnitude and trend. When stratified by educational attainment, participants who reported less than a bachelor's degree and lived in areas in the highest quartile of 3-year average annual days over 85F had 1.47(CI:1.00, 2.16) times greater SLE hazard compared to those in the lowest quartile. SLE hazard was slightly lower for participants who attained a bachelor's degree or higher (HR:1.24; CI:0.78, 1.97) and lived in the hottest areas.

Conclusion: Environmental heat exposure was associated with increased hazard of SLE. Associations were slightly modified by educational attainment, a proxy for potential availability of socioeconomic resources to mitigate heat exposure. Environmental heat exposure should be further assessed as a potential risk factor for SLE.

Abstract Number: 1691

Standardizing DXA Screening in Childhood-Onset Systemic Lupus Erythematosus at A Single Center: A Quality Improvement Initiative Using a Decision-Tree Algorithm

Andrea Gutierrez[1], Stephanie Armendariz[2], Muniza Mogri[3] and Kristina Ciaglia[4], [1]UT Southwestern Medical Center, Dallas, TX, [2]Texas Scottish Rite Hospital, Dallas, TX, [3]UT Southwestern Medical Center / Children's Health Dallas, Dallas, TX, [4]UT Southwestern, Children's Medical Center, and Scottish Rite for Children, Dallas, TX

SESSION INFORMATION

Session Date: Monday, October 27, 2025

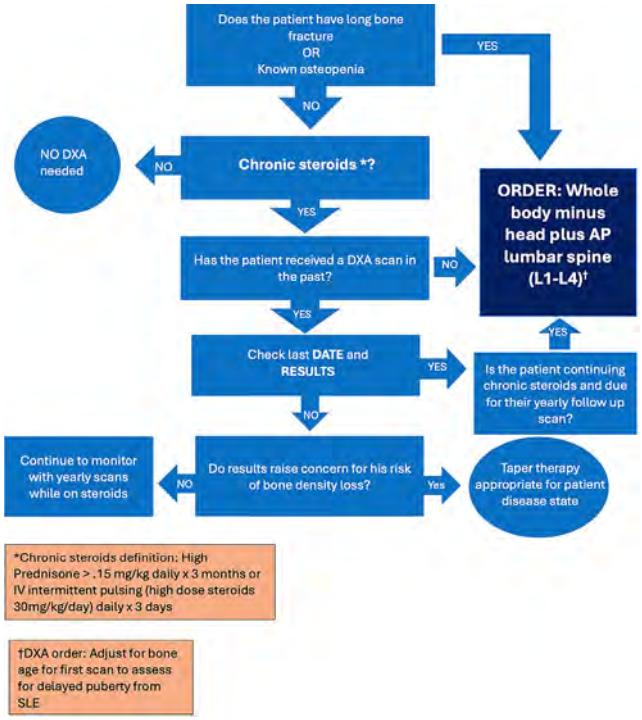
Session Title: Abstracts: ARP I: Multidimensional Influences on Health in SLE (1686–1691)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

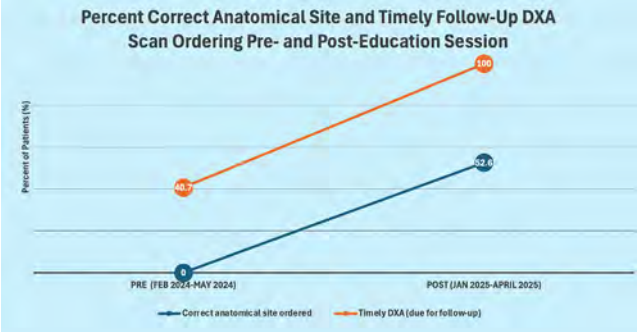
Background/Purpose: Patients with childhood-onset systemic lupus erythematosus (cSLE) are at increased risk of low bone mineral density, with studies showing a 40% frequency of osteopenia (Lilleby, 2007). Guidelines for adults with SLE recommend yearly screening for patients on chronic steroids with dual X-ray absorptiometry (DXA). However, pediatric-specific protocols are lacking, leading to inconsistencies in care. The aim of this project was to assess current DXA screening practices at a pediatric rheumatology outpatient clinic and evaluate the early impact of a decision-tree algorithm on screening consistency.

Methods: A retrospective chart review of 70 cSLE patients seen from February 2024-May 2024 was performed to assess baseline screening practices and barriers. Quality improvement tools, including root cause analysis and a driver diagram with provider input, prompted the development of a decision-tree algorithm, based on current guidelines and expert input. This

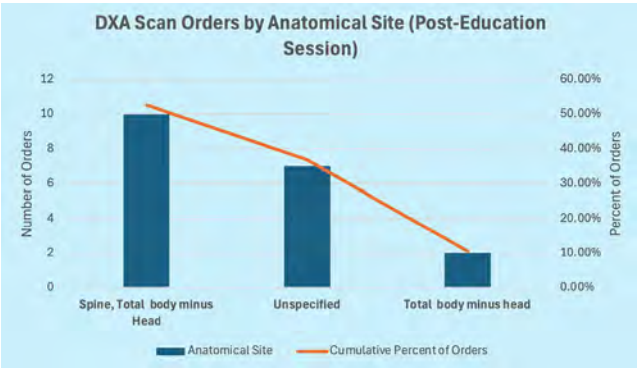


Decision-tree algorithm guiding DXA screening for childhood-onset SLE patients to standardize patient selection, timing, and site selection at a pediatric rheumatology outpatient clinic.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Line chart illustrating improvements in timely follow-up DXA orders (40.7% to 100%) and correct anatomical site selection (0% to 52.6%) among pediatric SLE patients from baseline (January-May 2024) to post-intervention ((January-April 2025) after introduction of the DXA screening algorithm and guidelines in an education session.



Pareto chart illustrating the frequency of anatomical sites ordered for DXA scans among pediatric SLE patients after introduction of the DXA screening algorithm and guidelines in an education session (January-April 2025), highlighting that 52.6% of provider orders adhered to recommended pediatric DXA guidelines.

algorithm specified DXA eligibility (chronic steroids), frequency (yearly), and recommended sites (total body less head and lumbar spine). The algorithm was introduced to providers during an educational session in September 2024. DXA screening practices were then compared before and after the intervention.

Results: At baseline, screening rates varied by insurance status, with commercial insurance patients at 78.6%, government-insured at 66.7%, and uninsured at just 12.5%. Despite relatively high screening rates among the insured, 59.3% of eligible patients did not receive timely follow-up DXA scans and most DXA results were not accessible in the EMR. Additionally, there was significant inconsistency in anatomical site selection for DXA scans.

Following the educational intervention, chart review of 87 cSLE patients seen from January to April 2025 showed a marked improvement in correct anatomical site ordering, increasing from 0% to 52.6%. Appropriate, timely DXA ordering for patients due for follow up also increased from 40.7% to 100%. Overall, if a DXA was due, whether for an initial visit or follow-up visit, it was ordered 84% of the time, and the correct decision regarding DXA ordering was made 94.1% of the time. An informal, oral survey revealed ongoing difficulty among providers in instantly recalling the correct anatomical site, suggesting more sustainable interventions will help maintain consistent improvement.

Conclusion: These findings highlight a knowledge gap among providers of who, when, and where to DXA screen pediatric SLE patients. Early assessment of this intervention suggests a decision-tree algorithm can help address this gap by improving clarity, guiding providers to appropriate decisions, and standardizing DXA screening for optimal care. Ongoing efforts are focusing on sustainable implementation, including posting the algorithm in clinic workspaces and integrating a default DXA order set into the EMR, with future steps to address access disparities. Enhancing screening consistency

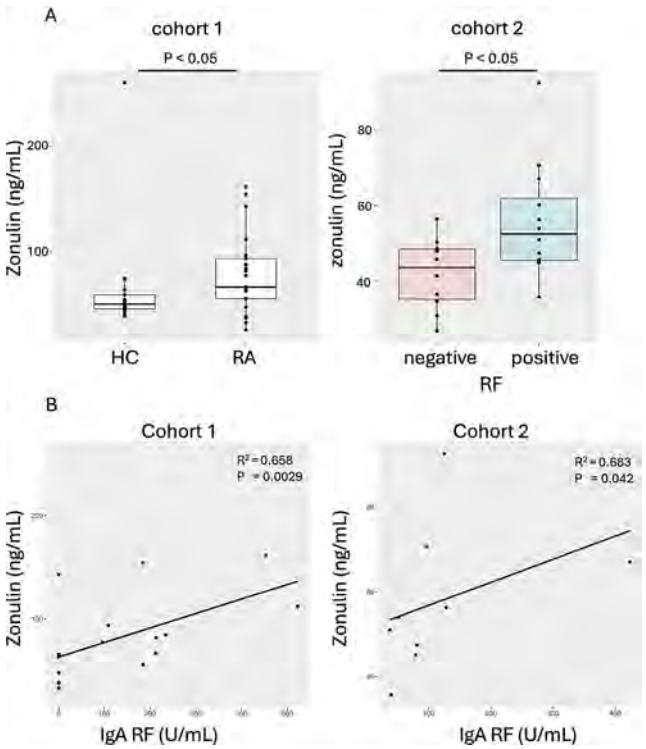
Rheumatoid factor is associated with increased gut permeability and migration of B cells to the joint via CXCR3 in rheumatoid arthritis

Ken Yasaka[1], Nida Pellett[2], Daria Krenitsky[1] and Jennifer Anolik[2], [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical center, Rochester, NY

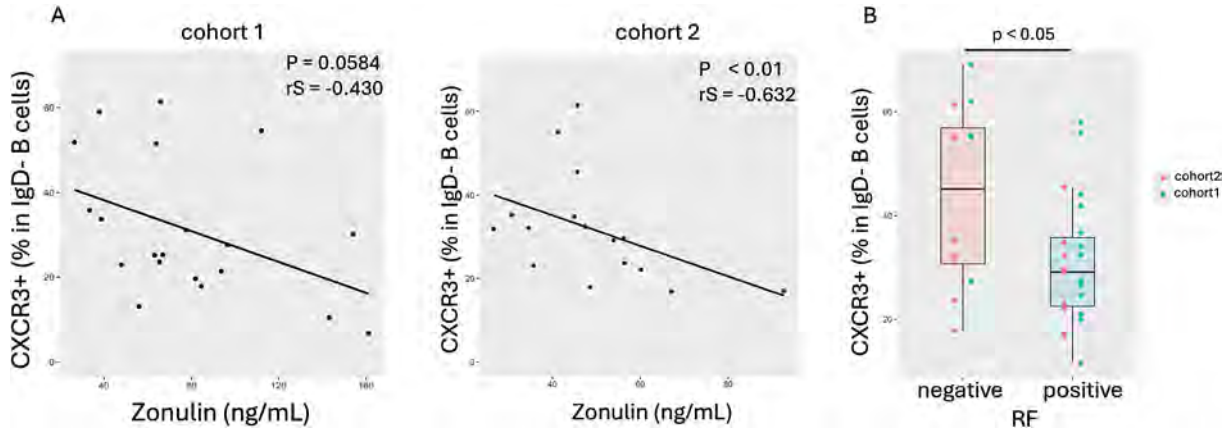
SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1692–1697)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: It has been proposed that the mucosal environment is associated with the pathogenesis of rheumatoid arthritis (RA). In addition to gut dysbiosis, intestinal barrier dysfunction has been reported prior to disease onset and may potentiate immune activation but has not been well-studied in relation to B cell dysregulation. Here we examined serum zonulin as a read-out of gut permeability and its relationship with autoantibodies and B cell subsets in RA to decipher the impact of increased gut permeability on autoimmunity.



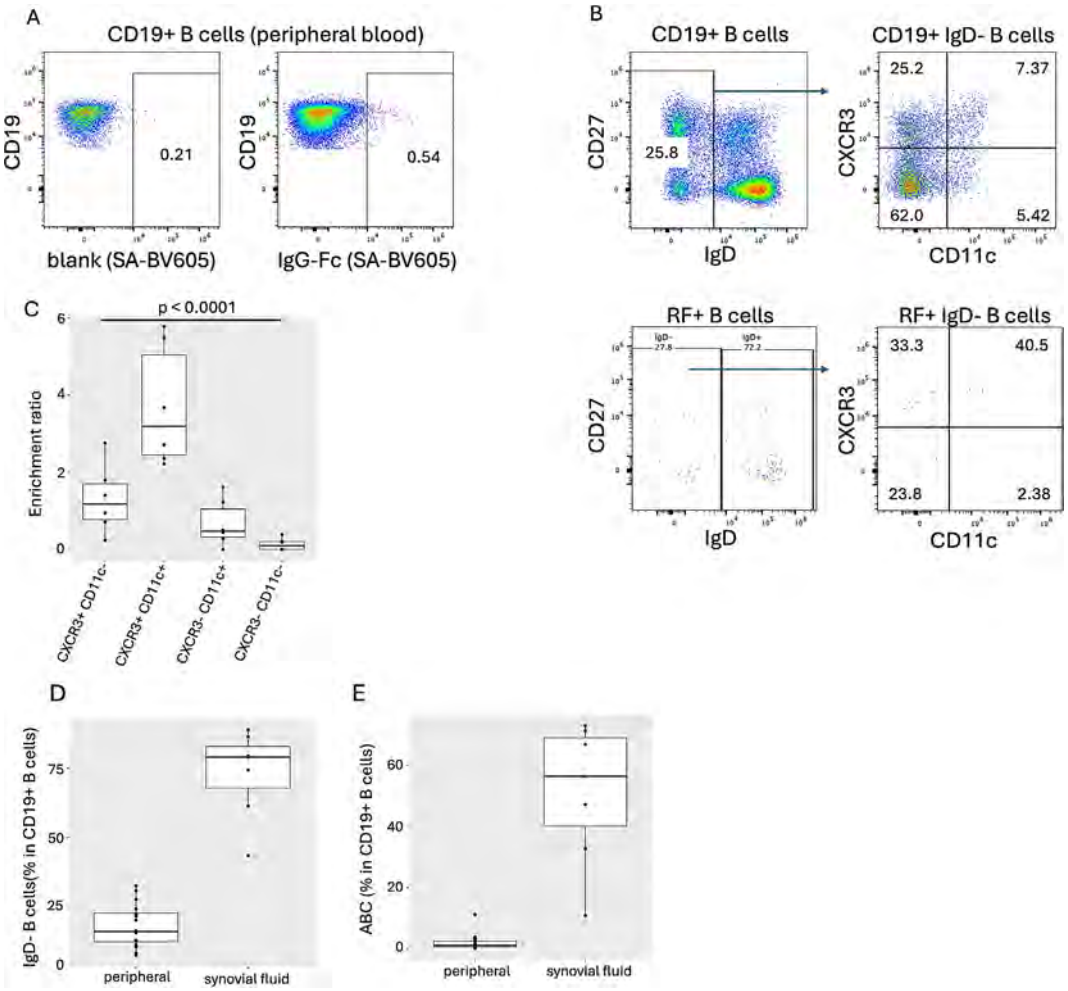
A. Serum zonulin levels. The Mann-Whitney U test was done in both cohorts. B. The correlation analysis between serum zonulin and IgA-RF titer. The Spearman's correlation test was done.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



A. Correlation between serum zonulin levels and expression of CXCR3 in IgD- B cells in both cohort 1 and 2. The Spearman's correlation test was done. B. Comparison of the expression of CXCR3 in IgD- B cells between RF- RA (n=12) vs RF+ RA (n=23). The Mann-Whiney U test was done.

Methods: Cohort 1 were composed of 20 RA patients (85% positive for either rheumatoid factor (RF) or anti-CCP antibodies (CCP)) and 16 age-matched healthy controls (HC). Cohort 2 comprised 22 RA patients with a higher seronegative fraction (40%) in order to examine the impact of autoantibody status. Serum zonulin levels were measured by zonulin ELISA kit (Immundiagnostik AG), serum IgA-RF titer was measured by ELISA kit (Abonova), and flow cytometry was conducted to



A. The gating of RF+ B cells using blank control (only SA-BV605 was added). B. The distribution of RF+ B cells in terms of CD11c and CXCR3 expression. C. The analysis of enrichment of RF+ B cells in each subset in RA (n=6). Enrichment ratio = (% in RF+ IgD- B cells / % in CD19+ IgD- B cells). Kruskal-Wallis test was done. D and E Comparison of each subset between unpaired peripheral and synovial samples.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

characterize B cell subsets. In CD19+ IgD- antigen-experienced B cells, Age-associated B cells (ABCs) were defined as CD11c+ and CXCR5-, and the expression of CXCR3 was determined using isotype control. RF+ B cells were detected using biotinylated IgG-Fc fragment followed by streptavidin – BV605 in peripheral blood samples (n=6). Flow cytometry was also conducted on synovial fluid samples from RA patients (n = 7) to characterize ABCs.

Results: Serum zonulin levels were significantly elevated in RA compared to HC (cohort 1) and higher in RF+ RA patients (cohort 2) (Figure 1A), while there was no statistically significant difference between CCP+ and CCP- patients. Moreover, both IgM and IgA-RF titers were significantly correlated with zonulin levels (Figure 1B). In IgD- B cells, CXCR3 was more highly expressed in ABCs than other B cells. CXCR3 expression in IgD- B cells was inversely correlated with zonulin levels in both cohorts (Figure 2A). Moreover, CXCR3 expression in IgD- B cells was significantly lower in RF+ patients (Figure 2B). Of note, there was no significant difference of the frequencies of ABC between HC and RA, and the frequencies of ABC were associated with neither RF positivity nor zonulin.

RF+ B cells were detected in the peripheral samples (Figure 3A). In IgD- B cells, RF+ B cells were enriched in the CXCR3+ CD11c+ subset (Figure 3B and C). Out of two synovial fluid samples on which RF+ B cells were investigated, RF+ B cells were detected (0.56% in total B cells) in one sample. In this sample, RF+ B cells were also enriched in CD11c+ CXCR3+ subset. Overall, in the synovial samples, majority of B cells were IgD-, and ABCs were more expanded than peripheral blood (Figure 3D and E).

Conclusion: Increased gut permeability was associated with the presence of RF. Serum zonulin was inversely correlated with circulating CXCR3+ B cells, and RF+ B cells were enriched in CXCR3+ CD11c+ B cells. We hypothesize that pathological B cells including ABCs may migrate to the joint via a CXCR3 – CXCL9/10 axis in the setting of increased gut permeability resulting in the decrease in CXCR3+ B cells in the circulation. Our ongoing research investigates how the migratory process of B cells is influenced by gut factors as well as how this affects the clinical outcome.

Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1692–1697)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) is a severe autoimmune disease, characterized by ANCAs targeting myeloperoxidase (MPO) or proteinase-3 (PR3). ANCA-specific B cells have a central role in AAV pathophysiology, but current knowledge of their markers and pathways is limited. Rituximab is an effective treatment, but relapses remain challenging. Therefore, there is an unmet need for treatments that achieve durable remission. Aim of this study is to characterize ANCA-specific B cells in AAV patients to gain pathophysiologic insight and identify novel treatment targets.

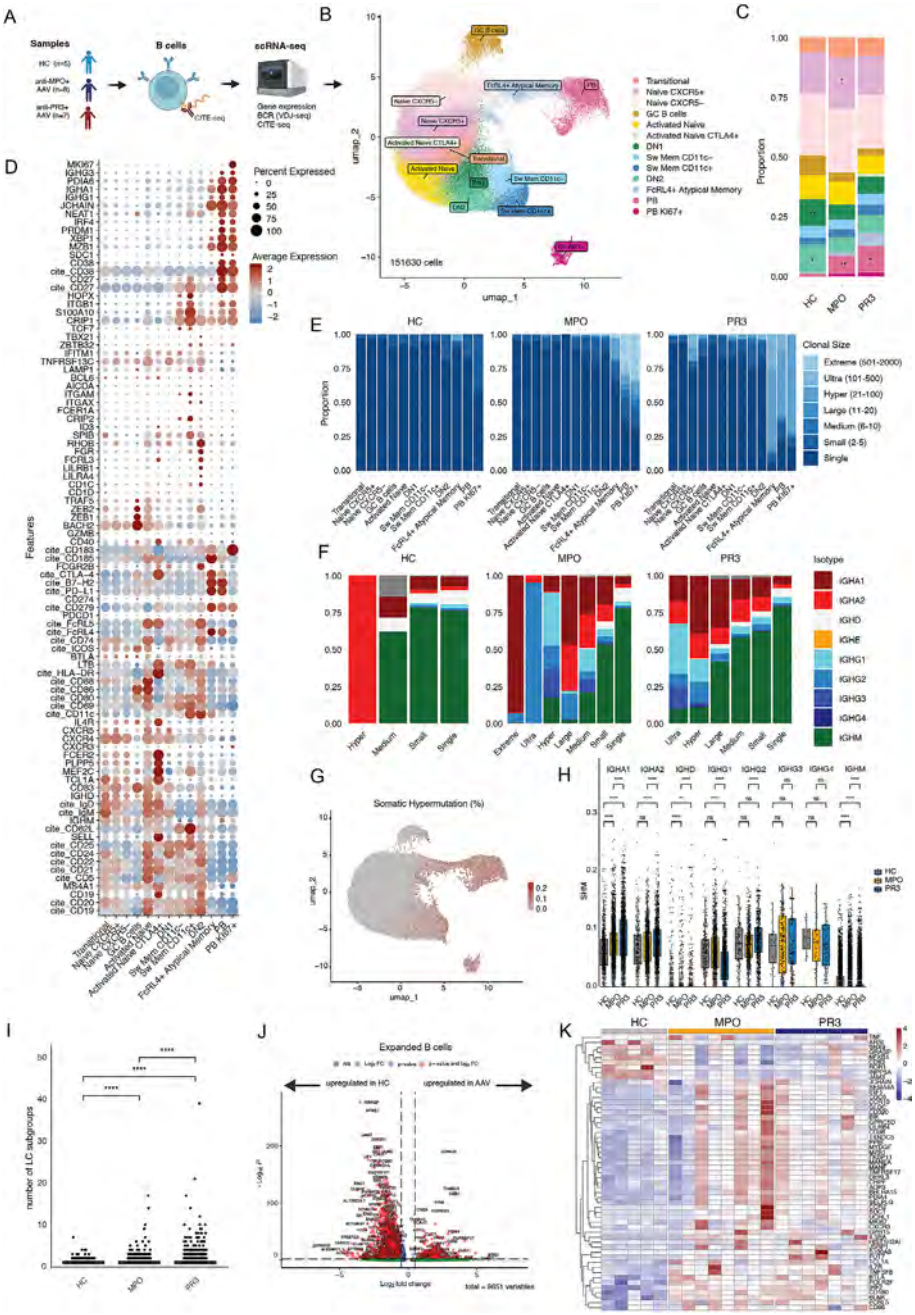

Figure 1. Overview of single cell RNA sequencing of B cells and B cell receptor (BCR) repertoires in ANCA-associated vasculitis patients (n=15) and healthy controls (n=5). A) Whole transcriptome and BCRs of B cells from 8 anti-MPO and 7 anti-PR3 AAV and 5 HC were analyzed with single cell RNA sequencing combined with CITE-seq. B) Thirteen distinct B cell subsets were identified after unsupervised clustering and annotated based upon gene and CITE-seq expression, visualized in a UMAP plot (n=151630 cells). C) Proportions of different B cell clusters for HC, anti-MPO, anti-PR3 AAV patients. *p<0.05, **p<0.01. D) Dotplot of gene and CITE-seq expression of B cell markers which was used to annotate the different B cell clusters. E) Clonal family size of B cells in the different B cell clusters in HC, anti-MPO and anti-PR3 AAV patients. F) Isotypes within the different clonal family size groups for HC, anti-MPO and anti-PR3 AAV patients. G) Umap plot with somatic hypermutation frequency displayed. H) Somatic hypermutation per isotype in different patient subgroups. I) Number of light chain rearrangements within each clonal family based on heavy chain. J) Differential gene expression analysis of expanded B cells, comparing AAV versus HC. K) Heatmap of normalized pseudobulk expression of genes which are significantly differently expressed in expanded B cells comparing AAV versus HC.

Methods: B cell receptor repertoires and whole transcriptomes of B cells were analyzed with single cell RNA sequencing combined with CITE-seq in 15 AAV patients and 5 healthy controls (HCs) (Fig 1A). 184 monoclonal antibodies (mAbs) and 25 germlines were expressed of highly expanded and/or mutated B cells. Their target antigens were screened with ELISAs and affinity (Kd) was measured with bio-layer interferometry (Fig 2A). Neutrophils of HCs were isolated, fixed with ethanol and stained with mAbs to study ANCA staining patterns.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. B cell receptor repertoire studies. A) Simplified methods overview of the expression of monoclonal antibodies. Sequences from highly expanded and/or mutated BCR repertoires were selected and expressed as monoclonal antibodies for downstream analyses. B) Heatmap of ELISA binding of monoclonal antibodies (n=184) and germline antibodies (n=25) from 12 AAV patients. mAbs were titrated (10, 3, 1, 0.33 ug/ml) on MPO, PR3 and mutated PR3 ELISAs. Mutated PR3 has a point mutation at S176A, resulting in lack of enzyme activity, and lack the N-terminal propeptide, resulting in mature PR3 (as published previously Specks et al. 2000 Arthritis Res.). C-F) Characteristics of MPO-specific B cells including C) Cell types, D) Isotypes, E) Clonal expansions, F) Somatic hypermutation. G-J) Characteristics of PR3-specific B cells incuding G) Cell types, H) Isotypes, I) Clonal expansions, J) Somatic hypermutation. ** p<0.01, *** p<0.001, **** P<0.0001.

Results: Both anti-MPO$^+$ and anti-PR3$^+$ AAV patients had significantly increased proportion of plasmablasts (PBs) and decreased DN1 and DN2 B cells as compared to HCs (Fig 1B-D). Additionally, PBs exhibited large clonal expansions in AAV (Fig 1E), which were mostly IgA and IgG isotypes (Fig 1F). Somatic hypermutation (SHM) was significantly higher in IgA1$^+$ and IgA2$^+$ and lower in IgD$^+$ and IgM$^+$ B cells in AAV (Fig 1G-H). AAV patients had increased light chain rearrangements per clonal family (Fig 1I). Overall, the lambda usage was significantly higher and increased with larger clonal families (data not shown). Differential gene expression analysis of expanded B cell clones identified several significant up- and down-regulated genes in AAV as compared to HC, including *TNFRSF17*, *SDC1* and *JCHAIN* (Fig 1H-I), involved in B cell activation, survival, migration and antibody production.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

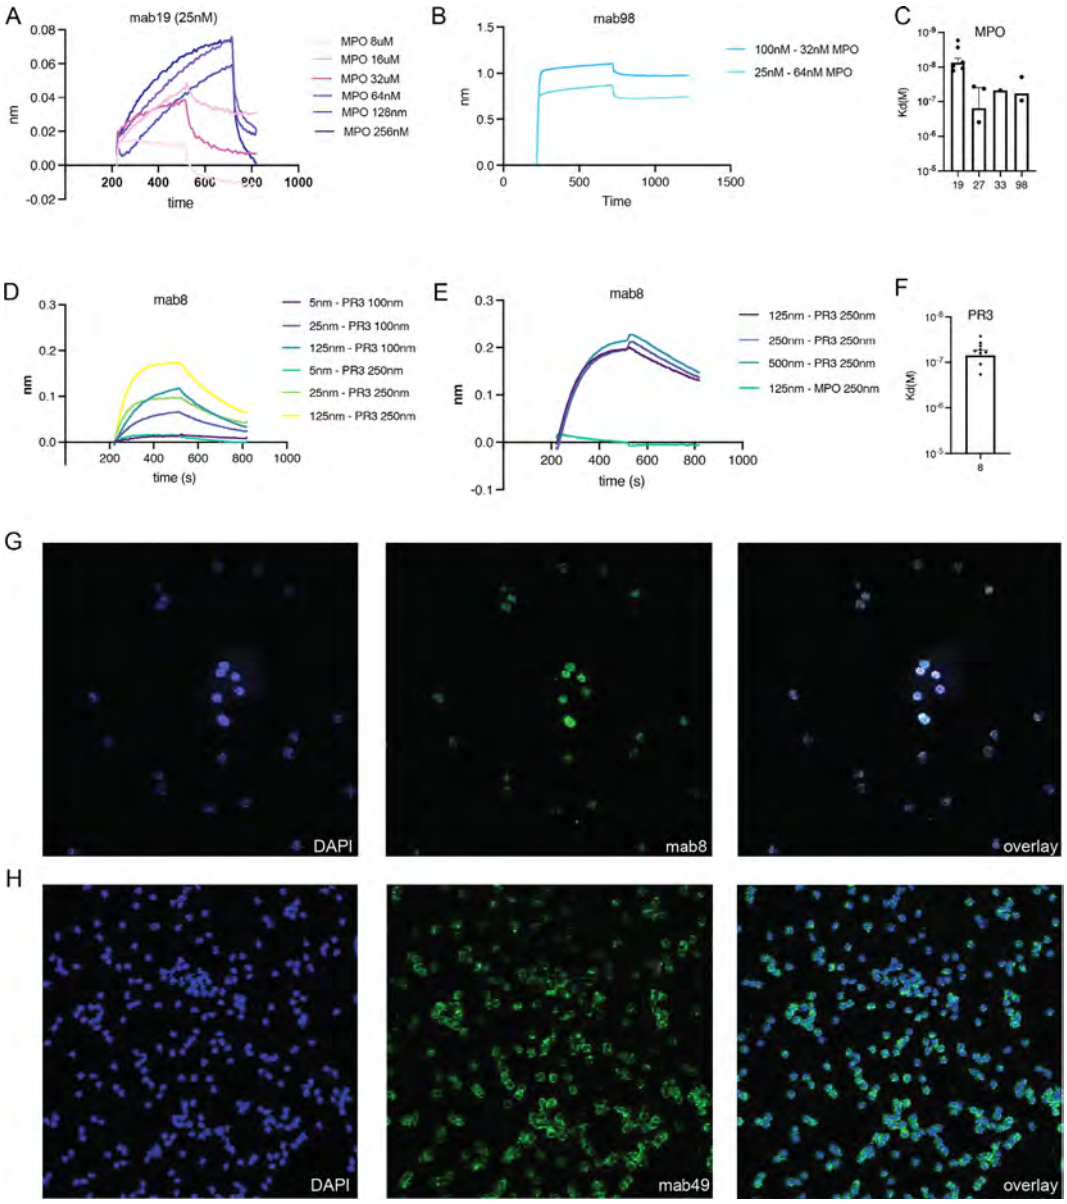

Figure 3. The binding affinity (Kd) of several mAbs with MPO or PR3 was measured with bio-layer interferometry. A) 25nM mab19 binding affinity curves with different molarities of MPO. B) 25nM and 100nM mab98 binding affinity curves with different molarities of MPO. C) Binding affinity Kd values of several mAbs for MPO. D-E) Titration of mAb 8 binding affinity curves with different molarities of PR3. F) Binding Affinity Kd values of mab 8 for PR3. G-H) Neutrophils were isolated and fixed with ethanol on ibidi slides, afterwards stained with 1ug/ml mab8 (G) or 1ug/ml mab49 (H), secondary anti-human IgG-Alexa488, DAPI and visualized with fluorescence microscopy.

We identified 28 mAbs targeting MPO (7 anti-MPO$^+$ and 2 anti-PR3$^+$ patients) and 9 targeting PR3 (3 anti-PR3$^+$ patients)(Fig 2B). The majority of MPO-specific B cells were IgA$^+$/IgG$^+$ PB or switched memory B cells (Fig 2C-D), clonally expanded and had increased SHMs (Fig 2E-F). PR3-specific B cells were clonally expanded IgG1-2-4 switched memory B cells (Fig 2G-J). Bio-layer interferometry demonstrated that the affinity (Kd) of several mAbs was 10^{-7}–10^{-8} nM for the ANCA antigens (Fig 3A-F). Neutrophil stainings confirmed c-ANCA and p-ANCA pattern for respectively PR3- and MPO-specific mAbs (Fig 3G-H).

Conclusion: Our single cell RNA-seq analysis of B cells in AAV patients reveals significant alterations in B cell populations and their functional characteristics. AAV patients exhibit increased clonal expansions, somatic hypermutation in IgA$^+$ B cells and light chain rearrangements. Our findings suggest a potential ongoing mucosal immune activation in these AAV patients. Our characterization of ANCA-specific B cells and their dysregulated activation provides insight into the pathogenic

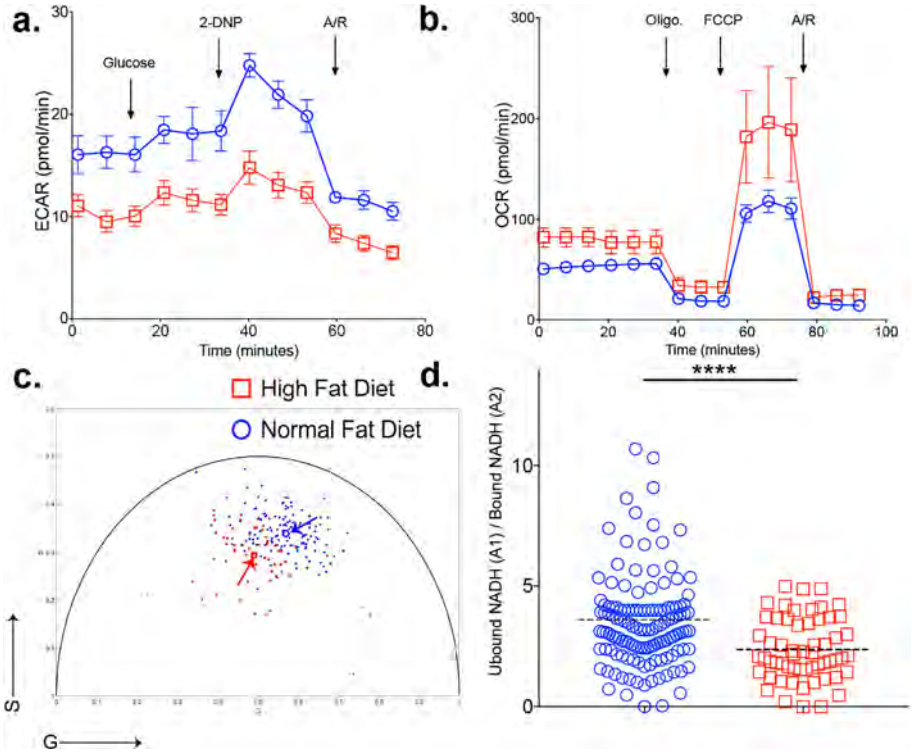
Obesity Exacerbates Autoimmunity by Dysregulating B Cell Behavior

Munir Akkaya, Sohret Gokcek, Billur Akkaya and Wael Jarjour, The Ohio State University, Columbus, OH

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1692–1697)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Obesity is a major public health concern in the United States, affecting over 100 million individuals. While its detrimental effects on multiple organ systems are well documented, the impact of obesity on immune responses remains incompletely understood. In this study, we address this knowledge gap by identifying obesity-driven B cell dysfunction that exacerbates autoimmunity in a diet-induced obesity mouse model.



B cells in obese mice has higher tendency towards oxidative phosphorylation and lower tendency towards glycolysis as compared to their lean counterparts. a,b) Seahorse extracellular flux assay, c,d) Fluorescence life time imaging microscopy

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. B cells in obese mice have distinct transcriptional remodeling as compared to B cells in lean mice both at rest and upon infection.

Novel strategy to detect nuclear antigen specific (self reactive) B cell clones

Methods: We developed a diet-induced obesity model in C57BL/6 mice and monitored B cell development and differentiation under both steady-state conditions and following immune challenges, including LCMV and *Plasmodium* infections, NP-CGG immunizations, and topical imiquimod (a TLR7 ligand) application to induce a lupus-like autoimmune setting. We assessed:

1. changes in B cell activation markers;
2. alterations in cellular metabolism using state-of-the-art fluorescence lifetime imaging microscopy and extracellular flux assays;
3. the frequency of self-reactive B cell clones using our novel nuclear antigen staining strategy coupled with flow cytometry; and
4. transcriptional changes via single-cell RNA sequencing.

Additionally, we conducted a thorough clinical comparison between obese and lean mice in both TLR7-induced and genetic (NZM) lupus models.

Results: . Int

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Interestingly, obese mice developed spontaneous germinal centers (GCs), yet paradoxically exhibited reduced responsiveness to NP-CGG immunization and infection, indicating disrupted B cell development and differentiation. Using our novel nuclear antigen staining strategy, we found that these spontaneous GCs in obese animals were predominantly composed of nuclear antigen-specific clones, suggesting a heightened propensity for autoimmunity.

Adoptive transfer experiments demonstrated that obesity-induced B cell dysregulation is cell-intrinsic, as the dysfunction persisted even after transferring B cells from obese donors into lean recipients. Further cellular and metabolic analyses revealed extensive remodeling in B cells from obese mice, including altered surface marker expression, a metabolic shift toward increased fatty acid utilization, and enhanced sensitivity to leptin receptor signaling. Single-cell RNA sequencing uncovered distinct transcriptional profiles in B cells from obese mice, both at baseline and following infection.

In lupus-like autoimmune models, obese mice exhibited a more severe and rapidly progressing disease course, characterized by skewed antibody responses, an increased frequency of autoreactive B cell clones, and accelerated mortality.

Conclusion: Collectively, these findings provide novel mechanistic insights into how obesity alters humoral immune responses and establish a direct link between obesity and heightened autoimmune risk.

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1692–1697)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by joint inflammation and bone destruction. RA is preceded by a subclinical phase defined by elevated levels of RA-associated autoantibodies, most preeminently anti-citrullinated protein antibodies (ACPA). Nonetheless, we have an incomplete understanding of the changes in the B cell compartment that contribute to the breaking of tolerance that underlies risk of RA development. Here, we performed a multi-omics study of peripheral B cells from ACPA+ at-risk individuals (ARI) and longitudinally studied those ARI that progressed to clinical RA, referred to as disease 'converters'.

Methods: We applied single-cell RNA sequencing (scRNA-seq) and flow cytometry to peripheral blood from 45 ACPA+ ARI. For converters, we profiled blood samples over a period of 2 years prior to the onset of clinical RA (n=13). The productive immunoglobulin heavy chain (IgH) isotype of B cell subsets was determined from scRNA-seq data. We applied spectral flow cytometry to characterize cytokine profiles of activated peripheral B cells from age-matched ACPA- control and ACPA+ ARI after TLR9 ligand and CD40 stimulation.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Upon productive IgH isotype labeling, IGHG3 sterile IgH expression by unswitched naive B cells was significantly increased among ARI (FDR=0.1). This suggests a greater likelihood that naïve B cells of ARI will class-switch to the IgG3+ isotype upon activation. A subset of naïve B cells also expanded in RA converters (FDR=0.02), a feature previously reported to correlate with activation in ACPA+ individuals (Inamo et al. 2023, JCI). Pathway analysis showed increased activation and antigen presentation activity compared to controls. Upon in vitro stimulation, naive B cells from ARI had higher frequencies of IL-6+ and RANKL+ cells compared to controls (FDR< 0.05) and trended toward elevated TNFα+ cells (FDR=0.19), suggesting they are primed for proinflammatory cytokine and RANKL secretion. Further, we identified a subset of CD27- ITGAX/CD11c+ effector memory B cells that increase in abundance during progression to clinical RA (FDR=0.11). This population has transcriptional features of chronic BCR engagement, including elevated class-switched cells as compared to the non-expanding effector memory subset, and a gene program associated with long-lived humoral immunity. Together these data show broad activation across naive and memory ARI B cell populations with evidence of a naive B cell primed state in ACPA+ ARI.

Conclusion: Our results indicate proinflammatory-skewed naive and memory B cell subsets among ARI, coinciding with systemic inflammation. An increased activation signature and *IGHG3* GLT suggest that naive B cells from ARI may be in a functionally "primed" state. Further, a subset of CD27- atypical or effector memory B cells with an activated transcriptional profile are found in converters as clinical RA approaches. Collectively, these data suggest that in addition to ACPA production, ongoing B cell activation is a feature of progression to clinical RA.

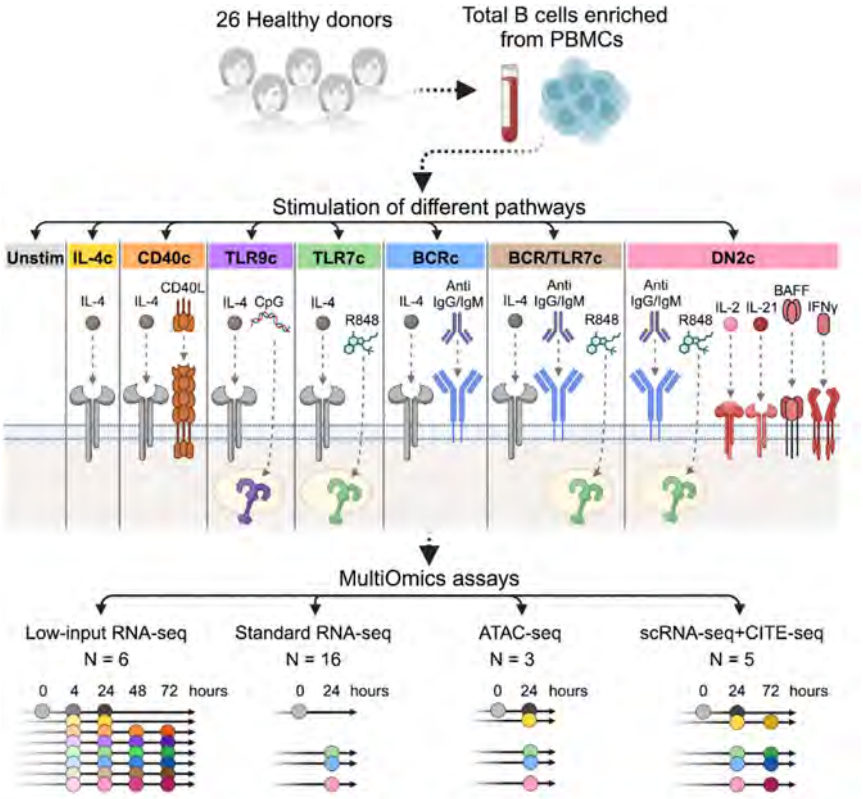

Figure 1. B cell activation resource. Illustration of experimental design, activation conditions used, and assays performed. Created with Biorender.

Background/Purpose: Most genetic variants that confer risk of complex autoimmune diseases affect gene regulation in specific cell types. Their target genes and focus cell types are often unknown, partially because some effects are hidden in untested cell states. B cells play important roles in autoimmune diseases, including systemic lupus erythematosus (SLE), rheumatoid arthritis, and multiple sclerosis. However, despite this established importance, B cell activation states are underrepresented in functional genomics studies.

Methods: In this study, we obtained B cells from 26 healthy female donors. We stimulated B cells *in vitro* with six activation conditions targeting key pathways: the B cell receptor (BCR), Toll-like receptor 7 (TLR7), TLR9, CD40, and a cocktail that promotes differentiation into double negative 2 (DN2) IgD^{-} $CD27^{-}$ $CD11c^{+}$ $CD21^{-}$ B cells, a likely pathogenic B cell subset for autoimmunity (**Fig. 1**). We profiled up to 24 human B cell activation states and up to 5 control conditions using RNA-seq, single-cell RNA-seq coupled with surface protein markers (CITE-seq), and ATAC-seq.

Results: We provide an in-depth characterization of how autoimmune disease-associated genes respond to stimuli and group into modules with distinct functions (**Fig. 2a-c**). Using high-depth RNA-seq data, we find pervasive splicing effects during B cell activation. Using single-cell data, we describe stimulus-dependent B cell fates (**Fig. 2d-g**). Chromatin data reveal the transcription factors likely involved in stimulus-dependent B cell activation. These open chromatin regions capture a significant proportion of the genetic risk of multiple autoimmune diseases and elucidate autoimmune disease genetic risk variants with previously unknown function.

To validate the utility of our findings, we performed fine-mapping for an SLE risk locus and identified a candidate causal variant (**Fig. 3a**) that overlaps an open chromatin region specific for B cells activated with the DN2-cocktail (**Fig. 3b**). This intergenic open chromatin peak is 15kb away from *TNFSF4*, which codes for OX40L and mediates interaction with activated T

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. cells. *TNFSF4* gets upregulated with DN2-cocktail activation at 48 and 72 hours (**Fig. 3c**). We used CRISPR inactivation in a B cell line to silence the putative enhancer where the SLE risk variant is located, which demonstrated that its target gene is *TNFSF4* (**Fig. 3d**).

We have made our multiomics resource available via an interactive browser that can be used to query the dynamics of gene regulation and B cell differentiation during activation by different stimuli, enhancing further investigation of B cells and their role in autoimmune diseases.

Conclusion: Our B cell activation multi-omics resource reveals how B cells are transcriptionally and epigenetically wired to respond to distinct stimuli, highlighting pathway-specific activation programs. It also offers mechanistic insights into the genetic basis of autoimmune diseases, including functional validation of a lupus-associated risk locus.

SESSION INFORMATION

Session Date: Monday, October 27, 2025
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1692–1697)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Treatment of autoimmune disease with T cell engagers (TCEs) leads to profound peripheral B cell depletion, followed by their reconstitution. However, the dynamics of B cell depletion as well as concomitant T cell activation, are poorly understood.

Methods: 14 patients with RA were treated with the CD19xCD3 TCE blinatumomab, 10 patients with SSc, IIM, IgG4-RD and GD were treated with the BCMAxCD3 TCE teclistamab. All patients had active, multi-drug-resistant AID. Longitudinal high dimensional flow cytometry was performed on peripheral blood mononuclear cells (PBMCs). 1-year follow-up was available for 8/14 patients treated with blinatumomab. 6-months follow-up was available for 8/10 patients treated with teclistamab.

Results: TCE therapy led to a rapid B cell depletion (Fig. 1A-B). 11/14 RA patients had circulating B cells at baseline (median 114/nl), and 3/14 patients had no B cells because of recent rituximab therapy. Complete B cell depletion was reached in 8/11 RA patients (in 2 patients after the first cycle, in 4 patients after the second cycle and in 2 patients after a third cycle).

Teclistamab led to complete B cell depletion in all patients (in 4/10 patients after the first dose and in 6/10 patients after the third dose). A significant decrease of serum immunoglobulins and free light chains indicated effective depletion of the plasma cell compartment via teclistamab, in contrast to blinatumomab.

B cells reconstituted after a median of 61 days after blinatumomab and a median of 157 days after teclistamab (Fig. 1C). Reconstituted B cells were mostly of a naive phenotype. Correspondingly, $CD19^+$ $CD27^+$ memory B cells decreased substantially (blinatumomab: average 16% to 7%; teclistamab: average 8% to 2%). One year after blinatumomab treatment

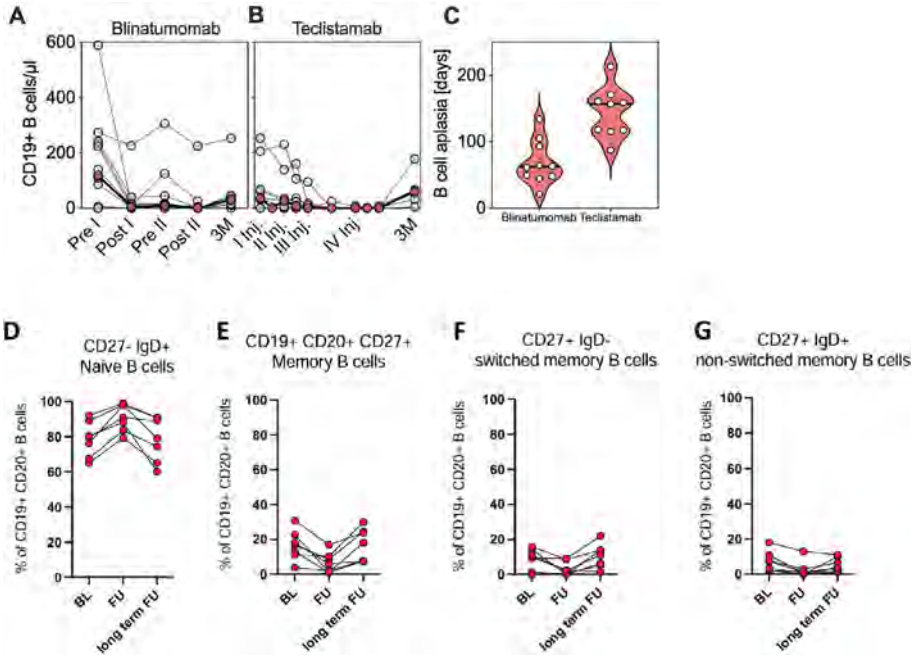

Fig. 1: A-B. Quantification of B cells during therapy with A. blinatumomab and B. teclistamab. C. B cell aplasia after treatment with TCEs, D-G. Frequencies of D. Naive, E. Memory, F. switched memory, and G. non switched memory B cells at short term follow-up (FU) and at 1-year follow-up (long term FU) after Blinatumomab.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

initiation (6/14 patients), both CD27^{+}IgD^{+} non-switched and CD27^{+} IgD^{-} switched memory B cells re-emerged, while CD20^{+}CD27^{-} naive B cells slightly decreased (Fig. 1D-G). Plasmablasts were depleted after both therapies and stayed depleted at long-term follow up.

Circulating T cells transiently decreased during TCE therapy (Fig. 2A-B). A relative shift towards CD8^{+} cells during teclistamab indicated a stronger activation and expansion of cytotoxic T cells (Fig. 2C-D). TCE therapy led to a noticeable increase in exhaustion related T cell phenotypes. PD1+ CD8^{+} T cells accumulated after the first cycle (blinatumomab: from 11.2 to 20.7%; teclistamab: from 6.9 to 24.3%). CD8^{+} CD62L^{-} CD45RA^{-} CD8^{+} effector memory (EM) and CD62L^{-} CD8^{+} effector memory re-expressing CD45RA (EMRA) T cells expressed more PD-1 compared to the other CD8^{+} subpopulations, suggesting increased exhaustion (Fig. 2E-F).

Teclistamab led to an increase in CD8^{+} TEM and TEMRA, which also expressed more PD-1 compared to the other CD8^{+} subpopulations. CD4^{+} T cells were less influenced in both therapies, a slight increase of CD4+ CD62L^{+} CD45RA^{-} central memory (CM) T cells was observed during both treatments.

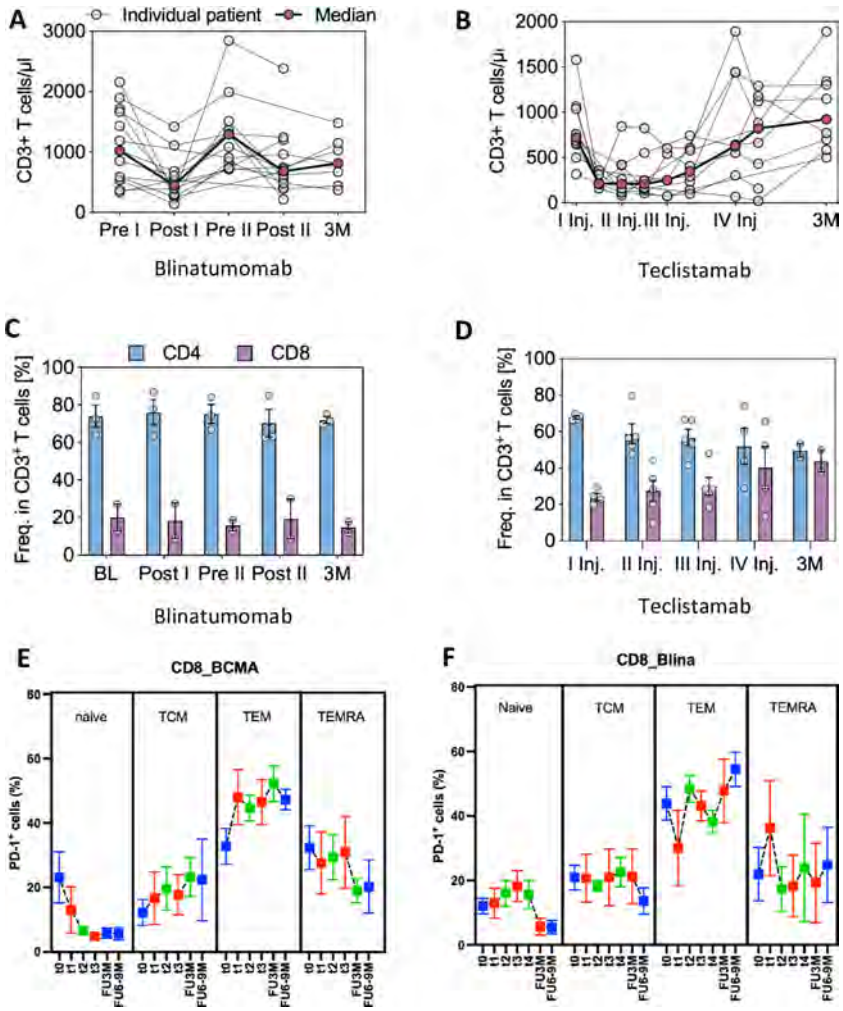

Fig. 2: A-B. Quantification of CD3+ T cells during therapy with A. blinatumomab and B. teclistamab. C-D. T CD4+/CD8+ cell ratio during treatment with TCEs, E. expression of PD-1 in T cell subpopulations during treatment with teclistamab at baseline (t0), after the 3rd injection (t1), at 14-days (t2) and 1-month follow up (t3) and at 3-months follow up (FU3M), F. expression of PD-1 in T cell subpopulations during treatment with blinatumomab at baseline (t0), during the first infusion (t1), between the first and second infusion (t2), during the second infusion (t3), after the second infusion (t4), at 3-months follow-up and at 6-9-months follow-up.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Together, these data demonstrate the dynamic impact of TCEs on B cell depletion and reconstitution in AIDs. Furthermore, strong effects on the T cell compartment are observed, raising the intriguing possibility that their mechanism of action is not limited to the B cell depletion alone.

Abstract Number: 1698

X Chromosome DNA Methylation Changes Suggest Epigenetic Contributions to Immune Dysregulation in Male Lupus

Desire Casares Marfil[1], Gülşah Kavrul Kayaalp[2], Vafa Guliyeva[2], Özlem Akgün[2], Şeyma Türkmen[3], Elif Kilic Konte[4], Sezgin Sahin[4], Ozgur Kasapcopur[5], Betul Sozeri[6], Selçuk Sözer Tokdemir[7], Nuray Aktay Ayaz[8] and Amr Sawalha[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]Istanbul University Faculty of Medicine, Istanbul, Turkey, [3]University of Health Sciences, Umraniye Research and Training Hospital, Istanbul, Turkey, [4]Istanbul University Cerrahpasa Medical School, Istanbul, Turkey, [5]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, istanbul, Turkey, [6]Health sciences university, Istanbul, Turkey, [7]Istanbul University, Istanbul, Turkey, [8]Istanbul University Medical School, Istanbul, Turkey

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Genetics, Genomics & Proteomics (1698–1703)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: DNA methylation plays a critical role in the pathogenesis of lupus. Although most epigenetic studies have focused on autosomal regions, the X chromosome remains underexplored. In this study, we investigate X chromosome DNA methylation patterns in male patients with lupus. Studying male individuals allows us to circumvent the analytical complexities posed by random X-inactivation in female patients with two X chromosomes, enabling a clearer view of epigenetic changes that may contribute to disease mechanisms.

Methods: A total of 16 male patients with childhood-onset lupus and 14 healthy male controls were included. DNA from peripheral blood mononuclear cells (PBMCs) was isolated to assess DNA methylation patterns using the Infinium MethylationEPIC v2.0 array (Illumina). Data processing and statistical analyses were conducted using the *minfi* and *limma* R packages. Group differences in methylation patterns were tested via linear regression, adjusting for age and estimated cell-type proportions. Gene ontology enrichment analysis was performed with Metascape.

Results: A total of 23,364 DNA methylation sites (CpGs) on the X chromosome were analyzed. Differential methylation analysis between cases and controls identified 1,120 CpG sites with suggestive associations ($p < 0.05$), mapping to 593 genes. Approximately half of these sites were hypomethylated in patients compared to controls, with several CpGs located in immune-related genes. Notably, several hypomethylated CpGs were found in genes involved in the toll-like receptor (TLR) signaling pathway, including *TLR7*, *TASL*, and *BTK*, which are key components of innate immune signaling pathways that drive the expression of pro-inflammatory cytokines. Pathway enrichment analysis of the top 100 most significant differentially methylated CpGs revealed overrepresentation of immune and regulatory pathways, such as positive regulation of type I interferon production, response to interleukin-1, and regulation of cellular response to growth factor stimulus, suggesting epigenetic remodeling of critical processes in disease pathogenesis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: These findings highlight previously underrecognized X chromosome DNA methylation changes in lupus, particularly in immune-related genes and pathways. Our results suggest that epigenetic dysregulation on the X chromosome may contribute to immune activation and disease pathogenesis, underscoring the importance of including sex chromosomes in lupus epigenetic studies.

Abstract Number: 1699

Protein-coding Somatic Genetic Variation in Lymphocytes in Systemic Lupus Erythematosus

Siva Kasinathan[1], Minh Pham[2] and Ansuman Satpathy[2], [1]Stanford University School of Medicine, Palo Alto, CA, [2]Stanford University School of Medicine, Stanford, CA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Genetics, Genomics & Proteomics (1698–1703)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: The genetic and environmental factors underlying pathogenesis of systemic lupus erythematosus (SLE) are incompletely resolved. While inherited genetic variation has been extensively queried in lupus, post-zygotically acquired somatic mutations remain largely unexplored. Somatic lesions are continually generated in all cells by physiologic processes and exogenous exposures, rendering every human a genetic mosaic. Lymphocytes are especially prone to mutagenesis in part due to programmed genomic instability during antigen receptor maturation. We therefore sought to survey somatic single nucleotide variants (sSNVs) in lymphocytes towards testing the hypothesis that mosaicism contributes to impaired self-tolerance in autoimmunity.

Methods: Subjects aged 6 – 21 years who met 2019 ACR/EULAR SLE classification criteria (n = 22) and unaffected controls (JIA, n = 6; low-titer ANA positive without disease, n = 4) were recruited from Stanford Pediatric Rheumatology clinics between August 2023 and October 2024. Peripheral blood mononuclear cells were obtained from controls at one timepoint and from SLE cases during active (n = 14, SLEDAI >4) and/or quiescent disease (n = 14). B cells, CD4 and CD8 T cells, and monocytes were isolated via fluorescence-activated cell sorting and sSNVs were detected via deep cell type-specific exome sequencing (~300X coverage).

Results: We discovered 9,650 candidate sSNVs with median variant allele frequency (VAF) of 3.4% (range 1.9 – 20.1%) across 112 exome datasets representing 4 cell types and 38 samples from 32 subjects. Based on sequencing synthetic mixtures of well-characterized cell lines, our workflow recovered SNVs with VAF ≥1.5% with precision >95% and recall >60%. B cells in active SLE were enriched for non-synonymous sSNVs relative to quiescent lupus and controls (median 62 vs. 40 – 52, p = 0.028, Mann-Whitney U test). Similarly, CD8 T cells in active SLE carried more sSNVs than in quiescent disease or in controls (median 65 vs. 40 – 41, p = 0.004, Mann-Whitney U test). Differences in age-stratified sSNV burden and cell type-specific VAFs were not significant. Genes harboring sSNVs in SLE lymphocytes included *JAK1*, *STAT3*, and *RELB*. Pooled analysis of non-synonymous sSNVs in SLE lymphocytes identified enrichment of survival signaling pathway genes ($p < 0.001$, hypergeometric test, Bonferroni corrected).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Interim analysis of immunogenetic mosaicism identified frequent protein-coding candidate sSNVs in peripheral B and T cells in clinically active SLE. Together with ongoing validation of sSNVs, sequencing of additional pediatric and adult subjects, and longitudinal analyses, we expect that future mechanistic studies will clarify the role of somatic variation in lupus pathogenesis and heterogeneity.

Abstract Number: 1700

Altered Gene Expression in Male SLE Is Mapped to a Male-specific Y Chromosome Locus Associated with Microdeletions

Mikhail Olferiev[1], Kyriakos Kirou[1], Emily Wu[2], Dina Greenman[1] and Mary Crow[3], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Union City, NJ, [3]Hospital for Special Surgery, New York

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Genetics, Genomics & Proteomics (1698–1703)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: SLE occurs more frequently in females than males, with relative prevalence 9-10:1. While the impact of hormones on immune function may contribute to the female predominance of SLE, recent interest has focused on the immune functions conferred by the two X chromosomes in women. To identify unique mechanisms that may result in SLE in males, we generated RNA transcript data from male and female subjects with SLE or from healthy individuals.

Methods: Female and male SLE patients were characterized in detail based on demographic, clinical and laboratory features. Multiple correspondence analysis of 95 parameters was used to optimally match 15 female and 15 male SLE patients, along with healthy donors. A PBMC sample for RNAseq analysis was selected for each patient at the time of their lowest level of disease activity. RNA sequencing was performed and data analyzed using principal component analysis (PCA) and determination of differentially expressed gene transcripts.

Results: PCA distribution of RNAseq data showed male SLE patients distinct from healthy males and female SLE patients. As observed for the overall SLE population, type I interferon-stimulated genes dominate transcripts differentially expressed between SLE males and healthy males, with SLE males also showing higher expression of NFkB pathway genes and pro-inflammatory cytokines/chemokines compared with healthy males. Among the differentially expressed genes, 4 Y chromosome-encoded transcripts (*TXLNGY, ENSG00000267793*, *BCORP1* and *KDM5D*) were significantly decreased in SLE males compared with healthy males and 1 Y chromosome-encoded gene (*EIF1AY*) was increased in SLE males. Of those, *KDM5D*, also called *SMCY*, encoding lysine demethylase 5D, is of particular interest as it mediates the removal of methyl groups from histone lysine residues at the K4 position and regulates both promoters and enhancers throughout the genome. Remarkably, review of the Y chromosome location of those differentially expressed genes revealed that all 5 genes share a portion of a genomic locus (termed AZFb) in the male-specific region of Y that is associated with microdeletions and male infertility.

Conclusion: Males with SLE demonstrate altered expression of several genes occupying a common Y chromosome locus, along with increased expression of NFkB and pro-inflammatory cytokine genes. Among the Y chromosome-encoded transcripts decreased in male SLE, *KDM5D*, a histone demethylase, warrants further investigation. *KDM5D* is expressed in

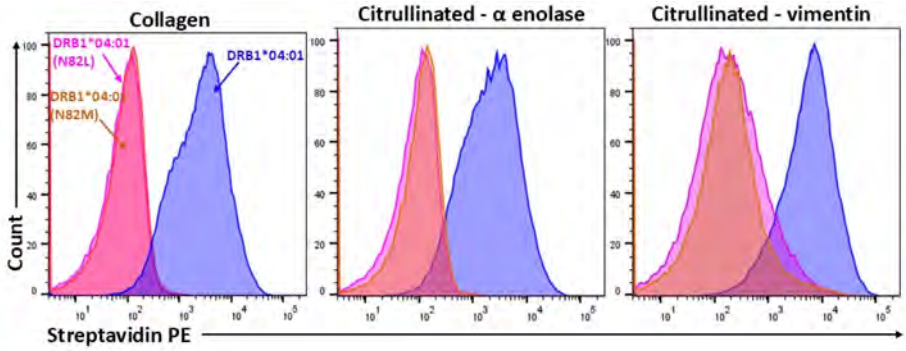
Gene Editing of HLA-Class II DRB1*04:01 at Position 82 Abrogates Binding of Citrullinated Arthritogenic Peptides and Collagen

Vibha Jha[1], Brian Freed[2], Niyun Jin[1], Manjula Miglani[1] and Christina Roark[2], [1]University of Colorado, Aurora, CO, [2]Clinimmune Labs Immunology, School of Medicine, Aurora, CO

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Genetics, Genomics & Proteomics (1698–1703)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease with a strong genetic association to Class II HLA-DRB1*04:01. Presentation of arthritogenic peptides bound to DRB1*04:01 results in activation of autoreactive T cells which then mediate arthritic inflammation. Our previous work has demonstrated that a single amino acid change from lysine (K) to glutamic acid (E) at position 71 of DRB1*04:01 blocks binding of collagen$^{258\text{-}272}$ and abrogates collagen-specific CD4^{+} T cell activation without inducing alloreactivity (1). However, the K71E edit does not block binding of native or citrullinated vimentin$^{66\text{-}78}$ and α-enolase$^{11\text{-}25}$ peptides. Position 71 is located in pocket 4 of the peptide binding groove. Here we investigate if changing the amino acid in pocket 1 (position 86) or in pocket 2 (position 82) would eliminate binding of citrullinated arthritogenic peptides in addition to the immunodominant collagen peptide.



Mean MFI from three different repeats

HLA-Class II allele	Collagen	Citrullinated α enolase	Citrullinated vimentin
DRB1*04:01	3889	3867	7131
DRB1*04:01(N82L)	77	122	1082
DRB1*04:01(N82M)	71	97	339

Figure 1: Binding of arthritogenic peptides with unedited DRB1*04:01, and edits at position 82

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We edited DRB1*04:01 at position 82, from N to either leucine (L) or methionine (M) and at position 86 from glycine (G) to L. The edited DRB1*04:01^{N82L} (N82L), DRB1*04:01^{N82M} (N82M) and DRB1*04:01^{G86L} (G86L) molecules were expressed in T2 cells. Peptide binding of biotinylated citrullinated and native α-enolase$^{11-25}$, citrullinated and native vimentin$^{66-78}$ and native collagen$^{258-272}$ peptides was detected by streptavidin-PE using flow cytometry.

Results: All three edits blocked binding of the native forms of -enolase, vimentin and collagen. Citrullinated vimentin66-78 binding to DRB1*04:01N82L was reduced 85% and binding to DRB1*04:01N82M was reduced 95%. Similarly, binding of citrullinated α-enolase11-25 to DRB1*04:01N82L and to DRB1*04:01N82M was reduced by 97%. The G86L edit to DRB1*04:01 abrogated binding of citrullinated α-enolase11-25 and collagen258-272 but citrullinated vimentin66-78 could still bind.

Conclusion: Replacing N at position 82 of DRB1*04:01, with either L or M, abrogates peptide binding of citrullinated a-enolase, citrullinated vimentin and collagen. Blocking the binding of citrullinated peptides to edited DRB1*04:01 on APCs would prevent presentation of these autoantigens to autoreactive T cells. Our results demonstrate that introducing mutations at position 82 in DRB1*04:01 blocks binding of all arthritogenic peptides and thus has potential to be used as gene therapy to safely halt progression of RA in patients carrying DRB1*04:01

Powerful and Accurate Case-Control Analysis of Spatially Resolved Molecular Data in Autoimmune Disease

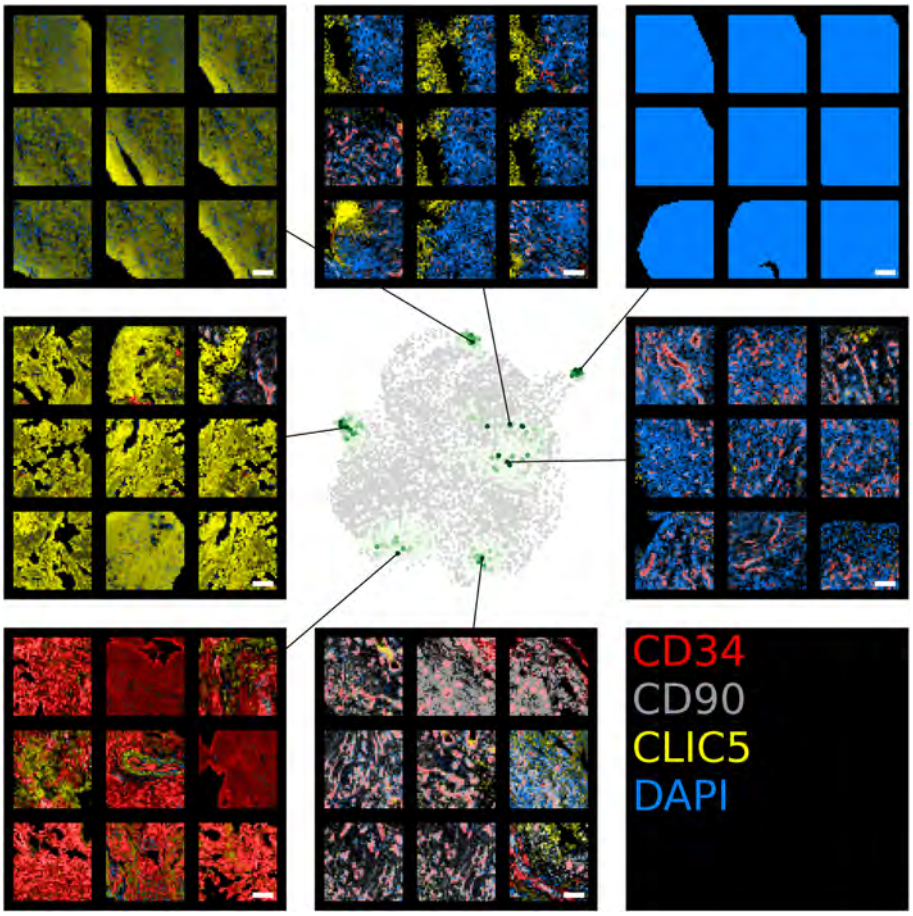
Yakir Reshef[1], Lakshay Sood[1], Michelle Curtis[1], Laurie Rumker[2], DANIEL STEIN[3], Mukta Palshikar[1], Saba Nayar[4], Andrew Filer[5], Anna Helena Jonsson[6], ilya Korsunsky[7], Soumya Raychaudhuri[7] and Accelerating Medicines Partnership: Autoimmune and Immune-Mediated Diseases Network (AMP AIM), Accelerating Medicines Partnership: RA/SLE Network (AMP RA/SLE), [1]Brigham and Women's Hospital, Boston, [2]Broad Institute, Boston, [3]Harvard University, Boston, [4]University of Birmingham, Birmingham, United Kingdom, [5]The University of Birmingham, Birmingham, United Kingdom, [6]University of Colorado School of Medicine, Aurora, CO, [7]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Genetics, Genomics & Proteomics (1698–1703)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Autoimmune diseases such as rheumatoid arthritis (RA) involve complex spatial organization of immune and stromal cells within inflamed tissues. As spatial molecular profiling methods grow in scale and resolution, there is increasing opportunity to identify clinically and pathophysiologically informative tissue structures through case-control comparisons. Existing approaches to define key pathological structures rely either on bespoke manual scoring systems such as the Krenn inflammation score or on clustering spatial neighborhoods of segmented and typed cells based on cell-type abundances. These approaches are limited by confirmation bias, segmentation error, loss of local spatial relationships among cells, and inability to model spatial overlap of multiple biological processes.

Methods: We developed variational inference-based microniche analysis (VIMA), an artificial intelligence-driven method for case-control analysis of spatial data. VIMA uses AI to learn numerical "fingerprints" of small tissue patches that capture their biological content, groups similar patches into thousands of overlapping "microniches" across samples, and identifies microniches whose abundance differs by condition. VIMA requires no cell segmentation or typing and can be used on any high-resolution spatial modality.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



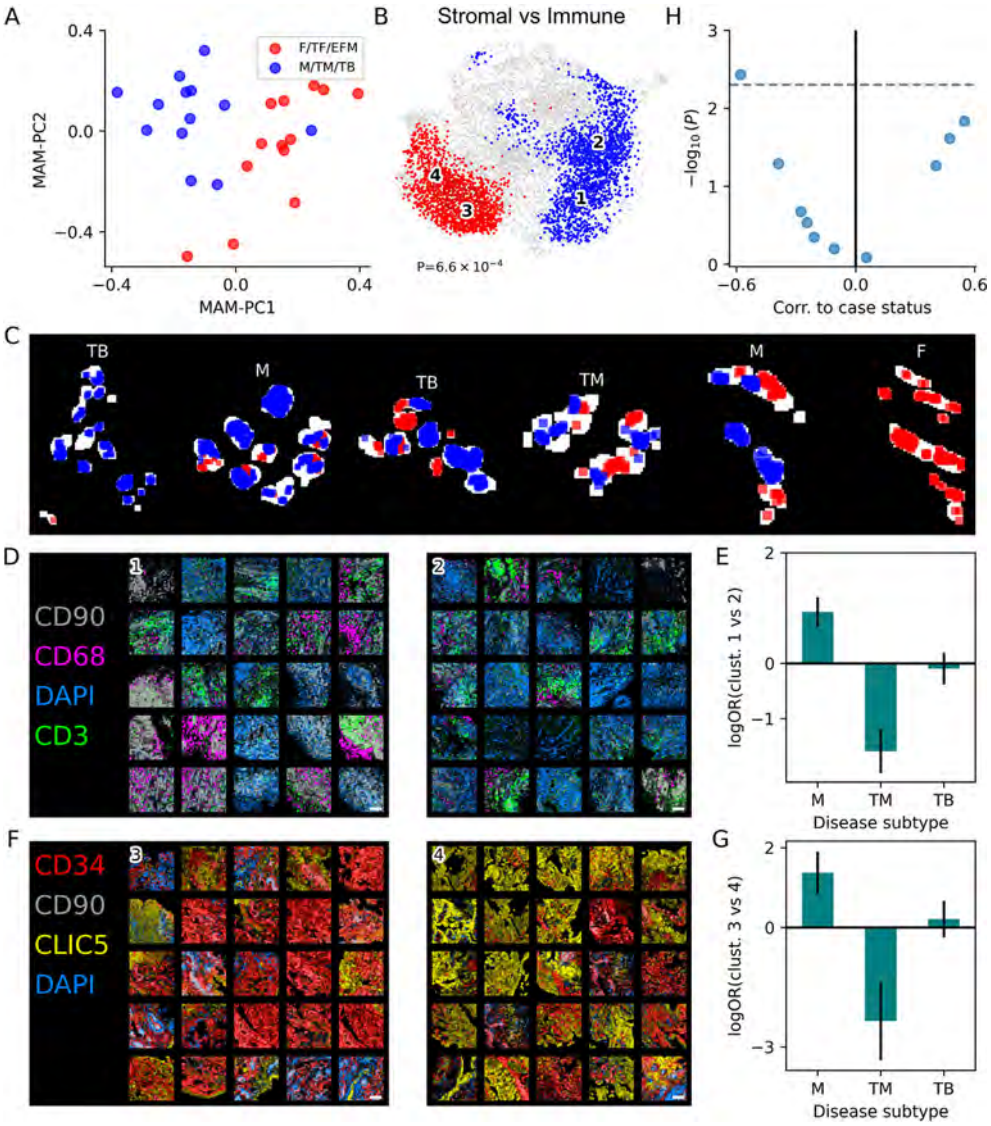
Examples of VIMA's microniches in the RA IHC dataset. We show a UMAP of all the patches in the dataset generated using the patch fingerprints, together with randomly selected patches drawn from 7 example microniches; these microniches are characterized by (clockwise from bottom-left): high CD34 intensity with interspersed CLIC5 signal, high CLIC5 intensity with minimal CD34 signal, high CLIC5 intensity but with a blurrier texture and interspersed DAPI signal, a vertical boundary between CLIC5-high/DAPI-low pixels and CLIC5-low/DAPI-high pixels, a DAPI staining artifact, DAPI-high infiltrate surrounding CD34-high regions that are likely blood vessels, and perivascular CD90-high pixels. All scale bars represent 100um.

Results: We first applied VIMA to a 7-marker N=22 immunohistochemistry (IHC) dataset in RA. Without prior labels, VIMA stratified samples into an "immune" and a "stromal" subtype (P=6.5e-4). The stromal subtype contained swathes of CLIC5+ staining and CD34+ regions; the immune subtype contained perivascular infiltrates and macrophages contacting sublining fibroblasts. These subtypes matched cell-type abundance phenotypes (CTAPs) defined previously in a much larger (N=79) non-spatial single-cell dataset, showing that VIMA can extract information from IHC that previously required state-of-the-art sequencing at large samle sizes to uncover. VIMA also revealed striking within-sample spatial heterogeneity, with many RA samples containing patches from both the stromal and immune subtypes, challenging the notion of one subtype per patient. We confirmed similar heterogeneity in subsequently collected synovial samples profiled with spatial transcriptomics as well.

We also applied VIMA to a 54-marker N=34 CODEX dataset in UC. Here, VIMA was able to powerfully distinguish UC samples from healthy samples (P=6.5e-4), and then to identify a dose-response relationship between duration of TNF inhibition and absence of lymphoid aggregates (P=1.4e-3). VIMA can therefore detect clinically relevant spatial signals -- including signatures of therapeutic immune modulation -- across diseases, technologies, and tissue types.

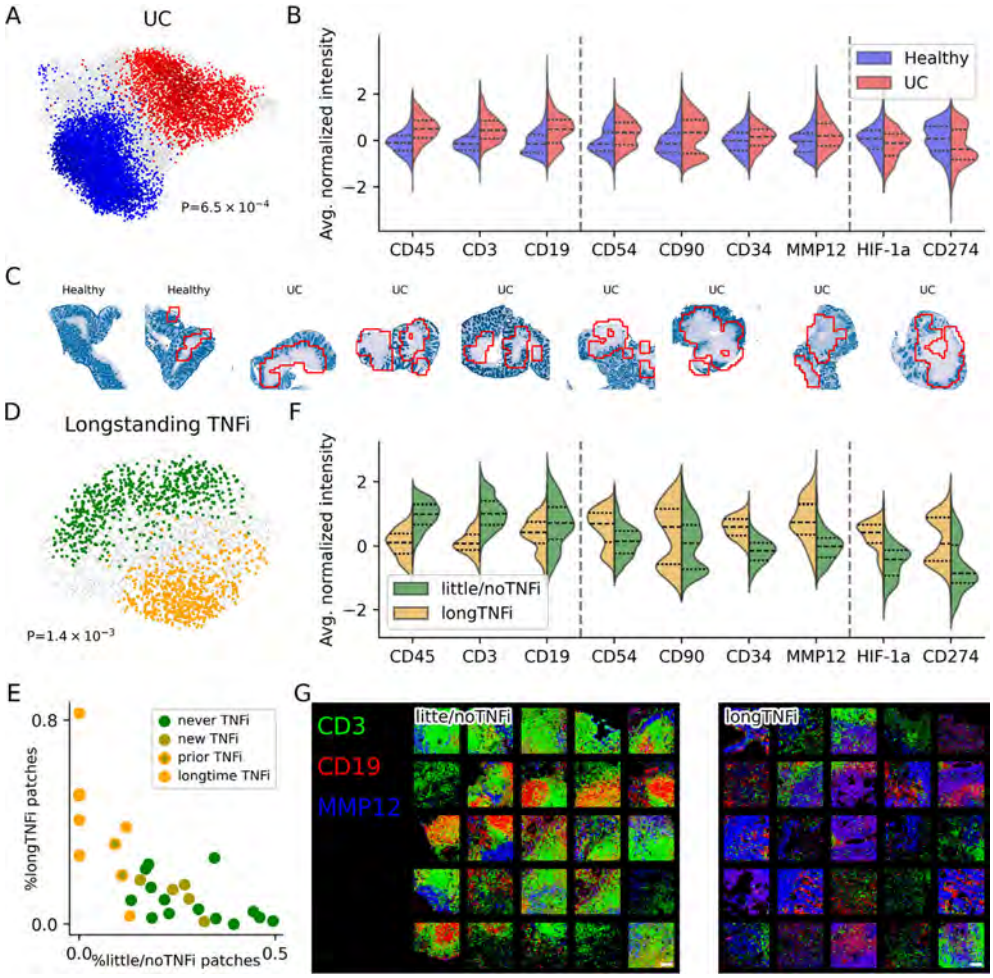
Conclusion: VIMA enables flexible, high-resolution spatial analysis of autoimmune disease. It identifies biologically meaningful signals missed by existing tools and reveals within-sample heterogeneity, demonstrating the promise of AI-based methods for advancing our understanding of autoimmune disease pathogenesis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



VIMA analysis of the RA IHC dataset. A) plot of the first two VIMA-determined principal components, with each dot representing a sample and samples colored by RA subtype (CTAP) as determined using a larger scRNA-seq dataset. F: fibroblast, TF: T-cell/fibroblast, EFM: endothelial/fibroblast/myeloid, M: myeloid, TM: T-cell/myeloid, and TB: T-cell/B-cell. B) Results of VIMA case-control analysis for the "stromal" (F/TF/EFM) versus "immune" (M/TM/TB) subtypes: a UMAP of all the patches in the dataset is generated using the patch fingerprints, and the anchor patches for microniches passing the 10% FDR threshold are colored in proportion to the correlation between the abundance of each microniche and sample-level stromal vs immune status, with red denoting stromal-enriched and blue denoting immune-enriched. The centroids of the two subclusters of each set of patches, respectively, are indicated with numbers. The global P-value for the association test is overlaid. C) A subset of 6 samples from the dataset exemplifying both spatial homogeneity in local stromal vs immune status within a sample (the leftmost and rightmost samples) and spatial heterogeneity in stromal vs immune status within a sample (middle samples), with disease subtype indicated above each sample. Each patch in each sample is colored red if it is stromal-associated by VIMA or blue if it is immune-associated. D) Randomly selected patches from each of the two clusters of immune-associated patches. E) Log-odds ratios among the immune-associated patches for belonging to cluster 1 (positive log-odds) vs cluster 2 (negative log-odds) as a function of disease subtype, with 95% confidence intervals. F) Randomly selected patches from each of the two clusters of stromal-associated patches. G) Log-odds ratios among the stromal-associated patches for belonging to cluster 3 (positive log-odds) vs cluster 4 (negative log-odds) as a function of disease subtype. H) A volcano plot showing that a cluster-based rather than microniche-based case-control analysis using the patch fingerprints learned by VIMA does not identify as robust of a signal. The Bonferroni significance threshold is shown with a dotted line. Scale bars represent 100um throughout.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



VIMA analysis of UC CODEX dataset. A) Results of VIMA case-control analysis for UC versus healthy: a UMAP of all the patches in the dataset is generated using the patch fingerprints, and the anchor patches for microniches passing the 10% FDR threshold are colored in proportion to the correlation between the abundance of each microniche and UC status, with red denoting to positive correlations and blue denoting negative correlations. The global P-value for the association test is overlaid. B) Distributions of average intensity per patch of selected markers among UC-associated and healthy-associated patches. The selected markers are grouped using dotted lines according to the relationship of their directions of effect to those in panel (F). C) Selected samples shown with cytokeratin staining in blue and contiguous areas of UC-associated patches outlined in red. D) Results of VIMA analysis of UC-associated patches only, comparing the samples with longstanding TNF inhibition (longTNFi) to those with no TNF inhibition, prior TNF inhibition only, or recent TNF inhibition only (little/noTNFi), with gold denoting positive correlation to longTNFi status and green denoting negative correlation. The global P-value for the association test is overlaid. E) Comparison of fraction of longTNFi-associated vs little/noTNFi-associated patches in each sample. For each sample, the percent of patches in that sample that anchor microniches significantly associated with longTNFi is plotted against the percent of patches in that sample significantly associated with little/noTNFi. Each sample is then colored by its detailed TNFi status. F) Distributions of average intensity per patch of selected markers among TNFi-associated and non-TNFi-associated patches. The selected markers are grouped using dotted lines as follows: markers that are higher in UC compared to control and in little/noTNFi compared to longTNFi (left), markers that are higher in UC compared to control but lower in little/noTNFi compared to longTNFi (middle), and markers that are lower in UC compared to control and lower in little/noTNFi compared to longTNFi (right). G) Randomly selected patches from the little/noTNFi-associated patches (left) and the longTNFi-associated patches (right).

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Genetics, Genomics & Proteomics (1698–1703)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Many patients living with rheumatoid arthritis (RA) can achieve remission with modern treat-to-target disease-modifying anti-rheumatic drugs (DMARDs), albeit with the risks associated with long-term immunosuppression. Some may choose to try reducing or stopping treatment, though this carries a risk of flare which is currently unpredictable. We explored whether high-throughput serial measurement of circulating proteomic biomarkers could predict risk of future arthritis flare after DMARD cessation.

Methods: We analyzed longitudinal expression of 250 soluble factors (NULISA technology) in serum collected from 115 patient with RA in remission at 0, 2, 5, 8, 12 and 24 weeks after stopping conventional synthetic DMARDs (BIO-FLARE study). Additionally, synovial tissue (ST) biopsies from 22 recent-onset untreated disease-active ACPA+ RA patients and 6 healthy individuals were imaged using spatial transcriptomic profiling (5,101 genes, 10x Genomics).

Results: Over 24 weeks, 57 BIOFLARE participants flared and 58 maintained drug-free remission. A linear mixed model identified 68 cytokines with significantly different expression trajectories between flare and remission groups. KEGG Pathways indicate enrichment in inflammatory pathways, including Cytokine-cytokine receptor interaction, Viral protein interaction with cytokine and cytokine receptor, and JAK-STAT signaling pathway, which are associated with RA flare pathology. Addition of a random forest algorithm achieved 88% accuracy in distinguishing flare events. The model identified a subset of cytokines that best predicted flare before it was clinically apparent. Of these, Xenium spatial imaging co-located *CXCL13, TNFSF13C* and *CD83* RNA expression to follicles containing memory B cells, plasma cells and peripheral/follicular helper T cells (Tph/fh). In contrast, *CXCL10* was expressed in small lining-adjacent foci by lining-layer fibroblasts and endothelial cells surrounded by CD8+GZMK+ T cells. Notably, these fibroblasts co-expressed type 1 interferon (IFN)-inducible genes, particularly *GBP1, GBP5, IFIT3* and *IFIT2* that are involved in anti-viral and anti-bacterial defence.

Conclusion: Biomarkers of flare after DMARD withdrawal, identified by integrating cytokine trajectory analysis, machine learning and spatial transcriptomics, reflect chemoattractants and soluble markers of activated memory B cells and Tph/fh to ST. Furthermore, spatial data suggest that pathogen-mediated type I IFN-induced chemoattraction of CD8+GZMK+ T cells contributes to RA disease flares. With validation, these circulating markers may improve monitoring of disease activity and provide opportunity for interception of flare during DMARD withdrawal.

Relationships between Neighborhood Disadvantage, Cumulative Social Disadvantage, and JIA Outcomes: A CARRA Registry Study

William Soulsby[1], John Boscardin[2], Daniel Horton[3], Andrea Knight[4], Karine Toupin-April[5], Emily von Scheven[2] and CARRA Registry Investigators, [1]University of California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA, [3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [4]Hospital for Sick Children, Toronto, ON, Canada, [5]University of Ottawa, Ottawa, ON, Canada

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Healthcare Disparities in Rheumatology (1704–1709)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Social determinants of health (SDOH) operate across individual, family, and community levels. We previously demonstrated that cumulative social disadvantage, comprised of individual and family-level SDOH, was associated with persistent disease activity among children with JIA in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry. However, the role of community-level SDOH, and their interaction with cumulative social disadvantage, in JIA health disparities is unknown.

Methods: In this cohort study of children with JIA in the CARRA Registry (July 2015-January 2022), a cumulative social disadvantage score was generated (range 0-3) for each subject with a score of 1 for each parameter (1) family income < $50,000/year, 2) guardian education at less than high school level, and 3) public or no insurance). Community-level SDOH

Table 1: Demographic and clinical characteristics of children with JIA in the CARRA Registry by National Area Deprivation Index (ADI) quartile

	National Area Deprivation Index (ADI) Quartiles

Hispanic	1.30 (1.08-1.58)	0.96 (0.78-1.18)
Asian	0.72 (0.60-0.89)	0.81 (0.68-0.96)
Other race	1.14 (0.92-1.41)	0.97 (0.77-1.24)
More than one race	1.36 (1.16-1.59)	1.25 (1.07-1.46)
Refused or Missing	1.27 (0.96-1.68)	1.12 (0.84-1.49)

[1]Defined in subjects with a Clinical Juvenile Arthritis Disease Activity Score-10 (cJADAS-10) >1.1 for oligoarticular JIA and >2.5 in all other JIA categories.
*Adjusted for age at enrollment, time from symptom onset to diagnosis, year of diagnosis, sex, JIA category, presence of secondary rheumatic disease, medication use during follow up (bsDMARD, csDMARD, small molecule), current steroid use, any steroid use during follow-up.
[α]Race and ethnicity were self-reported and are mutually exclusive categories.

Associations between area deprivation index and cumulative social disadvantage with any active disease throughout Registry follow-up

Table 3: The adjusted average proportion of the effect of area deprivation index quartile on disease activity mediated by the cumulative social disadvantage score and its components via causal mediation analysis[1,2] (n=50 cycles):

	Quartile 1	Quartile 2	Quartile 3	Quartile 4
Cumulative social disadvantage score	*Ref*	35.0%	74.4%	67.6%
Low income	*Ref*	27.8%	59.6%	80.2%
Underinsured status	*Ref*	14.7%	47.1%	75.2%
Low guardian education level	*Ref*	7.4%	56.9%	27.0%

[1]Causal mediation analysis quantifies the total effect of a predictor (highest ADI quartile as compared to lowest) into its direct effect on an outcome (disease activity by cJADAS-10 score) and indirect effect mediated through a proposed mediator (cumulative social disadvantage score), from which the total proportion of the effect that is mediated can be calculated (proportion mediated).
[2]Note: Age at enrollment, time from symptom onset to diagnosis, year of diagnosis, sex, JIA category, presence of secondary rheumatic disease, medication use during follow up (bsDMARD, csDMARD, small molecule), current steroid use, and any steroid use during follow-up were adjusted for in this analysis.

The adjusted average proportion of the effect of area deprivation index quartile on disease activity mediated by the cumulative social disadvantage score and its components via causal mediation analysis1,2 (n=50 cycles)

was assessed using the national Area Deprivation Index (ADI), a measure of neighborhood-level socioeconomic disadvantage geocoded at the census tract level. Descriptive statistics were performed to summarize demographic and clinical characteristics by ADI quartile. Mixed-effects logistic regression models were generated to investigate the association between ADI quartile and active disease (cJADAS-10 >1.1 for oligoarticular JIA; >2.5 for all other subtypes), adjusting for the cumulative social disadvantage score and other covariates. Multiple imputation (50 cycles) addressed missingness in ADI (17%), income (25%), and education (16%). Causal mediation analysis was used to assess the cumulative social disadvantage score and its components as mediators of the association between ADI and disease activity.

Results: Among 9,612 children with JIA, cumulative social disadvantage was more prevalent in the most disadvantaged neighborhoods (Table 1: ADI Q4: 64.9% with score >0 vs. Q1: 18.8%). While ADI was independently associated with persistent disease activity in unadjusted models (ADI Q4: OR 1.43, 95% CI: 1.15-1.76), this was significantly attenuated (ADI Q4: aOR 1.06, 95% CI: 0.85-1.32) upon adjustment for the cumulative social disadvantage score and covariates (Table 2). Cumulative social disadvantage mediated 67.6% of the relationship between most (ADI Q4) versus least (ADI Q1) neighborhood disadvantage and disease activity (Table 3). Low income and insurance mediated 80.2% and 75.2% of this relationship, respectively, while guardian education only mediated 27.0%.

Conclusion: While neighborhood-level deprivation (ADI) was independently associated with persistent disease activity, this relationship was largely mediated by individual and family-level SDOH, particularly household income and insurance status. Therefore, interventions that can address these individual/family-level factors, such as social work and patient navigator services, may be effective strategies for reducing JIA health disparities.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Healthcare Disparities in Rheumatology (1704–1709)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Adverse social determinants of health, or social risk factors (e.g., housing instability, food insecurity), contribute to disparities in rheumatic disease care and outcomes. Understanding differences in health care use among individuals with vs. without social risk factors is critical to inform resource allocation, prevention strategies, and outpatient care coordination. We aimed to examine associations between social risk factors and acute care use, including preventable and non-preventable emergency department (ED) visits and hospitalizations, among patients with rheumatic conditions.

Table 1. Patient Characteristics by Presence vs. Absence of Social Risk Factors

Characteristics	≥1 Social Risk Factor (N = 1,614)	No Social Risk Factors (N = 7,976)
Age - Mean (SD)	56 (16)	59 (15)
Gender - N (%)		
Female	1,297 (80)	5,961 (75)
Male	316 (20)	2,015 (25)
Race - N (%)		
White	1,009 (63)	6,818 (85)
Black / African American	215 (13)	333 (4.2)
Asian	69 (4.3)	348 (4.4)
More than One Race	37 (2.3)	54 (0.7)
Other	223 (14)	273 (3.4)
Ethnicity - N (%)		
Non-Hispanic	1,392 (86)	6,976 (87)
Hispanic	84 (5.2)	88 (1.1)
Primary language - N (%)		
English	1,440 (89)	7,774 (97)
Spanish	121 (7.5)	85 (1.1)
Other non-English Language	43 (2.7)	81 (1.0)
Insurance - N (%)		
Commercial	719 (45)	4,916 (62)
Medicare	510 (32)	2,594 (33)
Medicaid	373 (23)	427 (5.4)
Rheumatic Condition - N (%)		
Inflammatory Arthritis	975 (60)	5,094 (64)
Systemic Rheumatic Disease*	456 (28)	1,843 (23)
Osteoarthritis	359 (22)	1,825 (23)
Vasculitis	41 (2.5)	154 (1.9)
Crystalline Arthropathy	55 (3.4)	298 (3.7)

*Includes systemic lupus erythematosus, Behcet's, systemic sclerosis, Sjogren's/sicca syndrome, mixed/unspecified connective tissue disease, dermatomyositis/polymyositis/inclusion body myositis, and sarcoidosis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We identified adults ≥18 years with ≥2 ICD-10 codes for a systemic rheumatic condition, inflammatory arthritis, crystalline arthropathy, or osteoarthritis receiving care within a multihospital academic health system, who completed ≥1 social risk factor questionnaire at the time of a rheumatology visit (6/2022-12/2024). We compared the presence vs. absence of social risk factors by demographic factors. Using modified Poisson regression models, we estimated incidence rates (IRs) and incidence rate ratios (IRRs) with 95% confidence intervals for ≥1 ED visit and ≥1 hospitalization following screening among patients reporting ≥1 vs. 0 social risk factor, and by individual social risk factors. We also examined the IR and IRR of preventable ED visits[1] by social risk factor presence. Models were adjusted for age, sex, race, ethnicity, primary language, rheumatic condition, and Charlson-Deyo comorbidity index.

Results: Among 9,590 patients with rheumatic conditions screened for social risk factors, 1,614 (17%) reported ≥1 social risk factor. Patients with ≥1 (vs. 0) social risk factor more frequently identified as Black or Hispanic, were ≤50 years of age, spoke Spanish as their primary language, and were Medicaid beneficiaries (Table 1). Among patients with ≥1 social risk factor, 491 (30%) had ≥1 ED visit and 261 (16%) had ≥1 hospitalization following screening. Among patients without risk factors, 1,532 (19%) had ≥1 ED visit and 802 (10%) had ≥1 hospitalization. In adjusted models, there were higher rates of ED visits (IRR 1.38, 95% CI 1.33-1.43) and hospitalizations (IRR 1.59, 95% CI 1.52-1.67) among patients with vs. without social risk factors, and for all individual risk factors except digital access needs (Table 2). Education and transportation needs were associated with the highest rates of ED visits and hospitalizations, respectively. Among patients with any ED visit, 24 (4.9%) of those with risk factors and 63 (4.1%) of those without had ≥1 preventable visit (IRR 1.08, 95% CI 0.92-1.26).

Conclusion: Among patients with rheumatic conditions, presence vs. absence of social risk factors was strongly associated with higher rates of acute care use. The rate of preventable ED visits, however, did not differ. Limitations include inability to adjust for rheumatic disease severity and to account for health care use outside of the multihospital medical system. Future studies are needed to assess mechanisms behind these associations and to test the impact of interventions that address social needs on acute care use.

Table 2. Adjusted* Incidence Rates (IRs) and Incidence Rate Ratios (IRR) for ≥1 ED Visit and ≥1 Hospitalization by Presence vs. Absence of Social Risk Factors

	≥1 ED Visit		≥1 Hospitalization

Overcoming Barriers to ANA Testing in Pediatric Populations in Africa

Ekemini Ogbu[1], Angela Migowa[2], Rashmi Sahay[1], Dhriti Sharma[1], Patricia Vega-Fernandez[1], Michael Henrickson[1], Evans Omalla[3], Ayodele Faleye[4], Wafa Hamdi[5] and Hermine Brunner[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Aga Khan University Medical College East Africa, Nairobi, Kenya, [3]Pediatric Society of the African League Against Rheumatism, Nairobi, Kenya, [4]Lagos state university teaching hospital Ikeja, Lagos, Lagos, Nigeria, [5]Kassab Institute, Faculty of Medicine of Tunis UR17SP04, Tunis El Manar Univeristy, MANOUBA, Tunisia

SESSION INFORMATION
Session Date: Monday, October 27, 2025
Session Title: Abstracts: Healthcare Disparities in Rheumatology (1704–1709)
Session Type: Abstract Session
Session Time: 3:00PM–4:30PM

Background/Purpose: Timely diagnosis of children, adolescents and young adults with rheumatologic disorders remains a global challenge especially in *lower resource countries and areas (LRCs)*. There are several LRCs on the African continent with limited access to antinuclear antibodies (ANA) testing necessary to support a diagnosis of several pediatric rheumatic disorders (PRD; % of patients with positive ANA) including systemic lupus erythematosus (100%), juvenile dermatomyositis (60-75%), and juvenile idiopathic arthritis (40-60%). As the presence of ANA has near-ubiquitous utility in initially evaluating for a rheumatic condition, we aimed to understand physician perspectives on the barriers to ANA testing in pediatric populations across Africa, and the regional differences in barriers.

Methods: Electronic REDCap surveys were sent to physicians within the Pediatric Society of the African League Against Rheumatism (PAFLAR). Surveys were sent via individual email links from January to March 2025. Dillman's methods for surveys were used to optimize survey response rates. Descriptive analysis was done and comparisons considering geographic region and the World Bank classification of economies based on Gross National Income per capita.

Results: Response rate was 74% (38 of 50). Most respondents were attendings (89%), from Lower Middle-Income Countries (LMIC; 68%), and from North Africa (41%) (Table 1). All physicians had experience in treating PRDs, including 30% of respondents who lacked formal training in rheumatology. ANA testing was needed > 10 times a month (46%). The cost of ANA testing was high at $20 – 60/test (60%). Over 80% of respondents had little to no difficulty collecting and centrifuging venous blood for ANA testing. However, only 31% found it easy to ship samples to a lab within 1 - 2 days of sample collection. There was difficulty in processing ANA testing by ELISA which was worse in the Southern (100%), and West regions (83%) (p=0.03). Over 70% of respondents had difficulty receiving results of ANA testing quickly enough to support patient care which was worse with lower income countries and LMIC compared to others (p = 0.04); and in West and Central/East regions compared to others (p = 0.03). Even with local laboratories available, ANA testing was not readily available in public hospitals and so samples were often sent overseas.

TABLE 1: Demographic Characteristics of Study Respondents

Respondents	n (%)
Consultants (aka Attendings)	33 (89)
Fellows/Registrars	4 (11)
Primary Specialty	
Pediatric Rheumatology	6 (16)
Adult and Pediatric Rheumatology	12 (32)
Adult Rheumatology	8 (22)
Pediatric Nephrology	1 (3)
General Pediatrics	7 (19)
Internal Medicine	1 (3)
Clinical Immunology	1 (3)
Pediatric Cardiology	1 (3)
Respondent country by income level	
High Income Countries	2 (5)
Low Income Countries	8 (22)
Lower Middle-Income Countries	25 (68)
Upper Middle-Income Countries	2 (5)
Respondent country by region	
Central Africa	2 (5)
East Africa	11 (30)
North Africa	15 (41)
Southern Africa	3 (8)
West Africa	6 (16)
Most common rheumatic disease treated	
Juvenile Idiopathic Arthritis	20 (54)
Lupus	8 (22)
Sjogren's Syndrome	1 (3)
Other rheumatic diseases	8 (22)
Number of pediatric patients with rheumatic disease treated in past year	
1- 20	8 (22)
21 – 40	5 (14)
Over 40	24 (65)

Conclusion: Our results provide highly desired quantitative evidence of the urgent need to improve access to affordable, and robust ANA testing in LRCs in Africa. Specifically, our results highlight critical barriers to ANA testing that will inform successful scaling of testing methods and future research and intervention efforts that would improve early diagnosis of rheumatic conditions in children, adolescents and young adults.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Healthcare Disparities in Rheumatology (1704–1709)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a leading cause of end-stage kidney disease (ESKD) in young women, particularly among racial and ethnic minorities. Kidney transplantation is the preferred treatment for SLE-related ESKD, yet disparities in transplant access and outcomes persist. In 2014, the Kidney Allocation System (KAS) was revised to improve equity in organ distribution. This study evaluates racial and ethnic disparities in kidney transplant outcomes among SLE patients during the 10 years before and after the 2014 KAS revision.

Table 1: Demographic and Clinical Characteristics of SLE Patients Who Received Kidney Transplants Before and After the 2014 Kidney Allocation System (KAS) Revision

Δ= Post revision (2015-2024) - Pre revision (2005-2014); ORs adjusted for Recipient age, Donor age, Recipient sex, Dialysis status, HLA mismatch level, Functional status, Insurance type
Bolded p-values indicate statistical significance (p<0.05)

Methods: We conducted a retrospective cohort study using the United Network for Organ Sharing (UNOS) Standard Transplant Analysis and Research (STAR) files. Adult patients with SLE who received kidney transplants between 2005-2024 were identified and stratified into two cohorts: Pre-revision (2005–2014) and Post-revision (2015–2024).

We compared demographics, mean waitlist days, 1-year graft failure, and 1-year mortality across cohorts, stratified by race/ethnicity (Black, White, Hispanic, Other).

Multivariable logistic regression estimated the adjusted odds of 1-year graft failure and mortality by race/ethnicity (White as reference), adjusting for age, sex, HLA mismatch level, insurance type, and other clinical covariates.

Results: A total of 10,547 SLE kidney transplant recipients were included (4,255 pre-revision; 6,292 post-revision) (Table 1). Before KAS revision, Black patients had the longest mean waitlist time (938.8 vs 629.9 days for White patients). Post-revision, they had the largest decrease in wait time (–143.2 days; **p< 0.001**), while other groups showed no significant change (Table 2). All groups experienced increased 1-year graft failure post-revision, with the greatest increases among Black (+14.7%) and Hispanic (+13.0%) recipients. No significant changes were observed in 1-year mortality across groups.

In adjusted post-revision models, Black (OR 1.46, 95% CI 1.22–1.75; p< 0.001) and Hispanic (OR 1.28, 95% CI 1.04–1.56; p=0.017) recipients had significantly higher odds of graft failure compared to White recipients (Table 2). "Other" had lower odds (OR 0.72, 95% CI 0.54–0.97; *p=0.029*). Only Hispanic patients had significantly lower odds of 1-year mortality (OR 0.29, 95% CI 0.12–0.69**; p=0.005**).

Conclusion: Although the 2014 KAS revision reduced wait times for Black recipients, it was associated with increased 1-year graft failure across all groups, particularly among Black and Hispanic patients There were no significant corresponding changes in mortality. The reasons for these trends are likely multifactorial and may include changes in immunologic matching, or shifts in perioperative care and follow-up practices. The findings suggest that while the KAS revision may have improved access to transplantation, it may have inadvertently introduced new risks for certain populations. Further investigation is needed to understand the mechanisms driving these outcome disparities and to inform future refinements to transplant policy.

SESSION INFORMATION

Session Date: Monday, October 27, 2025

Session Title: Abstracts: Healthcare Disparities in Rheumatology (1704–1709)

Session Type: Abstract Session

Session Time: 3:00PM–4:30PM

Background/Purpose: Social determinants of health (SDoH) contribute significantly to disparities in care but are rarely addressed in subspecialty settings. The PRAPARE (Protocol for Responding to and Assessing Patients' Assets, Risks, and Experiences) tool is a validated questionnaire that screens for SDoH across multiple domains, including housing, employment, education, stress, and social support. Scores range from 0 to 22, with higher scores indicating greater social risk. At SUNY Downstate, the PRAPARE tool was implemented within a rheumatology and dermatology patient navigator program, which pairs 22 second-year medical students with 169 high-risk patients, yielding a navigator-to-patient ratio of 1:7.68. Since 2020, patients were recruited from subspecialty clinics based on identified needs such as severe disease manifestations, poor adherence to appointments or medications, and/or language barriers. Patients were randomly assigned to navigators unless a specific language preference was stated. Most participants were publicly insured (72%) and identified as Black or Caribbean (86.6%). The mean age was 48.5 years (SD 18.8), with a male-to-female ratio of 1:5.13. The most common conditions were lupus (53.6%) and hidradenitis suppurativa (52.0%).
