Conclusion: Our findings indicate that neuropeptide levels were higher in SpA patients than in HC. A tendency of a decrease in pain and disability perception with high neuropeptide levels was observed, probably due to neuropeptides have been depleted from the presynaptic terminal and secreted into the bloodstream. Although no association between neuropeptides and clinical disease activity was observed, indirect influence on clinical activity is highlighted with the downregulation of IL2 and IFNg.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Obstructive sleep apnea syndrome (OSAS) is a chronic respiratory disorder characterized by intermittent upper airway collapse during sleep. This mechanism can trigger systemic inflammation and metabolic dysregulation. Psoriatic arthritis (PsA) is associated with metabolic syndrome and emotional disorders, both of which are classic comorbidities of OSAS. Given the established relationship between PsA and metabolic syndrome, an association between PsA and OSAS would be expected; however, no studies to date have explored this potential relationship.

Therefore, the aim of this study was to evaluate the presence of OSAS and its association with clinical, inflammatory, and functional features, as well as sleep quality in a cohort of PsA patients.

Methods: A cross-sectional observational study was conducted with 247 PsA patients, classified according to the presence (n=22) or absence (n=225) of OSAS. Demographic, clinical, functional, disease activity, functional impairment, disease impact, sleep quality, and comorbidity variables were collected. Logistic regression analysis was performed to identify factors associated with OSAS.

Variable	Total (n=247)	OSAS (n=22)	No OSAS (n=225)	p-value

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Patients with OSAS had a higher mean age (58 vs. 54 years; p=0.02) and higher body mass index (BMI) (29.7 vs. 25.4 kg/m^2; p=0.02). Regarding inflammatory parameters, they exhibited greater disease activity (DAPSA 13.2 vs. 10.6; p=0.09) and a higher number of enthesitis sites according to mMASES (0.7 vs. 0.0; p=0.3), although not reaching statistical significance. Functionally, OSAS patients showed significantly greater impairment according to the HAQ-DI (1.1 vs. 0.3; p=0.002) and greater disease impact (PsAID-12: 3.8 vs. 2.8; p=0.04). They also presented higher levels of fatigue (FACIT-F: 30.5 vs. 38; p=0.04), anxiety (HADS-A: 7 vs. 5; p=0.02), depression (HADS-D: 7 vs. 3.5; p=0.005), and worse sleep quality (ISI 9.3 vs. 7.0; p=0.001). In logistic regression analysis, BMI was the only variable significantly associated with OSAS (OR: 1.1; 95% CI: 1.01–1.2; p=0.04).

Conclusion: OSAS was associated with obesity, greater functional impairment, higher levels of fatigue, anxiety, depression, and poorer sleep quality in PsA patients. These findings highlight the importance of early detection strategies for comorbidities and a multidisciplinary approach in the assessment of PsA patients, including evaluation for OSAS.

Sociodemographic Characteristics and Healthcare Utilization in Patients with IBD-Associated Arthritis vs. IBD Alone: A Nationwide Inpatient Analysis

Faria Sami[1], Maria I. (\"Maio\") Danila[2], Liron Caplan[3] and Rouhin Sen[4], [1]The University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham (UAB), Birmingham VA Medical Center, Birmingham, AL, [3]Medicine Service, Rocky Mountain Regional VAMC, Aurora, CO, [4]University of Alabama at Birmingham, Department of Medicine, Division of Clinical Immunology & Rheumatology, Birmingham

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Inflammatory bowel disease (IBD)-associated arthritis (IBD-A) can affect 24-44% of IBD patients and may represent an enhanced inflammatory state. IBD-A patients often experience a more severe disease course, increased hospitalizations, a higher need for surgical or biologic therapies, and worse outcomes compared to IBD alone. Prior studies have examined the reasons for hospitalizations for IBD, but the inpatient burden of IBD-A remains underexplored. Understanding differences in sociodemographic characteristics and healthcare utilization in patients with IBD-A vs IBD alone may help inform resource management and policy

Methods: We used the National Inpatient Sample (NIS) database to identify adult hospitalizations with a primary or secondary diagnosis of IBD from 2016 to 2020. Admissions with concurrent diagnosis of IBD-A were identified using ICD-10 codes. We compared demographics, insurance type, median household income, geographic location, length of stay (LOS), total hospital charges, and in-hospital mortality between patients with IBD-A and IBD alone. Survey-weighted analyses were used to generate national estimates. A p-value < 0.05 was considered statistically significant.

Income Q3	405480, 25.4%	510, 27.1%	0.457
Income Q4	376630 23.6%	595, 31.6%	0.337
In-hospital Mortality, n (%)	26130 (1.6%)	20 (1.1%)	—
Insurance status			
Medicare	681710, 42.7%	475 25.3%	<0.001
Medicaid	234785, 14.7%	400, 21.3%	<0.001
Private insurance	573070, 35.9%	905, 48.1%	<0.001
Self-pay	55955, 3.5%	70, 3.7%	0.820
Hospital Region in USA			
Northeast	342550, 21.5%	535, 28.5%	0.002
Midwest	393675, 24.7%	525, 30.0%	0.166
South	585545, 36.7%	420, 22.3%	<0.001
West	273275, 17.1%	400, 21.7%	0.046
Charlson Comorbidity Index, median (IQR)	1 (0-2)	0 (0-1)	<0.001

[1]*Income Q1–Q4 = Income quartiles based on median household income by patient ZIP code: Q1 = lowest quartile (<$55,999 Q2 = $56,000–$70,999, Q3 = $71,000–$93,999, Q4 = highest quartile (≥$94,000).*

Results: A total of 1880 adult IBD-A hospitalization events were included. The top reasons for hospitalizations for IBD-A patients were: Ulcerative colitis (12.2%), followed by sepsis (10.6%), and then Crohn's disease with and without complications (6.0%). Compared with IBD patients without arthritis, patients with IBD-A were more likely to be younger (median age 42 vs 55 years, p value < 0.001) and females (64.1% versus 56.2%, p value 0.002), more frequently had private insurance (48.1% vs 35.9%, p value < 0.001) or Medicaid (21.3% vs 14.7%, p value < 0.001), and less commonly were from lowest quartile of household income [$1 - 55,999] (16.2 % vs 24.1%, p value < 0.001). Geographically, compared to IBD-only patients, IBD-A admissions were more common in the Northeast (28.5% vs 21.5%, p value 0.002) and West (21.7% vs 17.1%, p value 0.046) and less frequent in the South (22.3% vs 36.7%, p value < 0.001). Compared to IBD admissions, IBD-associated arthritis admissions had a similar length of stay, total hospital charges, and in-hospital mortality (1.1% vs 1.6%) as shown in Table 1.

Conclusion: Hospitalizations with IBD-A were more prevalent in younger people and females. There were no differences in race/ethnicity, length of stay, or total hospital charges between the two groups of patients. Future studies should investigate the causes of admissions in patients who are younger and female, and explore if they are sub-optimally treated for their IBD or arthritis, leading to more hospitalizations.

Abstract Number: 2313

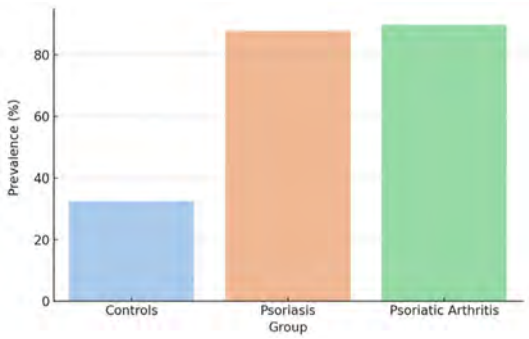
From Plaque to Plaque: Bridging Oral and Systemic Inflammation in Psoriasis and PsA

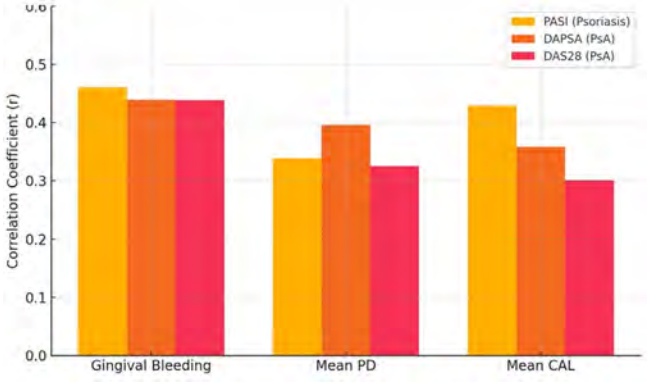
guru Vijay Chagalakondu, Vijaya prasanna Parimi and Pradeep S Anand, ESIC Medical College and Super Specilaity Hospital, hyderabad, Telangana, India

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriasis and psoriatic arthritis (PsA) are two chronic inflammatory conditions which have similar immunopathological mechanisms which also cause periodontal disease. The association between these conditions is often underrecognized. This study aims to assess the prevalence and severity of periodontitis in psoriasis and psoriatic arthritis, evaluate its correlation with disease activity indices and identify the potential of oral health as a surrogate marker of systemic inflammation.

Methods: In this prospective triple-arm, case-control study, 120 participants were recruited into the study and were equally divided into three groups- healthy subjects as controls, patients with psoriasis and patients with PsA. A detailed periodontal examination was conducted which included measurement of Oral hygiene Index (OHI), gingival bleeding, probing depth (PD), clinical attachment loss (CAL) and missing teeth. Disease activity was measured using Psoriasis Area and Severity Index (PASI) for psoriasis, DAS28 and DAPSA for psoriatic arthritis. Statistical analysis was done using Kruskal Wallis and Spearman's correlation coefficients and p value < 0.05 was considered as significant.





23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Periodontitis was found to be more prevalent in PsA (89.7%) and psoriasis (87.8%) groups compared to healthy controls (32.5%) (p< 0.001). PsA group demonstrated severe periodontal disease activity with higher OHI, bleeding scores, PD and CAL (p < 0.05 for all). The correlation between indices of psoriasis and PsA with periodontal disease was positive.

- **PASI** correlated with bleeding (r=0.460), PD (r=0.338), and CAL (r=0.429), all p< 0.001.
- **DAPSA** correlated with bleeding (r=0.439, p< 0.001), PD (r=0.396, p=0.013), and CAL (r=0.358, p=0.025).

DAS28 correlated with bleeding (r=0.438, p< 0.001), PD (r=0.325, p=0.043), and CRP (r=0.328, p=0.041) (Figure 2).

Conclusion: This study highlights the striking significant association between periodontal disease and disease activity of psoriasis. The study also highlights the fact that higher disease activity of periodontitis was observed in PsA group. Given the ease of periodontal assessment, it may serve as a non-invasive reflective biomarker of systemic inflammation in patients with PsA and psoriasis. The study also emphasizes the need for early periodontal screening in patients with psoriasis for timely identification and integrated approach of disease management (oral-systemic axis).

Radiographic and Ultrasonographic Assessments of Sesamoid Index in Patients with Psoriatic Arthritis

Hung Vo[1], Eugene Kissin[2] and Pablo Weilg[3], [1]Boston Medical Center, Peabody, MA, [2]Boston University, Newton, MA, [3]Kymera Independent Physicians, Roswell, NM

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The sesamoid index (SI), a radiographic measure of medial thumb sesamoid area, was originally described as a diagnostic tool in acromegaly[1] and later proposed as a tool to differentiate psoriatic arthritis (PsA) from other arthritides[2]. We investigated the relationship between SI and disease type, sex, age, and disease duration using both radiographic and ultrasonographic measurements, and examined longitudinal changes.

Methods: We enrolled PsA (n=41), RA (n=41), and OA (n=40) patients in a cross-sectional study. SI was measured on hand X-rays (length × width) and by ultrasound in medial and lateral planes using a 20 MHz probe. For the longitudinal analysis, 17 patients with ≥2 serial X-rays were included: RA (n=9), PsA (n=5), and OA (n=3). Group differences in SI were analyzed using Kruskal-Wallis with Dunn's test; sex differences by t-tests; and medial vs. lateral ultrasound SI by Wilcoxon signed-rank test. Spearman correlation assessed associations with age, BMI, and disease duration. Linear regression evaluated independent predictors, and mixed-effects modeling assessed longitudinal change.

Results: Radiographic SI was significantly higher in males across all groups (PsA: 31.8 vs. 18.2 mm^2, p=0.007; RA: 34.8 vs. 22.8, p=0.0016; OA: 28.7 vs. 22.8, p=0.011). SI correlated strongly with medial ultrasound SI ($\rho = 0.64$, $p < 0.001$) and moderately with lateral SI ($\rho = 0.45$, $p < 0.001$) (Figure 1). Lateral SI was larger than medial SI across all groups ($p < 0.01$). In a linear model ($R^2 = 0.27$), female sex predicted lower SI ($\beta = -11.4$ mm^2, $p < 0.001$), followed by age ($\beta = +0.16$ mm^2/year, $p = 0.046$) and disease duration ($\beta = +0.38$ mm^2/year, $p = 0.022$). In an interaction model ($R^2 = 0.29$),

Steroid Use	9 / 41 (22%)	0 / 41 (0%)	2 / 40 (5.0%)
Disease Duration (years)	4.8 ± 7.1	3.8 ± 6.2	2.3 ± 4.1

[1]Mean ± SD; n / N (%)

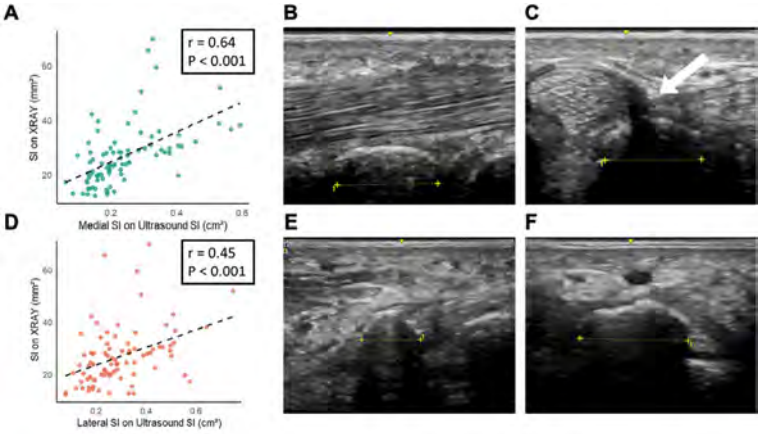

Figure 1. Correlation between Sesamoid Index (SI) measured by Radiographic XRAY and Ultrasound (US). Radiographic SI was calculated as maximum length x width on X-ray. Medial and lateral SI on US was derived from the longitudinal (B, E) and transverse (C, F) measurements respectively. Careful adjustment of the ultrasound probe is necessary to avoid edge shadowing artifacts on the transverse view of the medial sesamoid (white arrow in C). The Spearman correlation between radiographic SI and ultrasonographic medial SI was better than the correlation for lateral SI.

PsA showed a greater rate of SI increase per disease year vs. RA (β = +0.77 mm^2/year, p = 0.042), with no effect in OA. BMI had no impact. Group diagnosis was not independently significant at baseline. A linear mixed-effects model of 47 radiographs from 17 patients showed distinct SI trajectories. PsA patients exhibited progressive SI growth from 18.2 mm^2 (95% CI: 5.6–30.8) at timepoint 1 to 33.2 mm^2 (95% CI: 19.5–46.9) at timepoint 4, while SI remained stable in RA (32.7–36.2 mm^2) and OA (31.1–34.1 mm^2) in Figure 2. This supports greater periosteal remodeling in PsA.

Conclusion: SI is higher in males and increases with age and disease duration. PsA demonstrates the most robust longitudinal SI growth, supporting its potential as a structural marker of disease progression. Ultrasound, particularly medial SI, correlates well with radiography and may serve as a non-radiographic alternative for tracking periosteal changes. Future studies with larger longitudinal cohorts are warranted to validate these findings.

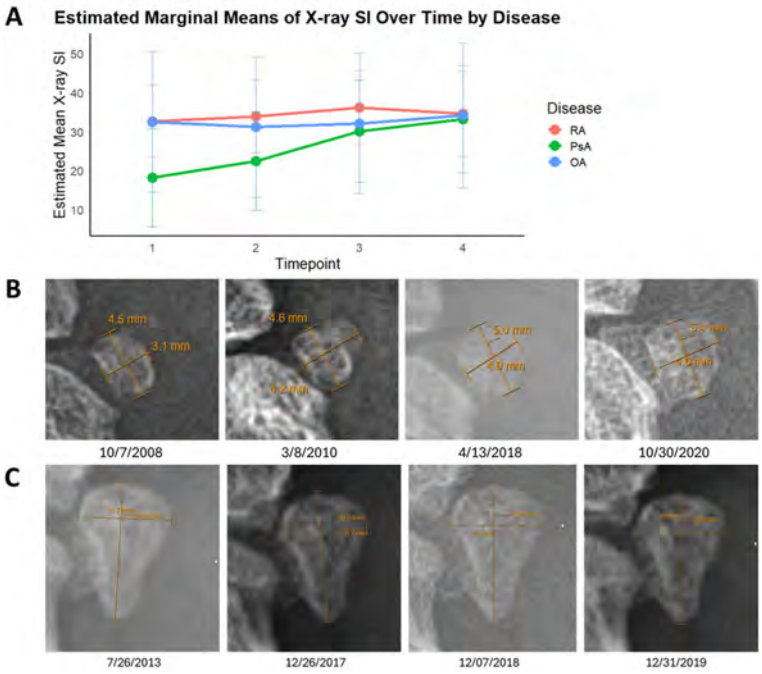

Figure 2. (A) Estimated marginal means of X-ray sesamoid index (SI) over time by disease group. PsA patients showed a progressive increase in SI from timepoint 1 to 4, while RA and OA patients exhibited minimal change. Error bars represent 95% confidence intervals. (B) Representative radiographs from a PsA patient showing progressive enlargement of the medial sesamoid bone over time. (C) Serial radiographs from a RA patient showing stable SI measurements across timepoints, with minimal change in sesamoid size.

Alterations in the Gut Microbiome in Ankylosing Spondylitis and Their Correlation with Disease Activity

Hyemin Jeong[1], Eun-Jung Park[2] and Chan Hong Jeon[1], [1]Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea, [2]National Medical Center, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The microbiome significantly influences immune dysfunction and gut dysbiosis in patients with ankylosing spondylitis (AS). This study seeks to define the distinct microbial characteristics of AS and biomarkers associated with disease activity.

Methods: Forty-four patients with AS and 50 healthy controls (HC) were recruited. 16S rRNA gene sequencing was performed to assess the microbiota in stool samples. The Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS-CRP) was calculated for all AS patients; scores ≥ 2.1 indicated high disease activity, and < 2.1 indicated low disease activity.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: The mean age of the AS group was 42.5 years, with 39 males (88.6%). Although the alpha diversity did not differ significantly between the AS and HC groups, marked differences were observed in beta diversity. The relative abundance of Proteobacteria, particularly Gammaproteobacteria, and Enterobacterales, including *Escherichia* spp., was significantly increased in the AS group. In contrast, the abundance of beneficial taxa, including Firmicutes, Clostridia, Clostridiales, Lachnospiraceae, Ruminococcaceae, and *Faecalibacterium*, was higher in the HC group. Among patients with AS, alpha diversity decreased in the high disease activity group compared to the low disease activity group, while beta diversity did not differ significantly. Moreover, *Coprobacter* spp. abundance positively correlated with the Bath Ankylosing Spondylitis Disease Activity Index ($p = 0.032$) and the ASDAS-CRP ($p = 0.023$).

Conclusion: Patients with AS exhibit distinct gut microbiota profiles, with increased Proteobacteria and decreased beneficial taxa such as Firmicutes. Higher disease activity is associated with reduced alpha diversity, while *Coprobacter* spp. abundance correlates with disease activity, suggesting its potential as a biomarker.

Sexual Dysfunction in Women with Axial Spondyloarthritis: A Meta-Analysis of FSFI Total and Domain Scores

Gabriela Moreira[1], Hemerli De Cinque Almeida Esteves[2], Nicole Felix[3] and **Jose Fernando Verztman**[1], [1]Hospital Federal dos Servidores do Estado do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil, [2]No current affiliation, Columbus, OH, [3]Federal University of Campina Grande, Fortaleza, Ceara, Brazil

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Beyond musculoskeletal manifestations, there is growing recognition of the systemic and psychosocial burden of axial spondyloarthritis (axSpA). Sexual health is an often-overlooked aspect of quality of life in affected women. However, the impact of axSpA on sexual dysfunction (SD) in women remains unknown.

Methods: We systematically searched PubMed, Embase, and Cochrane library for observational studies comparing women with axSpA fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria versus age-matched healthy controls. Our outcomes of interest were total FSFI and individual domain scores (desire, arousal, lubrication, orgasm, satisfaction, and pain). Mean differences (MD) and 95% confidence intervals (CI) were calculated using a random-effects model in R version 4.5.0.

Results: We included four cross-sectional studies comparing women with axSpA to age-matched healthy controls. A total of 174 women with axSpA were included (114 with radiographic axSpA and 60 with non-radiographic axSpA). The mean age was 38.3 years. The FSFI total score was significantly lower in women with axSpA compared to healthy controls (MD -4.69 points; 95% CI -8.83 to -0.54). Significant impairments were also observed in the following FSFI domains: desire (MD -0.81; 95% CI -1.53 to -0.09), arousal (MD -1.07; 95% CI -1.64 to -0.50), lubrication (MD -0.87; 95% CI -1.57 to -0.16) and pain scores (MD -0.59; 95% CI -1.13 to -0.05). However, there were no significant differences in terms of orgasm (MD -0.79; 95% CI -1.83 to 0.26) or satisfaction (MD -0.63; 95% CI -1.75 to 0.49).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Forest plot showing lower total FSFI scores in women with axial spondyloarthritis compared to healthy controls.

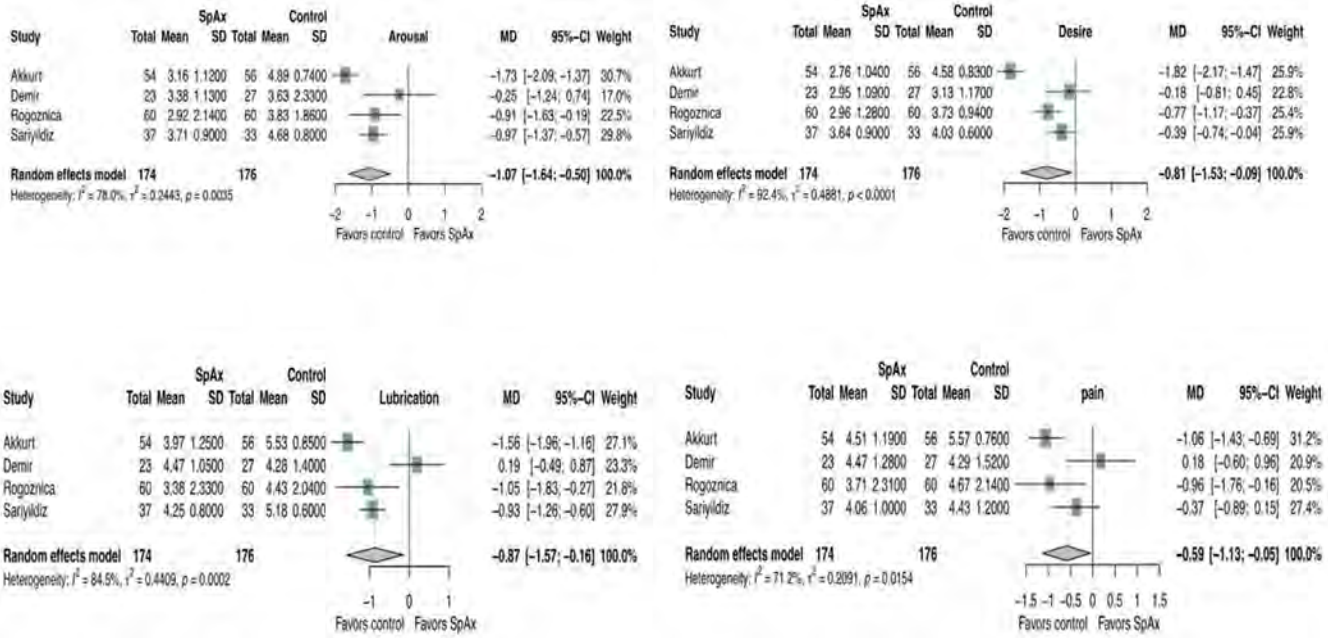

Figure 2. Forest plots showing lower FSFI scores in desire, arousal, lubrication, and pain domains among women with axSpA vs. controls. All differences were statistically significant.

Conclusion: In this meta-analysis, women with axSpA had signs of sexual dysfunction and worse sexual health as compared with age-matched healthy controls, highlighting the importance of incorporating sexual health evaluation into routine axSpA care, regardless of radiographic status.

Background/Purpose: Patients with PsA have an elevated risk of cardiovascular (**CV**) disease. We assessed whether specific PsA features may predict CV events among PsA patients.

Methods: Data are presented from patients seen at the University of California, San Diego's Healthcare system. Data were collected from 1/1/2012 through 4/5/2025 from all patients with a PsA ICD-10 code, and were procured through data extraction concierge services. All charts were then reviewed and 766 met inclusion criteria: at least one office visit, PsA diagnosis and features confirmed by a rheumatologist.

Participant characteristics were assessed at office visits. Patients were tracked from time of PsA diagnosis until occurrence of a CV event, or their last office visit before the end of the follow-up period. We define a CV event as a new occurrence of one of the following ICD-10 codes: coronary artery disease, peripheral vascular disease, heart failure and transient ischemic attack or stroke. We considered the following PsA features: dactylitis, enthesitis, nail pitting and severe psoriasis (PsO; defined as body surface area ≥%4). Presence/absence of each predictor was ascertained and was assessed as a binary predictor of CV events. Peripheral arthritis was not included as it was inconsistently noted in the charts reviewed.

Unadjusted Kaplan-Meier curves were estimated for each primary predictor. Cox regression models estimated CV risk (Hazard Ratios: HR) and are presented as unadjusted, adjusted for gender, age and smoking status (Model 1), and adjusted for gender, age, smoking status, BMI and race (Model 2).

Results: Mean tracked follow-up time was 4.35 years (SD 3.60) and the median was 3.53. Participant characteristics are shown in **Table 1**. 56 CV events were reported. **Table 2** shows estimated HRs (95% CI) for each predictor and model. Among the variables examined, the presence of dactylitis emerged as a significant predictor of CV events in the adjusted model 2 (HR 1.83; 95% CI [1.04, 3.23]; p=0.036) and neared significance in the adjusted model 1 (HR 1.75; 95% CI [1.00, 3.07]; p=0.05). Kaplan Meier survival curves are presented in **Figure 1**.

Table 1. Participant characteristics (N=766*)

Characteristic	Mean (SD)
Age	57.5 (15.0)
BMI	29.1 (6.3)
PsA duration (yrs)	4.35 (3.60)
	N (%)
Sex	
Male	337 (44.0)
Female	429 (56.0)
Smoking status	
Never	480 (63.3)
Former	224 (29.2)
Current	54 (7.12)
BMI category	
Underweight (<18.5)	12 (1.59)
Normal weight (18.5-25)	189 (25.0)
Overweight (25-30)	268 (35.5)
Obese (≥30)	297 (38.8)
CV event	56 (7.31)
Diabetes	89 (11.6)
Enthesitis	318 (41.5)
Dactylitis	308 (40.2)
Nail involvement	352 (46.0)
Severe psoriasis	300 (39.3)

*Values were not procured for every characteristic in all participants. Smoking status was available for 758 participants, BMI was available for 755, and severe psoriasis status was available for 764.

Table 2. Prediction of CV events by PsA features

Predictor	Unadjusted HR (SE) [95% CI] p	Adjusted model 1* HR (SE) [95% CI] p	Adjusted model 2 † HR (SE) [95% CI] p
Dactylitis	1.20 (0.33) [0.70, 2.06] 0.50	**1.75 (0.50) [1.00, 3.07] 0.05**	**1.83 (0.53) [1.04, 3.23] 0.036‡**
Enthesitis	1.11 (0.31) [0.65, 1.91] 0.70	1.19 (0.33) [0.69, 2.05] 0.52	1.13 (0.32) [0.66, 1.96] 0.65
Nail pitting	0.79 (0.22) [0.46, 1.36] 0.38	1.12 (0.32) [0.64, 1.96] 0.69	1.10 (0.31) [0.63, 1.93] 0.73
Severe PsO	1.35 (0.37) [0.79, 2.32] 0.27	1.47 (0.41) [0.85, 2.53] 0.17	1.41 (0.40) [0.81, 2.46] 0.22

*Adjusted for gender, age and smoking status
† Adjusted for gender, age, smoking status, BMI, and race
‡In models adjusting for each covariate independently, only the model adjusted for age is significant: HR (SE) [95% CI] p= 1.77 (0.51) [1.01, 3.10] 0.046 for dactylitis; 1.07 (0.01) [1.05, 1.10] <0.001 for age. Those with dactylitis are significantly younger than those without (mean difference=3.77 yrs, p=0.0008, Wilcoxon rank sum test).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Kaplan Meier survival analysis.

0 = No; 1 = Yes

Conclusion: Dactylitis was a significant predictor of CV events in the adjusted model 2. We suggest that confounding by age may have masked this association in the unadjusted model. Individuals with dactylitis were significantly younger than those without, and older age was associated with increased CV risk.

No significant association was observed between CV events and the other PsA features. Some limitations may have affected the strength of our conclusions. We did not have available complete information on PsA treatments, obviating the ability to adjust for this potential confounder. Nor were we able to definitively ascertain prior history of CV events, preventing exclusion of such higher risk patients. Our median tracked follow-up period was shorter than the 7.3 years found in a meta-analysis of 112 cohort studies examining CV outcomes (Magnussen C, et. al. N Engl J Med 2023). Future studies incorporating adjustment for treatment status, more stringent exclusion criteria and a longer follow-up period may help to adjudicate the discrepancy between our findings and literature reporting a link between PsA features and CV risk.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: There is a dearth of literature exploring challenges faced by rheumatologists in the referral, diagnosis, management, and monitoring of patients with suspected axial spondyloarthritis (axSpA) worldwide. Our study aims to understand such challenges faced by rheumatologists in the Gulf countries.

Methods: A cross-sectional online survey was conducted among practicing rheumatologists in six countries using 35-close ended questions. Items underwent refinement using a sensibility assessment framework and were pilot-tested among 12 rheumatologists, and followed international survey reporting guidelines. The survey assessed demographic characteristics, referral patterns, diagnostic features, monitoring practices, and management challenges related to axSpA. Descriptive statistics were applied and normalized average scores were computed for ranking questions and converted into percentages. Data collection occurred between April and May 2021.

Results: A total of 188 responses were received and analyzed (response rate 50.6% during COVID pandemic). Most respondents were consultants (68.1%), practiced in tertiary governmental hospitals (52.7%) and located in urban settings (95.1%) (Table 1).

Table 1: Participants' demographics

	N = 188[/]		N = 188[/]

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

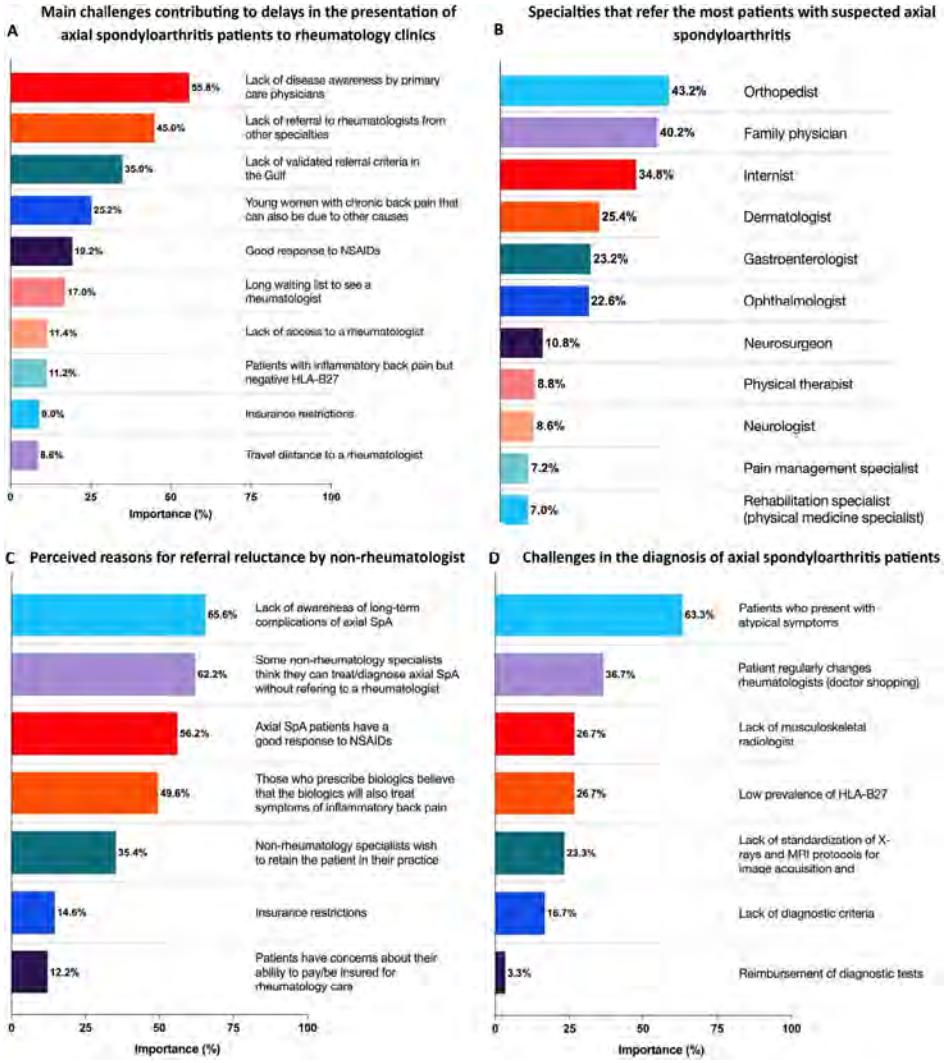

Figure 1. Perceived challenges and referral patterns in axial spondyloarthritis care: (A) Delays in referral to rheumatology, (B) Specialties most frequently referring patients, (C) Reasons for referral reluctance from non-rheumatologists, and (D) Diagnostic challenges.

A majority (88.6%) reported delayed presentation of axSpA patients, primarily due to low disease awareness among primary care physicians (55.8%) and absence of validated referral criteria (35.0%), Figure 1. Orthopedists, family physicians, and internists were among the top referring specialties. Nearly half of respondents believed that non-rheumatology specialists are reluctant to refer their axSpA patients to a rheumatologist.

Diagnostic challenges were reported by 65.5% of respondents, especially in patients with atypical symptoms or limited access to HLA-B27 testing and advanced imaging. Only 28.8% experienced difficulty ordering or interpreting HLA-B27, primarily due to test unavailability (66.7%), or perceived low prevalence of HLA-B27 in their patient population (31%).

The majority (76.6%) had access to a musculoskeletal radiologist to read X-rays and MRIs. Trust in radiology reports of sacroiliac X-rays and MRI for assessing suspected axSpA was generally moderate to high.

Figure 2 illustrates the preferred frequency of monitoring various axSpA disease metrics across different time intervals, including those rarely or never used.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

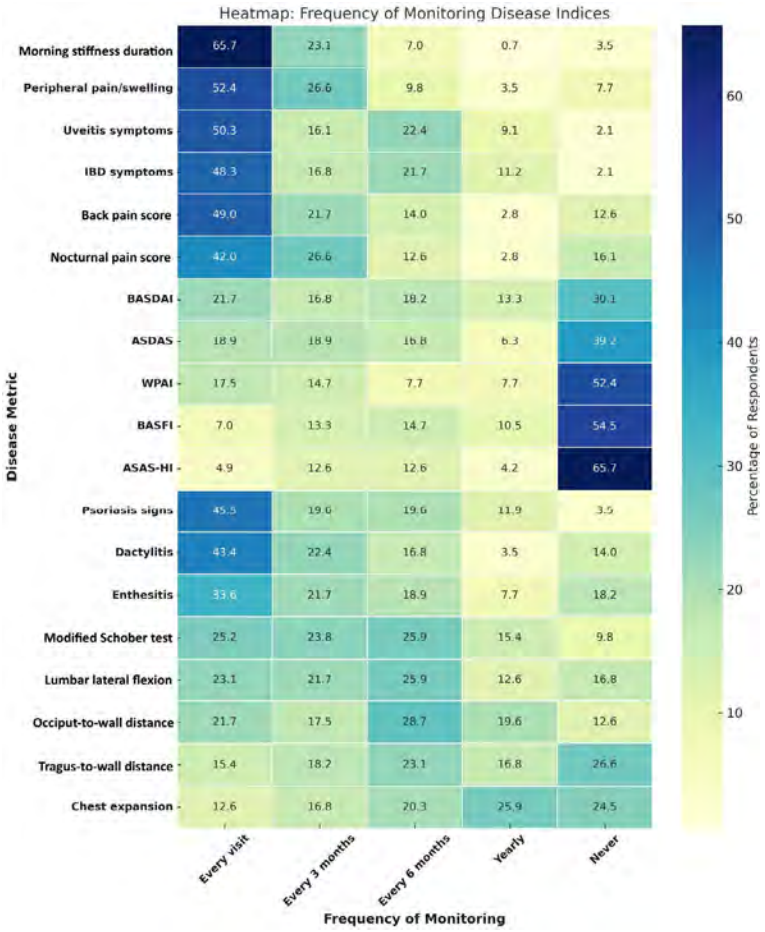

Figure 2: Frequency of monitoring disease metrics perceived by rheumatologists

About 47% and 31.5% of respondents reported difficulties in tracking patient-reported outcomes and physical exam findings, respectively—mainly due to busy schedule and lack of a nurse to support.

In terms of management, patient non-adherence due to fear of drug side effects (44.1%) or symptom improvement (43.1%) were leading obstacles. Only 12% had access to a rheumatology-trained nurse. Physiotherapy was considered to be usually useful by 45.2% of rheumatologists.

Conclusion: This is the first comprehensive study from the Middle East and North Africa region to explore clinical practices and challenges in the referral, diagnosis, management, and monitoring of axSpA among rheumatologists. Delays in diagnosis and referral suggest the need for educational initiatives targeting non-rheumatologists, and improved multidisciplinary support.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Imaging outcomes in ongoing cohort studies are typically evaluated across multiple reading rounds by several readers. Often, only scores from the most recent reading round are used, disregarding valuable data from previous rounds and potentially introducing selection bias by excluding participants lost to follow-up. Using an integrated analysis is an alternative incorporating scores from multiple readers and rounds. This method provides a more truthful reflection, but may introduce additional variability, potentially reducing the estimates' precision. Therefore, we assessed if an integrated analysis, using available imaging data over time from different reading rounds, affects the precision of change estimates in early axSpA, using a completers analysis as reference.

Methods: Patients with chronic back pain (≥3 months; ≤2 years; onset < 45 years) from the SPondyloArthritis Caught Early cohort with a rheumatologist's diagnosis of axSpA after two years of follow-up were included. MRIs and radiographs of the sacroiliac joints (SIJ) and spine obtained at baseline, 3 months, 1 and 2 years of follow-up were scored for inflammatory and structural lesions by ≥2 readers in two reading rounds: in round A, baseline, 3 months and 1 year were scored; in round B, baseline, 3 months, 1 and 2 years were scored. Change of each imaging outcome over time was analyzed with multilevel generalized estimating equations (considering the reader level), with time as explanatory variable. Two approaches were used: i) 'integrated analysis' (patients with ≥1 score from ≥1 reader from ≥1 reading round); ii) 'completers-only analysis' (patients with ≥1 score from ≥1 reader from round B at 2-year follow-up). The second and commonly used approach was considered the reference. We tested different time transformations to investigate which yielded the lowest quasi-likelihood under the independence model criterion, and the best model fit. In cases of comparable fit, the model with the simplest time format was chosen.

Results: In total, we analyzed 332 patients with axSpA (mean age 30 (SD 8) years; 53% males) of which 279 (84%) patients were included in the completers-only analysis. Binary and continuous variables for inflammatory lesions decreased over time in the MRI of the SIJ and spine, while structural lesions increased (Tables 1 and 2). Due to the best or very comparable fit, models with a linear time representation were used for all outcomes.

Structural lesions (radiograph-SIJ)		
mNY continuous grade (0-8)	0.06 (0.02; 0.09)	0.06 (0.03; 0.10)
SPINE		
Inflammatory lesions (MRI-spine)		
SPARCC spine score (0-414)	-0.56 (-0.90; -0.22)	-0.45 (-0.76; -0.15)
Structural lesions (MRI-spine)		
No. of erosions (0-92)	0.01 (-0.02; 0.03)	0.02 (-0.01; 0.04)
No. of fat lesions (0-92)	0.28 (0.13; 0.44)	0.35 (0.19; 0.50)
No. of bone spurs (0-92)	0.02 (-0.02; 0.06)	0.04 (-0.00; 0.08)
No. of ankylosis (0-46)	0.00 (0.00; 0.00)	0.00 (0.00; 0.00)
Total structural lesions (0-322)	0.37 (0.18; 0.55)	0.41 (0.23; 0.59)
No. of fat and/or erosions and/or bone spurs (0-276)	0.32 (0.15; 0.50)	0.41 (0.23; 0.59)
Structural lesions (radiograph-spine)		
mSASSS (0-72)	0.08 (0.01; 0.15)	0.08 (0.01; 0.16)

The 'integrated analysis' included patients with ≥1 score from ≥1 reader from ≥1 reading round, and the 'completers-only analysis' included patients with ≥1 score from ≥1 reader from round B at 2-year follow-up. The total of structural lesions in the MRI of the sacroiliac joints is a sum of erosions, fat lesions, (partial) ankylosis, and sclerosis. The total of structural lesions in the MRI of the spine is a sum of erosions, fat lesions, bone spurs and ankylosis. AxSpA: axial spondyloarthritis; CI, confidence interval; mNY continuous grade, sacroiliitis grade score conform the modified New York criteria; MRI, magnetic resonance imaging; mSASSS, modified stoke ankylosing spondylitis spinal score; No., number; SIJ, sacroiliac joints; SPARCC SIJ score, SpondyloArthritis Research Consortium of Canada score for inflammatory lesions.

Comparing both analyses, the integrated analysis included more patients but with similar levels of precision of the change estimates as the completers-only analysis for both the binary and continuous variables. Particularly for binary outcomes, a similar change was found by the integrated analysis with more precision compared to the completers-only analysis, e.g. sacroiliitis according to the ASAS criteria [estimated yearly % change (95% CI): -5.57 (-8.31; -2.83) vs -5.78 (-8.57; -2.99)].

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: In this longitudinal study, the integrated analysis was shown to allow for the inclusion of all available data, thereby reducing selection bias in determining the population for analysis, while maintaining precision of change estimates in patients with early axSpA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Sleep disturbance is a common and burdensome symptom in psoriatic arthritis (PsA), but its clinical determinants remain poorly understood. Using data from the Cohort for Psoriasis and Psoriatic Arthritis (COPPAR), we aimed to (1) compare the prevalence of sleep disturbance between patients who met Minimal Disease Activity (MDA) criteria and those who did not, and (2) identify clinical and patient-reported factors associated with sleep disturbance.

Methods: This cross-sectional study included patients with PsA enrolled in COPPAR. The primary outcome was the sleep item from the PsAID-9 questionnaire (0–10 scale). We compared the prevalence of clinically meaningful sleep disturbance (defined as PsAID sleep score > 4) between patients in MDA and those not in MDA using chi-square tests. We evaluated predictors using a general linear model (GLM) for the continuous PsAID sleep score. The initial models included age, sex, pain, itch, PHQ-8, FACIT fatigue, PROMIS anxiety, skin and joint global assessments, DLQI, MDHAQ, enthesitis score, tender/swollen joint counts, and topical treatment use. Sleep disorder diagnosis was added in sensitivity analysis.

Results: Among 204 patients with PsA, 112 (54.9%) were female, and 191 (93.6%) identified as White. MDA was achieved by 101 participants (49.5%). A diagnosis of sleep disorder was reported in 36 participants (17.6%). Most (n = 173, 84.8%) were on biologic, targeted synthetic, or conventional systemic therapy, and 111 (55%) used topical agents.

Table 1. Associations Between PsAID-9 Sleep Score and Clinical, Demographic, and Patient-Reported Factors: Results From Primary Analysis Using General Linear Model

Predictor	Estimate (B)	95% CI	Standard Error	p-value
Pain Global (NRS)	0.47	0.34 to 0.60	0.07	<0.0001
Itch Assessment (NRS)	0.25	0.12 to 0.39	0.07	0.0003
Topical Treatment Use (Yes vs No)	–0.60	–1.17 to –0.03	0.29	0.0386
FACIT Fatigue Score	–0.09	–0.12 to –0.05	0.02	<0.0001
PHQ-8 Score	0.08	–0.03 to 0.20	0.06	0.1441
Age*	0.00	–0.02 to 0.02	0.01	0.9573
Sex (Female vs Male)*	–0.02	–0.59 to 0.55	0.29	0.9494

NRS, Numerical Rating Scale

All estimates are from a fully adjusted model.
Beta coefficients represent the mean change in PsAID-9 sleep score per unit increase in the predictor (or the difference in means for binary predictors).

*Age and sex were retained in all models regardless of statistical significance

NRS, Numerical Rating Scale All estimates are from a fully adjusted model. Beta coefficients represent the mean change in PsAID-9 sleep score per unit increase in the predictor (or the difference in means for binary predictors). *Age and sex were retained in all models regardless of statistical significance

Table 2. Associations Between PsAID-9 Sleep Score and Clinical, Demographic, and Patient-Reported Factors: Results From A Sensitivity Analysis Including Sleep Disorder Diagnosis Using General Linear Model

Predictor	Estimate (B)	95% CI	Standard Error	p-value
Pain Global (NRS)	0.46	0.34 to 0.58	0.06	<0.0001
Itch Assessment (NRS)	0.24	0.10 to 0.38	0.07	0.0007
Topical Treatment Use (Yes vs No)	–0.64	–1.20 to –0.09	0.28	0.024
FACIT Fatigue Score	–0.05	–0.10 to –0.01	0.02	0.0287
PHQ-8 Score	0.11	0.00 to 0.22	0.05	0.0498
Sleep Disorder Diagnosis	0.90	0.20 to 1.61	0.36	0.013
Age*	0.00	–0.03 to 0.03	0.01	0.825
Sex (Female vs Male)*	0.05	–0.53 to 0.63	0.29	0.8689

NRS, Numerical Rating Scale

All estimates are from a fully adjusted sensitivity model including sleep disorder diagnosis.
Beta coefficients represent the mean change in PsAID-9 sleep score per unit increase in the predictor (or the difference in means for binary predictors).

*Age and sex were retained in all models regardless of statistical significance

NRS, Numerical Rating Scale All estimates are from a fully adjusted sensitivity model including sleep disorder diagnosis. Beta coefficients represent the mean change in PsAID-9 sleep score per unit increase in the predictor (or the difference in means for binary predictors). *Age and sex were retained in all models regardless of statistical significance

Among those in MDA, 9 (8.9%) reported a PsAID-9 sleep score > 4, compared to 37 (35.9%) among those not in MDA. PsAID-9 sleep scores were significantly associated with MDA status ($\chi^2 = 20.53$, $p < 0.0001$).

In the primary GLM ($R^2 = 0.52$), pain severity ($\beta = 0.47$, $p < 0.0001$) was the strongest independent predictor of worse sleep. Greater itch ($\beta = 0.25$, $p = 0.0003$) and fatigue (lower FACIT; $\beta = –0.09$, $p < 0.0001$) were also significantly associated with worse sleep. Current topical agent use was associated with better sleep ($\beta = –0.60$, $p = 0.039$). PHQ-8 score was not retained in the final model.

In the sensitivity model ($R^2 = 0.55$), sleep disorder diagnosis was independently associated with worse sleep ($\beta = 0.90$, $p = 0.013$). Pain ($\beta = 0.46$, $p < 0.0001$), itch ($\beta = 0.24$, $p = 0.0007$), fatigue ($\beta = –0.05$, $p = 0.0287$), and PHQ-8 score ($\beta = 0.11$, $p = 0.0498$) were also independently associated with worse sleep. Topical treatment use remained protective ($\beta = –0.64$, $p = 0.024$).

Conclusion: Patients in MDA were significantly less likely to report clinically meaningful sleep disturbance. In multivariable models, worse sleep was consistently associated with higher pain, greater itch, and more fatigue. Longitudinal studies are needed to better understand temporal relationships and inform targeted sleep interventions in PsA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Spondyloarthritis (SpA) impacts patient's life, including functionality, QoL, emotional state, and sexual function. The current study was conducted to determine the frequency of sexual function abnormalities and the risk factors associated with this complication.

Methods: We conducted a study at a tertiary care center in Mexico City from Oct 2024 to Apr 2025. We included patients diagnosed with SpA and used self-administered questionnaires to assess different PROs (disease activity, QoL, physical function, anxiety, and depression). Sexual function was evaluated using CSFQ-14. Additionally, patients were asked which specific manifestation of their disease harmed their sexual function from multiple different options, or to write it if not present. We also asked whether patients had discussed sexual health with their rheumatologist.

Results: Seventy-eight patients were included; 63% were men, with a median age of 48 years (IQR 34-57). Most patients had axial disease (n=44, 56.4%), and 55.7% (n=43) had a positive HLA-B27. Sexual dysfunction was reported by 60.3% (n=47). Table 1 summarizes the characteristics of patients with and without sexual dysfunction. Patients with sexual dysfunction had a higher prevalence of radiographic disease, more comorbidities, and higher depression scores. In the logistic regression, hypertension (OR 12.5, 95%CI 1.3-122.1) and depression score (OR 1.2, 95%CI 1.0-1.4) were associated with

sexual dysfunction; conversely, lower weight (OR 0.93, 95%CI 0.8-0.9) and non-radiographic axial disease (OR 0.06, 95%CI 0.007-0.53) were associated with a protective effect.

Three distinct patient clusters were identified using principal component analysis (PCA) of four standardized clinical variables (CSFQ-14, HAQ, BASDAI, ASQoL): cluster 1 (preserved sexual function, low disease activity, and better QoL), cluster 2 (moderate impairment across domains), cluster 3 (marked sexual dysfunction, high functional limitation, and poor QoL). PCA1 reflected the overall clinical burden (HAQ, BASDAI, ASQoL), while PCA2 distinguished the sexual function. This confirms that sexual health forms a distinct axis, partially independent from physical and inflammatory burden. (Figure 1A).

Most patients (n=47, 60.3%) considered that at least one disease manifestation harmed their sexual function (Figure 2). A high proportion of patients (n=53, 67.9%) reported they never talked about sexual function with their rheumatologist, but most (n=71, 91%) considered it was important for their rheumatologist to discuss these issues.

Conclusion: Sexual dysfunction is a frequent and often under-recognized complication in these patients. Radiographic disease, hypertension, and depression were independent risk factors, whereas non-radiographic SpA was associated with

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

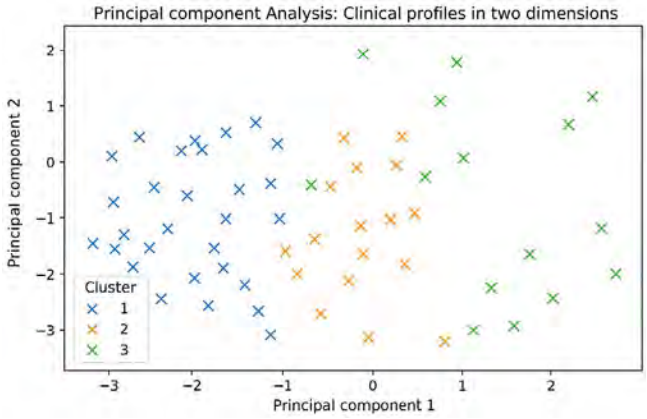

Figure 1. Principal component analysis identified two axes. Component 1 (52.7%) captured overall clinical burden (HAQ, BASDAI, ASQoL). Component 2 (25.7%) was defined by CSFQ-14, representing a distinct dimension of sexual dysfunction. Three clinical clusters emerged across these axes, including one with high disease burden and severe sexual dysfunction..

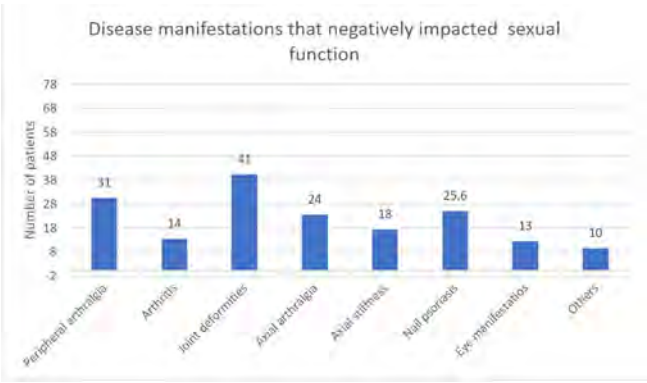

Figure 2. Most frequently reported disease manifestations that patients identified to have a negative impact on their sexual function

preserved sexual function. Cluster analysis revealed three distinct clinical profiles, highlighting a subgroup with substantial clinical impairment and another with preserved sexual function despite active disease, suggesting resilience mechanisms. These findings underscore the need for personalized strategies and for proactively addressing sexual health.t

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: This study sought to compare clinical characteristics between female and male patients with spondyloarthritis (SpA) in a Turkish population.

Methods: This study included 489 peripheral and axial SpA patients recruited from different regions of Türkiye in the ASAS-PerSpA study. Demographic and clinical characteristics such as axial involvement, peripheral arthritis, enthesitis, dactylitis, uveitis, psoriasis, and intestinal involvement, and clinometric information including BASDAI, ASDAS, tender joint count, swollen joint count, enthesitis count and FiRST fibromyalgia score were evaluated according to gender.

Results: Of the patients included in the study, 256 were male and 233 were female. The mean age was 40.24 (SD:11.27) years for males and 43.61 (SD:11.01) years for females (p=0.002). Body mass index was 26.23 (SD:3.97) kg/m^2 for males and 27.01 (SD:5.58) kg/m^2 for females (p=0.006). In axial SpA (n=391), 230 were male and 161 were female (p< 0.001), whereas in peripheral SpA (n=96), 43 were male and 53 were female (p=0.09), and in psoriatic arthritis (n=80), 19 were male and 61 were female (p< 0.001).

Back pain with age at onset < 45 years, sacroiliitis on pelvis x-ray, and HLAB27 positivity were more common in males than females (p< 0.05). While axial involvement of SpA was more common in males, past or present arthritis compatible with SpA, peripheral articular disease, spondyloarthritis-related enthesitis, psoriasis, and dactylitis were more common in females (p< 0.05). There were no significant differences between the genders in the uveitis and inflammatory bowel disease. Regarding

Table. Comparison of Clinical Characteristics According to Gender

	Sex mean (SD) or n (%)		Total	p
	Male	Female		
Age	40,24 ± 11,27	43,61 ± 11,01	41,84 ± 11,26	**0,002**

disease activity tender joint count, dactylitis, enthesitis, BASDAI and ASDAS scores of females were significantly higher than males ($p< 0.05$). FiRST fibromyalgia score were higher in females ($p< 0.001$) (Table).

Conclusion: There are some clinical differences according to gender in SpA. In our population, males had higher axial involvement and radiographic sacroiliitis, while females had more peripheral involvement, including arthritis, enthesitis, and dactylitis, as well as a higher prevalence of fibromyalgia and disease activity.

Background/Purpose: Psoriatic Arthritis (PsA) is a chronic rheumatic disease that develops in up to one-third of patients with psoriasis. Identifying predictive factors for PsA in patients with psoriasis referred to rheumatology clinics can facilitate early detection and improve disease outcomes.

Objectives: To identify predictive factors for the development of psoriatic arthritis (PsA) after 12 months of follow-up in patients with a diagnosis of psoriasis referred to a rheumatology clinic.

Methods: An observational, analytical, retrospective study was conducted on 109 patients with psoriasis referred to rheumatology from the dermatology department. Demographic, clinical and analytical data were collected at the first visit to the rheumatology clinic and after 12 months of follow-up. Patients were classified as having PsA yes/no at the 12-month visit based on the rheumatologist's opinion. Baseline characteristics potentially predictive of a PsA diagnosis were analysed using chi-squared and Student's t-tests. Finally, multivariate logistic regression was performed to evaluate the predictive factors independently associated with the development of PsA.

Results: Among the 109 patients evaluated, 54.1% were female and the mean age was 50.8 (12.1) years. A total of 52.9% had plaque psoriasis, and 55.6% had nail involvement. The most frequent reasons for referral were arthralgias (66.1%) and arthritis (16.5%). Additionally, 25% of the referred patients were already receiving biologic treatment prescribed by the dermatologist. A total of 41 patients (37.6%) were diagnosed with PsA after 12 months of follow-up.

Univariate analysis (table 1) showed that factors significantly associated with the development of PsA were: male gender (54.0% vs. 23.7%), arthritis as the reason for referral (61.0% vs. 29.2%), plaque psoriasis (54.1% vs. 14.3%), nail involvement (46.7% vs. 26.5%), elevated CRP (mean 12.0 vs. 5.3 mg/L) and being on biologic treatment (55.6% vs. 31.7%).

Finally, multivariate logistic regression (Table 1) demonstrated that male gender (OR 3.6, 95% CI 1.3 - 9.5) and plaque psoriasis (OR 6.0, 95% CI 2.0 - 7.2) were the most important predictors for the development of PsA. Conversely, patients referred for symptoms other than arthralgias or arthritis had a lower risk of developing PsA (OR 0.2, 95%CI 0.1 - 0.7).

Conclusion: This study in routine clinical practice suggests that male gender, the presence of plaque psoriasis and referral for arthritis or arthralgia are independently associated with the development of PsA. Further long-term prospective studies are required to confirm these findings.

Background/Purpose: Spondyloarthritis (SpA) is a chronic inflammatory disease with heterogeneous clinical manifestations. While some patients exhibit mild forms, others progress to complex forms characterized by persistent inflammation, organ involvement (pulmonary, cardiovascular), or severe structural damage. Early identification of high-risk profiles is crucial for tailoring therapeutic strategies. Artificial intelligence (AI) represents a promising tool to predict disease progression based on simple, readily available clinical data.

The objective was to evaluate the performance of a machine learning model (Random Forest) in predicting complex clinical forms of SpA using routine clinical variables that are independent of the criteria defining complexity.

Methods: The study included 319 patients with SpA. A complex form was defined by the presence of at least two of the following criteria:

- Elevated CRP (>10 mg/L)
- Uveitis
- Pulmonary involvement
- Cardiovascular complications
- Hip involvement (coxitis)

The model was trained using five clinical variables unrelated to the definition of complexity:

- Age
- Sex
- CRP
- Erythrocyte sedimentation rate (ESR)
- Glomerular filtration rate (GFR)

The dataset was split into a training set (80%) and a test set (20%). The performance of the Random Forest model was assessed using accuracy, AUC-ROC, sensitivity, precision, and confusion matrix.

Results: The Random Forest model, based on five simple clinical variables (age, sex, CRP, ESR, GFR), achieved an overall accuracy of 78% on the test set. Its discriminative capacity, as measured by the area under the ROC curve (AUC), was high at 0.88, indicating strong ability to distinguish between simple and complex forms of SpA. The model correctly identified 71% of patients with a complex form (sensitivity), while maintaining a specificity of 81% for simple forms. The precision for complex cases was 65%, suggesting useful performance for identifying high-risk patients. It also demonstrated a high negative predictive value, indicating good reliability in ruling out severe forms.

Among the variables used, CRP was the most predictive factor, followed by ESR and GFR. Age and sex provided complementary contributions to model stability but were not major determinants.

Conclusion: This study shows that an artificial intelligence model based on simple and accessible clinical data can reliably anticipate complex forms of spondyloarthritis. AI does not replace the clinician but serves as a strategic partner in personalizing care and improving patient outcomes in rheumatology.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is an immune-mediated condition associated with an increased risk of cardiovascular (CV) events due to disease-specific characteristics. Galectin-3 (Gal-3) is a beta-galactoside-binding protein involved in cellular adhesion, proliferation, differentiation, and apoptosis. It is expressed by endothelial cells and fibroblasts, contributing to the secretion of multiple pro-inflammatory cytokines. This protein promotes angiogenesis and fibrosis in various tissues and is considered a biomarker for heart failure, coronary disease, and CV mortality. However, there is limited information regarding Gal-3 as a CV risk biomarker in patients with PsA. This study aimed to associate Gal-3 levels with echocardiographic parameters and disease characteristics in PsA patients.

Methods: This was a cross-sectional study including 78 patients diagnosed with PsA, according to the 2006 CASPAR classification criteria, aged >18 years. Patients with a history of major CV events were excluded. All study participants underwent transthoracic echocardiography performed by two certified cardiologists blinded to clinical information. Blood samples were collected to analyze Gal-3 levels using the ELISA method (Abcam, Cambridge, UK). Disease activity was assessed using the Disease Activity Index for Psoriatic Arthritis (DAPSA), the Psoriasis Area Severity Index (PASI), and the Nail Psoriasis Severity Index (NAPSI). Correlations between Gal-3 levels and other variables were analyzed using Spearman's correlation coefficient (rs). A p-value < 0.05 was considered significant.

Results: The mean age of PsA patients was 52.12 ± 11.91 years, and the median Gal-3 level was 11.5 (5.9–18.1) ng/mL. Clinical and demographic characteristics are shown in Table 1. A moderate positive correlation was observed between Gal-3 and global longitudinal strain (GLS) (rs = 0.305, p = 0.021), a low negative correlation between Gal-3 and left ventricular ejection fraction (LVEF) (rs = -0.255, p = 0.024), a moderate positive correlation between Gal-3 and PASI (rs = 0.331, p = 0.003), a low positive correlation between Gal-3 and DAPSA (rs = 0.237, p = 0.037), and a moderate positive correlation between Gal-3 and C-reactive protein (CRP) (rs = 0.332, p = 0.003) (Figure 1). No significant correlations were found with other variables. A multivariate analysis adjusted for age, body mass index, glycated hemoglobin, systolic blood pressure, and non-HDL cholesterol showed that Gal-3 levels were independently associated with worse GLS (β = 0.358, p = 0.013).

Conclusion: Elevated Gal-3 levels were independently associated with impaired GLS, a parameter reflecting early and subclinical left ventricular dysfunction. Normal GLS values range from -18% to -22%, with more positive values indicating worse myocardial strain. Additionally, higher Gal-3 concentrations were associated with lower LVEF, indicative of left ventricular

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease that impairs quality of life. While pharmacological treatment is central to axSpA management, non-pharmacological strategies are increasingly recognized for their benefits on disease outcomes. This study evaluates the impact of physical activity, obesity, and mobility impairment on the quality of life in patients with axSpA.

Methods: This was a cross-sectional data analysis from the Brazilian Spondyloarthritis Registry, including 19 centers nationwide. All patients included were diagnosed with axSpA by a rheumatologist and met the ASAS classification criteria for axSpA. Physical activity was measured using the International Physical Activity Questionnaire (IPAQ), obesity was defined by body mass index (BMI), mobility impairment was evaluated using the Bath Ankylosing Spondylitis Metrology Index (BASMI), and quality of life was measured by the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

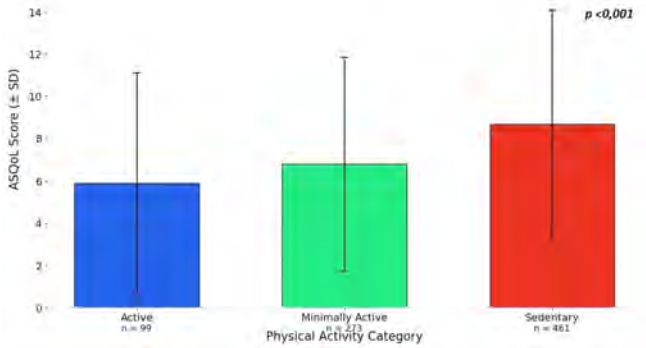

Figure 1. Comparison of Ankylosing Spondylitis Quality of Life (ASQol) values among Physical Activity levels - International Physical Activity Questionnaire (IPAQ) in axSpA paients.

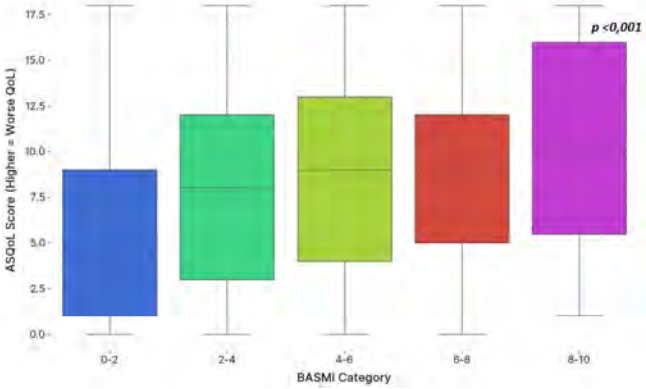

Figure 2. Comparison of Ankylosing Spondylitis Quality of Life (ASQol) values between Bath Ankylosing Spondylitis Metrology Index (BASMI) category in axSpA patients.

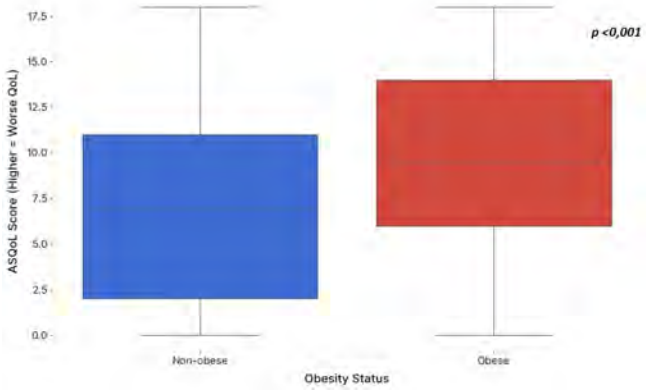

Figure 3. Comparison of Ankylosing Spondylitis Quality of Life (ASQol) values between Obesity status in axSpA patients. Obesity=Body Mass Index(BMI) ≥30.

Results: A total of 965 patients with axSpA were included (70.7% male; mean age 47.8 ± 12.9 years). HLA-B27 was positive in 631 patients (65.4%), negative in 204 (21.1%), and unknown or untested in 130 (13.5%). Subsequent analysis focused on 833 patients with complete data on physical activity (11.9% active; 32.8% minimally active; 55.3% sedentary). ASQoL values progressively worsened with lower physical activity levels: active, minimally active, and sedentary (5.9 ± 5.2 vs. 6.8 ± 5.0 vs. 8.7 ± 5.4, $p < 0.001$) (Figure 1). Pairwise comparisons showed differences between active vs. sedentary ($p < 0.001$) and minimally active vs. sedentary ($p < 0.001$), but no significant difference between active and minimally active

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

groups (p = 0.092). A positive correlation between BASMI and ASQoL was observed (Spearman r = 0.236, p < 0.001) (Figure 2), and patients classified as obese (BMI ≥30) exhibited significantly higher ASQoL compared to non-obese patients (9.3 ± 5.16 vs. 7.5 ± 5.07; p < 0.001) (Figure 3). Interestingly, no difference was observed between physical activity levels (active, minimally active, and sedentary) and BASMI (3.90 ± 2.09 vs. 3.94 ± 2.00 vs. 4.25 ± 2.11, p = 0.097) and frequency of obesity (28.4% vs. 22.9% vs. 23.8%, p = 0.523). Additionally, when comparing obese and non-obese axSpA patients, BASMI values were similar (4.25 ± 1.89 vs. 4.08 ± 2.13, p = 0.211).

Conclusion: Regular exercise was associated with a better quality of life, while obesity and mobility limitations independently had a negative impact. Remarkably, these variables did not influence each other, suggesting that additional factors may influence physical function, mobility, and body composition. These findings highlight the importance of incorporating non-pharmacological interventions, such as promoting physical activity, preventing disability, and managing weight, into the comprehensive care of axSpA patients to improve their quality of life.

Persistent Pain in PsA: A Distinct Phenotype of Depression, Fatigue, And Catastrophizing

Rebecca Haberman[1], Kyra Chen[2], Adamary Felipe[3], Stephanie Eichman[3], Uma Scher[4] and Jose Scher[5], [1]NYU Langone Health, New York, NY, [2]NYU Grossman School of Medicine and NYU Langone Health Psoriatic Arthritis Center, New York, [3]NYU Grossman School of Medicine, New York, [4]NYU School of Medicine, Scarsdale, NY, [5]New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Targeted synthetic and biologic DMARDs have transformed psoriatic arthritis (PsA) treatment. Still, a substantial subset of patients reports persistent joint pain despite well-controlled inflammation. We previously demonstrated that such patients fare worse across multiple PSAID domains. In this study, we aimed to more precisely characterize the psychological and functional profile of this potentially distinct phenotype.

Methods: PsA patients meeting CASPAR criteria were prospectively enrolled at the NYU Psoriatic Arthritis Center. Participants underwent a standardized clinical evaluation and completed multiple surveys, including Pain Catastrophizing Scale (PCS), Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F), Hospital Anxiety and Depression Scale (HADS- A/D), Patient Health Questionnaire-9 (PHQ-9), RAPID3, PROMIS29, and EQ-5D. Patients were categorized into three groups: active (≥1 SJC, ≥0 TJC), persistent pain (0 SJC, ≥1 TJC), or remission (0 SJC, 0 TJC).

TJC	1 (0, 4)	--	3 (1.3, 5)	4 (1, 6)	--
SJC	0 (0,1)	--	--	2 (1, 5)	--
Enthesitis	0 (0,0)	0 (0,0)	0 (0,0)	0 (0,1)	0.230
Dactylitis	0 (0,0)	0 (0,0)	0 (0,0)	0 (0,0)	0.004^
BSA	0.13 (0, 1)	0.4 (0, 1)	0 (0,0.5)	0.3 (0,1)	0.320
BMI	28.1 (24.5, 33.2)	26.1 (22.8, 30.9)	30.9 (26.5, 35.5)	29.3 (25.0, 32.5)	0.027*
Current Medication Use -- n(%)					
cDMARD	26 (28.6)	13 (32.5)	8 (33.3)	5 (18.5)	0.386
b/tsDMARD	82 (90.1)	35 (87.5)	24 (100.0)	23 (85.2)	0.159

IBD denotes inflammatory bowel disease, TJC tender joint count, SJC swollen joint count, BSA percent body surface area affected by psoriasis, BMI body mass index, cDMARD conventional disease modifying antirheumatic drug, b/ts biologic/targeted synthetic.
^ Dactylitis is significant between remission-active and remission-persistent pain.
* BMI significant between remission-perisstent pain.

Summary data was presented as numbers/percentages or medians/interquartile regions (IQR). Group comparisons were performed using Chi-squared tests and Kruskal-Wallis tests with post-Hoc Dunn's test for pair-wise comparisons with Bonferroni correction.

Results: 91 patients were assessed; 24 (26.4%) had persistent joint pain, 40 (43.9%) were in remission, and 27 (29.7%) had active inflammation (**Table 1**). Patients with persistent pain were more likely to be female (p=0.02), meet criteria for fibromyalgia (p=0.005), and have diabetes (p=0.003). Compared to those in remission, patients with persistent pain had a higher body mass index (30.9 (IQR 26.5, 35.5) vs 26.1 (22.8, 30.9), p=0.022) and worse psychologic profiles (**Figure 2**). They demonstrated higher levels of catastrophizing (PCS 11 (5.0, 15.8) vs 1.5 (0, 10.0), p= 0.004), depressive symptoms (PHQ-9 6.0 (48.6, 62.1) vs 2.5 (0.3, 4), p=0.001; HADS-D (5.0 (3.0, 8.5) vs 2.0 (0, 5.0), p=0.011) and fatigue (FACIT 33.0 (20.8, 42.8) vs 44.0 (40.0, 47.5), p< 0.001). There was no difference in anxiety level (HADS-A 6.5 (4.0, 11.8) vs 5.0 (2.0, 6.0), p=0.256). They reported decreased physical function (41.6 (37.0, 45.0) vs 47.6 (42.1, 56.9), p< 0.001), decreased ability to participate in social activities (48.2 (39.0, 51.8) vs 57.6 (48.2, 64.2), p= 0.004), more pain interference, (56.7 (52.2, 62.1) vs 51.7 (41.6, 55.7), p=0.008) and worse overall QoL (EQ5D 0.63 (0.4, 0.8) vs 0.8 (0.7, 0.9), p< 0.001). Patients with persistent pain had profiles similar to those with active inflammatory disease (and in many domains were numerically worse, **Table 2**).

Conclusion: Persistent joint pain in PsA, even without objective inflammation, is linked to a reproducible cluster of psychosocial distress and functional impairment. These patients may not fit the traditional treat-to-target approaches that focus on inflammation mitigation alone. Our findings underscore an unmet therapeutic need: integrative interventions targeting

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Comparison of physiologic indices (A) and patient reported outcomes (B) between patients in remission, with persistent joint pain, and active inflammatory disease. Medians and interquartile regions plotted with outliers in gray. Pain catastrophizing scale 0-52 possible range with higher numbers reflecting increased levels of catastrophizing. FACIT-F denotes Functional Assessment of Chronic Illness Therapy-Fatigue Scale and ranges 0-52 with lower scores indicating more fatigue. PROMIS Fatigue is reported as t-scores with higher scores indicating more fatigue. PHQ-9 denotes Patient Health Questionnaire-9 and ranges 0-27 with higher scores indicating more depressive symptoms. HADS-D and HADS-A denote Hospital Anxiety and Depression Scale-Depression and Anxiety, each ranging 0-21 with higher numbers indicating higher levels of depression and anxiety. Physical function, sleep disturbance, participation, and pain interference are all derived from PROMIS measures and are reported as t-scores with higher score indicating higher levels of that category (i.e., higher physical function scores reflect better physical function, lower participation score reflects decreased ability to participate). RAPID 3 is a composite index of physical function, pain, and patient global scores, ranging 0-30 with higher numbers indicating worse disease state. EQ5D measures quality of life (QoL), ranging 0-1 with one indicating the best overall health QOL status. *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$

Table 2. Comparison of physiologic indices and patient reported outcomes between patients with persistent joint pain and those with active inflammation

	Persistent Pain (n=24)	Active (n=27)	p-value
Psychologic Indices- median (IQR)			
PCS total	11 (5, 15.8)	6 (1.8, 16.5)	>0.999
PCS helplessness	4 (2,7)	2 (0.8, 7.3)	>0.999
PCS magnification	3 (1,6.8)	2.5 (0.8, 4)	0.692
PCS rumination	3 (0.3, 5)	1.5 (0, 5.3)	>0.999
FACIT-F	33 (20.8, 42.8)	38 (32, 43)	>0.999
PROMIS Fatigue	55.2 (49.2, 64.2)	53.2 (47.3, 59.0)	0.984
PHQ-9	6 (2.3, 11.5)	5 (3, 6.3)	0.883
HADS-D	5 (3, 8.5)	5 (2, 7)	>0.999
HADS-A	6.5 (4, 11.8)	4 (2, 9)	0.257
Patient Outcomes- median (IQR)			
Physical function	41.6 (37.0, 45.0)	42.9 (38.2, 45.2)	>0.999
Sleep disturbance	56.2 (48.6, 62.1)	52.4 (46.8, 56.8)	>0.999
Social participation	48.2 (39, 51.8)	51.8 (45.2, 61.2)	0.221
Pain inteference	56.7 (52.2, 62.1)	55.7 (52.4, 62.9)	>0.999
RAPID3	10.9 (5.8, 16.2)	12.8 (8.3, 15.0)	>0.999
EQ5D	0.63 (0.4, 0.8)	0.7 (0.6, 0.8)	>0.999

IQR denotes interquartile region, PCS denotes pain catatrophizing scale, FACIT-F denotes Functional Assessment of Chronic Illness Therapy-Fatigue Scale, PHQ-9 denotes patient Patient Health Questionnaire, HADS denotes Hospital Anxiety and Depression Scale.

Background/Purpose: Psoriasis, affecting 2–3% of the global population, is a chronic inflammatory disease with systemic effects beyond the skin. Its immune-mediated inflammation contributes to cardiovascular comorbidities including hypertension, diabetes, and atherosclerosis. Th1/Th17-driven pathways accelerate vascular risk, linking psoriasis to stroke. However, data on stroke risk remain limited due to small cohorts and insufficient confounder adjustment.

Methods: This meta-analysis evaluated the association between psoriasis and stroke by systematically reviewing observational studies published through December 2024. Study selection followed PRISMA guidelines, extracting data on patient characteristics and adjusted risk estimates.

Results: This meta-analysis of 18 studies encompassing 705,602 psoriasis patients and over 17.9 million controls demonstrated a significant association between psoriasis and stroke, with a pooled hazard ratio (HR) of 1.24 (95% CI: 1.15–1.35). Stratified analyses showed elevated stroke risk across all severities: mild (HR: 1.09; 95% CI: 1.02–1.16), overall (HR: 1.34; 95% CI: 1.05–1.73), and severe psoriasis (HR: 1.36; 95% CI: 1.21–1.53). Region-specific estimates indicated consistent associations in Asia (HR: 1.08), Europe (HR: 1.26), and North America (HR: 1.49), though with some heterogeneity. Age subgroup analysis also confirmed increased stroke risk in both older (≥45 years, HR: 1.27) and younger (< 45 years, HR: 1.18) patients. No significant publication bias or small-study effects were detected by funnel plot analysis and statistical testing.

Conclusion: This analysis confirms that psoriasis is associated with an increased risk of stroke, particularly in patients with severe disease. The association remains consistent across age groups and geographic regions. These findings highglight the need for routine cardiovascular risk assessment in psoriasis care. Future research should explore targeted anti-inflammatory therapies and lifestyle interventions to mitigate stroke risk in this population.

Abstract Number: 2329

Increased Risk of Atrial Fibrillation In Patients With Psoriasis: A Systematic Review And Meta-Analysis

Sehneet Grewal, Rubab Rizwan, Sri Varsha Banda and Mohammad Hazique, Nuvance Health, Poughkeepsie, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriasis, a chronic inflammatory skin condition, is increasingly linked to systemic cardiovascular risks. Atrial fibrillation (AF), the most common cardiac arrhythmia, is associated with elevated risks of stroke, heart failure, and mortality. This study evaluates the association between psoriasis and AF.

Methods: This meta-analysis evaluated the association between Psoriasis and Atrial Fibrillation by systematically reviewing observational studies published through December 2024. Study selection followed PRISMA guidelines, extracting data on patient characteristics and adjusted risk estimates.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Forest Plot Showing the Association Between Risk of Atrial Fibrillation in Psoriasis

Results: Eight studies comprising 11,579,730 participants (277,597 with psoriasis and 11,302,133 controls) were included. Psoriasis was associated with a significantly higher risk of AF (HR: 1.27; 95% CI: 1.17–1.38). Subgroup analyses revealed that severe psoriasis was associated with a higher risk of AF (HR: 1.32; $p < 0.05$) as compared to mild psoriasis (HR: 1.22; $p < 0.05$), but the difference was not statistically significant ($p = 0.41$). Age-stratified analysis showed an elevated risk in individuals aged ≥45 years (HR: 1.40; $p < 0.05$) compared to those < 45 years (HR: 1.21; $p < 0.05$). Regional analysis demonstrated comparable risks in Asia (HR: 1.27; $p < 0.05$) and non-Asia (HR: 1.28; $p < 0.05$), with no significant subgroup differences ($p = 0.93$). Publication bias was not evident based on visual inspection of the funnel plot and Egger's regression test ($p = 0.24$).

Conclusion: This analysis of observational studies shows an association between psoriasis and increased risk of AF risk. Subgroup analysis shows that risk of AF is higher in severe psoriasis and older patients. Future large studies are needed to clarify underlying mechanisms, and assess the potential role of AF screening in improving outcomes for this high-risk population.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriasis and psoriatic arthritis (PsA) are associated with several comorbid conditions including metabolic disease, chronic kidney disease as well as mental health disorders. However, limited studies have been conducted on the impact of duration of PsA on comorbidities, and long-term change in practice to manage these comorbidities and improve patient care.

The objective of this study is to determine the prevalence of comorbidities in patients with PsA in a cohort of elderly veterans and determine the correlation of prevalence of comorbidities with the duration of PsA.

Methods: Our cohort included PsA patients from PULSAR (Program to Understand Long-term Outcomes in Spondylarthritis) registry and VA Sacramento Medical Center. The duration of PsA disease was identified by age of onset of PsA noted in the databases and categorized as < 5 years, 6-10 years, 11-15 years, 16-20 years and >20 years. Various comorbidities were identified via ICD-10 codes (hypertension, hyperlipidemia, diabetes mellitus, gout and mental health disorders) and studied in these patients and classified according to the duration of PsA (Table 1).

Table 1: The prevalence of comorbidities in patients with psoriatic arthritis in elderly veterans: Data on the grouping of patients based on disease duration and prevalence of comorbidities.

Duration of PsA (years)	Median age at PsA diagnosis(year)	Number of patients (n=220)	Hyperlipidemia	Hypertension	Gout	Diabetes	Mental Health
0-5	57	73	63.0%	54.8%	9.6%	31.5%	41.1%
6-10	49	35	42.9%	37.1%	2.9%	22.9%	45.7%
11-15	43	40	52.5%	65.0%	5.0%	35.0%	40.0%
16-20	38	20	40.0%	55.0%	10.0%	35.0%	35.0%
>20	30	52	57.7%	73.8%	9.6%	26.9%	34.6%

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Bar diagram representative of correlation of prevalence of several comorbidities and disease duration.

Results: There were 220 patients available for study. PsA disease duration was as follows: < -5 years (73, 33.2%), 5-10 years (35,15.9%), 11-15 years (40,18.18%), 16-20 years (20, 9%) and more than 20 years (52, 23.6%). The prevalence of comorbidities in each of these groups was then calculated as listed in (Table 1). On subsequent comparison amongst the groups, as noted in Figure 1, the prevalence of hypertension increased with longer disease duration. A similar trend was not noted for the rest of the comorbidities. However, comorbidities that contribute to CVD risk were prevalent in one third to almost half of the PsA cohort, regardless of disease duration (Figure 1).

Conclusion: In this study, the prevalence of hypertension increased with PsA duration. Prevalence of the other comorbidities did not correlate with disease duration. Given the increased cardiovascular disease risks in PsA patients, our findings emphasize the need for hypertension control in PsA patients of longer disease duration. In addition, our findings demonstrate that PsA patients are at increased risk for several comorbidities, especially metabolic syndrome and mental health disorders irrespective of the duration of disease. So, preventive measures should be taken early in the disease course to screen and comprehensively manage these comorbidities and underlying psychosocial issues.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: To identify patient characteristics and disease phenotypes associated with coping strategies in axial spondyloarthritis (axSpA), and assess whether coping strategies change over time.

Methods: Data from the Outcome in AS International Study (OASIS) were used. Coping was assessed using Coping with rheumatic stressors (CORS) at 4 and 6 years of follow-up. The CORS assesses coping with three stressors – pain, limitations, and dependence –, based on 61 items across eight strategies (score 1–4 for each strategy). Factors associated with each strategy were analysed with Generalized Estimation Equations (GEE). Age, sex and education were the main independent variables of interest. Variables with $p < 0.20$ in univariable analyses were added to age, sex and education using manual forward selection and comprised of other patient characteristics (e.g., BMI, comorbidities) and disease phenotypes (e.g., peripheral and extra-musculoskeletal manifestations). Interactions and confounders were tested and evaluated. Additional models were built where axSpA health scores (e.g., ASDAS, BASFI) were added. In separate GEE analyses, changes in coping strategies over time were assessed, with time as the independent variable.

Results: In total 116 patients [72% male, mean age 48 years (SD 12)] had CORS data at ≥1 timepoint. Patients made most use of *comforting cognitions* (mean: 3.0; (SD: 0.5)) to cope with pain, of *pacing* (2.4; (0.5)) to cope with limitations and of *showing considerations* (2.8; (0.5)) to cope with dependence (Tables 1–3). Several differences in preference for coping

Mander Enthesitis Index, 0-90	**0.01 (0.00 to 0.01)** [a]	0.00 (0.00 to 0.01) [a]

[a] Confounded the relationship between one of the three main variables of interest (age, sex, education level) and the outcome in this model.
[b] In univariable analysis not significant for this strategy.
Bold indicates significance (p<0.05). Disease duration, presence of IBD, presence of uveitis, HLA-B27 status and BMI were also analysed but not included in the table as they were not significant in univariable analyses (p>0.20). RDCI: Rheumatic Disease Comorbidity Index.

strategy were seen between patients but without clear patterns. Using the strategies that were most used per stressor as an example, it can be seen that using *comforting cognitions* to cope with pain was associated with lower (vs higher) education (β: -0.22; (95%CI: -0.41 to -0.03)) and with a higher BMI (0.01; (0.00 to 0.03) (Table 1). *Pacing*, to cope with limitations, was used more by older individuals (0.01; (0.01 to 0.02)) (Table 2). *Showing considerations*, to cope with dependence, was used less by those with more comorbidities (-0.10; (-0.19 to 0.00)) (Table 3). When adding axSpA health scores as additional variables to the initial models, coefficients remained largely unchanged across all strategies. As an example, the effect of adding health scores to the *comforting cognitions* model is shown in table 1 (2nd column). ASDAS, BASFI and MCS (SF-36) had no independent effect, were not effect modifiers and only had some confounding effect on the main relationships of interest. Finally, for the analyses of change over time, 102 patients had full CORS data on both timepoints. Analyses showed that coping strategies did not change over time (range β_{time}: -0.04 to 0.07/year).

Conclusion: Coping strategies in axSpA appear more strongly influenced by patient characteristics, to a lesser extent disease phenotypes but not by axSpA related health scores. Furthermore, no change over time was found supporting that coping is a trait and more dependent on the person than the disease.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Recent studies have highlighted the potential of composite scores such as the DAPSA for assessing peripheral arthritis in axSpA and pSpA. However, the swollen (SJC66) and tender (TJC68) joint counts required for the DAPSA calculation are often unavailable in axSpA randomized controlled trials.

This study aimed to develop and evaluate the construct validity of a modified-DAPSA score using the 44-joint count in patients with SpA (axSpA, pSpA, and PsA).

Methods: In this ancillary analysis of the ASAS-PerSpA study, patients with axSpA, pSpA, or PsA were included and allocated at random by diagnosis and country into two a derivation (33%) and a validation cohort (66%). The derivation cohort was used to calculate conversion factors for SJC66/TJC68 to SJC44/TJC44, to allow the calculation of DAPSA44, using mixed-effects linear regression models. The validation cohort assessed the new score's construct validity through: i) agreement between original-DAPSA and DAPSA44, evaluated as a continuous score with the Intraclass Correlation Coefficient (ICC) and categorically with disease activity states with weighted kappa coefficients, along with Bland-Altman plots; ii) original-DAPSA and DAPSA44 correlations with external constructs, with a predefined 0.3-wide acceptable range of difference between the scores; iii) the discrimination between known groups, calculated using standardized mean differences (SMDs) after stratifying patients into active/inactive based on a combination of PGA (≥5/< 5) and SJC (≥1/0 or ≥2/< 2, median SJC). An SMD with higher absolute value indicates better discriminatory ability, and an SMD above 0.8 is considered as 'good'.

Results: A total of 4121 patients with complete data on disease activity measures were analyzed, including 2679 (65%) with axSpA, 428 (10%) with pSpA, and 1014 (25%) with PsA. A history of peripheral arthritis was reported in 2291 (56%) patients, predominantly with oligoarticular (43%) or polyarticular involvement (45%). The prevalence of peripheral arthritis varied across disease phenotypes: 36% in axSpA, 95% in pSpA and 91% in PsA. Conversion factors from the derivation cohort (n=1364) from TJC68 and SJC66 to TJC/SJC44 were 1.3 and 1.3, respectively. The mean DAPSA44 scores were similar

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table. Agreement between original-DAPSA and DAPSA44

	DAPSA44				
DAPSA	Remission 1.98 (1.21)	Low disease activity 8.52 (2.85)	Moderate disease activity 19.45 (3.83)	High disease activity 41.58 (14.37)	Total
Remission 1.97 (1.20)	**588 (99%)/(97%)**	6 (1%)/(0.5%)	0 (0%)/(0%)	0 (0%)/(0%)	594
Low disease activity 8.56 (2.85)	20 (1.5%)/(3.3%)	**1252 (97%)/(97%)**	24 (1.8%)/(3.7%)	0 (0%)/(0%)	1296
Moderate disease activity 19.42 (3.71)	0 (0%)/(0%)	32 (4.8%)/(2.5%)	**604 (90%)/(93%)**	30 (4.5%)/(3.4%)	666
High disease activity 40.73 (14.83)	0 (0%)/(0%)	0 (0%)/(0%)	22 (10.9%)/(3.4%)	**179 (89%)/(86%)**	201
Total	608	1290	650	209	

Agreement 98.6%
Kappa: 0.95
n (%) within DAPSA disease activity states/(%) within DAPSA44 disease activity states
Below each disease activity state, mean (SD)

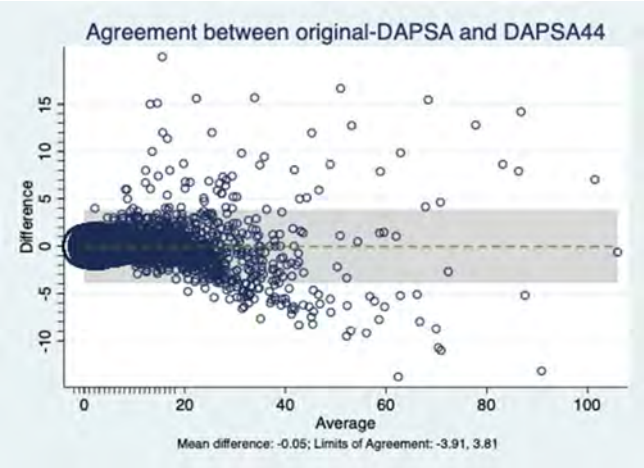

Figure 1. Bland–Altman plot. Agreement between original-DAPSA and DAPSA44.

between cohorts: 12.6 (SD 12.3) in the derivation and 12.2 (SD 12.4) in the validation cohort (p=0.33). The validation cohort (n=2757) analyses showed near-perfect agreement between DAPSA-original and DAPSA44, with a ICC 0.98, 95% CI 0.98–0.99 and kappa=0.95. The Bland–Altman plot demonstrated a mean difference of 0.25 points with a 95% limit of agreement between 0.25 and –0.02. (Figure 1)

In correlation analyses, Spearman coefficients between DAPSA44 and external constructs fell within the predefined 0.3-wide range of corresponding DAPSA-original coefficients, with some coefficients even showing identical values. For discrimination between active and inactive disease, DAPSA44 demonstrated excellent discriminatory ability (SDM >0.8) across all scenarios.

Conclusion: These findings support the use of DAPSA44 as a comparable tool to DAPSA-original for assessing disease activity due to peripheral arthritis, in situations where only a reduced joint count is available.

Abstract Number: 2333

Validation of a Corrected Axial Spondyoarthritis Metrology Index in 9 Randomized Clinical Trials

Dafne capelusnik[1], Philip Gardiner[2], Annelies Boonen[3], Elena Nikiphorou[4] and **Sofia Ramiro**[5], [1]Tel Aviv Sourasky Medical Center, Ramat Gan, Israel, [2]Altnagelvin Hospital, Londonderry, United Kingdom, [3]Maastricht University Medical Centre+ & Maastricht University, Maastricht, Limburg, Netherlands, [4]King's College London, London, United Kingdom, [5]Leiden University Medical Center, Bunde, Netherlands

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The MOBILITY study showed that BASMI often misclassifies spinal mobility, especially in older and taller individuals. To address this, the Corrected AxSpA Metrology Index (CASMI) was developed by adjusting BASMI for age, height, and sex to remove the variability introduced by these factors. This study evaluates CASMI's psychometric properties and compares them with BASMI in RCTs of axSpA patients treated with b/tsDMARDs.

Methods: RCTs in axSpA patients with complete BASMI component data (lateral spinal flexion, tragus-to-wall distance, intermalleolar distance, cervical rotation, and lumbar flexion) at baseline and the timing of the primary endpoint were included. Data were accessed and analyzed via the data-sharing platform Vivli. Age, sex, and height were used to adjust individual spinal mobility measures. BASMI- and CASMI-linear were calculated, and the following psychometric properties were analyzed: Construct validity: Known-group discrimination (Standardized Mean Difference -SMD) at baseline to distinguish between low and high functional impairment (BASFI< 3 vs >6); Longitudinal construct validity: Standardized Response Mean (SRM), Guyatt's responsiveness index (GRI), and effect size (ES); Trial discrimination: SMD. For all these psychometric properties, performance was classified as follows: low performance:< 0.5; adequate performance: ≥0.5 and < 0.8; good performance: ≥0.8. Lastly, a sensitivity analysis was conducted in patients with early disease (≤2 years of symptom duration).

Results: Nine RCTs, all having reached the primary endpoint, with complete BASMI component data and available age, sex, and height information were included. Six involved radiographic axSpA, three non-radiographic axSpA. Only 5 studies included patients with early disease and in varying proportions: 3–48%.

In seven of nine trials, CASMI had a lower mean value than BASMI (Table). For construct validity, most trials showed good discriminatory capacity, except COAST-W (TNFi-insuficient response population) and SELECT-AXIS. EMBARK was the only trial where CASMI showed a good discrimination between know-groups, while for BASMI it was only adequate. Regarding longitudinal construct validity, results were inconclusive, showing high variability across measures, but without important differences between BASMI and CASMI. All trials in bDMARD-naïve r-axSpA patients showed significant BASMI/CASMI improvements with active treatment, but trial discrimination was generally low for both, except for CASMI in ASSERT

*Discrimination ability to discriminate between know-groups (BASFI<3 and BASFI >6)
Construct validity: SMD < 0.5 Low (red); >=0.5 & <0.8 Moderate (amber); >=0.8 Good (green)
Longitudinal construct validity: Guyatt's ES, SRM, ES < 0.5 Low (red); >=0.5 & <0.8 Adequate (amber); >=0.8 Good (green)
Clinical trial discrimination: SMD < 0.5 Low (red); >=0.5 & <0.8 Adequate (amber); >=0.8 Good (green)
NR, not reported; SMD, Standardized Mean Difference; ES, Effect Size; GRI, Guyatt's responsiveness index; SRM, Standardized Response Mean.

(adequate) and TOFACITINIB (good). In all nr-axSpA studies, trial discrimination was low for both BASMI and CASMI. In analyses restricted to early disease patients, trial discrimination improved numerically but remained low (except for TOFACITINIB, where it remained good), with the exception of SELECT-AXIS, where discrimination became good for BASMI and adequate for CASMI.

Conclusion: While CASMI has been developed to be a more truthful measure than BASMI, both CASMI and BASMI have largely comparable measurement properties. This means that the current adjustments are still insufficient to detect change over time in spinal mobility.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The MOBILITY study, a study on spinal mobility measures in healthy individuals, showed that the Bath Ankylosing Spondylitis Metrology Index (BASMI) often overestimates spinal mobility as these measures also depend on height, sex and age, with a significant impact on older and taller individuals. To better address this, we developed a Corrected AxSpA Metrology Index (CASMI) and compared its construct validity with that of BASMI in patients with established axSpA.

Methods: Data from the MOBILITY study on spinal mobility in healthy individuals were used to develop a corrected version of the BASMI (CASMI). Age-, sex-, and height-specific normal limits were derived for each component (lateral spinal flexion -LSF-, tragus-to-wall -TTW-, intermalleolar distance -IMD-, Schobert's test, cervical rotation -CR-) from regression models or trigonometric calculations. Components were anchored using the 50th percentile of healthy individuals (MOBILITY study, score = 0) and the 95th percentile of axSpA patients (cohort study of axSpA used, score = 10). TTW was corrected using fixed thresholds. Construct validity of several CASMI versions were compared to BASMI in an axSpA population included in the OASIS cohort. Construct validity was assessed by comparing means, minimum and maximum values, floor and ceiling effects of BASMI and CASMI, and correlations with age, height and disease outcomes (BASFI, BASDAI, ASDAS, mSASSS and number of syndesmophytes). It was hypothesized that CASMI would reduce correlations with age and height while maintaining correlations with disease measures. Differences between BASMI and CASMI in the score distributions were visualized with density plots. Known group discrimination, as part of construct validity, was tested by comparing standardized mean differences (SMD) between known groups, stratified by: i) BASFI (≤3 vs ≥6), ii) mSASSS (≥1 vs >10), and iii) syndesmophyte count (≤1 vs 5). Higher absolute SMD values indicate better discrimination, with >0.8 considered as 'good'.

Results: Table 1 presents the formulae for the five components of BASMI, as well the formulae for the CASMI components. In the OASIS cohort, mean values for some corrected components were lower, whereas minimum values remained unchanged, and were slightly lower for CASMI. Floor effects increased in individual items (e.g., TTW: 0.5% to 52%) but

Table 1. Equations for the conversion of the assessments (A) into scores (S) for the five components of the BASMI and CASMI, including applied adjustments§

Instruments		S=0 (Normal Limit)# if:	S between 0-10:	S=10 (Severe limit)# if:	Age	Sex	Height

§ BASMI formulae are the ones from BASMI linear and the CASMI ones the same, with adjustments of the normal and severe limits
#Normal and severe limits for CASMI components were calculated based on appropriate adjustments for each individual's age, sex, or height
For CASMI components, age and sex correction factors were derived from the regression coefficients obtained in the MOBILITY study, whereas for height, both regression-based coefficients and those calculated using trigonometric formulae were applied. Adjustments reflected a specific formula for each normal/severe limit, for each spinal mobility measure.
* If male sex "+1.92", if female sex "-1.92"
** If male sex "+0.27", if female sex "-0.27"
A, assessment (of the individual spinal mobility measure); S, score

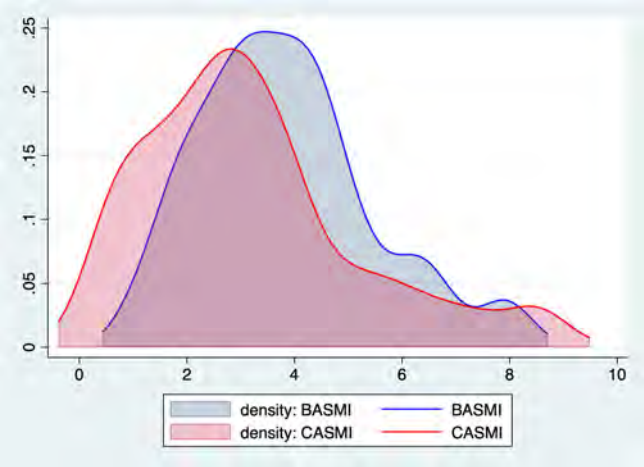

Figure 1. Density plots for BASMI and CASMI. CASMI represented here is CASMI_Ma which formula was adjusted using age, sex and hight correction factors derived from the regression coefficients obtained in the MOBILITY study.

Table 2. Descriptive data and construct of the BASMI/CASMI and their components in OASIS (n=204-216)

Missing data for LSF=11; IMD=2; LF=1; BASMI/CASMI=11

*The normal limit (anchor zero) for the BASMI components was defined based on their established minimal values, while for the CASMI components, it was set using the 50th percentile of BASMI values from the MOBILITY study (healthy individuals). The severe limit (anchor 10) for the BASMI components was defined based on their established maximum values, while for the CASMI components, it was set using the worse values from a longstanding established r-axSpA cohort.

In bolded BASMI/BASMI components values.

T: trigonometric-based adjustment formula; M: MOBILITY coefficient-based adjustment formula (except by TTW_M, where the normal limit was based on the mean value from the MOBILITY study.

a-d version correspond to the Tragus to wall version used.

Cells are colored green when the CASMI component reduces unwanted correlation of the CASMI (components) is reduced by more than 10% (>0.100) the correlation with age or height (i.e., improves), and red when it increases the correlation (by at least 10% i.e., worsens) in relation, when compared to BASMI (components).

remained 0% in the composite scores. Maximum values and ceiling effects increased in individual components but not in CASMI. As intended, correlation with age and height decreased in CASMI and several components, but no major changes in correlations with disease outcomes, confirming the hypotheses made (Table 2). The density plots showed that CASMI systematically yields lower scores and has a higher floor effect, suggesting better calibration and better sensitivity to capture subtle impairments in spinal mobility. Discrimination between known groups was good across all score versions and external constructs (SMD >0.80).

Conclusion: An age-, sex- and height-corrected mobility score, the CASMI, has been developed as a more personalised and truthful measure of mobility in axSpA, compared to BASMI.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Reducing diagnostic delay for people presenting with back pain who have axial spondyloarthritis (axSpA) has become a clinical imperative since effective treatments can limit progression of this debilitative disease. The absence of a simple blood test that is accessible by referring primary care physicians contributes to this delay. We presented data from the Bath Spondyloarthritis Biobank demonstrating that 14-3-3η AAbs distinguish referred patients with axSpA from those with mechanical backpain (MBP), with an 88% PPV. This challenge also exists at the community rheumatologist level, where experienced interpretation of radiographs and MRI scans may be limited. This study evaluates the performance of the 14-3-3η AAbs in combination with existing clinical parameters in an established Edmonton radiographic (r-axSpA) patient cohort.

Methods: Serum samples from 159 patients with a rheumatologist confirmed diagnosis and classified as r-axSpA (AS-modified New York criteria) were tested on the anti-14-3-3η multiplex assay. The control group comprised the 51 MBP patients previously tested from the Bath cohort. The serum differential expression of 14-3-3η AAbs, CRP and HLA-B27 between patients with r-axSpA and MBP was evaluated by ROC AUC. Regression models combining the 14-3-3η AAb Score derived from the Bath study were tested in two predictive models: one with CRP and HLA-B27 markers only and the other adding Age and Sex variables. Corresponding specificity (SP), sensitivity (SN), predictive values (PPV, NPV),

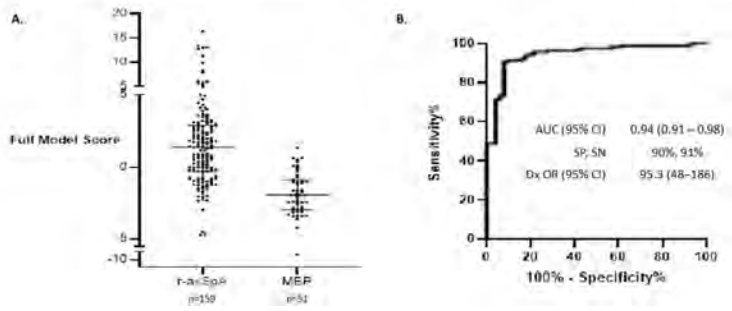
LR-	0.67	0.50	0.21	0.21	0.10
Dx OR (95% CI)	6.2 (2.8 - 13.5)	11.1 (5.6–22.5)	24.1 (12.3–45.1)	39.6 (20.5–76.3)	95.3 (48–186)
AIC	221	183	158	115	109

Figure 1. A. Score distribution for model that includes all markers with age and sex, and B. ROC AUC



likelihood (LR) and diagnostic odds ratios (DxOR) are provided. The Akaike Information Criterion (AIC) statistical measure was reported to compare the relative quality of predictive models.

Results: Mean age of patients with r-axSpA was 42 (69% male) and for MBP, 30 years (59% male), (Table 1). Differential expression of each of the biomarkers delivered significant ROC AUCs; 0.70 for 14-3-3η AAbs, 0.81 for CRP and 0.84 for HLA-B27. The latter two delivered respectively higher DxOR (6.2, 11.1, 24.1) as expected, considering that they were used in patient diagnosis. The model that included the 14-3-3η AAb score with CRP and HLA-B27 added had better discrimination of patients with axSpA versus MBP with an AUC of 0.93 and DxOR of 39.6 that further improved to an AUC of 0.94 and DxOR of 95.3 when age and sex variables were added (Figure 1). As shown in Table 2, the AIC of the predictive models supported the full model as the best fit.

Conclusion: This study demonstrates that the 14-3-3η AAb score when added to currently used CRP and HLA-B27 markers, improves the differentiation of people with MBP from established r-axSpA. While the pretest probability of CRP and HLA-B27 performance is higher in this cross-sectional study than would be expected in an early referral cohort,

including 14-3-3η AAb score may reduce diagnostic delay and potentially enable more confident and prompt initiation of therapy to improve outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The ESPALDA registry, developed by PANLAR, collects data from Latin America to better understand the clinical and epidemiological characteristics of patients with axial spondyloarthritis (axSpA). This analysis focuses on early axSpA, defined by ASAS criteria as a duration from the onset of back pain to diagnosis of less than two years, across the entire cohort and by region.

Methods: Patients aged ≥18 years meeting the ASAS 2009 criteria for axSpA were included. Data were collected from medical centers in nine LATAM countries. Baseline data included demographics, disease duration, clinical manifestations, comorbidities, disease activity (ASDAS, BASDAI), functionality (BASFI), laboratory tests (ESR, CRP, HLA-B27), and imaging (X-ray, MRI). Regions were categorized as South (Argentina, Chile, Uruguay, Paraguay), Andean (Colombia, Peru, Venezuela, Ecuador), and North (Mexico). Descriptive statistics and comparative analyses were performed using Chi-square tests and parametric or non-parametric methods as appropriate. Multivariable analysis was performed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In 419 patients, the prevalence of early axSpA was 31.49% (95% CI: 27.31% - 36.01%). Regional differences in prevalence were observed: South (38.19%), Andean (28.42%), and North (27.42%) (p=0.07). Differential characteristics of the entire cohort are detailed in Table 1. Multivariable analysis identified key factors positively associated with early axSpA: ASDAS high disease activity (HDA, OR = 17.808, 95% CI: 2.446 - 129.645, p=0.004) and BASDAI ≥4 (OR = 44.378, 95% CI: 4.943 - 398.394, p=0.001). Regional analyses highlighted distinct characteristics among early axSpA patients: South: Smoking (OR = 2.46, 95% CI: 1.30-4.64, p=0.01), positive sacroiliac maneuver (OR = 3.14, 95% CI: 1.58-6.26, p< 0.001), elevated CRP (OR = 2.25, 95% CI: 1.24-4.11, p=0.01), BASDAI (p< 0.001), and prolonged morning stiffness (p=0.01) were significantly associated. Andean: Enthesitis (OR = 4.73, 95% CI: 1.83-12.23, p< 0.001) was a key feature, while elevated CRP showed marginal significance (OR = 2.79, 95% CI: 1.02-7.62, p=0.08). North: Enthesitis (OR = 4.30, 95% CI: 1.59-11.64, p=0.01), elevated CRP (OR = 5.56, 95% CI: 2.34-13.26, p< 0.001), BASDAI (p=0.04), and prolonged morning stiffness (p=0.03) were highly distinctive, all variables in fig 1.

Conclusion: The ESPALDA registry highlights significant regional variations in early axSpA characteristics across LATAM.

Session Title: (2305–2337) Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Mediation modeling is used to determine mechanisms underlying the relationship between independent and dependent variables via other explanatory variables ("mediators"). Fatigue, pain, and morning stiffness are common ankylosing spondylitis (AS) symptoms that can contribute to decreased functional capacity and health-related quality of life (HRQoL) in AS patients. This study aimed to assess how tofacitinib affects HRQoL improvement directly and indirectly (via symptom improvement) in patients with AS.

Methods: Mediation modeling was used to analyze pooled data from phase 2 (NCT01786668) and phase 3 (NCT03502616) studies of tofacitinib. The initial mediation model is depicted by **Figures 1A** and **1B**; superimposition of both figures represents the full mediation model. The independent variable was treatment (tofacitinib 5 mg BID vs placebo) and the dependent variables were the SF-36 domains. Mediators included in the model were CRP, stiffness (represented

by the mean of BASDAI questions 5 and 6), mobility (measured by BASMI), fatigue (measured by FACIT-Fatigue total score), and pain (latent factor measured by two numerical rating scales [0-10] for nocturnal pain and total back pain). All available data from week 12 (phase 2 trial) and week 16 (phase 3 trial) were used. Based on the initial model results, the final model was respecified to include only paths that were statistically significant ($p < 0.05$) and/or meaningful (standardized path coefficient >0.1). The relative contribution of each path from treatment to SF-36 domain was reported in terms of percentages of the total effect of tofacitinib on an SF-36 domain.

Results: Data from 360 patients were included. The initial model demonstrated that tofacitinib treatment affects SF-36 mainly indirectly. In the final model (**Figure 2**), improvements in HRQoL were collectively mediated through five indirect pathways: (1) treatment→stiffness→pain→SF-36 domain, (2) treatment→stiffness→fatigue→SF-36 domain, (3) treatment→stiffness→pain→fatigue→SF-36 domain, (4) treatment→stiffness→mobility→SF-36 domain, and (5) treatment→CRP→mobility→SF-36 domain. For the Physical Functioning and Bodily Pain domains, paths via changes in stiffness and pain had the largest effect, mediating 35.3% ($p < .0001$) and 64.5% ($p < .0001$) of the tofacitinib treatment

Table. Contributions of final model pathways to the indirect effects of tofacitinib on SF-36 domains

Path	Mediated effect of treatment on SF-36 domain, %[a]							
	PF	RP	BP	RE	VT	SF	MH	GH
Treatment→Stiffness→Fatigue→SF-36 domain	23.6	37.6	18.3	51.5	51.5	51.5	51.5	51.5
Treatment→Stiffness→Pain→SF-36 domain	35.3	27.0	64.5					
Treatment→Stiffness→Pain→Fatigue→SF-36 domain	22.2	35.4	17.2	48.5	48.5	48.5	48.5	48.5
Treatment→Stiffness→Mobility→SF-36 domain	10.9							
Treatment→CRP→Mobility→SF-36 domain	8.0							

[a] All mediated effects are significant ($p<0.05$).

SF-36, 36-item Short Form Survey; PF, Physical Functioning; RP, Role Physical; BP, Bodily Pain; RE, Role Emotional; VT, Vitality; SF, Social Functioning; MH, Mental Health; GH, General Health

effect (**Table**). For remaining domains, paths via changes in stiffness and fatigue had the largest effect, mediating 37.6% (p=.0002) of the tofacitinib effect on the Role Physical domain and 51.5% (p< .0001) for the other domains. The effect of treatment mediated via changes in stiffness and mobility (10.9%, p< .0001) and via CRP and mobility (8.0%, p=.003) was present only for the Physical Functioning domain.

Conclusion: In patients with AS, the effect of tofacitinib treatment on HRQoL as measured by SF-36 domains was fully mediated via changes in fatigue, pain, stiffness, CRP, and mobility. Tofacitinib reduces the signs and symptoms of AS, which improves HRQoL. By closely assessing the signs and symptoms of AS, physicians can better improve patients' HRQoL and hence patient care and treatment. The results also suggest that HRQoL measurements may play an important role in assessing the signs and symptoms of AS.

Real-World Outcomes of Combined Tofacitinib and TNF Inhibitor Therapy in Refractory Inflammatory Arthritis: A Tertiary Care Experience from India

Aashish Agrawal and Balakrishnan Canchi, Hinduja Hospital, Mumbai, Maharashtra, India

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The use of combination biologic and targeted synthetic DMARDs remains controversial due to safety concerns, yet may offer benefit in refractory inflammatory arthritis. This study examines the outcomes of patients treated with a combination of tofacitinib and TNF inhibitors.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. 10	15	Male	SpA-axial	None	1	NA	TOFA	TOFA + ADA	17	Yes	No	No

Patient Characteristics and Outcomes

csDMARD: conventional synthetic DMARD; tsDMARD: targeted synthetic DMARD; TB: Tuberculosis PsA: Psoriatic arthritis; SpA: Spondyloarthritis; JIA: Juvenile Idiopathic Arthritis; RA: Rheumatoid arthritis; DM: Diabetes Mellitus type 2; MTX: Methotrexate; SFZ: Sulfasalazine; LEF: Leflunomide; ADA: Adalimumab; ETN: Etanercept; TOFA: Tofacitinib

Methods: We retrospectively analyzed patients with inflammatory arthritis treated with both tofacitinib and TNF inhibitors at our tertiary care centre. Demographic details, comorbidities, diagnosis, prior DMARD exposure, treatment duration, clinical response, adverse events, and remission status were recorded.

Results: A total of 10 patients were included: Spondyloarthritis (n=7), Rheumatoid arthritis (n=2), and Juvenile Idiopathic Arthritis (n=1). Except for one axial SpA patient, all had failed ≥2 conventional DMARDs and either tofacitinib or a TNF inhibitor previously.

The total follow-up duration was 131 patient-months. At last follow-up, 9 patients were in complete remission and 1 in partial remission. No patient discontinued therapy due to adverse effects. No serious infections, tuberculosis, or hospitalizations were reported. Only limited use of additional DMARDs was required. No patient was on steroids at last follow up.

Conclusion: In this real-world Indian cohort, combination therapy with tofacitinib and TNF inhibitors was effective in selected patients with refractory inflammatory arthritis, with a favorable safety profile. Larger, prospective studies are warranted to confirm these findings and guide clinical practice.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Data on disease progression and joint involvement patterns in early oligoarticular (oligo) PsA are sparse. In the FOREMOST study (NCT03747939), apremilast (APR) decreased the number of involved joints vs placebo (PBO) at Week (Wk) 16.[1] We assess patterns of involved joints at baseline and effect of APR on joint groups through Wk 48.

Methods: FOREMOST enrolled 308 patients (pts) with early oligo PsA (>1–≤4 swollen, >1–≤4 tender joints; 66–68 joints assessed). Pts were randomized 2:1 to APR (n=203) or PBO (n=105) for 24 wks (early escape at Wk 16), after which all pts received APR through Wk 48. Overall, 291 pts received ≥1 dose of APR (as randomized, n=203; switched from PBO, n=88). Concomitant NSAIDs and/or synthetic DMARDs were permitted at a stable dose for ≥2 wks or ≥3 months before baseline, respectively, and maintained through Wk 24. For each joint group (**Table 1**), percentage of pts (pt incidence) with ≥1 of the following was calculated at baseline, Wks 16 and 48: swollen and tender, swollen and/or tender, swollen only, and tender only. Baseline and Wk 16 data were analyzed for all randomized pts with the last observation carried forward for missing data; Wk 48 data were analyzed as observed for pts who received ≥1 dose of APR.

Results: Pts had low baseline joint involvement: mean swollen and tender joint count, 2.6 and 3.2, respectively;[1] baseline pt incidence of "swollen and tender" and "swollen and/or tender" joints was similar and higher than "swollen only" and "tender only" (**Fig 1A**). Based on "swollen and tender" joints, the most commonly involved joint groups at baseline included large and small joints: finger PIP (39.0% pts with ≥1 involved joint) and MCP (33.1%), followed by knee (19.8%), and ankle and tarsus/midfoot (18.8%) (**Fig 1A**). Baseline patterns of swollen and tender joints were similar for APR and PBO (**Fig 1B**).

Greater improvements in swollen and tender finger PIP, MCP, knee and ankle/tarsus/midfoot joints were observed from baseline to Wk 16 for APR vs PBO: finger PIP, –23.6% vs –9.5% pt incidence; MCP, –21.7% vs –13.3%; knee –16.3% vs +2.9%; and ankle/tarsus/midfoot, –12.3% vs –8.6% (**Fig. 1B, C**). Across joint groups, risk of ≥1 swollen and tender joint at Wk 16 was lower for APR vs PBO (**Fig. 1D**), with significant differences observed for the most commonly involved joints: odds ratio (APR vs PBO) (95% CI) for finger PIP, 0.55 (0.31, 0.98); MCP, 0.51 (0.27, 0.97); knee, 0.33 (0.16, 0.71); ankle/tarsus/midfoot, 0.41 (0.17, 0.94) (**Fig. 1D**). Improvements in joint involvement observed with APR at Wk 16 were maintained in pts continuing or switching to APR through Wk 48.

Conclusion: Our data indicate a mix of large and small joints involved in early oligo PsA, with hand and finger most common. We observed similar joint patterns as reported at PsA onset in real-world cohorts,[2,3] underscoring the value of FOREMOST in understanding early oligo PsA. Compared with PBO, APR significantly reduced joint involvement across large and small joints. Our findings can help orient physicians treating early oligo PsA.

Background/Purpose: Personalizing care in early psoriatic arthritis (PsA) is challenging. We set out to identify predictors of one-year response on the PASDAS using AI-based methods to guide treatment decisions and improve outcomes.

Methods: We analyzed the SPEED trial, a multicenter, open-label study of patients with early PsA and poor prognostic factors. Participants were randomized to standard step-up csDMARD therapy, combination csDMARD therapy, or early TNF inhibitor induction. Recursive partitioning (RPART) modeling identified predictors of PASDAS response at 48 weeks based on baseline variables, including BMI, treatment arm, baseline PASDAS, disease phenotype, disease duration, sex, age, education level, smoking status, and alcohol use. This approach mirrors clinical reasoning by breaking complex data into clear, logical steps, generating a decision tree based on real-world patient characteristics. The resulting tree begins with the most influential predictor and branches by relevant cutoffs. An importance plot showed each variable's contribution to the outcome, and decision rules derived from the tree offer actionable insights to guide personalized treatment.

Results: Among 192 patients (median age 49 [IQR: 34–58]; median BMI 28.96 kg/m^2 [IQR: 26.06–33.63]), baseline PASDAS was 5.60 (IQR: 4.94–6.34), improving to 3.84 (IQR: 2.38–4.99) at week 48, with 37.1% achieving "good" PASDAS (< 3.2). Most (82.8%) had polyarticular involvement; 53.5% were non-smokers, and 64.7% reported alcohol use.

BMI was deemed the most influential baseline predictor of lower PASDAS at 48 weeks (fig. 1); treatment ranked sixth.

Table 1. Recursive partitioning-derived prediction rules for PASDAS at week 48

Predicted PASDAS	Baseline PASDAS	BMI (kg/m²)	Age (years)	Phenotype	Disease Duration	Treatment
2.6	≥ 5.4	< 27	–	–	–	Early TNFi
3.2	–	27–29	< 74	Polyarticular	< 12 months	–
3.2	–	≥ 27	< 74	Oligoarticular	–	–
3.4	< 5.4	25–27	–	–	–	–
4.0	≥ 5.4	< 27	–	–	–	Standard/ csDMARD combination
4.3	–	≥ 29	< 74	Polyarticular	< 12 months	–
4.6	–	≥ 27	< 51	Polyarticular	≥ 12 months	–
6.0	–	≥ 27	51–74	Polyarticular	≥ 12 months	–

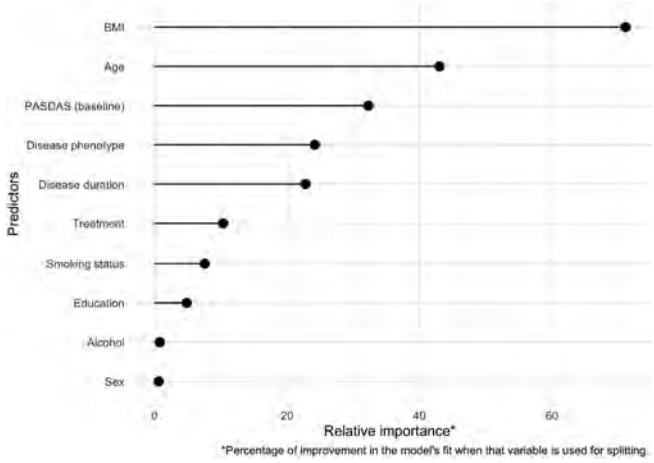

Figure 1. Variable Importance Plot from Recursive Partitioning Model Identifying Key Predictors of ASDAS at One Year

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

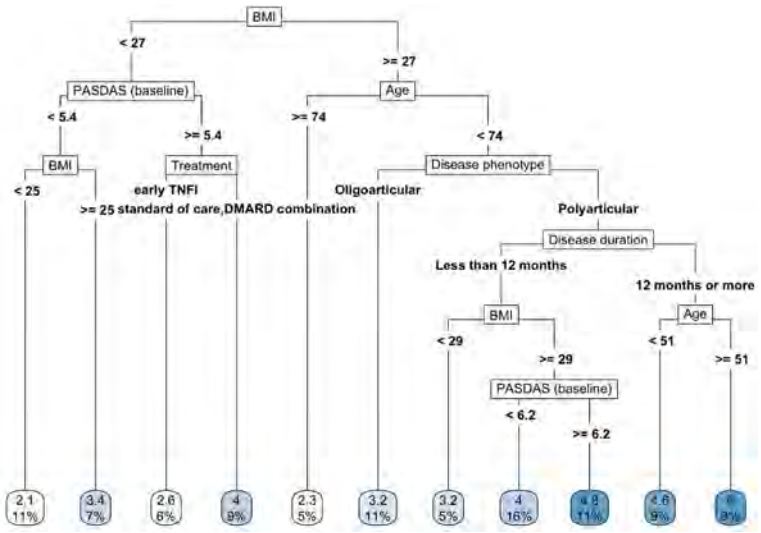

Figure 2. Decision Tree Plot Depicting Prediction Rules for One-Year PASDAS Based on BMI and Other Baseline Characteristics. Each node represents a decision point based on key patient characteristics (e.g., BMI, baseline PASDAS). The final leaves show the predicted PASDAS score at 48 weeks, with the numbers representing the mean PASDAS value and the percentage indicating the proportion of patients in that group. To interpret the tree, follow the path from the root to the leaves, where each branch splits based on the patient's characteristics, leading to a predicted treatment outcome.

The RPART-derived prediction rules reveal important trends in treatment response (tbl. 1, fig. 2): (1) patients with BMI < 25 kg/m^2 and lower baseline disease activity (PASDAS < 5.4) experienced the most favorable outcomes (predicted PASDAS = 2.1) at week 48—regardless of treatment type; (2) among patients with higher baseline disease activity (PASDAS ≥ 5.4) and BMI < 27 kg/m^2, early TNF inhibitor therapy was associated with better outcomes (PASDAS = 2.6) compared to standard or combination csDMARD therapy (PASDAS = 4.0), highlighting the potential benefit of early biologic intervention; (3) poorer outcomes were observed in patients with higher BMI (≥ 27 kg/m^2), longer disease duration (≥ 12 months), and polyarticular disease, particularly among those aged 51–74, with predicted PASDAS scores reaching as high as 6.0. Findings highlight the cumulative negative effect of obesity, chronicity, and disease severity.

Conclusion: BMI was the most influential predictor of achieving a lower PASDAS at one year, even more so than treatment exposure. As a modifiable factor, maintaining a BMI below 27 kg/m^2—ideally under 25 kg/m^2— can significantly improve patient outcomes. High baseline disease activity, obesity, and chronicity predicted poorer responses, and in these groups, treatment with early TNF inhibitors was superior to csDMARDs reinforcing the need for aggressive therapy in such patients. The predictive rules derived from this analysis offer clinicians valuable insights to support personalized care and encourage patients to prioritize weight management as a key component of their PsA treatment strategy.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A. The PsA Impact of Disease-12 (PsAID-12) questionnaire is a disease-specific patient (pt)-reported outcome measure that assesses impact of PsA on 12 physical, social, and psychological domains.[1,2] We report long-term efficacy of BKZ treatment using the PsAID-12 questionnaire to 3 years (yrs) in pts with active PsA.

Methods: BE OPTIMAL (NCT03895203; biologic DMARD [bDMARD]-naïve) and BE COMPLETE (NCT03896581; TNF inhibitor inadequate response/intolerance [TNFi-IR]) assessed subcutaneous (sc) BKZ 160 mg every 4 weeks (wks; Q4W) in pts with PsA; both were placebo (PBO)-controlled to Wk 16. At Wk 16, PBO pts switched to BKZ (PBO/BKZ). BE OPTIMAL included a reference arm (sc adalimumab 40 mg Q2W; data not shown). BE OPTIMAL Wk 52 and BE COMPLETE Wk 16 completers could enter BE VITAL (open-label extension; NCT04009499).

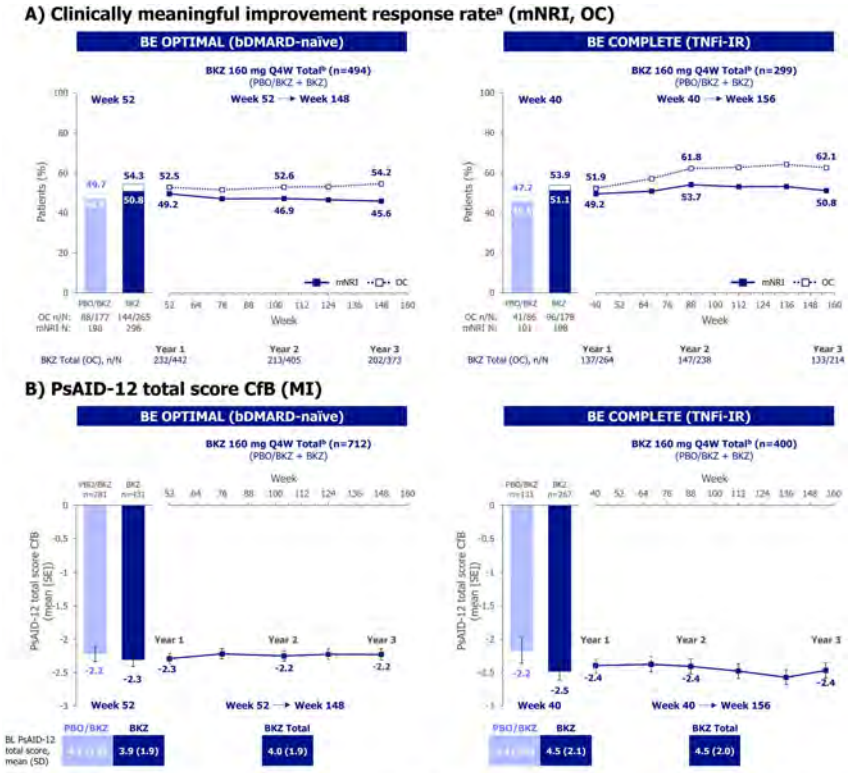
PsAID-12 total and single-item domain scores range from 0–10; higher scores indicate worse status.[2] Change from baseline (BL; CfB), clinically meaningful improvement response rates (≥3-point decrease from BL when respective BL PsAID-12 score ≥3) and symptom or impact severity based on PsAID-12 total score were assessed.[1]

PsAID-12 questionnaire was administered to Wk 148/156 (BE OPTIMAL/BE COMPLETE). Data reported for the BKZ Total group (PBO/BKZ and BKZ-randomized pts) as observed case, modified non-responder imputation (mNRI; binary) or multiple imputation (MI; continuous). mNRI considered all visits following discontinuation due to adverse events or lack of efficacy as non-response; all other missing data imputed with MI and the response derived from the imputed values.

Results: Overall, 555/712 (77.9%) bDMARD-naïve and 299/400 (74.8%) TNFi-IR BKZ Total group pts completed Wk 148/156.

Achievement of clinically meaningful improvement responses in PsAID-12 total score observed at Wk 52 (49.2%) and Wk 40 (49.2%) in bDMARD-naïve and TNFi-IR pts were sustained to Wk 148 (45.6%) and Wk 156 (50.8%; **Figure 1A**). Clinically meaningful improvement responses were achieved by 47.5–70.7% of pts across all single-item domains at Wk 148/156.

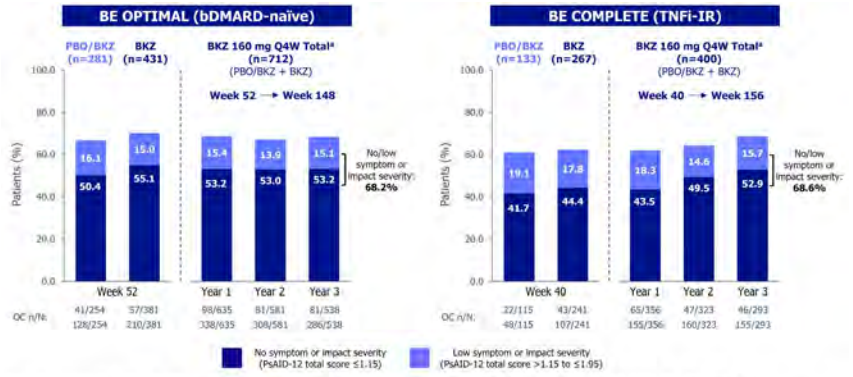
23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Randomized set. Data reported from Year 1 (Week 52 in BE OPTIMAL and Week 40 in BE COMPLETE) to Year 2 (Week 104 in BE OPTIMAL and Week 88 in BE COMPLETE) and Year 3 (Week 148 in BE OPTIMAL and Week 156 in BE COMPLETE). [a] Clinically meaningful improvement response: ≥3-point decrease from baseline when respective PsAID-12 score is ≥3 at baseline; [b] BKZ Total group includes BKZ-randomized patients and PBO patients that switched to BKZ at Week 16. PsAID 12 scores range from 0–10; higher scores indicate worse status.[1]

bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; BL: baseline; CfB: change from baseline; MI: multiple imputation; mNRI: modified non-responder imputation; OC: observed case; PBO: placebo; PsAID-12: Psoriatic Arthritis Impact of Disease-12; Q4W: every 4 weeks; SD: standard deviation; SE: standard error; TNFi-IR: prior inadequate response or intolerance to tumor necrosis factor inhibitors.

Figure 1. (A) Clinically meaningful improvement response rate and (B) PsAID-12 total score CfB to Year 3 (MI, mNRI, OC)

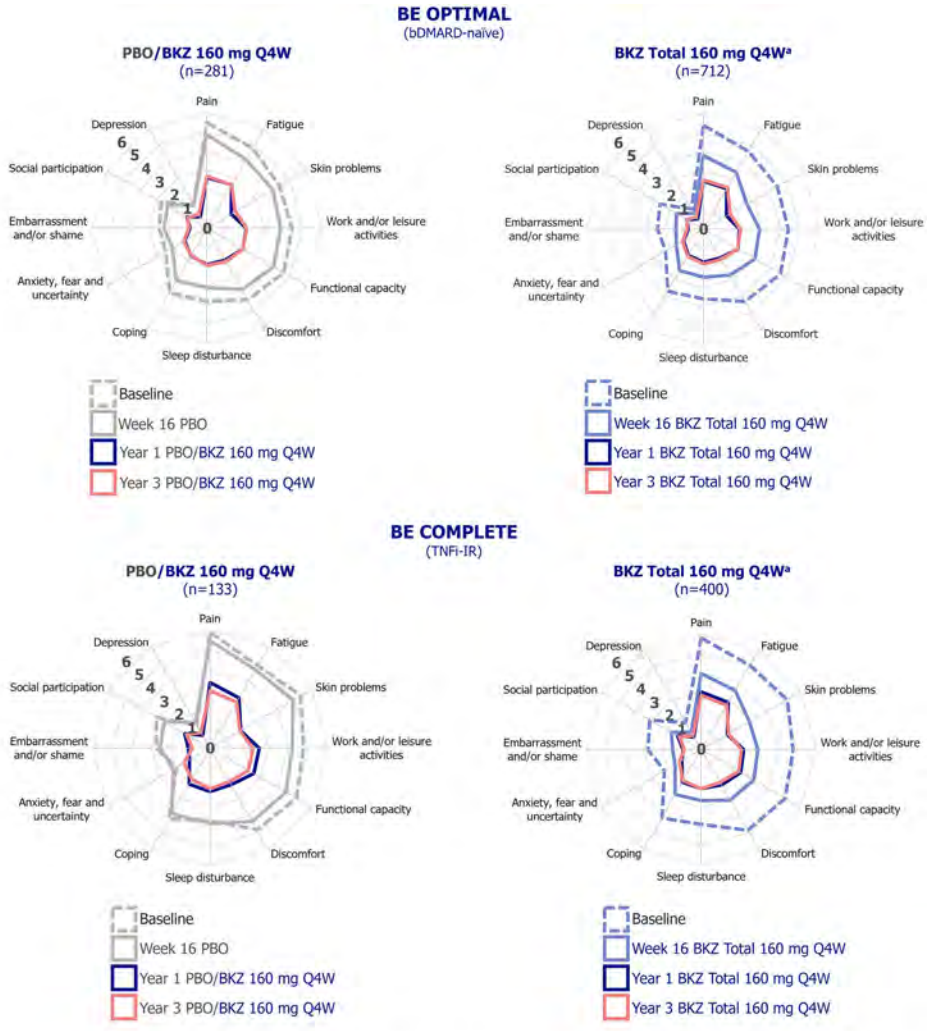


Randomized set. Data reported from Year 1 (Week 52 in BE OPTIMAL and Week 40 in BE COMPLETE) to Year 2 (Week 104 in BE OPTIMAL and Week 88 in BE COMPLETE) and Year 3 (Week 148 in BE OPTIMAL and Week 156 in BE COMPLETE). No or low symptom or impact severity defined by a PsAID-12 total score of score ≤1.95.

bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; OC: observed case; PBO: placebo; PsAID-12: Psoriatic Arthritis Impact of Disease-12; Q4W: every 4 weeks; TNFi-IR: prior inadequate response or intolerance to tumor necrosis factor inhibitors.

Figure 2. No or low symptom or impact severity by visit for PsAID-12 total score to Year 3 (OC)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Randomized set. Data reported from Week 16 to Year 1 (Week 52 in BE OPTIMAL and Week 40 in BE COMPLETE) and Year 3 (Week 148 in BE OPTIMAL and Week 156 in BE COMPLETE). [a] BKZ Total group includes BKZ-randomized patients and PBO patients that switched to BKZ at Week 16. PsAID-12 scores range from 0–10; higher scores indicate worse status.[1]

bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; MI: multiple imputation; PBO: placebo; PsAID-12: Psoriatic Arthritis Impact of Disease-12; Q4W: every 4 weeks; TNFi-IR: prior inadequate response or intolerance to tumor necrosis factor inhibitors.

Figure 3. PsAID-12 single-item domain mean scores at baseline, Week 16, Year 1, and Year 3 (MI)

Similarly, proportions of pts achieving no/low symptom or impact severity for PsAID-12 total score (score ≤1.95) at Wk 52/40 were sustained to Wk 148/156 in 68.2% bDMARD-naïve and 68.6% TNFi-IR pts (**Figure 2**).

Improvements from BL in PsAID-12 total score were sustained from 1 yr to 3 yrs of BKZ treatment: mean CfB (standard error) –2.3 (0.1) at Wk 52 and –2.2 (0.1) at Wk 148 in bDMARD-naïve pts; –2.4 (0.1) at Wk 40 and –2.4 (0.1) at Wk 156 in TNFi-IR pts (**Figure 1B**). Improvements from BL across all PsAID-12 single item domain mean scores observed at Wk 52/40 were sustained or further improved to Wk 148/156 in the BKZ Total group (**Figure 3**).

Conclusion: BKZ treatment resulted in clinically meaningful improvements in PsAID-12 scores across physical, social and psychological domains in pts with active PsA, indicating reduced disease impact. Improvements were sustained to 3 yrs and consistent responses were seen in pts who were bDMARD-naive or had TNFi-IR.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

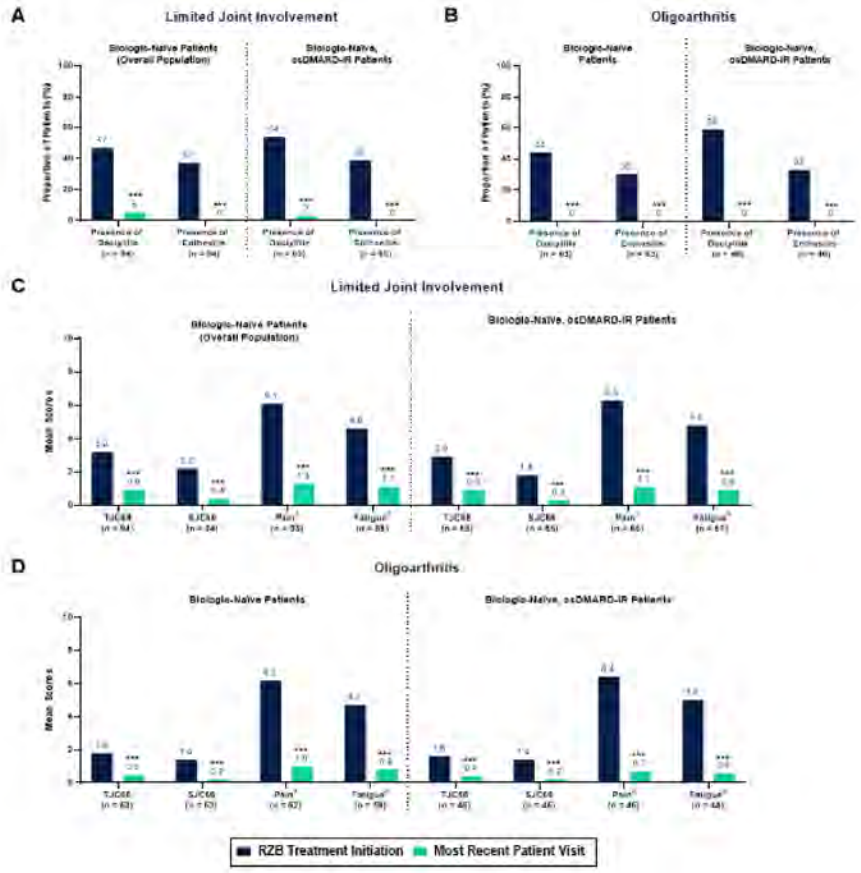
Background/Purpose: This study evaluated real-world effectiveness and patient- and physician-satisfaction with risankizumab (RZB) for biologic-naïve PsA patients with limited joint involvement or oligoarthritis.

Methods: Data were drawn from the Adelphi Spondyloarthritis VI Disease Specific Programme™ collected from June 2023 to June 2024 focusing on biologic-naïve patients with PsA who received RZB 150 mg and had limited joint involvement (≥ 1 to ≤ 8 TJC or SJC ≥ 1 to ≤ 8 ; 1–16 total active joints) or oligoarthritis (≥ 1 to ≤ 4 TJC or ≥ 1 to ≤ 4 SJC; 1–8 total active joints) at treatment initiation. Patients were located in the US and Europe (France, Germany, Italy, Spain, and the UK). Data were collected from cross-sectional questionnaires completed by physicians (treatment effectiveness and satisfaction) and their consulting patients (satisfaction) during recent visits. Outcomes were evaluated in the overall population of patients naïve to biologics with limited joint involvement and 3 subgroups: (1) patients naïve to biologics with limited joint involvement and an inadequate response to ≥ 1 conventional synthetic DMARD (csDMARD-IR), (2) patients with oligoarthritis naïve to biologics, and (3) patients with oligoarthritis naïve to biologics and csDMARD-IR.

Results: In the overall population, there were 94 biologic-naïve patients were included (23% [n = 22] from the US, 77% [n = 72] from Europe); mean age 43.3 years old, 40% female, 16.1% BSA affected by PsO at treatment initiation. Mean RZB treatment duration was 9.3 months in the overall population; mean TJC and SJC at treatment initiation was 3.2 and 2.2, respectively. Baseline characteristics were similar across the subgroups. Improvements in the presence of dactylitis and enthesitis and mean changes in TJC68, SJC66, pain, and fatigue were reported from treatment initiation to most recent visit for all groups ($P \leq .001$ for all) (**Figure 1**). High rates of complete resolution of dactylitis (89%) and enthesitis (100%), TJC68 ≤ 1 (69%), SJC66 ≤ 1 (79%), and clinically meaningful improvements in pain (94%) and fatigue (76%) were observed with RZB

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Proportion of Patients With Presence of Dactylitis or Enthesitis and Mean Scores in TJC68, SJC66, Pain, and Fatigue in PsA Patients Treated with RZB



csDMARD, conventional synthetic DMARD; IR, inadequate response; RZB, risankizumab.
Proportion of patients with presence of dactylitis or enthesitis in patients with limited joint involvement (A) or oligoarthritis (B). Mean scores in TJC68, SJC66, pain, and fatigue at the time of treatment initiation with RZB and at the most recent visit for patients with limited joint involvement (C) and those with oligoarthritis (D).
***P < .001. Probability was evaluated from the initiation of RZB treatment to most recent visit via McNemar test (proportion of patients) or t test (mean scores).
[a]Assessed using a numeric rating scale (range 0 to 10), where higher scores indicate worse pain or fatigue outcomes.

in the overall population (**Figure 2A**). Effectiveness results were consistent in the csDMARD-IR subgroup (n = 65) with limited joint involvement (**Figures 1-2**). Patients with oligoarthritis who presented with dactylitis or enthesitis at treatment initiation, including 100% of both the biologic-naïve (n = 63) and csDMARDs-IR (n = 46) subgroups, demonstrated complete resolution of dactylitis and enthesitis. Clinically meaningful improvements were also seen in TJC68 ≤ 1 (69% and 73%), SJC66 ≤ 1 (82% for both), pain (95% and 98%), and fatigue (82% and 89%) in the biologic-naïve and csDMARD-IR oligoarthritis subgroups, respectively (**Figure 2B**). In the overall population, high patient (100%, n = 18) and physician (98%, n = 94) satisfaction rates were reported for the ability of RZB to control the disease.

Conclusion: In biologic-naïve patients with PsA and limited joint involvement or oligoarthritis, RZB treatment demonstrated effectiveness and high levels of satisfaction among patients and physicians in real-world clinical practice.

Abstract Number: 2343

Risk of Arrhythmias Following IL-17 Inhibitor Use; A Pharmacosurvellience Study of FDA Adverse Event Reporting System (FAERS)

Asim Khanfar[1], Omar Hamdan[2], Anil Regmi[3], Mayra Goreja[4] and Anthony Ocon[5], [1]Rochester General Hospital, Rochester, NY, [2]University of Jordan, Az-Zarqa, Jordan, [3]Parkview Health, Fort Wayne, IN, [4]Rochester General Hospital, Rochester, [5]Rochester Regional Health, Fairport, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Interleukin-17 (IL-17) inhibitors, such as secukinumab and ixekizumab, are used for their anti-inflammatory effects in conditions like psoriasis and ankylosing spondylitis. IL-17 signaling has been implicated in cardiovascular disease pathogenesis, including atrial fibrillation and other arrhythmias. This study evaluates the incidence and characteristics of arrhythmias associated with IL-17 inhibitors using the FDA Adverse Event Reporting System (FAERS).

Methods: The FAERS database was searched for cardiac arrhythmias (Tachycardia, bradycardia, atrial fibrillation, QRS complex abnormalities, QT interval abnormalities, bundle branch block (BBB), atrioventricular blocks (AV blocks), and supraventricular tachycardia (SVT)) associated with the use of IL-17 inhibitors (secukinumab, ixekizumab, bimekizumab). Disproportionality analysis was done and data were reported as frequencies and as reporting odds ratios (ROR) with a 95% confidence interval (95% CI). RORs were only reported for adverse reactions with frequencies of 3 or more.

Results: We analyzed 30,179,725 adverse event reports from the FAERS database. A total of 181,052 reports were associated with the use of the three anti-IL-17 drugs; 60.9% of them were females, and 33.2% were in the age group between 18-64 years. Cardiac arrhythmias were reported in 0.54% of cases. Most of the cases were associated with secukinumab use (88.9%), followed by ixekizumab (9.5%). Among bimekizumab users, atrial fibrillation was the most common arrhythmia and accounted for 57.1% of all arrhythmias included in our analysis (Figure 1). However, when tested using ROR, the reporting odds of atrial fibrillation weren't higher in bimekizumab users compared to other drugs users. On the other hand, the most reported arrhythmias among secukinumab were tachycardia (45.6%) and bradycardia (41.9%) (Figure 2). When compared to other anti IL-17 medications, secukinumab was significantly associated with

Figure 1. Frequency of arrhythmias

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

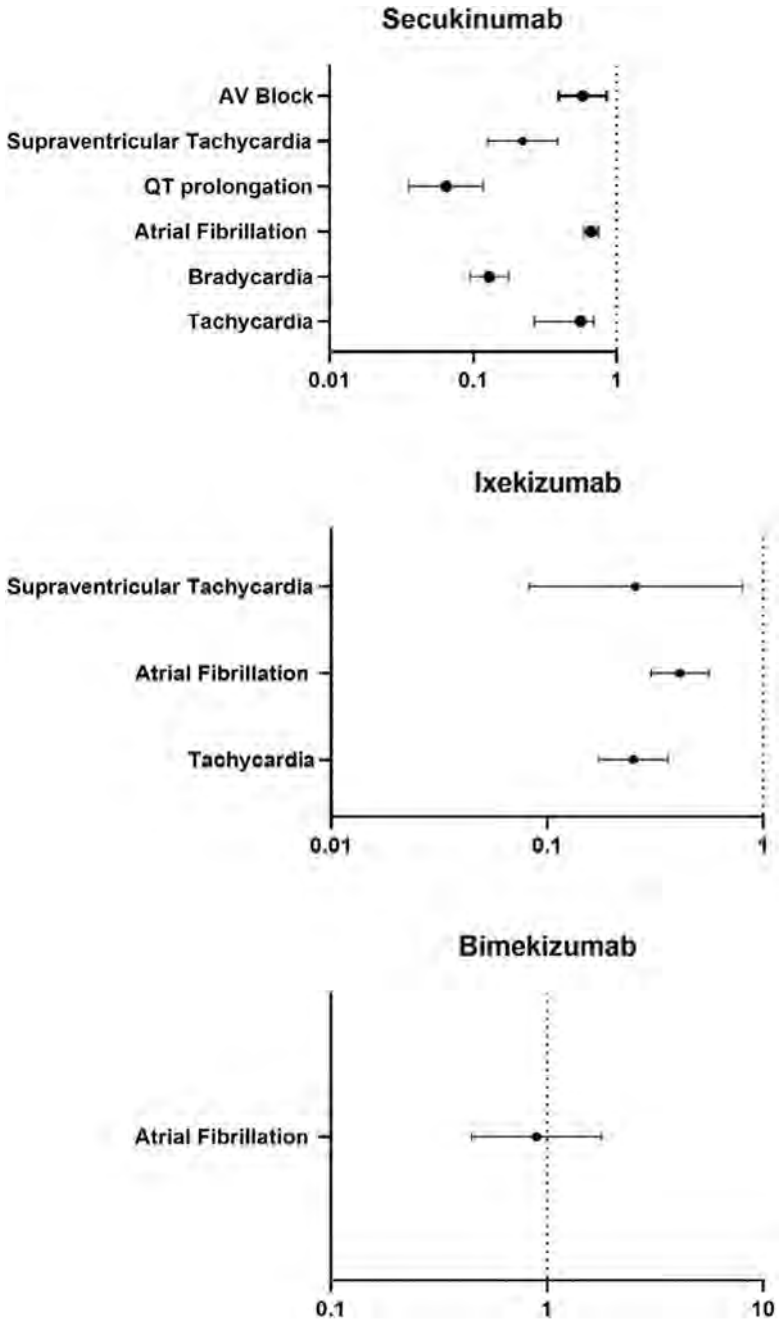

Figure 2. Reported Odds Ratio (ROR) of Anti-IL 17 drugs

higher odds of multiple arrhythmias, including tachycardia (ROR=12.27; 95% CI: 8.623-17.47), bradycardia (ROR=12.27; 95% CI: 4.469 – 34.91), atrial fibrillation (ROR=7.101; 95% CI: 5.317 – 9.484), Supraventricular Tachycardia (ROR=3.747; 95% CI: 1.208 – 11.62) and AV block (ROR=8.118; 95% CI: 2.833 – 23.26) (Table 1).

Conclusion: This study suggests that IL-17 inhibitors, particularly secukinumab, may be associated with increased reporting of cardiac arrhythmias, including tachycardia, bradycardia, atrial fibrillation, supraventricular tachycardia, and atrioventricular block. These findings support the need for further investigation into the cardiovascular safety of IL-17 inhibitors to guide clinical decision-making.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal antibody that simultaneously blocks IL-17A, IL-17F, and their heterodimer, key cytokines involved in the pathogenesis of spondyloarthritis (SpA) and psoriatic arthritis (PsA). Unlike other therapies targeting IL-17A alone, BKZ has demonstrated rapid and sustained efficacy in both joint and skin manifestations

in clinical trials. Benefits have been observed in both biologic-naïve patients and those previously exposed to treatment, with a favorable safety profile. This study aims to broaden real-world experience with BKZ by evaluating its persistence, effectiveness, and patterns of use in routine clinical practice.

Methods: This is an observational, ambispective and multicenter study conducted in Spain. The study included patients >18 years diagnosed with SpA (according to ASAS classification criteria and/or the modified New York criteria) or PsA (according to CASPAR classification criteria) who initiated treatment with BKZ between January 1, 2024, and December 31, 2024. Demographic and clinical characteristics, as well as treatment patterns and response to BKZ were described

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. using data from the electronic database. Changes in musculoskeletal (MSK) disease activity indices at 6 months and psoriasis (PsO) from baseline (start of BKZ treatment) were assessed.

Results: A total of 124 patients receiving BKZ were identified (41.1% SpA, 57.2% PsA), mainly women in both groups, with a median age of 53.6 ± 11 years and a long disease duration averaging 11.1 ± 9.3 years. Eleven patients presented active or previous neoplasms (8.8%). The most frequent MSK domain was mixed (peripheral and axial) in 44.3% of patients, and enthesitis was present in 52.9%, slightly more common in SpA. Patients had previously received a mean of 2.6 ± 2 b/tsDMARDs, mainly TNF inhibitors (85.4%) and IL-17 inhibitors (49.2%), with similar patterns in SpA and PsA.

Most patients initiated BKZ as third-line therapy or beyond (67.7%), with concomitant DMARD use in nearly half of cases. The main reason for prescription was MSK involvement, though one-third also had active PsO (Table 2). At the 6-month follow-up (n=88/124 patients; 33 SpA, 55 PsA), an overall retention rate of 86.3% (n=76/88) for BKZ was observed, being greater in SpA (90.9%; n=30/33) compared to PsA (83.6%; n=46/55). BKZ was discontinued in 10 patients (3 SpA/ 8 PsA): 7 due to loss of effectiveness and 3 due to adverse events.

Among the patients with effectiveness data available for MSK disease at 6 months (Table 2), 42% (45% PsA, 30,3% SpA) achieved low disease activity and 9% (3% SpA, 12,7% PsA) achieved remission. A significant improvement in MSK outcomes was observed across all axial and peripheral measures (axial and peripheral VAS, BASDAI, ASDAS-CRP, DAPSA, 68/66 joint counts all $p< 0.01$). In patients with PsO and data available, a significant ($p< 0.01$) reduction in PASI (n=20) and BSA (n=28) was observed at 6 months.

Conclusion: BKZ was mainly used in patients with long-standing, refractory SpA/PsA, with prior IL-17 inhibitor use in half of the cases. Despite this, the 6-month retention rate was high (86.3%), with favorable efficacy across all domains.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Previous research has shown that women with psoriatic arthritis (PsA) often have lower rates of clinical response to medication but less severe radiographic joint damage. Despite this, few randomized controlled trials (RCTs) in PsA report sex-disaggregated results. Here, we assessed sex-disaggregated radiographic progression (RP) in DISCOVER-2 (NCT03158285), a Phase 3 study of biologic-naïve PsA pts treated with GUS, considering sex differences in structural damage and whether this is associated with early improvements in joint disease activity (DA).

Methods: Biologic-naïve pts with active PsA were randomized (1:1:1) to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo with crossover to GUS 100 mg Q4W at W24. Early (W8) response in joint DA, (based on clinical DA Index for PsA [cDAPSA LDA; ≤13]), was assessed among pts with cDAPSA >13 at BL, without adjustment for sex-specific differences at BL. Multivariate repeated measures mixed models assessed associations between sex and changes in total PsA-modified van der Heijde-Sharp [vdH-S] score through W100 (**Fig 1**), association between early response in joint DA and RP when stratified by sex (**Fig 2**); time-averaged and visit-specific LSM changes.

Results: Of 739 PsA pts enrolled, 47.5% were female. At BL, female vs male pts were more likely to be older (29.3% vs 21.9% ≥55 years of age; p=0.0204) and have dactylitis (60.6% vs 50.3%; p=0.0049), and on average had higher BMI (29.5 vs 28.4 kg/m^2; p=0.0144), lower CRP levels (1.6 vs 2.3; p< 0.0001), less extensive/severe psoriasis (Psoriasis Area and Severity Index [PASI] score: 7.5 vs 12.1; p< 0.0001), more functional disability (Health Assessment Questionnaire-Disability Index [HAQ-DI] score: 1.4 vs 1.2; p< 0.0001), and worse fatigue (Functional Assessment of Chronic Illness Therapy [FACIT]-Fatigue score: 28.5 vs 30.9; p=0.0007). BL cDAPSA (46.1 vs 46.4) and PsA-modified vdH-S (26.2 vs 25.5) scores were similar (p >0.05) between sexes.

In unadjusted analyses of GUS-treated pts, male sex was associated with greater progression of structural damage through W100 (ΔLSM=1.02; p=0.0260). After adjusting for known risk factors of RP, BL characteristics with sex-specific differences in the pooled cohort, and disease duration and non-biologic DMARD use at BL, the difference between sexes in RP decreased but remained significant (ΔLSM=0.90; p=0.0406); LSM changes from BL in PsA-modified vdH-S scores in males vs females were 1.36 vs 0.69 (p=0.0502) at W52 and 2.22 vs 1.10 (p=0.0475) at W100 (**Fig 1**). Early (W8) cDAPSA LDA was achieved by 18.9% of men vs 15.3% of women. In men, this was associated with significantly less RP through W100 (time-averaged change in PsA-modifed vdH-S scores from BL to W100 in cDAPSA LDA responders vs nonresponders: 0.39 vs 2.24; p=0.0288); in females only, numerical differences were observed (-0.15 vs 0.91; p=0.1732; **Fig 2**).

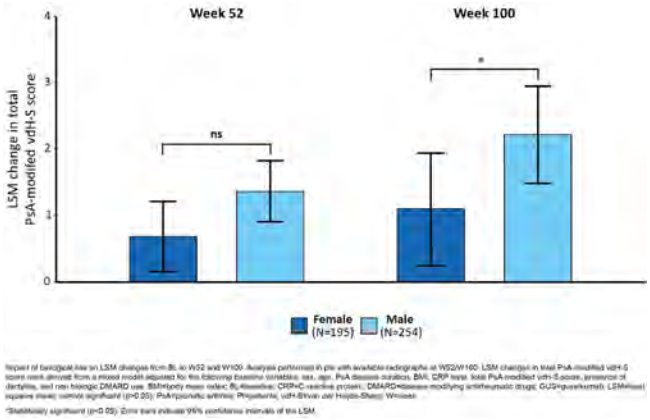

Figure 1. Change in Total PsA-modified vdH-S Score from BL Through W100 in Male and Female PsA Pts Treated with GUS

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Multivariate Association of cDAPSA LDA Achievement at W8 with Time-Averaged Change in Total PsA-modified vdH-S Score from BL Through W100 in Male and Female PsA Pts Treated with GUS

Conclusion: These results confirm the independent association of male sex with more rapid RP. The previously reported relationship between early improvement in joint DA and diminished RP (Mease PJ, et al. Clin Rheumatol 2024) was found to be stronger in males than females, which may be due to the lower rate of RP in females.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Ankylosing spondylitis (AS) significantly impacts quality of life across multiple domains. To date, no studies have evaluated the impact of initial biological therapy on sexual function, despite its critical role in overall quality of life.

We aimed to evaluate the impact of initial biologic/targeted synthetic disease modifying anti-rheumatic drug (b/tsDMARD) therapy on sexual function in men with AS.

Methods: Men with AS initiating b/tsDMARD therapy within the Czech ATTRA registry completed the International Index of Erectile Function (IIEF; higher score represents better function) at baseline (M0) and after six months (M6). Routine clinical and laboratory data was collected, with patient-reported outcomes regarding function and quality of life (Health Assessment Questionnaire (HAQ), 36-Item Short Form Health Survey (SF-36), EuroQoL 5-Dimension Questionnaire (EuroQoL) and Multidimensional Health Assessment Questionnaire (MDHAQ)). Comparisons were performed using the Wilcoxon test, with p-values adjusted for multiple comparisons using the Benjamini-Hochberg method. Variable selection for baseline predictors and factors associated with improvement in IIEF domains was performed using Elastic Net regression.

Results: 52 sexually active men completed the study (mean±SD age: 40±9 years; 92.3% HLA-B27 positive). 96.2% received anti-TNF agents, 3.8% an IL-17 inhibitor (Table 1). At M6, we observed significant reductions in inflammatory markers (ESR, CRP) and disease activity (ASDAS), as well as improvements in function and quality of life (HAQ, MDHAQ, EuroQoL, SF-36) ($p< 0.05$ for all). Due to the potential ceiling effect in IIEF scores, we stratified participants by baseline presence of erectile dysfunction (ED) (IIEF Erectile Function < 26, n=12). The patients with ED experienced a significant median (IQR) increase in erectile function from 17.5 (11.5-23.5) to 26.0 (23.3-28.3) ($p=0.033$). There were also significant improvements in the domains of sexual desire ($p=0.046$) and intercourse satisfaction ($p=0.033$) (Figure 1). In contrast, patients without ED at baseline (n=40) maintained consistently high scores.

On the level of bivariate analysis, improvements in sexual function were linked with reduced disease activity, and improvements in physical and mental health. LASSO regression identified baseline IIEF domain scores as the strongest predictors of sexual function outcomes. Weaker predictions were observed for functional status (thoracic expansion, occiput-to-wall

Figure 1. International Index of Erectile Function
Group: Erectile dysfunction present at baseline (n = 12)

SF-36: Mental Component Score (5.5–63.6)	45.9 (34.9, 52.5)	37.7 (28.8, 45.9)	48.3 (40.0, 52.9)
SF-36: Physical Component Score (16.6–57.9)	31.8 (24.1, 41.1)	36.5 (25.5, 45.0)	31.1 (23.9, 38.6)

Table 1 shows the baseline characteristics overall and divided into subgroups based on the baseline presence of erectile dysfunction (defined as IIEF Erectile Function <26). Data are shown as median (IQR) or n (%). Acronyms: ASDAS, Ankylosing Spondylitis Disease Activity Score; CRP, C-reactive protein; ED, Erectile Dysfunction; ESR, Erythrocyte sedimentation rate; HAQ, Health Assessment Questionnaire; IIEF, International Index of Erectile Function; MDHAQ – RAPID3, Multidimensional Health Assessment Questionnaire; SF-36, Short Form Health Survey Questionnaire.

Table 2. Predictors of Sexual Function Improvement

IIEF Domain (follow-up – baseline)	Coefficients
IIEF Erectile Function	IIEF Erectile Function (-3.56), IIEF Orgasmic Function (-2.15), Thoracic Expansion (0.32), EuroQoL (0.29), Chin to chest distance (-0.21), Morning Stiffness (-0.13), Disease Activity (-0.09), Cardiovascular Disease (-0.02)
IIEF Orgasmic Function	IIEF Orgasmic Function (-2.23), Occiput-to-wall Distance (-0.14), Schober Test (0.09), COX-2 Inhibitor Use (-0.07), SF-36 Mental Component Score (0.05)
IIEF Sexual Desire	IIEF Sexual Desire (-0.52), Antidepressant Use (0.27), ASDAS (-0.19), NSAIDs Use (0.17), Alcohol Consumption (-0.15), IIEF Orgasmic Function (-0.12), COX-2 Inhibitor Use (-0.09), Chin to Chest Distance (-0.02), Occiput-to-wall Distance (-0.02), SF-36 Mental Component Score (-0.02)
IIEF Intercourse Satisfaction	IIEF Intercourse Satisfaction (-1.88), IIEF Orgasmic Function (-0.49), ESR (-0.1), Thoracic Expansion (0.05), SF-36 Physical Component Score (0.04)
IIEF Overall Satisfaction	IIEF Orgasmic Function (-0.61), IIEF Overall Satisfaction (-0.39), Metabolic Disease (-0.12)

Table 2 shows the baseline predictors associated with improvements in IIEF domains. These variables were selected using the LASSO regression method – we are reporting the standardized coefficients to better report the effect of the variables. Acronyms: ASDAS, Ankylosing Spondylitis Disease Activity Score; COX-2, Cyclooxygenase-2; ESR, Erythrocyte Sedimentation Rate; EuroQoL, European Quality of Life; IIEF, International Index of Erectile Function; NSAIDs, Non-Steroidal Anti-Inflammatory Drugs; SF-36, 36-Item Short Form Health Survey.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

distance, Schober test), quality of life (EuroQoL, SF-36 mental component score), comorbidities (cardiovascular disease, metabolic disease), medication use (antidepressants, NSAIDs, COX-2 inhibitors), and disease activity measures (ASDAS, CRP, ESR) (Table 2).

Conclusion: Initial biological therapy significantly improved sexual function in men with AS, with the most striking benefits observed in those with baseline erectile dysfunction. Improvements were linked to better quality of life and reduced disease activity. These findings highlight the broader benefits of b/tsDMARD therapy beyond disease control.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

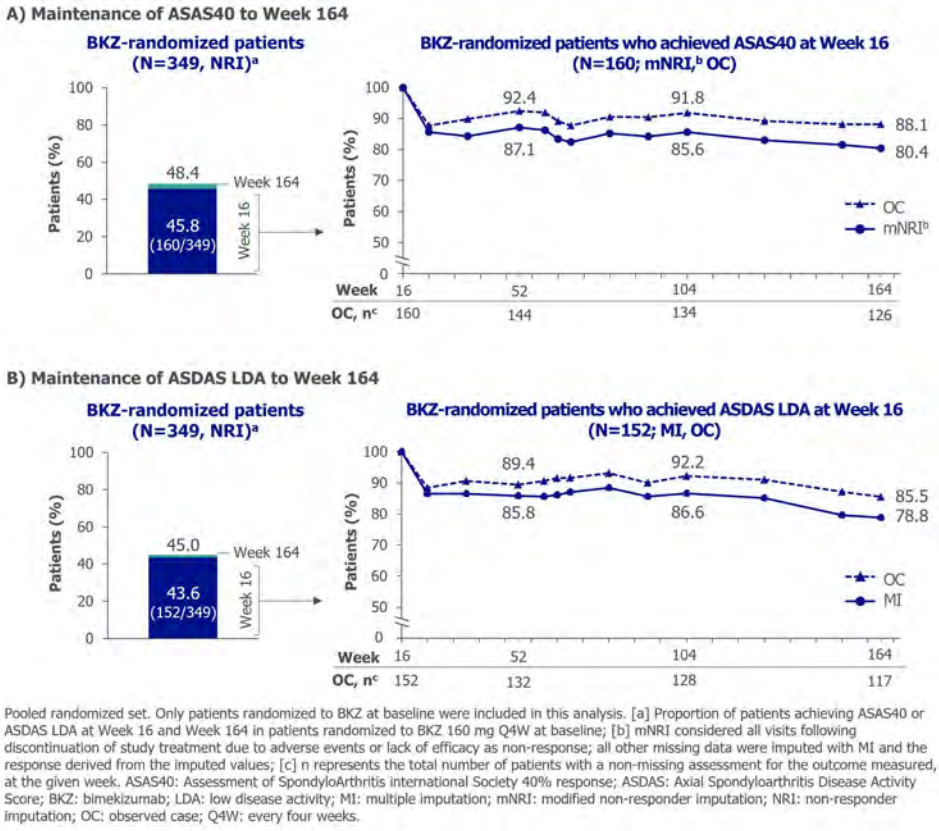
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease which requires optimal management.[1] In clinical trials, Assessment of SpondyloArthritis international Society ≥40% improvement (ASAS40) is a stringent outcome used to assess efficacy, while in clinical practice, focus is on axSpA Disease Activity Score (ASDAS) low disease activity (LDA; < 2.1). Maintenance of response, an internationally recommended axSpA treatment target,[1] can be measured by these outcomes.

Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A. In patients (pts) across the full disease spectrum of axSpA (i.e., non-radiographic [nr-] and radiographic [r-]axSpA), BKZ has demonstrated sustained clinical efficacy to 2 years in the phase 3 studies BE MOBILE 1 and 2, and their combined open-label extension (OLE).[2] This analysis assessed the maintenance of response to BKZ over 3 years in pts who achieved responses at Week (Wk) 16 in these studies, including in pts who never lost their response at any subsequent visit.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Pooled randomized set. Only patients randomized to BKZ at baseline were included in this analysis. [a] Proportion of patients achieving ASAS40 or ASDAS LDA at Week 16 and Week 164 in patients randomized to BKZ 160 mg Q4W at baseline; [b] mNRI considered all visits following discontinuation of study treatment due to adverse events or lack of efficacy as non-response; all other missing data were imputed with MI and the response derived from the imputed values; [c] n represents the total number of patients with a non-missing assessment for the outcome measured, at the given week. ASAS40: Assessment of SpondyloArthritis international Society 40% response; ASDAS: Axial Spondyloarthritis Disease Activity Score; BKZ: bimekizumab; LDA: low disease activity; MI: multiple imputation; mNRI: modified non-responder imputation; NRI: non-responder imputation; OC: observed case; Q4W: every four weeks.

Figure 1. Maintenance of (A) ASAS40 and (B) ASDAS LDA to Week 164 among BKZ-randomized patients who achieved each respective outcome at Week 16

Methods: BE MOBILE 1 (NCT03928704; nr-axSpA) and 2 (NCT03928743; r-axSpA) both comprised a 16-wk double-blind, placebo-controlled period followed by a 36-wk maintenance period.[3] From Wk 16, all pts received subcutaneous BKZ 160 mg every 4 wks. At Wk 52, eligible pts could enroll in the OLE (BE MOVING; NCT04436640).

The proportion of pts achieving ASAS40 or ASDAS LDA at Wk 164 was assessed among BKZ-randomized pts that achieved each respective outcome at Wk 16. The proportion of pts who achieved ASDAS LDA at Wk 16 and never lost their response at every subsequent visit from Wk 16 to Wk 164 is also reported, including those who achieved ASDAS major improvement (ASDAS-MI; ≥2.0-unit change from baseline [CfB]) and ASDAS clinically important improvement (ASDAS-CII; ≥1.1-unit CfB).

Presented data, pooled across studies, use non-responder imputation (NRI), modified non-responder imputation (mNRI) or multiple imputation (MI; ASDAS only). Observed case (OC) data are also reported.

Results: A total of 128 pts and 221 pts were randomized to BKZ across BE MOBILE 1 and 2, respectively (N=349). A high proportion of pts who achieved a response at Wk 16 maintained their response at Wk 164 (**Figure 1**).

Of the 160 pts (45.8%; NRI) who achieved ASAS40 at Wk 16, 80.4% still achieved ASAS40 at Wk 164 (mNRI). Of the 152 pts (43.6%; NRI) who achieved ASDAS LDA at Wk 16; 78.8% still achieved ASDAS LDA at Wk 164 (MI; **Figure 1**).

From Wk 16 through to Wk 164, 50% of pts never lost their ASDAS LDA status at any assessed visit (MI), with a further 22.4% only losing their ASDAS LDA status at one visit, and 6.1% at two visits, respectively (MI). The majority of pts who never lost their ASDAS LDA status from Wk 16 and entered the OLE achieved ASDAS-MI or ASDAS-CII at Wk 52, 104 and 164 (94.5%, 94.5%, and 90.9%, respectively; **Figure 2**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. BKZ-randomized patients who achieved ASDAS LDA (<2.1) at Week 16 and (A) never lost their ASDAS LDA status to Week 164 or (B) lost their ASDAS LDA status at least once to Week 164 (OC)

Conclusion: A high proportion of BKZ-randomized pts who achieved stringent clinical responses at Wk 16 maintained these to Wk 164 across the full disease spectrum of axSpA. Half of pts achieving ASDAS LDA at Wk 16 never lost their response up to Wk 164.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Immune-mediated rheumatic diseases (IMRDs) are chronic inflammatory disorders driven by multiple overlapping immunological pathways. Although biologic DMARD monotherapy has substantially improved outcomes, a subset of patients remains refractory due to compensatory "immune escape" mechanisms and incomplete pathway inhibition. Off-label combination therapy targeting two distinct immune axes has been proposed to overcome these challenges, yet real-world data on its efficacy and safety are sparse and not reflected in current guidelines.

Methods: We conducted a retrospective, cross-sectional study at a tertiary reference center (CEIMI, Hospital General Universitario Gregorio Marañón, Madrid) including twenty adult patients (13 women; mean age 48.5 years) diagnosed with rheumatoid arthritis (n = 5), psoriatic arthritis (n = 5), psoriasis (n = 1), spondyloarthritis (n = 3), inflammatory bowel disease (n = 2), systemic lupus erythematosus (n = 2), or juvenile idiopathic arthritis (n = 2). All had failed a median of four prior st/bDMARDs (6.6 in RA) and initiated off-label dual therapy with agents targeting distinct immune pathways. Clinical, laboratory, efficacy (remission or low disease activity [LDA] by standardized indices), and safety data were extracted at baseline and at 1, 3, 6, 12, and up to 36 months post-CBT. Descriptive statistics summarized outcomes.

Results: At CBT initiation, 65 % of patients had high disease activity and were on glucocorticoids. Sixteen regimens were used; the most common paired a CD20 inhibitor with a JAK inhibitor (25 %), and rituximab featured in nine. Mean exposure was 27 months (range 2–68), and 80 % remained on CBT. By month 1, 65 % achieved remission or low disease activity

ABA (Abatacept), ADA (Adalimumab), ANK (Anakinra), APR (Apremilast), ASDAS (Axial Spondyloarthritis Disease Activity Score), BAR (Baricitinib), BEL (Belimumab), BRO (Brodalumab), CRP (C-reactive protein), CTZ (Certolizumab), DAPSA (Disease Activity in PSoriatic Arthritis), DAS28-CRP (Disease Activity Score 28), ETN (Etanercept), F (Female), GOL (Golimumab), GUS (Guselkumab), HBI (Harvey-Bradshaw Index), IBD (Inflammatory bowel disease), IFX (Infliximab), IXE (Ixekizumab), JIA (Juveniile idiopathic arthritis), M (Male), MSK (Musculoskeletal), PASI (Psoriasis Area Severity Index), RA (Rheumatoid arthritis), RF (Rheumatoid factor), RIS (Risankizumab), RTX (Rituximab), SCK (Secukinumab), SLE (Systemic erythematosus lupus), SLEDAI-2K (Systemic Lupus Erythematosus Disease Activity Index 2000), SpA (Spondyloarthritis), TCZ (Tocilizumab), TOF (Tofacitinib), UPA (Upadacitinib), USK (Ustekinumab), VED (Vedolizumab).

Main clinical and serological features and outcomes of patients under CBT

(LDA), rising to 87 % at month 3. At 6 months (n=12), 100 % were in remission/LDA and 78 % had reduced or stopped glucocorticoids. Sustained rates were 71 % at 12 and 91 % at 18 months.

All five RA patients reached remission/LDA by month 3, with one flare at 24 months. Both RF-positive JIA cases improved by month 1; one achieved LDA at month 3 and both discontinued steroids. PsA patients showed durable PASI and DAPSA score improvements. Two of three SpA patients remained in remission; one experienced worsened gastrointestinal symptoms. Both IBD patients improved clinically; one ceased CBT upon stable remission. In SLE patients, SLEDAI-2K scores dropped by 9–10 points at month 1. Four regimens (20 %) were discontinued—one for progressive neutropenia (resolved after stopping rituximab + belimumab), one for surgery, one at patient request, and one due to sustained remission.

Conclusion: In this real-world cohort of refractory IMRD patients, dual biologic/synthetic targeted therapy produced rapid, sustained remission or LDA across diverse diagnoses, enabled glucocorticoid tapering, and demonstrated a manageable safety profile. These findings warrant prospective studies to define the role of multidimensional pathway blockade in difficult-to-treat rheumatic disease.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The concept of difficult-to-manage axial spondyloarthritis (D2M-axSpA)[1], may vary over time. Transitions between D2M and non-D2M classifications throughout the disease course remain unclear. This study evaluates the consistency of the D2M-axSpA classification over time and identifies differences of non-D2M and persistent and episodic D2M-axSpA cases at the b/tsDMARD initiation.

Methods: This is a cross-sectional assessment patients with axSpA who were on b/tsDMARD for at least one year and visited our rheumatology clinic between April-December 2023. Patients were assessed at two timepoints for fullfillment of D2M-axSpA: first visit at the study inclusion period and second visit between 6-12 months after the first visit. Using these two-timepoint data patients were categorized into three groups as follows:'persistent D2M' (D2M-axSpA' patients at both assessments), 'persistent non-D2M'(non-D2M-axSpA' patients at both assessments), 'episodic D2M-axSpA' (D2M-axSpA in only one of the assessments). Demographic, clinical and disease activity indices as well as comorbidities of the patients at the initiation of b/ts DMARD were evaluated and compared between groups. The factors associated with D2M-axSpA status on univariate analysis with significance at the 0.20 level were entered into a multivariable model. Backward elimination method was used at a significance of 0.05 level.

Table 1. Comparison of demographic, clinical and therapeutic characteristics of patients with Persistent D2M, Persistent Non-D2M and Episodic D2M receiving at least one b/tsDMARD

	Persistent D2M (n:62)	Episodic D2M (n:81)	Persistent non-D2M (n:635)	p values

Crp, b/tsDMARD initiation	1.00(0.95-1.06)	0.82		

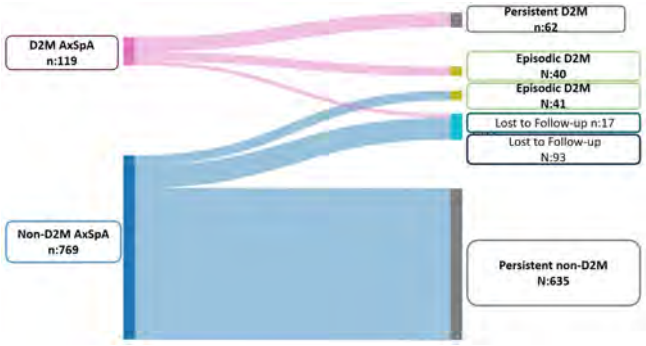

Figure 1. Temporal changes in D2M AxSpA and Non-D2M AxSpA patients

Results: Overall 888 patients were included in this assessment . From the initial D2M-axSpA patients(n=119), 52.1% were persistent-axSpA, 33.6% were episodic D2M-axSpA. 14.2% (17/119) did not attend follow-up visits. Of the initial non-D2M-axSpA (n=769), 82.5% were persistent non-D2M-axSpA, 5.33%were episodic D2M-axSpA, and 12.09% did not participate in follow-up visits (Figure 1). Persistent D2M-axSpA patients were more often female and had higher rates of hypertension, COPD/asthma, and diabetes mellitus. BASDAI and VAS global scores were significantly higher in the persistent D2M-group at b/tsDMARD initiation (Table 1). In the multivariable logistic regression analysis, a higher BASDAI score at the initiation of b/tsDMARD therapy was identified as a significant factor associated with the development of D2M-axSpA (either episodic or persistent) among patients initially classified as non-D2M (OR: 1.48 [1.15–1.91], p = 0.002) (Table 2).

Conclusion: Our study revealed that 33.6% of patients initially diagnosed with D2M-axSpA eventually transitioned to a non-D2M state and overall 10% of the population has transitioned from one category to another. Persistent D2M-axSpA patients were more often female and had a higher prevalence of comorbidities. Physicians should be aware that D2M-axSpA criteria fullfilments may change over time, with factors that potentially affecting subjective measures like BASDAI, HAQ, and VAS global scores.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Upadacitinib (UPA) is a Janus Kinase inhibitor (JAKi) selective for JAK1, approved for the treatment of both Psoriatic Arthritis (PsA) and Axial Spondyloarthritis (axSpA). In May 2022, the Basque Health Service prioritized UPA use over other JAK inhibitors following the failure of Adalimumab biosimilars.

The aim of this study is to describe the demographic and clinical characteristics of patients with axSpA and PsA treated with UPA and to explore sex-related differences.

Methods: 7 hospitals in our region (1.5 million inhabitants) participated in a multicenter, observational and ambispective study that included patients with UPA prescription from June 2021 to May 2024, with follow-up until Dec 2024.

Among the 415 patients enrolled, 87 were diagnosed with AxSpA and 78 with PsA. Data were collected on comorbidities, disease duration and pattern, extra-articular manifestations (EAMs) and disease activity (measured by BASDAI and ASDAS for AxSpA, and DAPSA for PsA)

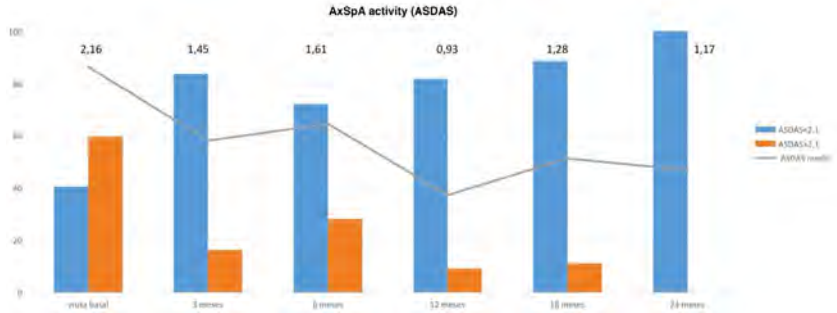

FIgure 1. AxSpA Activity (ASDAS).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

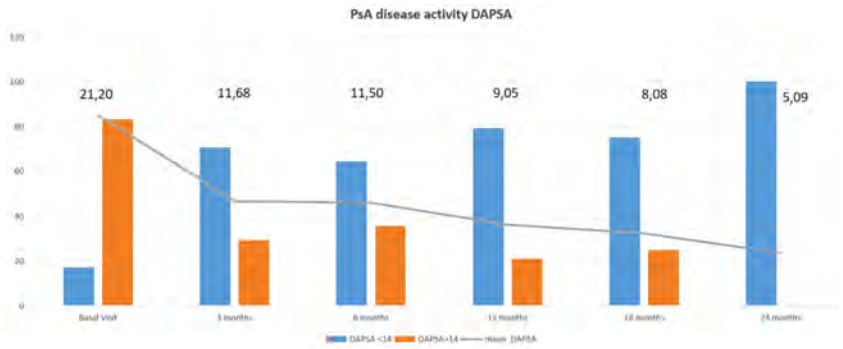

Figure 2. ApS activity (DAPSA)

Results: Axial Spondyloarthritis (AxSpA) Subgroup (n=87):

49.1% were women, with a mean age of 52.2 years (SD 11.6) and a mean disease duration of 102.2 months (SD 92.7), longer in men (123.7 vs. 76.3 months). HLA-B27 was positive in 55%, 65.1% had radiographic disease, and 19.3% had ankylosis (more frequent in men). Peripheral manifestations were observed in 51.2% (arthritis), 23.5% (enthesitis). EAMs included inflammatory bowel disease (16.5%), uveitis (9.6%), and psoriasis (9.9%). UPA median persistence was 13.1 months (SE 2.73), with no significant difference by sex or prior biologic exposure. The disease activity was shown in Figure 1.

Psoriatic Arthritis (PsA) Subgroup (n=78):

54.5% were women, with a mean age of 53.5 years (SD 10.2) and a disease duration of 116.5 months (SD 93.9). Age at diagnosis was later in women (46.6 vs. 40.3 years). The majority had peripheral (61.5%) or mixed (35.9%) patterns, with axial-only forms being rare (2 men). Women more frequently presented with peripheral PsA (76%), while men showed more mixed forms (51.4%). Cutaneous psoriasis was present in 80.8%, mostly plaque-type (65%), with no sex-based differences.

The disease activity was shown in Figure 2. UPA median persistence was 19 months (95% CI 11.6), slightly longer in women (16.4 months in men), though not statistically significant.

Sex-related differences in clinical presentation were observed in both diseases: men had longer disease duration and more axial involvement, while women had more peripheral manifestations and delayed diagnosis. Despite these differences, there were no significant sex-based differences in treatment history, response to UPA, or persistence in either AxSpA or PsA. A non-significant trend toward better persistence in women with PsA was noted.

Conclusion: UPA appears effective in the treatment of both AxSpA and PsA, even among patients with refractory and long-standing disease. While sex-based differences in clinical patterns were observed, outcomes and persistence were similar between men and women. These findings support the role of UPA across the Spondyloarthritis spectrum. Further studies with larger sample sizes are warranted to confirm potential sex-related differences in treatment outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

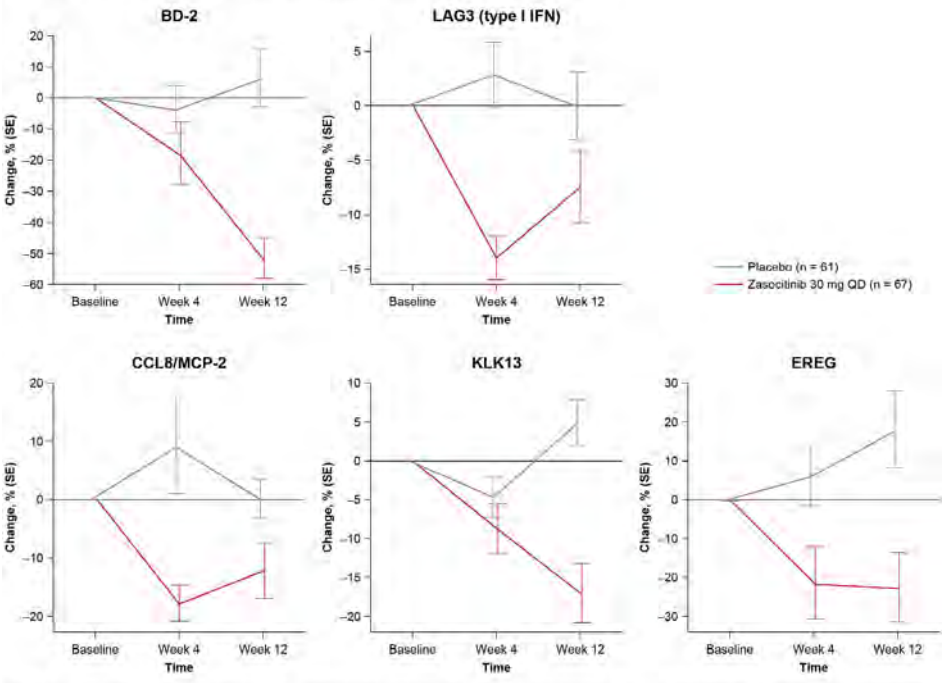
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: There is a significant unmet need for clinically informative biomarkers of disease activity and therapeutic response in immune-mediated inflammatory diseases (IMIDs). Tyrosine kinase 2 (TYK2) is a crucial mediator of pro-inflammatory pathways fundamental to the pathophysiology of some IMIDs, including psoriasis and psoriatic arthritis (PsA).

Zasocitinib (TAK-279) is an investigational, oral, allosteric, highly selective, and potent TYK2 inhibitor for IMIDs. This *post hoc* analysis of a phase 2b trial of patients with active PsA evaluated the effect of zasocitinib 30 mg once daily (QD) on TYK2

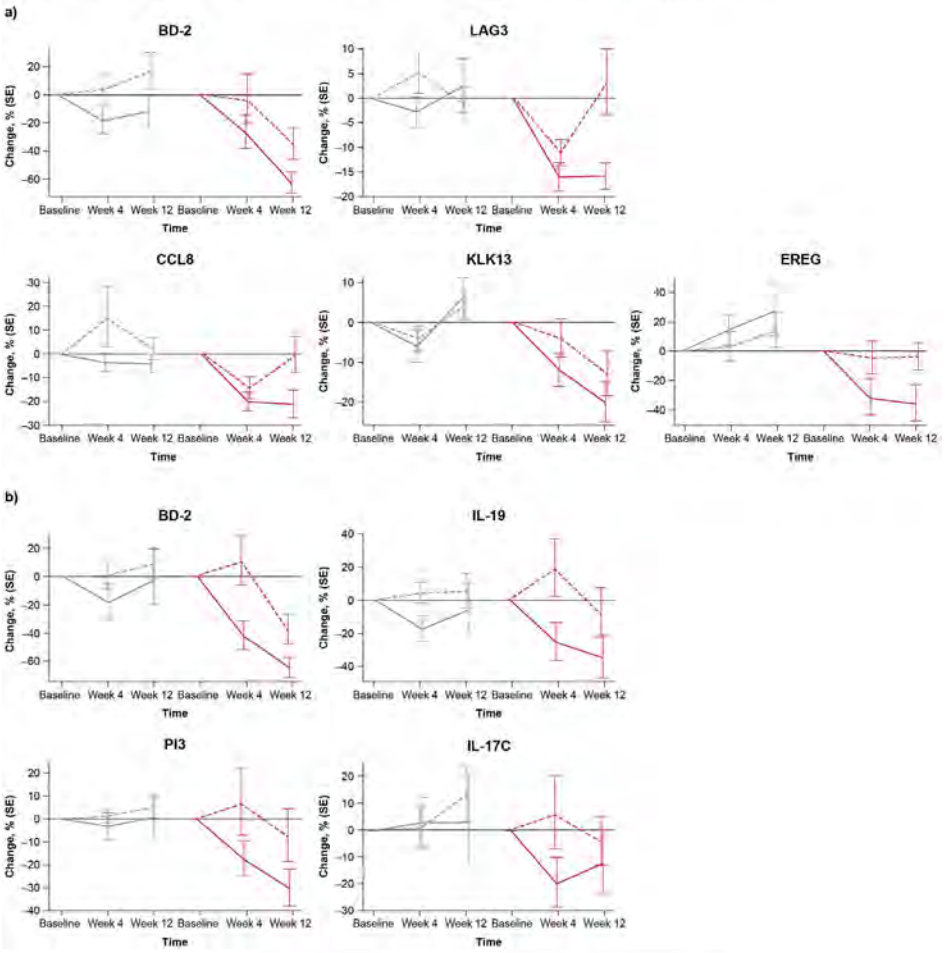
Figure 1. Modulation of TYK2 pathway- and PsA activity-related biomarkers in plasma.



Percent change from baseline in the levels of TYK2 pathway- and PsA activity-related proteins at Week 4 and Week 12 in patients given placebo and zasocitinib 30 mg QD. Relative abundance of biomarkers in serum was quantified using the Olink Explore HT platform, based on the binding of oligonucleotide-labeled antibodies pairs to the target protein. These unique hybridization sequences are then amplified and sequenced on Illumina platforms. The raw count was processed and normalized across blocks using reference samples based on normalization. The biomarker quantification, reported on a relative and logarithmic 2 scale as NPX values, were used for downstream expression modulation comparison across different dosing arms.
BD-2, β-defensin-2; CCL8, CC-chemokine ligand 8; EREG, epiregulin; IFN, interferon; KLK13, kallikrein-related peptidase 13; LAG3, lymphocyte activation gene-3; MCP-2, monocyte chemotactic protein 2; NPX, Normalized Protein eXpression; PsA, psoriatic arthritis; QD, once daily; SE, standard error; TYK2, tyrosine kinase.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Modulation of a) TYK2- and b) PsA disease-specific biomarkers, in ACR20 responders and non-responders with PsA.



Percent change from baseline in the levels of TYK2 pathway- and PsA activity-related proteins at Week 4 and Week 12 in patients given placebo and zasocitinib 30 mg QD. Biomarker levels, reported on a relative and logarithmic 2 scale as NPX values, in each treatment group were quantified at different time points and were compared between treatment groups. To calculate change from baseline, the NPX for biomarkers of interest at baseline were subtracted from the NPX at each time point (baseline, Week 4, and Week 12) for each patient. The longitudinal change from baseline for each biomarker was modeled using a mixed-effect model, with baseline value, treatment, time, and treatment–time interaction as fixed effects, and the patient as the random effect. The least-squares mean and standard error were back transformed to percent change and plotted for each biomarker at each time point. ACR20/PASI 75 responders were defined as patients who achieved ACR20/PASI 75 response at Week 12.

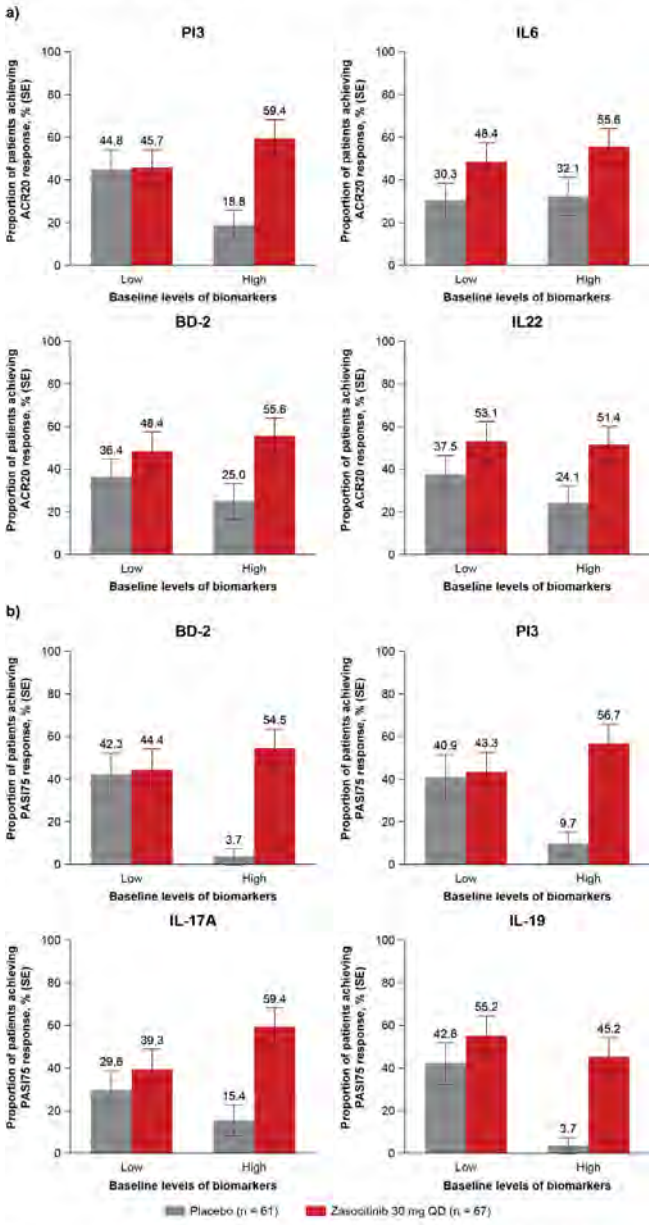
ACR20, American College of Rheumatology 20; BD-2, β-defensin-2; CCL8, CC-chemokine ligand 8; EREG, epiregulin; IL, interleukin; KLK13, kallikrein-related peptidase 13; LAG3, lymphocyte activation gene-3; NPX, Normalized Protein eXpression; PASI, Psoriasis Area and Severity Index; PI3, peptidase inhibitor 3; QD, once daily; TYK2, tyrosine kinase.

pathway- and PsA activity-related biomarkers, and reported the association between baseline levels of biomarkers and American College of Rheumatology (ACR20) and Psoriasis Area and Severity Index (PASI 75) response.

Methods: In a phase 2b multicenter, double-blind, placebo-controlled, dose-ranging study, 290 patients with active PsA were randomized 1:1:1:1 to receive oral zasocitinib (5, 15, or 30 mg) or placebo QD for 12 weeks (NCT05153148). Blood samples were collected from patients in each group at baseline, Week 4, and Week 12 (pre-dose, if applicable). Concentrations of plasma biomarkers associated with the TYK2 pathway (β-defensin-2 [BD-2] and lymphocyte activation gene-3 [LAG3]) and with PsA (CC-chemokine ligand 8 [CCL8], kallikrein-related peptidase 13 [KLK13], epiregulin [EREG], interleukin [IL]-19, peptidase inhibitor 3 [PI3], IL-17C, IL-6, IL-22, and IL-17A) were measured using the Olink Explore HT. Biomarker levels in each treatment group were quantified at each timepoint; results for zasocitinib 30 mg are described.

Results: Zasocitinib 30 mg induced modulation of TYK2 pathway-related biomarkers (BD-2 and LAG3) and PsA activity related biomarkers (CCL8, KLK13, and EREG) as early as Week 4 and through Week 12 ($p < 0.01$; **Figure 1**); modulation of these biomarkers was numerically greater in ACR20 responders versus non-responders ($p < 0.01$; **Figure 2a**), and modulation of BD-2, IL-19, PI3, and IL-17C was numerically greater in PASI 75 responders versus non-responders ($p < 0.01$; **Figure 2b**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



For each biomarker, the median cutoff was used to group patients into "biomarker low" and "biomarker high" groups. For each group and each treatment, the mean and standard error of the biomarker were calculated.
ACR20, American College of Rheumatology 20; BD-2, β-defensin-2; IL, interleukin; PASI, Psoriasis Area and Severity Index; PI3, peptidase inhibitor 3; QD, once daily; SE, standard error.

In patients with elevated baseline plasma levels of PI3, IL-6, BD-2, and IL-22, zasocitinib 30 mg treatment resulted in greater ACR20 response rates versus those receiving placebo ($p < 0.01$; **Figure 3a**). In patients with elevated baseline serum levels of BD-2, PI3, IL-17A, and IL-19, zasocitinib 30 mg treatment demonstrated greater PASI 75 response rates versus those receiving placebo ($p < 0.01$; **Figure 3b**).

Conclusion: In this phase 2b trial, zasocitinib 30 mg QD treatment led to modulation of key TYK2 pathway- and PsA activity-related biomarkers that mediate pathophysiology in patients with active PsA, particularly in ACR20 clinical responders. Baseline levels of key biomarkers may predict joint and skin responses to zasocitinib.

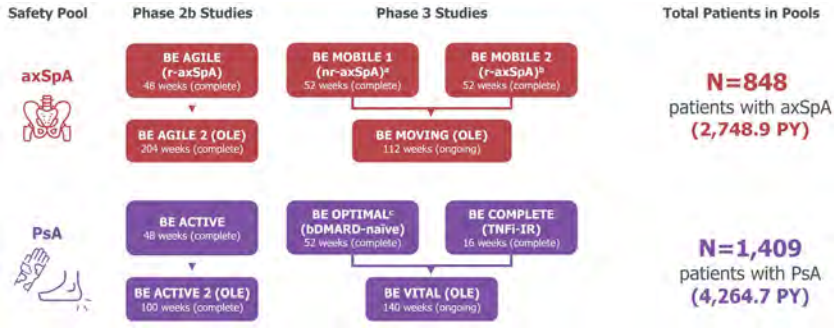
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM



Data from the September 2024 (axSpA) and August 2024 (PsA) data-cuts shown; including all patients who received ≥1 dose of BKZ 160 mg Q4W in the phase 2b/3 studies. Duration of overall treatment period shown; BKZ treatment duration by data-cut varied between patients, depending on study duration and initial randomization in the feeder studies. [a] Patients with nr-axSpA met Assessment of SpondyloArthritis international Society (ASAS) classification criteria. Patients with radiographic sacroiliitis were excluded; [b] Patients with r-axSpA met modified New York criteria and fulfilled ASAS classification criteria; [c] BE OPTIMAL also included an adalimumab treatment arm. Data from patients treated with adalimumab were not included in the PsA safety pool prior to switching to BKZ, but were included following the switch. ASAS: Assessment of SpondyloArthritis international Society; axSpA: axial spondyloarthritis; bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; nr-axSpA: non-radiographic axSpA; OLE: open-label extension; PsA: psoriatic arthritis; PY: patient-year; Q4W: every 4 weeks; r-axSpA: radiographic axSpA; TNFi-IR: tumor necrosis factor inhibitor inadequate response.

BE AGILE: NCT02963506; BE AGILE 2: NCT03355573; BE MOBILE 1: NCT03928704; BE MOBILE 2: NCT03928743; BE MOVING: NCT04436640; BE ACTIVE: NCT02969525; BE ACTIVE 2: NCT03347110; BE OPTIMAL: NCT03895203; BE COMPLETE: NCT03896581; BE VITAL: NCT04009499.

Figure 1. Two safety pools (axSpA, PsA) of patients treated with BKZ 160 mg Q4W across six phase 2b/3 studies and their open-label extensions

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. axSpA: axial spondyloarthritis; BKZ: bimekizumab; CI: confidence interval; EAIR: exposure-adjusted incidence rate; PY: patient-years; Q4W: every 4 weeks.

Figure 2. Incidence of uveitis in patients with axSpA stratified by history of uveitis

Background/Purpose: Uveitis is a common extra-musculoskeletal manifestation in patients (pts) with spondyloarthritis (SpA); incidence varies with SpA type and disease duration.[1–3] IL-17 has been implicated in uveitis pathogenesis.[4] However, previous data demonstrating IL-17A inhibition efficacy in managing uveitis are limited and conflicting.[5–7]

The exposure-adjusted incidence rate (EAIR) per 100 pt-years (PY) of uveitis was lower in pts with non-radiographic and radiographic axial SpA (axSpA) randomized to bimekizumab (BKZ; 1.8/100 PY), which selectively inhibits IL-17F in addition to IL-17A, vs placebo (15.4/100 PY) after 16 weeks in phase (Ph)3 studies.[8] Previously reported long-term data over ~2 years (data cut-off: Jul 2023) showed that uveitis rates remained low in BKZ-treated pts with axSpA (1.3/100 PY) and psoriatic arthritis (PsA; 0.1/100 PY).[9]

We report updated uveitis incidence in BKZ-treated pts with axSpA or PsA in Ph2b/3 studies with an additional year of treatment duration in the Ph3 studies (data cut-off in axSpA: Sep 2024; PsA: Aug 2024).

Methods: Data are reported for two pools, each comprising one Ph2b and two Ph3 studies and their open-label extensions, in pts with axSpA and PsA, respectively (**Figure 1**).

Uveitis events were identified using the preferred terms "autoimmune uveitis", "iridocyclitis", "iritis", and "uveitis", classified using the MedDRA v19.0; "acute anterior uveitis" was not a specific preferred term available in MedDRA v19.0.

Uveitis rates and EAIR/100 PY for pts who received ≥1 BKZ 160 mg every four weeks (Q4W) dose are reported.

Results: Pts with axSpA (N=848) and PsA (N=1,409) had a mean (SD) age of 40.3 (11.9) and 49.3 (12.4) years, respectively. Mean (SD) time since diagnosis was 6.1 (7.8) years in pts with axSpA and 7.0 (8.0) in pts with PsA. Of pts with axSpA, 130 (15.3%) had a history of uveitis (PsA: 21 [1.5%]). Most pts with axSpA were HLA-B27 positive (717/848 [84.6%]).

In pts with axSpA across the pooled Ph2b/3 data, BKZ exposure was 2,748.9 PY. In total, uveitis occurred in 33/848 (3.9%; EAIR [95% CI]: 1.2/100 PY [0.8, 1.7]) pts overall and in 20/130 (15.4%; 5.0/100 PY [3.0, 7.7]) pts with history of uveitis. In pts without a history of uveitis, 13/718 (1.8%; 0.6/100 PY [0.3, 1.0]) pts had uveitis events (**Figure 2**). Most events were mild/moderate, one was severe; two (0.2%) patients discontinued treatment due to uveitis.

Incidence of uveitis in pts with PsA was low across the pooled Ph2b/3 data (total BKZ exposure: 4,264.7 PY); uveitis occurred in 4/1,409 (0.3%; 0.1/100 PY [0.0, 0.2]) pts overall; two had a history of uveitis. No uveitis events led to treatment discontinuation.

Conclusion: With an additional year of BKZ treatment from previously reported data, the incidence of uveitis in pts with SpA receiving BKZ long-term, over 3 years, remained low.

Abstract Number: 2353

Efficacy of Vunakizumab in Reducing Pain in Ankylosing Spondylitis: A Post-Hoc Analysis of a Phase 2/3 Clinical Trial

Jian Xu, Yifan Yang, Shuang Liu, Ru Bai, Shu Li, Guofang Zhang, Xiangyu Wang, Xinyu Xu, Mai Zheng and Daying Feng, The First Affiliated Hospital of Kunming Medical University, Kunming, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease that primarily affects the spine and sacroiliac joints, resulting in significant pain, stiffness, and functional impairment. The interleukin-17 (IL-17) signaling pathway plays a central role in the pathogenesis of AS. Vunakizumab, a humanized monoclonal antibody targeting IL-17A, has demonstrated clinical efficacy in a randomized, double-blind, phase 2/3 trial. Since pain is the most common and serious symptom experienced by patients with AS, it is very important to develop and use effective treatment strategies to manage it. This post-hoc analysis aimed to evaluate the efficacy of vunakizumab in reducing pain outcomes in patients with active AS.

Methods: Eligible participants were adults with active AS, diagnosed according to the modified New York criteria (1984 revision), who had an inadequate response to, intolerance of, or contraindications to non-steroidal anti-inflammatory drugs (NSAIDs). All patients included in this study fulfilled the American College of Rheumatology (ACR) classification criteria. In phase 2, patients were randomized in a 2:2:1 ratio to receive either 120 mg or 240 mg of vunakizumab, or placebo. At week 16, patients initially receiving placebo were re-randomized 1:1 to one of the treatment groups. In phase 3, patients were randomized in a 2:1 ratio to receive 120 mg of vunakizumab or placebo. Study drug was administered at weeks 0, 2, 4, 8, and 12, followed by dosing every four weeks through week 32. Pain outcomes included total back pain, nocturnal back pain, and questions 2–4 from the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI): spinal pain (pain in the back, neck, or hip), peripheral joint pain/swelling, and enthesitis (pain in areas tender to touch).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Pain Scores in the Placebo and Vunakizumab Groups from Baseline to Week 32.

(A) Total back pain; (B) Nocturnal back pain; (C) Spinal pain; (D) Peripheral joint pain/swelling; (E) Enthesitis.

Table 1. Comparison of Pain Scores Between Placebo and Vunakizumab Groups from Baseline to Week 16.

	Placebo Baseline (N=146)			Vunakizumab (N=294)				
	Baseline	Week 16	Change in Week 16 Relative to Baseline	Baseline	Week 16	Change in Week 16 Relative to Baseline	Nominal P value for Baseline vs Week 16[a]	Nominal P value for the Overall Period from 0 to 16 Weeks[b]
Total back pain VAS score, mean (standard deviation [SD])	6.20 (1.26)	4.39 (2.07)	-1.83 (2.06)	6.16 (1.24)	3.27 (1.95)	-2.89 (2.11)	<0.0001	<0.0001
Nocturnal pain VAS score, mean (SD)	5.77 (1.66)	4.04 (2.18)	-1.76 (2.20)	5.78 (1.61)	2.72 (1.94)	-3.06 (2.20)	<0.0001	<0.0001
Spinal pain, mean (SD)	6.51 (1.31)	4.48 (2.29)	-2.03 (2.09)	6.41 (1.24)	3.48 (2.00)	-2.95 (2.03)	<0.0001	<0.0001
Peripheral joint pain/swelling, mean (SD)	3.96 (2.44)	2.72 (2.26)	-1.25 (2.17)	4.22 (2.50)	2.12 (2.00)	-2.13 (2.38)	0.0001	<0.0001
Enthesitis, mean (SD)	5.77 (1.46)	3.95 (2.10)	-1.80 (2.32)	5.80 (1.43)	2.87 (1.95)	-2.94 (2.08)	<0.0001	<0.0001

[a]Change from baseline to week 16 between groups was compared using an independent-samples t-test (one-sided).

[b]P values for the overall period from 0 to 16 weeks were calculated using a mixed-effects model for repeated measures.

Results: This post-hoc analysis demonstrated significant reductions in all five pain outcome scores for patients receiving vunakizumab 120 mg compared to placebo over the 16-week period (all nominal $p < 0.0001$ by repeated measures mixed-effects model; Figure 1). Specifically, at week 16, the vunakizumab group showed a mean reduction in total back pain of -2.89 versus -1.83 in the placebo group (nominal $p < 0.0001$). Similar significant improvements were observed in nocturnal back pain (-3.06 vs. -1.76, nominal $p < 0.0001$), spinal pain (-2.95 vs. -2.03, nominal $p < 0.0001$), peripheral joint pain/swelling (-2.13 vs. -1.25, nominal $p = 0.0001$), and enthesitis (-2.94 vs. -1.80, nominal $p < 0.0001$) (Table 1).

From weeks 16 to 32, patients initially assigned to placebo who switched to vunakizumab 120 mg at week 16 experienced accelerated reductions in all five pain outcomes after the switch, although the magnitude of improvement remained slightly less than that observed in patients who received continuous vunakizumab throughout the study.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Vunakizumab provided statistically significant and clinically meaningful reductions in pain outcomes in patients with active AS. Importantly, patients who switched from placebo to vunakizumab at week 16 experienced rapid pain improvement, supporting vunakizumab as an effective treatment strategy for managing pain in AS.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: While traditional analysis relies on statistical software such as SPSS, emerging tools like ChatGPT introduce the possibility of performing statistical tests, interpreting results, and generating figures via natural language prompts.

The neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) are accessible inflammatory markers increasingly used in the monitoring of chronic diseases like Spondyloarthritis.

This study aims to compare traditional statistical analysis using SPSS (V.20.0) with AI-based analysis using ChatGPT (Model 4o) in longitudinal NLR and PLR data, evaluating their consistency, usability, and impact on research efficiency.

Methods: We performed a retrospective observational study of 85 Spondyloarthritis patients treated with Secukinumab from 2016 to 2023. NLR and PLR were recorded at baseline and every six months for four years. The Friedman test was applied to assess variation over time using both SPSS v25 and ChatGPT's 4o built-in Python environment (Advanced Data Analysis). Results, narrative outputs, and figures were compared

Results: Patients showed a mean age of 53.6 years; 66% had axial Spondyloarthritis and 34% Psoriatic Arthritis, with balanced sex distribution. Common comorbidities included smoking (41.2%), Hypertension (27.1%), Diabetes (21.2%), and Dyslipidaemia (28.2%).

Both platforms detected a decreasing trend in NLR and PLR over time. Neither test showed statistically significant differences across timepoints (NLR $p = 0.41$, PLR $p = 0.62$ in both SPSS and ChatGPT). Outputs were numerically identical, with ChatGPT also providing clinical context and suggestions for graphical representation. While SPSS required software setup and manual processing, ChatGPT offered a simplified, efficient alternative with real-time interpretation.

*Statistical significance according to Friedman's test with ChatGPT 4o (Python module) *Statistical significance according to Friedman's test with SPSS*

Conclusion: ChatGPT with integrated statistical capabilities provides a reliable, efficient alternative for exploratory data analysis in clinical research. Its results matched those from SPSS while offering added value in interpretability and ease of use. Although not a replacement for regulated statistical tools in all contexts, its potential to accelerate early-stage research and support non-specialists is notable.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Ixekizumab (IXE) is an FDA-approved monoclonal antibody that targets interleukin-17A.

Methods: Psoriatic Arthritis Real-World Study in the US (PARTUS) was a prospective, multicenter, non-interventional cohort study in patients with active Psoriatic Arthritis (PsA) beginning treatment with either IXE or an interleukin-23 inhibitor (IL-23i). The study assessed the effectiveness of Ixekizumab or Interleukin-23 in disease domains and subgroups. Clinical Disease Activity Index for PsA (cDAPSA) endpoints for key subgroups and outcomes in PsA disease domains were assessed at baseline (BL), week (W) 4, and W12. Change from baseline (CFB) in cDAPSA was assessed in the following subgroups: prior biologic failure (failure due to lack of efficacy and/or intolerance), duration of disease, sex, body mass index (BMI) (normal: BMI < 25 kg/m^2, patients with overweight BMI 25 to < 30 kg/m^2, patients with obesity: BMI ≥30 kg/m^2), patients with baseline presence of enthesitis, dactylitis, nail psoriasis, or Body Surface Area (BSA) of psoriasis skin involvement (BSA < 3%, BSA ≥ 3%) (Figure (Fig.) 1). To assess PsA domains, CFB in tender/swollen joint count (TJC)/ (SJC), Leeds enthesitis index, dactylitis count and nail psoriasis Visual Analogue Scale (VAS) score and proportion of patients achieving BSA < 3 were evaluated (Table 2). Descriptive statistics are presented for both IXE and IL-23i arms.

Results: BL characteristics of 121 patients from the IXE cohort and 116 patients from the IL-23i cohort (risankizumab) (n=67) and guselkumab (n=49)) are presented in Table 1.

The mean (SD) CFB in the cDAPSA score at W4 was -13.8 (15.9) and -9.3 (15.4), and at W12 was -17.3 (19.6) and -14.0 (19.3) in the IXE and IL-23i cohort respectively. At W4, 10.6% in the IXE cohort and 3.0% in the IL-23i cohort achieved remission of disease activity. These proportions increased for both cohorts by W12 (Table 2).

Improvements in disease activity, as measured by the mean (SD) CFB in cDAPSA are reported for the following subgroups in the IXE cohort: ≤2 Years duration of disease since diagnosis (W4:-12.1 (15.0), W12: -16.3 (16.4)), >2 Years duration of disease since diagnosis (W4:-14.4 (16.3), W12 -17.7 (20.8)), male patients (W4:-16.0 (16.2), W12:-19.1 (20.1)), female patients (W4:-11.8 (15.6), W12 -15.7 (19.2)), patients with prior failure to any biologic (W4:-16.8 (16.8), W12: -21.5 (19.9)), patients with no prior failure to any biologic (W4:-12.4 (15.4), W12:-15.4 (19.4)). The mean (SD) CFB in cDAPSA in the above subgroups in the IL-23i cohort is in Fig. 1.

The mean (SD) CFB in cDAPSA by PsA domains is in Fig. 1.

Table 1. Demographic and Clinical Characteristics at Baseline in patients with active PsA treated with IXE or IL-23i (GUS and RZB) Note: Data are mean (SD) unless otherwise stated. Abbreviations: BSA= body surface area; cDAPSA= clinical Disease Activity Index for Psoriatic arthritis; GUS=-guselkumab; IL-23i=interleukin-23p19 inhibitor; IXE=ixekizumab; LEI=Leeds enthesitis index; N=number of patients in each cohort; n=number of patients in the specified category; PsO=psoriasis; RZB=risankizumab; SD=standard deviation; VAS=visual analogue scale

Parameter	IXE (N=121)	IL-23i (N=116)
Age, years	54.4 (13.3)	53.0 (14.1)
Female, n (%)	63 (52.1)	75 (64.7)
BMI, kg/m^2	33.1 (6.8)	31.4 (7.3)
Years since PsA diagnosis	7.5 (8.8)	9.0 (10.5)
Tender joint count	16.1(13.1)	16.4 (15.4)
Swollen joint count	7.7(7.5)	7.1 (7.0)
Clinical version of the disease activity index (cDAPSA)	35.5(19.8)	34.6(21.4)
Presence of enthesitis (LEI>0), n (%)	72 (59.5)	84 (72.4)
Leeds enthesitis index (Among patients with LEI >0)	2.5(1.5)	3.0(1.6)
Presence of dactylitis (dactylitis count >0), n (%)	45 (37.2)	35 (30.2)
Nail PsO VAS	18.2 (20.4)	21.1(25.3)
Presence of PsO affecting BSA, %	7.1(13.4)	11.9(17.7)

Table 2. Efficacy results in patients with active PsA treated with IXE or IL-23i (GUS and RZB) Note: Data are mean (SD) unless otherwise stated. Abbreviations: BL=Baseline; BMI=Body mass index; BSA= body surface area; cDAPSA= clinical Disease Activity Index for Psoriatic arthritis; GUS=guselkumab; IL-23i=interleukin-23p19 inhibitor; IXE=ixekizumab; N=number of patients in each cohort; n=number of patients in the specified category; PsO=psoriasis; RZB=risankizumab; SD=standard deviation; VAS=visual analogue scale

Clinical outcomes	IXE (N=121)	IL-23i (N=116)
Disease activity by mean (SD) CFB in cDAPSA		
Week 4	-13.8 (15.9)	-9.3 (15.4)
Week 12	-17.3 (19.6)	-14.0 (19.3)
Remission of disease activity (cDAPSA ≤4), n (%)		
Week 4	11 (10.6)	3 (3.0)
Week 12	18 (18.8)	10 (10.8)
Low disease activity (cDAPSA ≤13, cDAPSA score >13 at BL), n (%)		
Week 4	29 (29.9)	16 (17.8)
Week 12	38 (43.7)	36 (43.4)
mean (SD) CFB in tender joint count (TJC)		
Week 4	-5.9 (10.6)	-4.8(11.7)
Week 12	-7.7 (12.2)	-7.1 (14.4)
mean (SD) CFB in swollen joint count (SJC)		
Week 4	-4.6 (6.8)	-2.6 (4.6)
Week 12	-5.7 (7.8)	-4.1 (5.2)
mean (SD) CFB in Leeds Enthesitis Index (LEI) (LEI > 0 at BL)		
Week 4	-1.0 (1.4)	-1.2 (1.6)
Week 12	-1.4 (1.7)	-1.8 (2.0)
mean (SD) CFB in dactylitis count (DC) (DC > 0 at BL)		
Week 4	-1.4 (2.2)	-1.0 (2.2)
Week 12	-1.4 (2.3)	-1.8 (2.3)
mean (SD) CFB in nail PsO VAS (nail PsO VAS score ≥ 1 at BL)		
Week 4	-8.0 (16.7)	-11.2 (15.4)
Week 12	-13.4 (16.6)	-10.8 (22.6)
Proportion of patients who achieved BSA <3% (BSA > 3 at BL), n (%)		
Week 4	24 (47.1)	17 (27.4)
Week 12	29 (67.4)	31 (57.4)

Conclusion: The results from the PARTUS study showed that patients with active PsA treated with IXE achieved rapid and meaningful improvements at W4 in disease activity across different subgroups of patients including BMI, sex, disease duration, prior biologic experience and PsA domains in real-world settings reaching the target of disease activity control as recommended in treatment guidelines. Further improvements were observed at W12. Trends in improvement were also

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

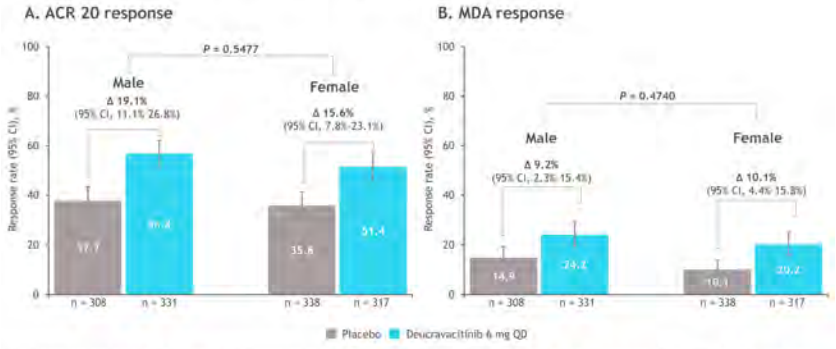
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: PsA affects male and female patients equally; however, variations in clinical manifestations and treatment responses between sexes have been reported. Deucravacitinib is an oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor under investigation for the treatment of PsA. This post hoc pooled analysis of 2 pivotal randomized, placebo (PBO)-controlled, phase 3 studies (POETYK PsA-1 [NCT04908202] and POETYK PsA-2 [NCT04908189]) evaluated the clinical efficacy of deucravacitinib vs PBO and patient-reported outcomes (PROs) by sex at W16 in patients with active PsA.

Methods: Patients in POETYK PsA-1 and PsA-2 were randomized to PBO or deucravacitinib 6 mg once daily (in PsA-2, a group included only as a safety reference arm received apremilast) through W16. The primary endpoint was ACR 20 at W16. Secondary endpoints included assessments of PsA disease activity, joints, skin, and quality of life vs PBO at W16. Binary data were analyzed using a logistic regression model that included treatment, sex, and treatment-sex interaction. Continuous data were analyzed using an ANCOVA model that included treatment, sex, baseline value, and treatment-sex

Figure 1. ACR 20 (A) and MDA (B) responses at W16 by sex



All randomized patients in PsA-1 and PsA-2 were included. Nonresponder imputation was used for the occurrence of the ICE of study treatment discontinuation prior to W16. After ICEs were handled, nonresponder imputation was used for missing data. The 95% CI was calculated using the Clopper-Pearson exact method. The *P* value corresponds to the treatment-sex interaction in the logistic regression model, including treatment, sex, and treatment-sex interaction.

ACR 20, American College of Rheumatology 20% improvement in response; ICE, intercurrent event; MDA, minimal disease activity; QD, once daily; W, week.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. DAPSA disease remission or LDA	28.2 (23.3-33.6)	39.6 (34.3-45.1)	11.3 (3.5-18.6)	21.3 (17.1-26.1)	37.9 (32.5-43.4)	16.6 (9.1-23.5)	0.2165
DAS28-CRP disease remission or LDA	28.9 (23.9-34.3)	42.9 (37.5-48.4)	14.0 (6.1-21.3)	21.0 (16.8-25.7)	39.1 (33.7-44.7)	18.1 (10.8-25.1)	0.2714
Enthesitis (SPARCC) resolution[b]	39.8 (32.8-47.1)	49.7 (42.4-57.1)	9.9 (-0.2-19.9)	32.9 (26.6-39.6)	44.6 (37.7-51.7)	11.7 (1.6-21.0)	0.7458
Dactylitis resolution[c]	38.8 (29.4-48.9)	53.2 (44.1-62.1)	14.3 (1.0-27.1)	50.6 (39.5-61.6)	64.3 (53.1-74.4)	13.7 (-1.4-28.4)	0.9669
Continuous data, mean CfB (95% CI)			Adj mean diff (SE) (95% CI)			Adj mean diff (SE) (95% CI)	
DAPSA	-13.1 (-14.8 to -11.4)	-18.7 (-20.3 to -17.0)	-5.59 (1.21) (-7.96 to -3.22)	-12.5 (-14.3 to -10.8)	-19.6 (-21.4 to -17.8)	-7.10 (1.27) (-9.60 to -4.60)	0.3708

All randomized patients in PsA-1 and PsA-2 were included. Study treatment discontinuation prior to W16 was considered an ICE. For binary variables, nonresponder imputation was used for handling ICEs. For continuous variables, the CfB value was set to 0 to imply no improvement or worsening relative to baseline. After ICEs were handled, nonresponder imputation was used for missing binary data, and a control-based pattern multiple imputation was used for missing continuous data. The logistic regression mode (for binary variables) included treatment, sex, and treatment-sex interaction. The ANCOVA model (for continuous variables) included baseline value, treatment, sex, and treatment-sex interaction. The *P* value corresponds to the treatment-sex interaction. PASI 75 was defined as a ≥ 75% improvement in PASI score vs baseline. DAPSA disease remission and LDA were defined as a score ≤ 4 and a score > 4 and ≤ 14, respectively. DAS28-CRP disease remission and LDA were defined as a score < 2.6 and score ≥ 2.6 and ≤ 3.2, respectively. Enthesitis (SPARCC) resolution was defined as a SPARCC score of 0 in patients with a SPARCC score ≥ 1 at baseline. Dactylitis resolution was defined as a tender dactylitis count of 0 in patients with a tender dactylitis count ≥ 1 at baseline.

[a]Assessed in patients with a BSA ≥ 3% and an sPGA score ≥ 2 at baseline (male patients: PBO, n = 180 and deucravacitinib, n = 175; female patients: PBO, n = 139 and deucravacitinib, n = 141). [b]Assessed in patients with a SPARCC score ≥ 1 at baseline (male patients: PBO, n = 191 and deucravacitinib, n = 189; female patients: PBO, n = 216 and deucravacitinib, n = 204). [c]Assessed in patients with a tender dactylitis count ≥ 1 at baseline (male patients: PBO, n = 103 and deucravacitinib, n = 126; female patients: PBO, n = 85 and deucravacitinib, n = 84).

adj, adjusted; ANCOVA, analysis of covariance; BSA, body surface area; CfB, change from baseline; DAPSA, Disease Activity Index for Psoriatic Arthritis; DAS28-CRP, Disease Activity Score 28 with C-reactive protein; diff, difference; ICE, intercurrent event; LDA, low disease activity; PASI, Psoriatic Area and Severity Index; PASI 75, ≥ 75% improvement in the Psoriasis Area and Severity Index; PBO, placebo; QD, once daily; SPARCC, Spondyloarthritis Research Consortium of Canada; sPGA, static Physician Global Assessment; W, week.

Table 2. Select PROs at W16 by sex

Endpoint at week 16	Male			Female			*P* value

All randomized patients in PsA-1 and PsA-2 were included. Study treatment discontinuation prior to W16 was considered an ICE. For binary variables, nonresponder imputation was used for handling ICEs. For continuous variables, the CfB value was set to 0 to imply no improvement or worsening relative to baseline. After ICEs were handled, nonresponder imputation was used for missing binary data, and a control-based pattern multiple imputation was used for missing continuous data. The logistic regression mode (for binary variables) included treatment, sex, and treatment-sex interaction. The ANCOVA model (for continuous variables) included baseline value, treatment, sex, and treatment-sex interaction. The *P* value corresponds to the treatment-sex interaction.

[a]Assessed in patients with an HAQ-DI score ≥ 0.35 at baseline. Clinically meaningful improvement in HAQ-DI was defined as ≥ 0.35 improvement from baseline HAQ-DI score.

adj, adjusted; ANCOVA, analysis of covariance; CfB, change from baseline; diff, difference; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy - Fatigue; HAQ-DI, Health Assessment Questionnaire Disability Index; ICE, intercurrent event; MCS, mental component summary; PCS, physical component summary; PRO, patient-reported outcome; QD, once daily; SF-36, 36-Item Short Form Questionnaire; W, week.

interaction. *P* values were provided for the treatment-sex interaction. A *P* value > 0.05 indicated that the treatment effect between deucravacitinib and PBO was similar for male and female patients.

Results: Across POETYK PsA-1 and PsA-2, 646 patients were randomized to PBO (male, n = 308; female, n = 338), and 648 were randomized to deucravacitinib (male, n = 331; female, n = 317). At W16, ACR 20 was achieved in more patients treated with deucravacitinib vs PBO, with no difference between male and female patients (male, 56.8% vs 37.7%; female, 51.4% vs 35.8%; *P* = 0.5477) (**Figure 1A**). Similar trends in both male and female patients were observed for ACR 50 and ACR 70 responses. MDA was also achieved in more patients treated with deucravacitinib vs PBO at W16 (male, 24.2% vs 14.9%; female, 20.2% vs 10.1%; *P* = 0.4740) (**Figure 1B**). Response rates in patients treated with deucravacitinib were higher at W16 vs PBO for secondary endpoints of PASI 75, DAPSA and DAS28-CRP disease remission or low disease activity, enthesitis (SPARCC) resolution, and dactylitis resolution as well as a greater change from baseline (CfB) in DAPSA score in both male and female patients (**Table 1**). For PROs, more patients treated with deucravacitinib vs PBO achieved a clinically meaningful improvement in HAQ-DI score and showed greater CfB in HAQ-DI, SF-36 PCS and MCS, and FACIT-Fatigue scores at W16 in both male and female patients (**Table 2**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Efficacy at W16 was similar for male and female patients who received deucravacitinib, and patients treated with deucravacitinib had superior efficacy vs PBO across multiple endpoints, including overall disease activity measures, musculoskeletal and dermatologic manifestations, and quality of life. Results of this post hoc pooled analysis were consistent with that of the overall POETYK PsA-2 population W16 results at a study level and those observed in the phase 2 study of deucravacitinib in active PsA in the overall population and by sex.

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: PsA is a chronic inflammatory disease affecting heterogeneous tissues, with unmet need for therapies with robust efficacy across disease domains. Sonelokimab (SLK) is a novel Nanobody that binds to both IL-17A and IL-17F with similarly high affinity. The Phase 2 ARGO trial in active PsA met the primary endpoint of ACR50 at Week (W) 12 for

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. SLK 60mg with induction (WI) and SLK 120mg WI, with robust responses observed for high-hurdle endpoints including ACR70, PASI 100, and minimal disease activity (MDA) through W24 (McInnes *et al*, EULAR 2024). Patient characteristics, including sex, weight, concomitant methotrexate (MTX) use, and baseline disease activity levels may influence responses to bDMARDs (Eder *et al*, *Lancet Rheumatol*. 2023). Hence, we analyzed efficacy outcomes in ARGO according to key patient baseline characteristics.

Methods: ARGO (NCT05640245) was a global, randomized, prospective, double-blind Phase 2 trial of SLK in patients with active PsA that comprised a 12-week PBO-controlled phase followed by a further 12-week active-treatment phase. Three SLK doses were assessed: 60mg no induction (NI), SLK 60mg WI, or SLK 120mg WI (induction doses at W0, 2, 4, and 6). We report efficacy outcomes at W24 for patients assigned to the SLK arms throughout the study. *Post hoc* analyses were conducted to assess efficacy outcomes according to key baseline characteristics. For these analyses, data were pooled from all three SLK dose arms to maximize patient numbers.

Results: 207 patients were randomized; 49% female, 17% with weight ≥100 kg, 71% with concomitant MTX use, 17% with PASI ≥10, and 68% with DAPSA score >28 (**Table**). By W24, 58.1–61.0% of patients randomized to the SLK arms achieved the primary endpoint of ACR50, with robust achievement irrespective of sex, weight, concomitant MTX use, baseline PASI (≥10 vs. < 10), or DAPSA (>28 vs. ≤28) score (**Figure**). The higher threshold of ACR70 was achieved by 39.0–41.9% of patients randomized to the SLK arms, with robust ACR70 responses observed across key patient subgroups, including female patients, patients with weight ≥100 kg, no concomitant MTX use, baseline PASI ≥10, and baseline DAPSA score >28 (**Figure**). Overall, 68.8–80.8% of patients randomized to the SLK arms achieved PASI 90 at W24, and 59.4–63.0% of patients achieved PASI 100. High levels of PASI response were observed across different subgroups, including patients with moderate-to-severe psoriasis at baseline. Overall, 46.3–61.0% of patients randomized to the SLK arms achieved MDA, with robust achievement across key subgroups, as well as in ≥40% of patients with PASI ≥10 or DAPSA score >28 at baseline (**Figure**). Sonelokimab was well tolerated, with a safety profile consistent with IL-17 inhibition.

Conclusion: Robust efficacy with SLK was observed irrespective of key baseline clinical characteristics in ARGO, including for populations in which disparate outcomes of treatment have been reported, such as female patients. Ongoing Phase 3 studies (IZAR-1: NCT06641076; IZAR-2: NCT06641089) will further evaluate SLK 60mg and 120mg in active PsA.

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated clinical efficacy and safety to 3 years (yrs) in patients (pts) with PsA.[1,2] Given PsA is a chronic inflammatory condition with a heterogenous clinical presentation,[3] it is critical to understand how varying baseline (BL) demographics, disease characteristics, and comorbidities influence treatment efficacy. Here, we assess the impact of BL characteristics on the efficacy of BKZ in pts with PsA at Week (Wk) 16 vs placebo (PBO), and longer-term to 1 yr.

Methods: Pooled post hoc analysis of data from BE OPTIMAL (NCT03895203; biologic DMARD [bDMARD]-naïve) and BE COMPLETE (NCT03896581; TNF inhibitor inadequate response/intolerance [TNFi-IR]). Both studies assessed subcutaneous BKZ 160 mg every 4 wks in pts with PsA and were PBO-controlled to Wk 16, then PBO pts switched to BKZ (PBO/BKZ). BE COMPLETE Wk 16 completers could enter BE VITAL (NCT04009499; open-label extension), in which all pts received BKZ.

TJC (of 68 joints)	17.8 (13.1)	17.4 (12.5)

Randomized set from BE OPTIMAL and BE COMPLETE (including data from BE VITAL). [a] Data were pooled for all PBO/BKZ and BKZ-randomized patients who were bDMARD-naive or TNFi-IR; [b] PBO n=411; BKZ n=689.

bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; BMI: body mass index; hs-CRP: high sensitivity C-reactive protein; PBO: placebo; PsA: psoriatic arthritis; Q4W: every 4 weeks; SD: standard deviation; SJC: swollen joint count; TJC: tender joint count; TNFi: tumor necrosis factor inhibitors; TNFi-IR: prior inadequate response or intolerance to TNFi.

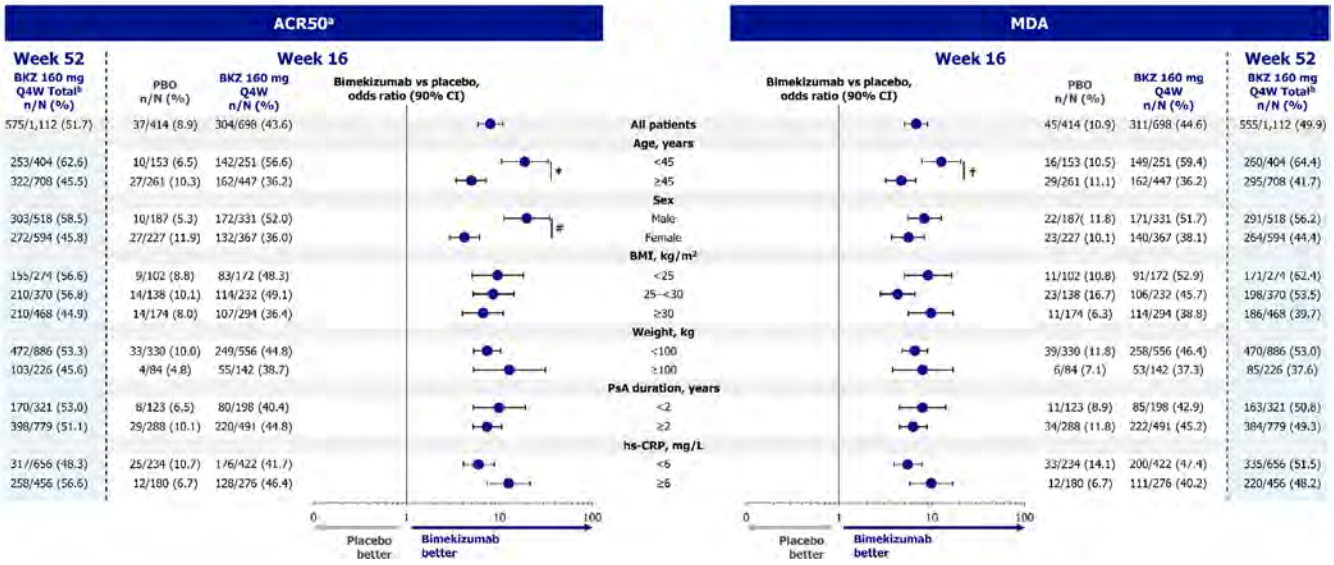

Figure 1. ACR50 and MDA response rates at Week 16 and Week 52 by baseline demographics and disease characteristics (NRI)

Efficacy outcomes are reported by BL pt characteristic subgroups. Efficacy outcomes included ≥50% improvement from BL in ACR response criteria (ACR50), the composite outcome minimal disease activity (MDA), complete resolution of swollen joint count (SJC=0), and 100% improvement from BL in Psoriasis Area and Severity Index (PASI100; in pts with BL psoriasis ≥3% body surface area). Data are reported by randomization group at Wk 16; for the BKZ Total group (PBO/BKZ and BKZ-randomized) at Wk 52. The association of BKZ-treated vs PBO pts achieving Wk 16 response overall and for each subgroup was estimated via odds ratios using logistic regression with factors for treatment, study, region, subgroup, and treatment by subgroup interaction (subgroup and interaction excluded in the overall). All p values are nominal and generated for the treatment by subgroup interaction term; missing data imputed using non-responder imputation.

Results: Of the 1,112 pts randomized to PBO (n=414) or BKZ (n=698), 1,073 (96.5%) completed Wk 16 and 1,002 (90.1%) completed Wk 52. Overall BL demographics and disease characteristics were generally similar across the treatment groups (**Table**).

Randomized set from BE OPTIMAL and BE COMPLETE (including data from BE VITAL). At Week 16, data were pooled for all PBO-randomized patients or all BKZ-randomized patients who were bDMARD-naive or TNFi-IR. At Week 52, data were pooled for patients in the BKZ Total group who were bDMARD-naive or TNFi-IR. *Indicates significance of treatment by subgroup interaction, p=0.035. P values are generated for the treatment by subgroup interaction term from the logistic regression model. A significant p value for the interaction term suggests that the effect of treatment on the outcome differs across the subgroups. [a] SJC=0 is assessed in 66 joints; [b] BKZ Total group includes BKZ-randomized patients and PBO patients that switched to BKZ at Week 16; [c] In patients with psoriasis affecting ≥3% BSA at baseline; PBO n=228, BKZ n=393, BKZ Total n=621.

bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; BSA: body surface area; BMI: body mass index; CI: confidence interval; hs-CRP: high sensitivity C-reactive protein; NE: not evaluable; NRI: non-responder imputation; OR: odds ratio; PASI100: 100% improvement from baseline in Psoriasis Area and Severity Index; PBO: placebo; PsA: psoriatic arthritis; Q4W: every four weeks; SJC: swollen joint count; TNFi-IR: prior inadequate response or intolerance to tumor necrosis factor inhibitors.

Figure 2. SJC=0 and PASI100 response rates at Week 16 and Week 52 by baseline demographics and disease characteristics (NRI)

Achievement of ACR50, MDA, SJC=0, and PASI100 responses were greater with BKZ vs PBO within all pt subgroups at Wk 16, with consistent efficacy responses with BKZ treatment for most pt subgroups. Younger pts (< 45 yrs) treated with BKZ were significantly more likely than older pts (≥45 yrs) to achieve ACR50 (p=0.001), MDA (p=0.006), and SJC=0 (p=0.035) at WK 16. Males were significantly more likely than females to attain ACR50 (p< 0.001). Improved efficacy responses with BKZ treatment were sustained or increased from Wk 16 to Wk 52 across all subgroups (**Figure 1–2**).

Conclusion: BKZ demonstrated durable and greater improvements in clinical joint, skin, and composite outcomes measures vs PBO at Wk 16, which were sustained to 1 yr, regardless of pt demographics and clinical presentation at BL.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The inhibitory effect of TNF inhibitor (TNFi) treatment on spinal radiographic progression in patients with radiographic Axial Spondyloarthritis (r-axSpA), remains controversial. However, current evidence suggests that TNFi treatment seems to stabilize the structural damage of hip arthritis in these patients[1]. The aim of this studyis to investigate whether the addition of an NSAIDS to TNFi therapy in patients with r-axSpA, might have a better inhibitory effect on radiographic progression in the spine and hip, compared to TNFi therapy alone.

Methods: 262 patients with r-axSpA [189 men; age: 44±12years, disease duration: 7.3 years (IQR:2;15)] were included. Radiographs of spine and pelvis, obtained at baseline (i.e., before TNFi initiation), compared retrospectively to those obtained after 2.5±0.7 and 7±2.3 years of TNFi combined, or not with NSAIDs. Spinal X-rays were scored by mSASSS. Both hips were scored by BASRI-hip score and mean joint space width (MJSW)[1]. The spinal radiographic progression was assessed as the formation of new syndesmophytes (at corners with at least 1 at baseline) or ΔmSASSS-score/year ≥1 unit/year. Hip involvement was assessed radiographically as mean baseline BASRI-hip score ≥2. The significance of changes was tested by mixed linear models for longitudinal data.

Results: Combination therapy with TNFi and NSAIDs received 100/262 (38%) patients. Indeed, more females (52/73, 71%) than males (110/189, 58%), (p=0.052) were under concomitant NSAIDs. New syndesmophytes occurred in 58% of patients in TNFi monotherapy vs. 36% of those in concomitant NSAIDs (p=0.001). Moreover, the

ΔmSASSS-score/year was significantly higher in patients receiving only TNFi [0.7 (IQR:0.1;1.50], compared to those under combination therapy [0.1 (IQR:0;0.7], (p=0.0009).The mSASSS increased significantly both after 2.5±0.7 and 7±2.3 years of TNFi treatment. Nevertheless, the concomitant NSAIDs intake correlated negatively with the mSASSS (table 1). In patients with hip involvement at baseline, BASRI-hip score and MJSW did not change significantly during follow up (table 2). In those without baseline hip involvement, the BASRI-hip score remained unchanged after 2.5±0.7 years, but increased significantly compared to the baseline score after 7±2.3 years. The latter increase could be attributed to aging (b=0.007, CI:0.0006;0.01). In contrast, the MJSW did not change significantly during follow up (table 3). The NSAIDs co-administration had no effect on the evolution of both MJSW and BASRI-hip scores, irrespective of the baseline structural damage level (table 2 and 3).

Abstract Number: 2360

Treatment adherence in ankylosing spondylitis: A comparison of TNFi, IL-17i, and JAKi using real-world data

Marina Magrey[1] and Jennifer Murphy[2], [1]Case Western Reserve University School of Medicine/University Hospitals Cleveland, Richfield, OH, [2]University Hospitals, Cleveland Medical Center, cleveland, OH

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Treatment adherence is essential for achieving sustained disease control and improving outcomes in patients with ankylosing spondylitis (AS). This study aimed to evaluate real-world drug survival and treatment adherence among patients with AS treated with tumor necrosis factor inhibitors (TNFi), interleukin-17 inhibitors (IL-17i), or Janus kinase inhibitors (JAKi).

Methods: We conducted a retrospective cohort study using a de-identified, federated electronic health record database (TriNetX Research Network, Cambridge, MA; Date of access: May 28, 2024), which includes data from 89 healthcare organizations and over 125 million patients.

Table 1. Baseline characteristics between therapeutic class cohorts, before and after propensity score matching for demographics and comorbidities. Separate propensity score models were conducted to compare TNFi vs. IL-17i and TNFi vs. JAKi.

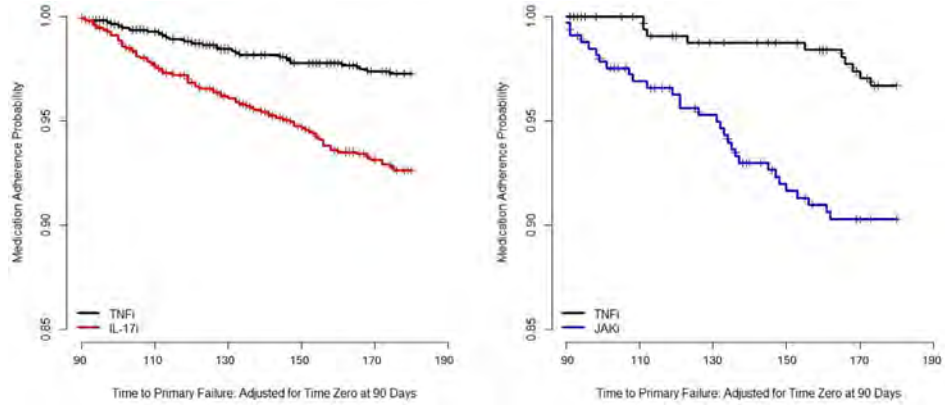

Figure 1. Kaplan-Meier survival curve for medication adherence probability 90-180 days following initial prescription date by TNFi vs. IL-17i (left panel) and TNFi vs. JAKi (right panel), after propensity score matching for demographics and comorbidities.

We included adult patients (≥18 years old) with a diagnosis of AS; ICD-10: M45.9) between 2004 and 2024 who were initially treated with a tumor necrosis factor inhibitor (TNFi), interleukin-17 inhibitor (IL-17i), or Janus kinase inhibitor (JAKi) for at least 90 days following their AS diagnosis. Patients receiving combination therapy (i.e., multiple medication classes initiated on the same day) or who did not meet the 90-day treatment duration threshold were excluded. The primary outcome was medication non-adherence, defined as a switch to a different medication class within 180 days of the initial prescription date.

To address baseline differences across treatment groups, we performed 1:1 greedy nearest-neighbor propensity score matching with a caliper = 0.1, conducted separately for the TNFi vs. IL-17i and TNFi vs. JAKi comparisons. Matching covariates included age at index, race, ethnicity, and additional comorbidities (see Table 1). Logistic regression models were used to assess the association between therapeutic class and non-adherence, with results presented as odds ratios (ORs) and 95% confidence intervals (CIs). Time to treatment withdrawal (TPTW) was evaluated using Cox proportional hazards regression, with results presented as hazard ratios (HR) and 95% confidence intervals. The results were visualized using Kaplan-Meier Curves. Results are reported both before and after propensity score matching.

Results: The study included patients with AS, 12,180 were initiated on TNFi, 1,211 on IL-17i, and 327 on JAKi. After propensity matching for age, sex, race, ethnicity and co-morbidities, the groups were well balanced (Table 1). Non-adherence risk was seen in 2.6% on TNFi compared to 7.1% on IL-17i and 3.1% on TNFi compared to 9.2% on JAKi. Non-adherence odds were significantly higher in patients initially prescribed IL-17i before and after matching (OR= 2.85, 95% CI:1.87, 4.4.47) than in patients started on TNFi. Similarly, the odds of non-adherence were higher in patients with JAKi before and after matching (OR=3.20, 95% CI: 1.59, 7.00) than in patients on anti-TNF (Table 2). Kaplan-Meier analysis (Figure 1) demonstrated higher treatment adherence and drug survival among TNFi users, compared to both IL-17i and JAKi (Figure 1).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In this large real-world cohort of AS patients, initial treatment with TNFi was associated with significantly better adherence and drug survival compared to IL-17i and JAKi therapies. These findings may inform therapeutic decision-making and highlight the importance of initial treatment choice in AS management.

Secondary Outcomes from a Series of N-of-1 NSAID Trials in Axial Spondyloarthritis: Functional, Quality-of-Life, and Safety Results from a Bayesian Analysis

Mark Hwang[1], Seokhun Kim[2], Shervin Assassi[3], Joyce Samuel[1], Charles Green[1], Jon Tyson[2] and John Reveille[4], [1]UTHealth Houston, Houston, TX, [2]UTHealth Houston, Houston, [3]Division of Rheumatology, UTHealth Houston, Houston, Texas, USA, Houston, TX, [4]Department of Medicine, University of Texas Medical Center, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: We previously reported primary outcomes from a Bayesian series of N-of-1 trials comparing celecoxib, meloxicam, and naproxen in axial spondyloarthritis (axSpA), demonstrating improved ASDAS disease activity with individualized NSAID selection. Here, we present secondary outcomes evaluating function, quality of life, and safety, hypothesizing that the preferred NSAID would also yield superior patient-reported and disease-specific outcomes compared to eliminated NSAIDs.

Methods: This single-center, double-blind, randomized N-of-1 trial enrolled adults with active axSpA (ASDAS ≥2.1). Participants completed two treatment cycles in random sequence, receiving each of three NSAIDs for four weeks. Of 42 enrolled, 30 completed the full trial series and were included in the secondary analysis. Prespecified secondary outcomes included BASDAI, BASFI, BASMI, CRP, Maastricht enthesitis score (MASES), VAS Pain, VAS Global, Standard Gamble (SG), and PROPr utility scores. Bayesian multilevel models estimated both average NSAID-specific effects and within-patient

Table 1. Secondary Outcomes from the series of N-of-1 trials (n=30)

comparisons between preferred and eliminated NSAIDs. Posterior probabilities of benefit (PPB) were calculated to assess clinical meaningfulness.

Results: The preferred NSAID was associated with substantial improvements across multiple domains. Mean differences (preferred minus eliminated) included: BASDAI 1.39 (95% credible interval [CrI]: 0.99–1.78; PPB >0.99), BASFI 0.86 (95% CrI: 0.44–1.28; PPB >0.99), BASMI 0.27 (95% CrI: 0.09–0.45; PPB >0.99), and MASES 0.65 (95% CrI: 0.05–1.24; PPB = 0.98). Smaller differences were observed for VAS Pain (1.24; CrI: –0.69 to 3.19; PPB = 0.89) and VAS Global (1.13; CrI: –0.82 to 3.06; PPB = 0.87). Utility improved with PROPr (–0.05; CrI: –0.09 to 0.00; PPB = 0.98), though SG showed non-significant trends. Adverse events were infrequent and mild across all NSAIDs, with only one serious adverse event (diarrhea) reported (Table 2). Average differences between NSAIDs across all patients were smaller and less consistent (Table 3).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Bayesian N-of-1 trials not only individualized NSAID selection in axSpA but also identified clinically meaningful improvements in function, pain, and quality of life with preferred medications. These findings support the broader utility of this personalized approach beyond disease activity metrics, offering a feasible strategy to optimize treatment in axSpA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Risankizumab (RZB), an anti-interleukin 23p19 monoclonal antibody, is approved for the treatment of adults with active PsA. We report the efficacy and safety of RZB in patients with active PsA through week 244 of the KEEPsAKE 1 trial.

Methods: The ongoing, global, phase 3 KEEPsAKE 1 trial evaluates RZB for patients with moderately to severely active PsA (NCT03675308). Eligible patients were aged ≥ 18 years, naïve to biologic therapy, and demonstrated an inadequate response, intolerance, or contraindication to ≥ 1 conventional synthetic DMARD (csDMARD-IR). After a 24-week double-

ACR, American College of Rheumatology score; ACR20/50/70, ≥ 20%/≥ 50%/≥ 70% improvement in American College of Rheumatology score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue Questionnaire; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; LS, least squares; MDA, minimal disease activity; mNAPSI, modified Nail Psoriasis Severity Index; PASI 90, ≥ 90% improvement from baseline in Psoriasis Area and Severity Index; PBO, placebo; PGA-F, Physician's Global Assessment of Fingernail Psoriasis; PsA-mTSS, Psoriatic Arthritis modified Total Sharp Score; RZB, risankizumab; SF-36 PCS, 36-Item Short Form Health Survey Physical Component Summary.

[a]Results are based on as observed data with missing data imputed as nonresponse except for those missing due to COVID-19 or geopolitical conflict, which were imputed by multiple imputation (NRI-MI).

[b]Reported for patients psoriasis affecting ≥ 3% of body surface area at baseline.

[c]Results are based on mixed effect model repeated measurement; data as observed are included in the model.

[d]Reported for patients with nail psoriasis at baseline.

[e]Defined as LEI = 0; reported for patients with LEI > 0 at baseline.

[f]Defined as LDI = 0; reported for patients with LDI > 0 at baseline.

[g]Defined as PsA-mTSS change from baseline ≤ 0.

[h]Results are based on as observed data.

[i]Reported for patients with axial spondylitis at baseline.

[j]Modified BASDAI consists of BASDAI without the question related to peripheral joint pain/swelling.

All deaths	1 (0.4)	0	12 (0.3)[c]

MACE, major adverse cardiovascular event; MI, myocardial infarction; NMSC, nonmelanoma skin cancer; PBO, placebo; PY, patient-years; RZB, risankizumab; TEAE, treatment-emergent adverse events.

Any RZB 150 mg includes all patients who received RZB 150 mg during the study, regardless of whether they started on RZB at randomization or switched from PBO to RZB.

Treatment-emergent is defined as onset on or after the first dose and up to 140 days after the last dose of RZB.

[a]Data have been previously reported in Kristensen, et. al. *Ann Rheum Dis*. 2022;81(2):225–31.

[c]There were 11 treatment-emergent deaths: 2 related to COVID-19; 1 due to complications of acute leukemia; 1 due to dyspnea; 1 due to multiorgan failure as a complication from anastomosis surgery; 1 patient was hospitalized for pneumonia, developed urosepsis and died from related complications; 1 patient was hospitalized for anxiety and depression, developed septicemia, and died from unknown causes a week later; 4 due to of unknown causes; and 1 patient died due to cardiorespiratory arrest on day 363 (166 days after the last dose; nontreatment emergent).

blind treatment period where patients were randomized to subcutaneous (SC) RZB 150 mg or PBO patients receive open-label SC RZB 150 mg every 12 weeks in an extension period. Efficacy outcomes at week 244 and treatment-emergent adverse events (TEAEs) through data cutoff for all randomized patients who received ≥ 1 dose of study drug are reported.

Results: Of 964 randomized patients, 939 (97.4%) entered the extension period and 714 were actively enrolled at the data cutoff date. At week 244, 36.2% of patients receiving continuous RZB 150 mg (RZB) and 38.0% of patients who switched from PBO to RZB 150 mg (PBO/RZB) achieved ACR50 (**Figure 1**). Rates of achieving minimal disease activity were 33.7% with RZB and 34.7% with PBO/RZB. In patients with psoriasis affecting ≥ 3% of their body surface area at baseline, a ≥ 90% improvement from baseline in the Psoriasis Area and Severity Index was achieved by 64.5% of patients with RZB and 59.9% of patients with PBO/RZB (**Table 1**). In patients with nail psoriasis at baseline, the modified Nail Psoriasis Severity Index and the Physician's Global Assessment of Fingernail Psoriasis scores least squares (LS) mean improvements from baseline were 14.7 points and 1.6 points with RZB and 14.7 points and 1.5 points with PBO/RZB, respectively. In patients with enthesitis at baseline, resolution was achieved by 59.9% with RZB and 60.7% with PBO/RZB. For patients with dactylitis at baseline, 73.6% in the RZB group and 72.8% in the PBO/RZB group achieved resolution. The LS mean change from baseline in Psoriatic Arthritis modified Total Sharp Score (PSA-mTSS) was 0.9 with RZB and 2.1 with PBO/RZB; 88.4% of patients receiving RZB and 80.7% of patients receiving PBO/RZB showed no radiographic progression (PSA-mTSS change from baseline ≤ 0). In patients with axial spondylitis at baseline, the LS mean change from baseline in the modified Bath Ankylosing Spondylitis Disease Activity Index was –2.2 with RZB and –2.4 with PBO/RZB. Patient-reported measures of quality

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

of life and fatigue maintained improvements from baseline. Rates of TEAEs (119.0 events/100 person-years [E/100PY]), serious TEAEs (7.6 E/100PY), and TEAEs leading to discontinuation of study drug (1.8 E/100PY) remained stable and were comparable to rates in the double-blind period (**Table 2**).

Conclusion: The 244-week results of the ongoing KEEPsAKE 1 trial demonstrate the durable efficacy of RZB 150 mg in treating clinical manifestations of PsA, sustaining bone structure, and improving quality of life for patients with PsA who are csDMARD-IR. RZB continues to be well tolerated, with no new safety signals identified.

Background/Purpose: Patients with psoriatic arthritis (PsA) are at increased risk for major adverse cardiovascular events (MACE) and venous thromboembolism (VTE), yet the comparative safety of biologic therapies remains poorly defined. This study aimed to compare the risk of MACE and VTE among users of IL-17, IL-12/23, and IL-23 inhibitors, with anti-TNF agents serving as the reference group.

Methods: We conducted a retrospective cohort study using the TriNetX Research Network, a de-identified, federated electronic health record database (accessed May 28, 2024). Adults (≥18 years) diagnosed with PsA (ICD-10: L40.5) between 2004 and 2024 on at least one biologic agent including anti-TNF, anti-IL-17, IL-23 or IL-12/23 were included. Eligible patients had at least one year of follow-up. Exclusion criteria included: use of multiple biologic agents from different drug classes, known hypercoagulable state, pregnancy and malignancy (prostate, lung, colon, bladder, kidney, lymphoma, leukemia, endometrial, ovarian, stomach, and pancreatic). Primary outcomes were new onset myocardial infarction (MI), stroke (ischemic and hemorrhagic), deep vein thrombosis (DVT), and pulmonary embolism (PE). Patients with prior history of these outcomes were excluded from analyses.

To address baseline differences across treatment groups, we conducted weighted logistic regression using inverse probability of treatment weighting (IPTW) based on the average treatment effect (ATE) and a threshold of < 0.1. Propensity scores were estimated using covariates listed in Table 1. These weights were then applied in logistic regression models to assess

Table 1. Baseline characteristics across biologic therapy classes, with standardized mean differences (SMD) shown before and after inverse probability of treatment weighting (IPTW) adjusted by the average treatment effect (ATE).

Baseline Characteristics	Overall N = 28,973[1]	Anti-TNF N = 21,589[1]	IL 12/23 N = 1,405[1]	IL-17 N = 4,697[1]	IL-23 N = 1,282[1]	Unadjusted Max SMD[3]	Adjusted Max SMD[3]

the association between biologic therapy and the primary outcomes. Results are presented as odds ratios with 95% confidence intervals, and findings from both unweighted and weighted models are reported.

Results: A total of 28,973 patients with PsA treated with biologic agents were included in the study. The majority received anti-TNF therapy, followed by IL-17 inhibitors, IL-12/23 inhibitors, and IL-23 inhibitors (Table 1). Prior to weighting, comorbid conditions varied across groups; however, after IPTW baseline characteristics were well balanced. The mean age was 52.2 years, 56% were female, and common comorbidities included hypertension (31.1%), hyperlipidemia (28.4%), obesity (19.8%), and diabetes (12.2%) (Table 1).

In PsA cohort, IL-17 inhibitor use was associated with significantly reduced odds of DVT (OR 0.58, $p < 0.001$), PE (OR 0.45, $p < 0.001$), MI (OR 0.50, $p < 0.001$), and stroke (OR 0.56, $p < 0.001$). Similarly, IL-23 inhibitor use was associated with lower odds of DVT (OR 0.49, $p = 0.02$), PE (OR 0.12, $p = 0.005$), MI (OR 0.29, $p < 0.001$), and stroke (OR 0.35, $p = 0.002$) compared to anti-TNF agents. In contrast, IL-12/23 inhibitor use was associated with increased odds of stroke (OR 1.41, $p = 0.04$), with no significant differences observed for DVT, PE, or MI (Table 2).

Conclusion: In PsA, IL-17 and IL-23 inhibitors were consistently associated with significantly lower odds of stroke, MI, DVT, and PE compared to anti-TNF agents. In contrast, IL-12/23 inhibitor use was linked to increased odds of stroke and showed no significant protective effect across other outcomes.

Real-World Characteristics and Treatment Patterns of Difficult-to-Treat Psoriatic Arthritis

Milad Heydari-Kamjani[1], Jennifer Murphy[2] and Marina Magrey[3], [1]University Hospitals Cleveland Medical Center/ Case Western Reserve University, Cleveland, OH, [2]University Hospitals, Cleveland Medical Center, cleveland, OH, [3]Case Western Reserve University School of Medicine/University Hospitals Cleveland, Richfield, OH

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous inflammatory disease with variable clinical presentation and treatment response. A subset of PsA patients are difficult to treat (D2T). This study compared baseline characteristics, extra-articular manifestations (EAMs), and comorbid conditions between D2T and non-difficult-to-treat (ND2T) PsA patients.

Methods: We performed a retrospective study using a de-identified federated database with 89 contributing healthcare organizations, including over 125 million patients (TriNetX Research Network, Cambridge, MA; date of data access: Feb 28, 2025). Patients with PsA (ICD-10: L40.59), ≥18 years, and at least one follow-up were included. We identified 7,403 adults with PsA treated with conventional DMARDs (Sulfasalazine, Methotrexate, Leflunomide) and recorded post-treatment CRP levels. There is no consensus for definition of D2T PsA, but we proposed the following: prior cDMARD use, ≥2 biologic/targeted synthetic DMARDs from two different classes and elevated CRP (≥8 mg/L). Demographics, comorbidities, and

Deucravacitinib	3 (0.0%)	10 (0.8%)	<0.001	2 (0.2%)	10 (0.8%)	0.021

EAMs were collected. We performed 1:1 propensity score matching for age, sex, race, and ethnicity. Continuous and categorical variables were analyzed using t-tests and chi-squared tests ($\alpha = 0.05$).

Results: The study included 7,403 patients (6,154 ND2T, 1,249 D2T). After propensity score matching, both groups had 1,248 patients. The D2T cohort had a higher BMI (33.1 vs. 31.7, $p < 0.001$) (Table 1). Comorbidities, including Crohn's disease (3.2% vs. 1.9%, $p = 0.045$) and other psoriasis types (66% vs. 61.5%, $p = 0.02$), were more prevalent in the D2T group.

Table 3: Number of drug classes and total biologic and targeted synthetic used between difficult to treat and not difficult to treat psoriatic arthritis, before and after propensity score matching for demographics (age, sex, race, and ethnicity).

	Before matching		After matching	
	Not difficult to treat N = 6,154[1]	Difficult to treat N = 1,249[1]	Not difficult to treat N = 1,248[1]	Difficult to treat N = 1,248[1]
Number of b/tsDMARDs drug classes				
0	2,481 (40.3%)	0 (0.0%)	450 (36.1%)	0 (0.0%)
1	2,953 (48.0%)	0 (0.0%)	635 (50.9%)	0 (0.0%)
2	492 (8.0%)	764 (61.2%)	112 (9.0%)	763 (61.1%)
3	178 (2.9%)	389 (31.1%)	34 (2.7%)	389 (31.2%)
≥4	50 (0.8%)	96 (7.7%)	17 (1.4%)	96 (7.7%)
Total b/ts DMARDs used after c-DMARD				
0	2,481 (40.3%)	0 (0.0%)	450 (36.1%)	0 (0.0%)
1	2,188 (35.6%)	0 (0.0%)	454 (36.4%)	0 (0.0%)
2	884 (14.4%)	370 (29.6%)	214 (17.1%)	369 (29.6%)
3	343 (5.6%)	350 (28.0%)	73 (5.8%)	350 (28.0%)
≥4	258 (4.2%)	529 (42.4%)	57 (4.6%)	529 (42.4%)

[1]n (%)

D2T patients also had elevated CRP levels (50.4 vs. 28.4 mg/L, $p < 0.001$) and higher HLA-B27 positivity (2.2% vs. 0.8%, $p = 0.005$). Additionally, the D2T group demonstrated significantly greater use of biologic and targeted synthetic DMARDs across all major therapeutic classes (Table 2). TNF inhibitors were used in 88.3% of D2T patients vs. 51.9% of ND2T ($p < 0.001$), with adalimumab most frequently prescribed (55.2% vs. 32.8%, $p < 0.001$). Abatacept was also more common in D2T (15.6% vs. 1.9%, $p < 0.001$). IL-17 inhibitors were more frequent in D2T (86.3% vs. 15.7%, $p < 0.001$), primarily secukinumab (57.6% vs. 9.9%, $p < 0.001$). IL-23 use was higher in D2T (30.1% vs. 5.8%, $p < 0.001$), with guselkumab most used (18.0% vs. 3.6%, $p < 0.001$). IL-12/23 inhibition with ustekinumab was also more common (36.3% vs. 6.6%, $p < 0.001$). JAK inhibitor use was greater in D2T (31.6% vs. 5.9%, $p < 0.001$), mainly tofacitinib (22.7% vs. 4.1%, $p < 0.001$). Though rare overall, TYK2 inhibition with deucravacitinib was more common in D2T (0.8% vs. 0.2%, $p = 0.021$). Nearly half of the D2T group (42.4%) received four or more individual b/tsDMARDs after cDMARDs (Table 3).

Conclusion: Our study showed that in a matched cohort, D2T PsA patients had higher BMI, greater prevalence of Crohn's disease, additional psoriasis types, higher CRP levels, and more HLA-B27 positivity. They also had significantly higher use of biologics and targeted synthetic DMARDs across all major classes.

Figure. GRAPPA individual domain response and change from baseline at Year 1 and Year 3 from BE OPTIMAL, BE COMPLETE, and pooled BE MOBILE 1 and BE MOBILE 2 (MI, mNRI, NRI, OC)

Background/Purpose: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated sustained efficacy to 3 years (yrs) in phase 3 clinical trials of patients (pts) with PsA, psoriasis, or axial spondyloarthritis (axSpA).[1–4] The Group for Research and Assessment of Psoriasis and PsA (GRAPPA)-based treatment recommendations focus on six core domains and the PsA-related conditions uveitis and IBD.[5] Here, long-term BKZ efficacy is shown across GRAPPA domains up to 3 yrs, corresponding to an additional 1 yr of BKZ treatment, from phase 3 trials in PsA and axSpA.

Methods: Included pts were randomized to subcutaneous BKZ 160 mg or placebo (PBO) every 4 weeks (wks; Q4W) in BE OPTIMAL (NCT03895203; biologic DMARD [bDMARD]-naïve pts with PsA), BE COMPLETE (NCT03896581; pts with PsA with inadequate response or intolerance to TNF inhibitors [TNFi-IR]), BE MOBILE 1 (NCT03928704; non-radiographic axSpA) and BE MOBILE 2 (NCT03928743; radiographic axSpA, i.e., AS). From Wk 16, all PBO-randomized pts received BKZ 160 mg Q4W. Wk 52/16 BE OPTIMAL/BE COMPLETE completers were eligible for BE VITAL open-label extension (OLE; NCT04009499); BE MOBILE 1 and 2 Wk 52 completers could enter BE MOVING (OLE; NCT04436640).

Outcomes reported by GRAPPA domain (**Table**) to Yr 3 (Wk 160/156 BE OPTIMAL/BE COMPLETE) in PsA; uveitis and IBD reported to Wk 156 (BE OPTIMAL/BE COMPLETE). We report axial domain outcomes in axSpA to assess BKZ efficacy in axial disease, in accordance with GRAPPA recommendations,[5] to Wk 164 (BE MOBILE 1/2). Missing data imputed using modified non-responder and multiple imputation (mNRI; MI) for binary and continuous outcomes, and reported using observed case (OC).

22265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Wk 160/156/164 completion was similar across all trials (BE OPTIMAL: 546/712 [76.7%], BE COMPLETE: 299/400 [74.8%], BE MOBILE 1: 175/254 [68.9%], BE MOBILE 2: 247/332 [74.4%]). Baseline demographics and disease characteristics were previously reported.[6–8]

For the majority of GRAPPA domains, 1-yr improvements were sustained to 3 yrs across all studies. Individual domain responses were consistent between bDMARD-naïve and TNFi-IR pts (**Figure**). Improvements in axial outcomes were sustained to 3 yrs in BE MOBILE 1 and 2 (**Table, Figure**). Exposure-adjusted incidence rates per 100 pt-yrs for uveitis and definite or probable adjudicated IBD to Wk 156 were 0.2 (95% confidence interval 0.1, 0.6) and 0.3 (0.1, 0.7) in BE OPTIMAL and 0 and 0.1 (0.0, 0.6) in BE COMPLETE, respectively.

Conclusion: BKZ treatment resulted in sustained and consistent improvements across GRAPPA domains from 1 to 3 yrs in both bDMARD-naïve and TNFi-IR pts with PsA, with low rates of IBD and uveitis reported. Results from studies in pts across the full disease spectrum of axSpA further support BKZ efficacy in the axial domain and suggest BKZ efficacy for axial disease in PsA.[8]

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory condition primarily affecting the joints and skin.[1] More severe symptoms are associated with lower health-related quality of life, and many patients (pts) on recommended treatments (txs) achieve suboptimal responses.[2,3] This study evaluated association between degree of joint and/or skin symptom resolution and improvements in patient-reported outcomes (PROs) among pts with PsA who initiated biologic or targeted synthetic (b/ts) DMARDs in the CorEvitas PsA/Spondyloarthritis Registry, a prospective, non-interventional United States research registry.

Methods: Eligible pts had a PsA diagnosis and initiated a b/tsDMARD on or after registry entry (first therapy in Registry) between April 2017–March 2025. Included pts had either body surface area (BSA) affected by psoriasis ≥3% or swollen joint count in 66 joints (SJC) ≥1 at initiation and were tx-persistent at follow-up 6 months (range: 5–9 months) post-initiation. Changes from initiation to follow-up in EuroQoL Visual Analog Scale (EQ-VAS) and pain VAS scores were each fit to linear regression models using BSA and SJC at follow-up as continuous exposure variables with their interaction, and using a categorical variable combining BSA and SJC with 6 levels: BSA=0% and SJC=0; BSA=0% and SJC ≥1; BSA >0% to < 3% and SJC=0; BSA >0% to < 3% and SJC ≥1; BSA ≥3% and SJC=0; BSA ≥3% and SJC ≥1. Results were summarized with counts, means, and standard deviation (SD) for continuous variables, and counts and percentages for categorical variables.

Table 1. Baseline demographic, lifestyle, and disease characteristics among patients with PsA in the CorEvitas PsA/Spondyloarthritis Registry initiating a b/tsDMARD therapy[a]

Characteristic	Total Patients Included (N=994)
Demographic Characteristics	
Age (years), mean (SD) [N]	54.1 (12.8) [994]
Sex (female), n/N (%)	581/991 (58.6)
Race (white), n/N (%)	877/977 (89.8)
Ethnicity (non-Hispanic or Latino), n/N (%)	811/893 (90.8)
Lifestyle Characteristics	
BMI, n/N (%)[b]	
Underweight/Normal (<25 kg/m²)	133/991 (13.4)
Overweight (≥25–<30 kg/m²)	261/991 (26.3)
Obese (≥30 kg/m²)	597/991 (60.2)
Private Insurance Only, n/N (%)	718/993 (72.3)
Full-Time Work Status, n/N (%)	547/992 (55.1)
Current Smoker, n/N (%)	125/987 (12.7)
Disease Characteristics	
Duration of PsA (years), mean (SD) [N]	6.2 (7.8) [990]
Age at PsA Onset (years), mean (SD) [N]	44.1 (14.2) [983]
Family History of PsA, n/N (%)	27/994 (2.7)
Treatment Characteristics	
Current PsA Therapy by MOA, n/N (%)	
TNFi[c]	419/994 (42.2)
IL-17i[d]	312/994 (31.4)
IL-23i[e]	118/994 (11.9)
JAKi[f]	76/994 (7.6)
IL-12/23i[g]	44/994 (4.4)
CD80/86i[h]	25/994 (2.5)
Comorbidities, n/N (%)	
Depression	199/994 (20.0)
Diabetes	167/994 (16.8)
Anxiety	122/994 (12.3)
Malignancies	106/993 (10.7)
Cardiovascular Disease	102/994 (10.3)
Osteoporosis	27/994 (2.7)
IBD	21/994 (2.1)
Uveitis	10/994 (1.0)

[a] Approved bDMARDs: abatacept, adalimumab, bimekizumab, certolizumab pegol, etanercept, golimumab, guselkumab, infliximab, ixekizumab, risankizumab, secukinumab, and ustekinumab; approved tsDMARDs: tofacitinib and upadacitinib; **[b]** CDC BMI categories for adults 20 year of age and older; **[c]** Adalimumab, certolizumab pegol, etanercept, golimumab, and infliximab and its biosimilars; **[d]** Bimekizumab, ixekizumab, and secukinumab; **[e]** Guselkumab and risankizumab; **[f]** Tofacitinib and upadacitinib; **[g]** Ustekinumab; **[h]** Abatacept. b/tsDMARD: biologic or targeted synthetic disease-modifying antirheumatic drug; BMI: body mass index; CD: cluster of differentiation; CDC: Centers for Disease Control and Prevention; i: inhibitor; IBD: inflammatory bowel disease; IL: interleukin; JAK: Janus kinase; MOA: mechanism of action; PsA: psoriatic arthritis; SD: standard deviation; TNF: tumor necrosis factor.

Activity Impairment	43.0 (29.6) [979]	32.3 (28.8) [971]

[a] Follow-up was 6 months (range: 5–9 months) post-initiation. BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BSA: body surface area; cDAPSA: Clinical Disease Activity Index for PsA; EQ-5D-5L: EuroQoL 5-Dimension 5-Level; EQ-VAS: EuroQoL VAS; HAQ-DI: Health Assessment Questionnaire Disability Index; IGA: Investigator Global Assessment; LEI: Leeds Enthesitis Index; mACR50: 50% Improvement in modified American College of Rheumatology response; MDA: minimal disease activity; mPASDAS: modified Psoriatic Disease Activity Score; PGA: Physician Global Assessment; PRO: patient-reported outcome; PsA: psoriatic arthritis; PtGA: Patient Global Assessment; SD: standard deviation; SJC66: swollen joint count in 66 joints; SPARCC: Spondyloarthritis Research Consortium of Canada; TJC68: tender joint count in 68 joints; VAS: Visual Analog Scale; VLDA: very low disease activity; WPAI: Work Productivity and Activity Impairment.

Results: Among 994 enrolled pts, mean age was 54.1 years; 581 (58.6%) were female, and 877 (89.8%) were white (-**Table 1**). At tx initiation, mean (SD) BSA was 7.7% (13.4%) and mean (SD) SJC was 4.3 (6.0). At follow-up, BSA and SJC decreased to 2.4% (5.2%) and 1.9 (3.7), respectively. Mean EQ-VAS increased 5.0 points and pain decreased 12.9 points from initiation (**Table 2**). Compared with pts achieving optimal response at follow-up (235 [25.2%]; BSA=0% and SJC=0), pts who did not achieve optimal response had improvements in EQ-VAS with deficits ranging from −1.0 (BSA >0% to < 3% and SJC=0) to −8.4 (BSA ≥3% and SJC ≥1) and improvements in pain VAS with deficits ranging from −10.2 (BSA >0% to < 3% and SJC ≥1) to −15.8 (BSA ≥3% and SJC ≥1). Pts with BSA >0% to < 3% and SJC=0 at follow-up had minimal deficit in pain VAS improvement (**Figure 1**). Using continuous BSA and SJC, pts who had joint resolution without skin clearance, or had skin clearance without joint resolution, had deficits in EQ-VAS and pain VAS improvement compared with pts who achieved both at follow-up.

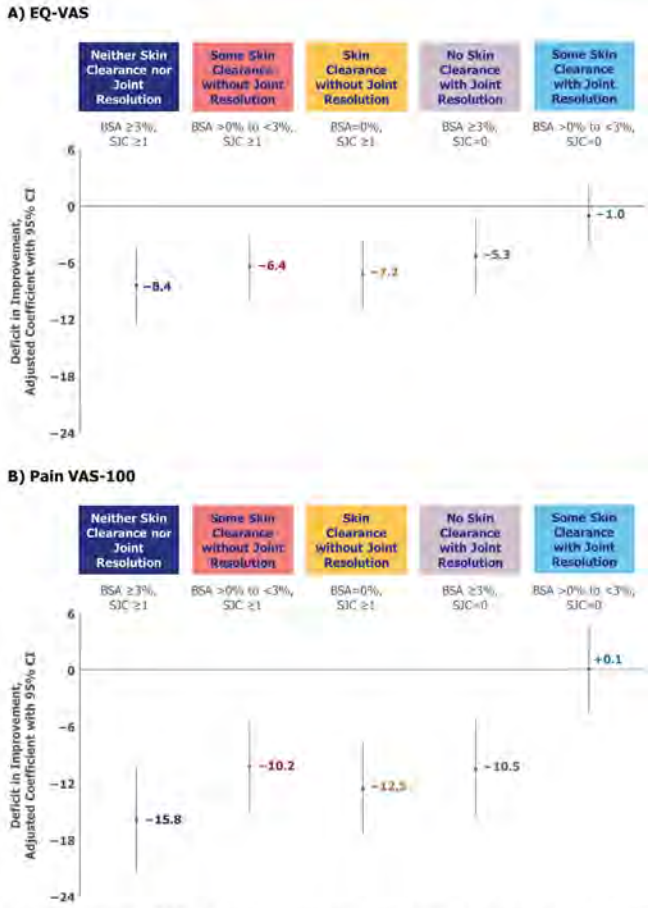
Figure 1. Deficits in (A) EQ-VAS and (B) Pain VAS-100 improvement compared with patients who achieved optimal response[a] stratified by combined BSA and SJC categorical exposure variable



Negative values indicate a deficit in improvement compared with patients who achieved optimal response. P values for all categorical exposure variable coefficients in the linear regression models were <0.001 with the exceptions of change in EQ-VAS in BSA >0% to <3% and SJC=0 (p=0.562), change in EQ-VAS in BSA ≥3% and SJC=0 (p=0.010), and change in pain VAS in BSA >0% to <3% and SJC=0 (p=0.963). Values were adjusted for covariates. Covariates included in the model for change in EQ-VAS were age, BSA and SJC at biologic initiation and at follow-up 6 months post-initiation, fatigue, stiffness severity, EQ-VAS, PtGA of Arthritis and Psoriasis, and current use of opioids. Covariates included in the model for change in pain VAS-100 were PGA of Arthritis and Psoriasis, BSA and SJC at biologic initiation and at follow-up 6 months post-initiation, pain, fatigue, spine pain, WPAI, current employed status, prior use of b/tsDMARDs, current use of NSAIDs, and current use of opioids. **[a]** Optimal response was defined as BSA=0 and SJC=0. BSA: body surface area; b/tsDMARD: biologic or targeted synthetic disease-modifying antirheumatic drug; CI: confidence interval; EQ-VAS: EuroQoL VAS; NSAID: nonsteroidal anti-inflammatory drug; PGA: Physician Global Assessment; PtGA: Patient Global Assessment; SJC: swollen joint count in 66 joints; VAS: Visual Analog Scale; WPAI: Work Productivity and Activity Impairment.

Conclusion: In this real-world cohort, optimal achievement of both joint resolution and skin clearance remained low 6 months after b/tsDMARD initiation and was associated with greater improvements in PROs compared with achieving only joint resolution, only skin clearance, or neither. These results highlight the importance of complete skin and joint symptom control for pts with PsA compared with focusing on either aspect alone.

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Axial involvement is a clinically relevant manifestation of psoriatic arthritis (PsA) that can influence management strategies. Evidence on the real-world effectiveness of advanced therapies, in particular, interleukin-23's (IL-23), on axial symptoms in PsA is scarce. This study aimed to evaluate the real-world effectiveness of risankizumab (RZB) on axial symptoms in routine clinical practice among biologic-naïve (bDMARD) patients with PsA across the United States (US) and Europe.

Methods: In this retrospective analysis (June 2023 to June 2024) using data from the Adelphi Spondyloarthritis VI Disease Specific Programme™, biologic-naïve patients with PsA receiving RZB 150 mg were included from the US and Europe (France, Germany, Italy, Spain, and the United Kingdom). The analysis was based on cross-sectional questionnaires completed by physicians and their consulting patients during their most recent visits. Effectiveness assessments of axial symptoms at treatment initiation and the most recent patient visit included change in the proportion of patients with physician-reported inflammatory back pain (IBP) or spinal pain, morning stiffness, pain on movement, pain at rest, nocturnal pain, persistent lower back pain, pain associated with morning stiffness, sleep disturbance, and sacroiliitis (either by X-ray or MRI). These outcome assessments were compared using McNemar tests ($P < .05$). Outcomes were evaluated in bDMARD-naïve ± conventional synthetic (cs)DMARD patients with PsA (overall patient population) and in bDMARD-naïve patients with an inadequate response (IR) to ≥ 1 csDMARD (csDMARD-IR/bDMARD-naïve).

Results: A total of 162 patients who initiated treatment with RZB were included in the analysis, with 62 (38%) from the US and 100 (62%) from Europe (**Table 1**). Patients were on average 44.8 years old at the time of data collection, 42% were female, 73% managed by rheumatologists, and body surface area (BSA) affected by psoriasis was 13.7% at treatment initiation. The mean duration of RZB treatment was 9.8 months, and the mean TJC68 and SJC66 at treatment initiation were 5.5 and 3.4, respectively. The csDMARD-IR/bDMARD-naïve subgroup comprised 96 patients with a mean age of 43.8, BSA of 16.4%, and mean TJC68 and SJC66 at treatment initiation of 5.1 and 2.5, respectively. The prevalence of IBP at treatment initiation was 28% in the overall group and 34% in the csDMARD-IR/bDMARD-naïve subgroup. Overall, the presence of all axial symptoms significantly decreased from treatment initiation to the most recent visit (all comparisons, $P < .001$) (**-Figure 1**). Significant improvements in axial symptoms were observed in the overall population and the csDMARD-IR/bDMARD-naïve subgroup (**Figure 1**).

Mean (SD)	5.5 (7.4)	5.1 (7.2)
SJC at initiation	n=162	n=96
Mean (SD)	3.4 (5.6)	2.5 (5.2)
Concurrent medication use	n=162	n=96
csDMARDs	25 (15%)	25 (26%)
NSAIDs	11 (7%)	10 (10%)

Figure 1. Proportion of Patients with Presence of Axial Symptoms at Treatment Initiation and Most Recent Patient Visit

Note: Mean time between treatment initiation and most recent patient visit was 9.8 months for bDMARD-naïve patients and csDMARD-IR/bDMARD-naïve patients.

Conclusion: In real-world clinical settings, biologic-naïve patients with PsA who initiated RZB treatment demonstrated significant improvements in axial symptoms, highlighting effectiveness of RZB in managing a key manifestation of PsA.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

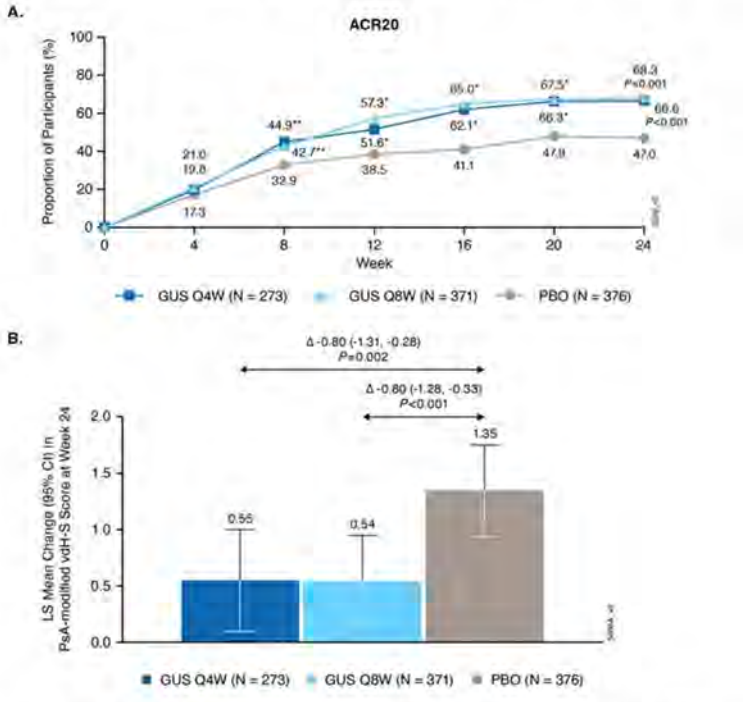
Session Time: 10:30AM–12:30PM

Background/Purpose: Patients with active psoriatic arthritis (PsA) are at risk of irreversible joint damage that may significantly impact quality of life. Guselkumab (GUS), a fully human monoclonal antibody that selectively targets IL-23p19 subunit and shows enhanced potency for inhibiting IL-23 signaling, has demonstrated efficacy and a favorable safety profile in patients with active PsA. The study reported findings through Week (W)24 of the ongoing phase 3b, randomized, double-blind, placebo (PBO)-controlled APEX study (NCT04882098), aimed at further evaluating GUS effects on clinical and radiographic outcomes in participants (pts) with active PsA.

Methods: APEX enrolled biologic-naïve adults with active PsA (≥3 tender and ≥3 swollen joints; C-reactive protein ≥0.3 mg/dL) and ≥2 joints with erosions on radiographs of hands and feet, despite previous non-biologic DMARDs, apremilast, or NSAIDs. Pts were randomized 5:7:7 to subcutaneous GUS 100mg Q4W; GUS 100mg at W0, W4, then Q8W; or PBO Q4W. The primary and major secondary endpoints were: 1) proportion of pts achieving ≥20% improvement in ACR response criteria (ACR20); 2) mean change from baseline (BL) in PsA-modified van der Heijde-Sharp (vdH-S) score (average of 2 readers blinded to chronological order), respectively, at W24 (both multiplicity-controlled for each GUS regimen vs PBO). Efficacy analyses include all randomized pts except those from Ukrainian sites unable to support key study operations (modified full analysis set [mFAS], N=1020); safety analyses include all pts who received ≥1 dose of study treatment through W24 (N=1054).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Fig 1. Proportions of pts (mFAS) achieving ACR20 over time through W24 (A) and LS mean change from baseline to W24 in PsA-modified vdH-S score (Reading Session 1; B)



* nominal $P \leq 0.001$; ** nominal $P < 0.01$. P-values at W24 are multiplicity controlled using a fixed sequence testing procedure. For ACR20, p-values for W4-W20 are not multiplicity controlled, are considered nominal, and may not be used to claim statistical significance. For ACR20, p-values are based on CMH test. Participants were considered nonresponders if they discontinued study treatment for any reason other than ND/MD, initiation or increase in dose of csDMARD or oral corticosteroid, or initiation of protocol-prohibited PsA therapies. Missing data due to ND/MD, as well as data impacted by ND/MD, were imputed using multiple imputation. Other missing data were imputed using NRI. PsA-modified vdH-S score was an average of scores from two readers who were blinded to treatment and radiographic sequence. For PsA-modified vdH-S score at W24, statistics are based on ANCOVA. For PsA-modified vdH-S score at W24, missing data and data impacted by ND/MD were imputed using multiple imputation.

ACR20, ≥20% improvement in American College of Rheumatology response criteria; ANCOVA, Analysis of Covariance; CMH, Cochran Mantel Haenszel; csDMARD, conventional synthetic disease-modifying antirheumatic drugs; GUS, guselkumab; LS, least squares; ND/MD, natural disaster/major disruption; NRI, nonresponder imputation; PBO, placebo; PsA, psoriatic arthritis; Q8W, every 8 weeks; Q4W, every 4 weeks; vdH-S, van der Heijde-Sharp; W, week.

Results: In mFAS (Q4W: 273, Q8W: 371, PBO: 376 pts), BL characteristics were generally balanced across treatment groups. The mean age was 53 yrs; 55% of pts were male. At BL, mean duration of PsA (7.3 yrs), PsA-modified vdH-S total (27.0) and erosion (13.5) scores, and tender (20.7) and swollen (11.9) joint counts indicated established and highly active joint disease. The primary and major secondary endpoints were met. Significantly greater proportions of GUS Q4W (67%) and Q8W (68%) vs PBO (47%) pts achieved ACR20 response at W24 ($P < 0.001$; **Fig 1A**). Pts receiving GUS Q4W and Q8W exhibited significantly less radiographic progression vs PBO at W24 (least squares mean changes in PsA-modified vdH-S score of 0.55 and 0.54 vs 1.35; $P=0.002$ and < 0.001, respectively; **Fig 1B**). Similar response patterns were seen for changes in joint space narrowing and erosion scores, proportions of pts with no radiographic progression, and additional clinical efficacy outcomes at W24 (**Table 1**).

Through W24, AEs occurred in 38%, 42%, and 37% of pts (most commonly respiratory infections, headache, diarrhea, and psoriatic arthropathy), and serious AEs occurred in 2%, 3%, and 3% of pts, in GUS Q4W, GUS Q8W, and PBO groups, respectively. No new safety signals were identified.

Conclusion: APEX is the first study to show significant inhibition of structural progression with both Q4W and Q8W of GUS, a dual-acting selective IL-23i. The GUS safety profile in these biologic-naïve pts with active PsA is consistent with that previously established for GUS across a broad range of pts with PsA, psoriasis, and/or inflammatory bowel disease.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Prior research reported that patients (pts) with psoriatic arthritis (PsA) treated with guselkumab (GUS) were 1.5x more likely to remain persistent with on-label treatment (tx) at 24 months (mo) vs those treated with subcutaneous (SC) interleukin-17A inhibitors (IL-17Ai; secukinumab or ixekizumab; Mease et al., CCR West 2024). However, there is a need for long-term real-world evidence comparing on-label tx persistence among biologic-naïve and biologic-experienced pts with active PsA initiating GUS vs SC IL-17Ai.

Methods: Adults with active PsA and ≥1 claim for GUS or SC IL-17Ai were selected from the IQVIA PharMetrics® Plus database (1/1/2011–6/30/2023; first claim = index date) to compare tx persistence among biologic-naïve and biologic-experienced pts. Pts were classified as biologic-experienced if they had ≥1 claim for PsA-indicated biologic DMARD (bDMARD) during the period of continuous insurance eligibility prior to the index date, and biologic-naïve otherwise. Pts had ≥12 mo of continuous insurance eligibility and no claims for confounding diseases/study medications prior to index date. On-label persistence was defined as no tx discontinuation and no dose modification per FDA-approved label. Baseline characteristics (12 mo prior to index date) between GUS and SC IL-17Ai cohorts were balanced separately for biologic-naïve and biologic-experienced pts using propensity score overlap weighting. For both populations, on-label persistence through 24 mo was compared between tx cohorts using weighted Kaplan-Meier (KM) curves and weighted Cox proportional hazards model.

Results: Among biologic-naïve pts, 362 GUS pts (mean age: 49.5 years [y]; 59.9% female [F]) and 845 SC IL-17Ai pts (mean age: 50.1y; 55.9% F) were included. Among biologic-experienced pts, 487 GUS pts (mean age: 49.9y; 59.5% F) and 1,756 SC IL-17Ai pts (mean age: 49.5 y; 60.7% F) were included. Weighted baseline characteristics were well-balanced between both tx cohorts among biologic-naïve and biologic-experienced pts. Among biologic-naïve pts, median time-to-discontinuation was 22.4 (GUS) vs 14.9 mo (SC IL-17Ai). For biologic-experienced pts, median time-to-discontinuation was 18.1 (GUS) vs 11.6 mo (SC IL-17Ai). Weighted KM on-label persistence rates among biologic-naïve pts at 6, 12, 18, 24 mo: 85.7%, 72.6%, 62.6%, 47.5% (GUS) vs 70.6%, 55.2%, 45.2%, 40.3% (SC IL-17Ai); for biologic-experienced pts, weighted KM on-label persistence rates: 76.7%, 54.4%, 51.0%, 43.3% (GUS) vs 67.1%, 48.6%, 39.3%, 32.0% (SC IL-17Ai) (all log-rank p≤0.01). Pts initiating GUS were significantly more likely to be persistent at 24 mo among both biologic-naïve (HR: 1.70, 95% CI: 1.32–2.20; p< 0.001) and biologic-experienced populations (HR: 1.33, 95% CI: 1.11–1.59; p=0.002).

Conclusion: This real-world study assessing long-term tx persistence among pts with active PsA in the US showed that GUS was associated with significantly greater rates of on-label tx persistence through 24 mo among both biologic-naïve and biologic-experienced pts, compared to pts using SC IL-17Ai. Sustained long-term on-label use may enhance disease management, leading to better functional status and quality of life.

Abstract Number: 2370

Comparative Efficacy and Safety of IL-17 Inhibitors Versus Adalimumab in Biologic-Naive Psoriatic Arthritis Patients: A Meta-Analysis of Randomized Controlled Trials

Punith Chirumamilla[1], Ravi Medarametla[2], Anjani Mahesh Kumar Cherukuri[3], Sri Laxmi Priya Sunkara[4], Pranathi Bandarupalli[5], Rithish Nimmagadda[6], Greeshma Erasani[7], Pavana Sakhamuri[8] and Stephen Lindsey[9], [1]Baptist Memorial Hospital North Mississippi, Oxford, MS, [2]Mamata Medical College, Guntur, Andhra Pradesh, India, [3]Guntur Medical College, Guntur, Andhra Pradesh, India, [4]White river medical center, batesville, AR, [5]Mercy St Vincent Medical Center, Toledo, OH, [6]One Brooklyn Health, New York, NY, [7]University of Missouri-Kansas city school of medicine, KCMO, MO, [8]LSUHSC, Lafayette, LA, [9]LSU Health Sciences Center-New Orleans, Baton Rouge, LA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic immune-mediated disease which involves joints, skin, and nails, leading to deformities, decreased function, lower quality of life, and in many cases higher mortality. While traditional synthetic DMARDs and TNF inhibitors(TNFi), such as adalimumab, are effective existing treatments, they both have their shortcomings. Despite this, most patients with PsA do not achieve complete disease remission with synthetic DMARDs, and TNFi may be ineffective for skin, and lose efficacy over time, or be limited for long-term use due to safety concerns. IL-17 inhibitors target a separate inflammatory pathway and have demonstrated greater skin clearance and comparable joint improvement compared with TNFi in clinical trials at 52 weeks. This meta-analysis compares IL-17i versus adalimumab in biologic-naive PsA populations to evaluate safety and efficacy of using IL-17i in PsA patients.

Methods: We systematically searched PubMed, Embase, Cochrane for English-language studies involving comparison of treatment effects between IL-17i and Adalimumab, and reported at least one relevant outcome. Three studies met inclusion criteria. Data were pooled using the inverse variance weighting method with a random-effects model in R Studio. Confidence intervals and heterogeneity were assessed, and forest plots were generated to visualise the pooled effect estimates.

Results: Three studies(Randomized controlled trials) involving 1990 patients were included. Analysis of IL-17i versus Adalimumab revealed comparable ACR50 responses (RR=1.06, 95% CI: 0.97–1.16, p=0.22) but significantly higher PASI75 achievement with IL-17i (RR=1.21, 95% CI: 1.11–1.31, p< 0.0001). The primary composite outcome (ACR50+PASI100) strongly favored IL-17i (RR=1.49, 95% CI: 1.26–1.78, p< 0.01). Serious adverse events were slightly less in IL-17i group but that change is not significant (RR=0.72, 95% CI: 0.35–1.50, p=0.38), and also IL-17i demonstrated significantly lower discontinuation rates due to adverse events (RR=0.56, 95% CI: 0.38–0.82, p< 0.01).

Figure 1a: ACR50

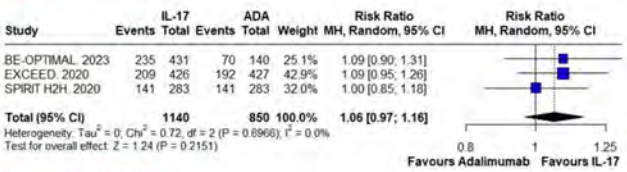

Figure 1b: PASI75

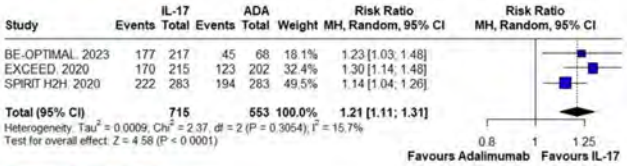

Figure 1c: PASI100

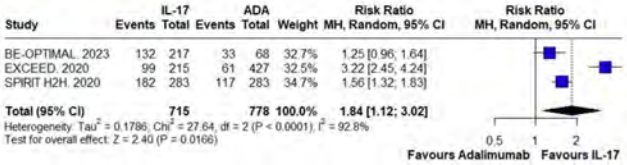

Figure 2a: ACR50 + PASI100

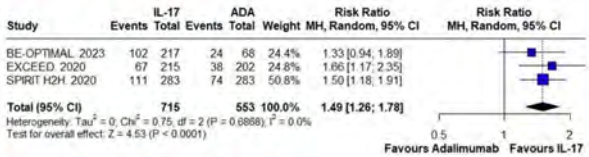

Figure 2b: Serious Adverse Events

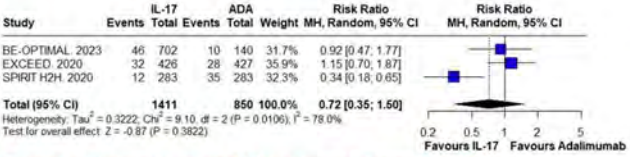

Figure 2c: Discontinuation of Drug due to Adverse Events

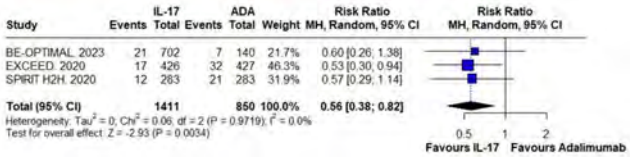

Conclusion: In biologically naive PsA patients, IL-17i showed comparable joint response, but has higher skin clearance compared to Adalimumab. IL-17i also has fewer discontinuations due to drug adverse events and overall it showed to be a great treatment option. Future Research should direct towards long-term outcomes and combination therapies to improve treatment algorithms.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous inflammatory disease requiring individualized treatment strategies. Early identification of patients likely to respond to therapy is essential to optimize outcomes and avoid unnecessary treatment exposure. Hematologic and inflammatory biomarkers, readily available in clinical practice, may offer predictive value in guiding treatment decisions. In this study, we aimed to identify a combination of clinical data and routinely available laboratory markers capable of reliably predicting which patients with PsA will respond to TNF inhibitors (TNFi).

Methods: This was a prospective analysis including 68 patients diagnosed PsA who fulfilled the CASPAR criteria. A multivariable logistic regression model was initially constructed using routinely measured inflammatory and hematologic parameters, with Disease Activity index for Psoriatic Arhritis (DAPSA) response as the dependent variable, defined as an improvement of >50% in the DAPSA score. To optimize model simplicity and performance, stepwise variable selection was applied in both forward and backward directions, based on the Akaike Information Criterion (AIC). This method iteratively adds or removes predictors to identify the model with the best balance between goodness-of-fit and parsimony. Model performance was evaluated using classification accuracy and the area under the ROC curve (AUC).

Table 1. Multivariate Analysis of Independent Factors Associated with Achieving >50% improvement in DAPSA after 6 months.

Table 1. Multivariate Analysis of Independent Factors Associated with Achieving >50% improvement in DAPSA after 6 months.

	OR (95%CI)	p-value
NLR	1.56 (0.87 – 3.23)	0.192
LMR	0.69 (0.40 – 1.06)	0.121
Complement C3 (mg/dL)	1.04 (1.01 – 1.08)	0.023
ESR (mm/H)	0.93 (0.87 – 0.98)	0.016
Baseline DAPSA	1.08 (0.98 – 1.21)	0.135

Hosmer and Lemeshow goodness of fit (GOF) test: X-squared = 8.2451, df = 8, p-value = 0.4099
DAPSA: Disease Activity index for Psoriatic Arhritis; ESR: erythrocyte sedimentation rate; LMR: lymphocyte-to-monocyte ratio; NLR: neutrophil-to-lymphocyte ratio;

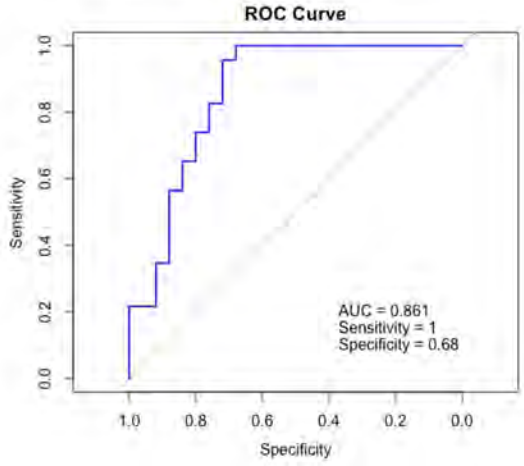
Figure 1. Receiver Operating Characteristic (ROC) Curve for the Prediction of TNFi response in PsA.



Results: A total of 68 patients were included, 55.8% of whom were male, with a mean age of 50 years (SD 16.7) and a mean disease duration of 7.2 years. A total of 31 patients (45.6%) responded to TNFi. The multivariable analysis (Table 1) identified five independent factors associated with achieving >50% improvement in DAPSA after 6 months: neutrophil-to-lymphocyte ratio (NLR) (OR 1.56), lymphocyte-to-monocyte ratio (LMR) (OR 0.69), complement C3 (OR 1.04), erythrocyte sedimentation rate (ESR) (OR 0.93), and baseline DAPSA score (OR 1.08). The final model demonstrated excellent discrimination, with an AUC of 0.861 (95% CI: 0.752–0.970) (Figure 1). It correctly classified 100% of the responders (sensitivity = 1.00) and 68% of the non-responders (specificity = 0.68).

Conclusion: A combination of routinely available hematologic and inflammatory markers can effectively predict clinical response to TNFi in patients with PsA, but further validation of this model is needed in independent cohorts. This predictive model may support more personalized and efficient treatment decisions in routine clinical practice.

Background/Purpose: In recent years, IL-23 inhibitors (IL23i)-have emerged as promising therapeutic options for psoriatic arthritis patients (PsA). Clinical trials have demonstrated their efficacy in both treatment-naïve patients and those with an inadequate response to TNF inhibitors [1-2] . However, real-world data on their effectiveness and long-term drug survival remain limited. This study aimed to evaluate the effectiveness, drug survival and reasons for therapy discontinuation of two IL-23i - Guselkumab and Risankizumab- in a cohort of PsA patients, reflecting real-world clinical practice.

Methods: We conducted a retrospective study of PsA patients, diagnosed according to the CASPAR criteria, who initiated treatment with Guselkumab or Risankizumab between 2019 and July 2024.

Data was extracted from medical records and included demographic and clinical parameters, along with disease activity scores - DAPSA and PASI- assessed at four time points during follow up: baseline (treatment initiation), 6 months, 12 months and the last follow up visit. IL-23i effectiveness was evaluated by means of DAPSA score with DAPSA≤14 indicating good clinical response. Reasons for treatment discontinuation were documented, and drug survival was analyzed using Kaplan-Meier plots.

Results: A total of 61 PsA patients were included (Table 1).

At baseline, the majority (57%) had moderate to high disease activity (DAPSA >14), while 18% were in remission (DAPSA ≤4) but had active skin involvement (mean PASI 6.75).

For most patients (80%), IL-23 inhibitors were the fourth or later b/tsDMARDs used, indicating a difficult-to-treat population.

By 6 months, 43% of patients achieved a DAPSA score ≤14, of whom 52% had a baseline DAPSA ≤14. This proportion declined to 30% by 12 months. Treatment discontinuation occurred in 30% of patients at 6 months and in 54% at 12 months. The primary reasons for discontinuation were persistent joint disease (65% at 6 months and 42% at 12 months) and combined joint and skin non-response (18% at 6 months, 24% at 12 months). Only 9% of patients discontinued therapy due to isolated skin disease activity.

IL23i treatment survival

Overall, 78% of patients discontinued treatment, with a median duration of 9.4 months (range: 4.9–24.4 months).

No significant differences were observed between Guselkumab and Risankizumab treatment groups.

Conclusion: In this real-world cohort of biologic-experienced, difficult-to-treat PsA patients, IL-23 inhibitors demonstrated modest effectiveness and low treatment persistence. The high discontinuation rate—primarily due to insufficient joint disease control—underscores the need for alternative therapeutic strategies in this challenging patient population.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease affecting joints, entheses, skin, nails, and spine. While treatment options have expanded, TNF inhibitors (TNFis) remain the most common first-line biologic in Spain due to favorable efficacy, safety, and reimbursement. However, evidence on biologic therapeutic sequencing remains limited, particularly regarding effectiveness and drug persistence.

The Manhattan study (CNTO1959PSA4009) assessed persistence, effectiveness, and tolerability of guselkumab (GUS), an anti-IL-23 inhibitor, compared to a second TNFi in adults with PsA who had failed to a prior first-line TNFi therapy.

Table 1. Demographic characteristics.

	Second-line GUS	Second-line TNFi
Sex, n (%)		
Male	39 (39.8%)	36 (46.8%)
Female	59 (60.2%)	41 (53.2%)
Age at PsA diagnosis (years), mean (SD)	44.8 (11.7)	44.2 (11.9)
BMI (kg/m²), mean (SD)	28.1 (6.3)	26.6 (5.5)
Comorbidities[1]	62 (63.3%)	52 (67.5%)
Arterial hypertension	19 (30.6%)	21 (40.4%)
Diabetes	13 (21.0%)	6 (11.5%)
Anxiety/drepression	12 (19.4%)	6 (11.5%)
Heart disease	7 (11.3%)	6 (11.5%)
PsA characteristics, n (%)		
Polyarticular PsA	58 (59.2%)	49 (63.6%)
Oligoarticular PsA*	34 (35.1%)	21 (27.3%)
Axial affectation*	22 (22.7%)	19 (24.7%)

Enthesitis*	21 (21.6%)	28 (36.4%)
Distal interphalangeal arthritis*	11 (11.3%)	15 (19.5%)
Mutilating arthritism*	4 (4.1%)	3 (3.9%)
TJC**, mean (SD)	6.1 (7.0)	5.2 (5.4)
SJC**, mean (SD)	3.3 (4.5)	2.7 (3.8)
DAPSA*, mean (SD)**	22.9 (13.4)	21.4 (11.5)
BSA**, mean (SD)**	4.3 (6.8)	2.3 (5.0)
Most common first-line TNFi, n (%)	Adalimumab, 71 (72.4%)	Adalimumab, 50 (64.9%)
Most common second-line TNFi, n (%)	NA	Etanercept, 31 (40.3%)
Concomitant conventional DMARDs, n (%)	42 (42.9%)	34 (44.2%)

[1]Based on n=114 patients (65.1%) with any comorbidity; * Of a total of 97 patients in the GUS group and 77 in the TNFi group; ** Of a total of 74 patients in the GUS group and 65 patients in the TNFi group; *** Of a total of 64 patients in the GUS group and 51 patients in the TNFi group; **** Of a total of 60 patients in the GUS group and 40 patients in the TNFi group.
NA: non applicable; DMARDs: disease-modifying antirheumatic drugs

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

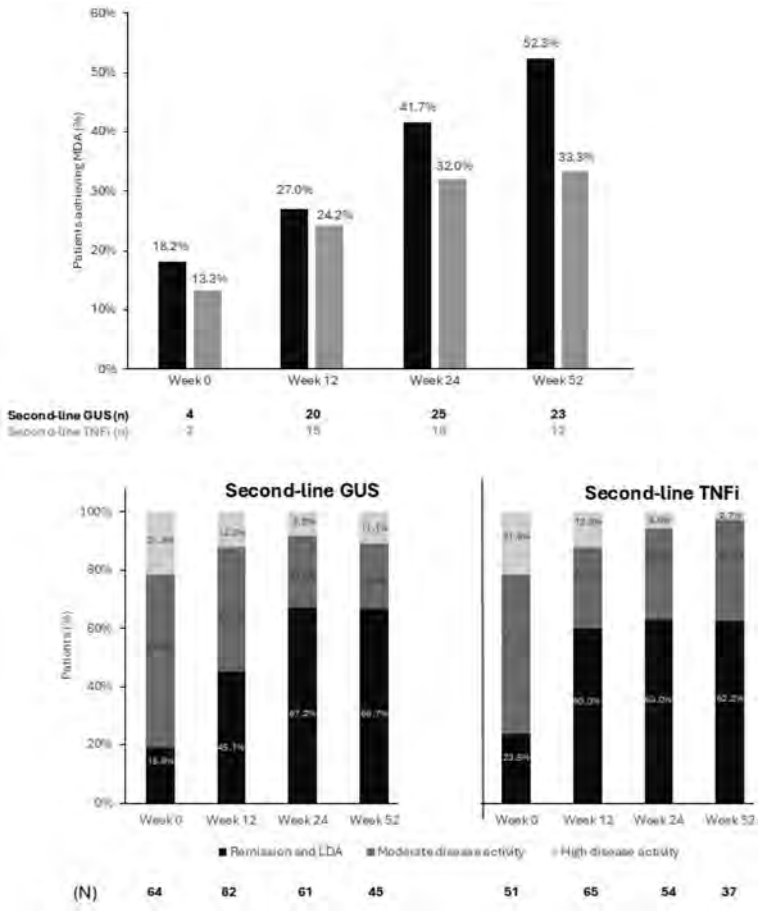

Figure 1. a) Percentage of patients achieving minimal disease activity (MDA) in second-line treatment (GUS or TNFi at week 0, week 12, 24 and 52). MDA was achieved if 5 of 7 criteria were met: TJC ≤1; SJC ≤1; BSA ≤ 3%; patient's assessment of pain by visual analogue scale (VAS) ≤15 mm; patient's global assessment of disease activity by VAS ≤20 mm; Health Assessment Questionnaire ≤0.5; and tender entheseal points ≤ 1 (assessed by the Leeds Enthesitis Index). b) percentage of patients achieving remission and low disease activity, moderate or high disease activity.

Methods: Manhattan is an ongoing ambispective, observational study across 37 Spanish centers. It includes PsA patients who switched to GUS or a second-line TNFi following first-line TNFi use. Among 193 recruited, 175 (98 on GUS and 77 on TNFi) patients were evaluated in this interim analysis regarding effectiveness and tolerability. Baseline data, and prior/ concomitant treatments were recorded. Endpoints included rates of disease activity (minimal (MDA), DAPSA low (LDA)/ remission), presence of dactylitis, nail psoriasis, enthesitis measurement (by the Leeds Enthesitis Index [LEI]), functioning and disability using the Health Assessment Questionnaire (HAQ), mean changes in psoriatic body surface area (BSA), and tender (TJC), and swollen joint count (SJC). Adverse events (AE) and drug-related events were recorded. Effectiveness and tolerability interim results up to week (W) 52 are presented.

Results: Baseline characteristics were similar across groups (Table 1).

MDA achievements increased to 52.3% (GUS) and 33.3% (TNFi) at W52 (Fig. 1A). DAPSA Remission/LDA rates rose from 18.8% at baseline to 66.7% at W52 (GUS), and from 23.5% to 62.2% (TNFi), respectively (Fig. 1B). TJC improved in both groups, showing mean absolute changes from baseline of –2.4 (W12) and -3.1 (W52) for GUS, and of –1.5 (W12) to –3.5 (W52) for TNFi. Similarly, SJC decreased over time: mean absolute changes of –1.9 and –2.1 (GUS), and of –1.2 and –2.4 (TNFi), at W12 and W52, respectively. Dactylitis prevalence decreased in both groups (Fig. 2A) and it disappeared in 46.2% (6/13) patients W12, 80.0% (8/10) W24, and 71.4% (5/7) W52 (GUS), and in 88.9% (8/9) W12, 75.0% (6/8) W24,

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

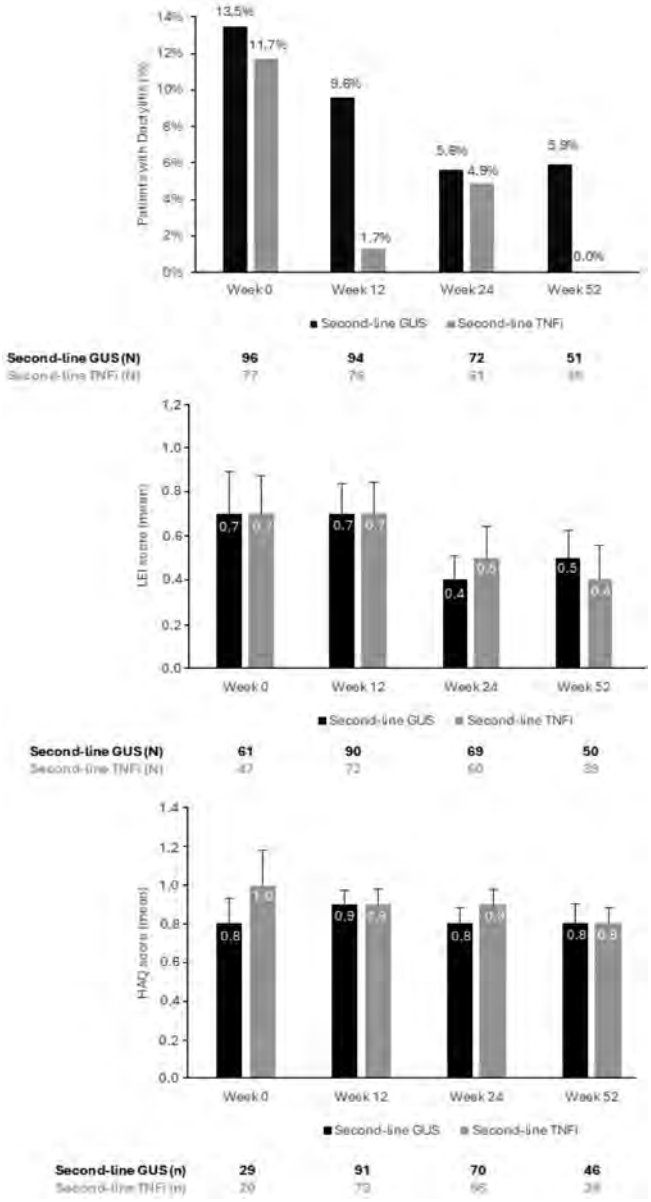

Figure 2. a) Percentage of patients with dactylitis, b) representation of the mean LEI score, c) representation of HAQ score in second-line treatment (GUS or TNFi at week 0, week 12, 24 and 52).

and 100.0% (5/5) at W52 (TNFi). LEI scores marginally improved with both treatments, whereas HAQ remained stable with GUS and slightly improved with TNFi (from 1.0 to 0.8 [W52]) (Fig. 2B and C).

Nail psoriasis mean absolute changed from baseline: –1.8 (W12), –3.2 (W24), and –10.5 (W52) in TNFi group, versus –0.9, –1.8, and –1.3, respectively, in the GUS group. BSA improvement favored GUS, showing mean absolute changes of –2.6 (W12), –3.2 (W24), and –3.9 (W52), versus –0.8, –1.1, and –1.7, respectively in the TNFi group.

Reported AEs in 35 patients: 19 (19.4%) GUS and 16 (20.8%) TNFi. Of total AEs, 4 (14.8%) and 7 (31.8%) were considered drug-related, respectively.

Conclusion: Guselkumab and second-line TNFis showed effectiveness through 52 weeks in diverse domains. GUS provided earlier MDA response and greater improvement in both skin outcomes and LDA/remission, supporting its use as a durable second-line option

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Given the chronic nature of psoriasis, and the loss of response observed with biologic therapies over time, it is crucial to establish the long-term efficacy and safety of biologic therapies for psoriasis. Here, we evaluate the efficacy and safety of bimekizumab (BKZ) treatment through 5 years in patients with moderate to severe plaque psoriasis from the US and Canada.

Methods: A US/Canadian patient subgroup completing the BE VIVID (NCT03370133)/BE SURE (NCT03412747)/BE READY (NCT03410992) phase 3 trials and their open-label extension (OLE), BE BRIGHT (NCT03598790; 4 years' total treatment) could enter a second 48-week extension (OLE2), in which they received BKZ 320 mg every 4 weeks (Q4W) or Q8W depending on Investigator's Global Assessment (IGA) response at entry.[1–4] Included patients received BKZ continuously from feeder study baseline to OLE2 entry; patients receiving BKZ Q4W to Week 16 then Q8W thereafter (BKZ Q4W/Q8W; approved dosing regimen) were also analyzed.[5]

Five-year efficacy data are reported (244 weeks' total treatment). Patients discontinuing treatment due to lack of efficacy/treatment-related adverse events were considered non-responders; multiple imputation was used for other missing data (modified non-responder imputation). Treatment-emergent adverse events (TEAEs) are reported through 5 years (Weeks 0–244) using exposure-adjusted incidence rates/100 patient-years [PY]).

Results: In total, 153 US/Canadian patients were analyzed; 52 received BKZ Q4W/Q8W.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

At Year 1 (Week 52) and Year 5 (Week 244), 75.2% and 67.7% patients treated with BKZ achieved 100% improvement from baseline in Psoriasis Area and Severity Index (PASI 100), respectively (BKZ Q4W/Q8W: 78.8% and 76.9%). At Year 1 and Year 5, 92.8% and 84.9% achieved PASI 90 (BKZ Q4W/Q8W: 96.2% and 88.5%).

Over 5 years, serious TEAEs (3.6/100 PY) and discontinuations due to TEAEs (0.3/100 PY) were low; zero deaths occurred. Most common TEAEs were nasopharyngitis (9.7/100 PY), oral candidiasis (7.6/100 PY), and corona virus infection (6.1/100 PY). The vast majority (99.3%) of oral candidiasis events were mild/moderate; none led to discontinuation. Safety results were generally similar in BKZ Q4W/Q8W patients.

Conclusion: BKZ demonstrated high rates of clinical response, which were durable over 5 years, in patients from the US and Canada with moderate to severe plaque psoriasis. BKZ was well-tolerated in this patient subgroup, with no unexpected safety findings.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Ixekizumab (IXE) is a selective interleukin-17A antagonist that has proven effective in Phase 3 and 4 clinical trials for patients with psoriatic arthritis (PsA).

Methods: Psoriatic Arthritis Real-World Study in the US (PARTUS) was a prospective, multicenter, non-interventional study conducted in patients with PsA who were starting treatment with IXE or an interleukin-23p19 inhibitor (IL-23i). We present improvements in patient-reported outcomes (PROs) from the study.

The following outcomes were assessed at Week (W) 4 and W12: proportion of patients achieving Psoriatic Arthritis Impact of Disease (PsAID)-12 remission, change from baseline (CFB) in the patient spinal pain score measured by question 2 (Q2) (spinal pain item) of Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) (in patients with axial involvement), and CFB in Patient Global Assessment of Disease Activity (PtGA) Visual Analog Scale (VAS) score. Minimal Clinically Important Differences were evaluated: proportion of patients achieving a ≥ 10 score decrease in patient pain VAS score, a ≥ 10 score decrease in PtGA VAS score, and a ≥4 score increase in Functional Assessment of Chronic Illness Therapy (FACIT)- Fatigue score. Abbreviated Treatment Satisfaction Questionnaire for Medication-9 (TSQM-9) scores were also assessed.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. TSQM-9 scores from patients with active PsA treated with IXE or IL-23i (GUS and RZB) Note: Data are mean (SD) unless otherwise stated. Abbreviations: GUS=guselkumab; IL-23i=interleukin-23p19 inhibitor; IXE=ixekizumab; N=number of patients in each cohort; PsA=psoriatic arthritis; RZB=risankizumab; SD=standard deviation; TSQM-9, abbreviated Treatment Satisfaction Questionnaire for Medication-9.

TSQM-9 scores	IXE (N=121)	IL-23i (N=116)
Effectiveness		
Week 4	62.4 (23.2)	57.6 (18.6)
Week 12	63.7 (24.1)	56.2 (23.7)
Convenience		
Week 4	82.3 (16.0)	79.3 (15.7)
Week 12	81.3 (16.6)	79.3 (15.8)
Global Satisfaction		
Week 4	65.0 (27.2)	61.7 (19.6)
Week 12	63.9 (27.2)	60.1 (25.7)

Descriptive statistics for IXE and IL-23i groups are presented.

Results: BL characteristics of 121 patients from the IXE cohort and 116 patients from the IL-23i cohort (risankizumab (n=67) and guselkumab (n=49)) are in Table 1.

At W4, 57.4% in the IXE cohort and 47.3% in the IL-23i cohort reported a ≥ 10 point decrease in patient pain VAS score. Both cohorts had additional progress by W12 (Figure (Fig.) 1B). The mean (SD) CFB in PtGA VAS score at W4 was -20.2 (24.5) and -8.6 (27.2), and at W12 was -22.9 (27.4) and -14.9 (27.6) in the IXE and IL-23i cohorts respectively (Fig. 1C). At W4, 73.8% and 53.1%, and at W12, 73.7% and 60.4% reported a ≥ 10 point decrease in PtGA VAS score in the IXE and IL-23i cohorts, respectively (Fig. 1D). At W4, 61.8% in the IXE cohort and 46.0% in the IL-23i cohort, and at W12, 69.9% in the IXE cohort and 60.2% in the IL-23i cohort reported ≥ 4point improvements in fatigue (Fig. 1E). The mean (SD) CFB in spinal pain score by Q2 of BASDAI was -1.4 (1.9) and -0.3 (2.9) at W4 and -1.6 (1.7) and -0.8 (2.5) at W12 for IXE and IL-23i cohorts (Fig. 1F). The proportions of patients achieving PsAID-12 remission at W4 were 13.0% and 3.1% in the IXE and IL-23i cohorts, respectively, with further improvements reported by W12 in both cohorts of patients (Fig. 1A).

The TSQM-9 convenience domain scores were higher than the other domains of effectiveness and global satisfaction (Table 2).

Conclusion: The findings from the PARTUS study demonstrate that IXE rapidly improves quality of life and disease severity as early as week 4 in real-world settings for patients with PsA, with further improvements through week 12. Meaningful improvements were observed in PsAID-12, BASDAI, patient pain VAS, PtGA VAS score, as well as in FACIT-Fatigue scores. Convenience was the highest scoring treatment satisfaction domain. The rapid week 4 improvements in IXE treated patients were also observed in IL-23i treated patients, although to a less numerical extent.

Abstract Number: 2376

Efficacy And Safety of Vunakizumab in Patients with Active Ankylosing Spondylitis Stratified by Disease Course: A Post-hoc Analysis of a Randomized, Double-Blind, Phase 2/3 Trial

XiaoFei Shi, Liqing Zhou and He Zhang, The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2338–2376) Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Vunakizumab, also known as SHR-1314, is a novel a recombinant humanized monoclonal antibody against interleukin-17A. A randomised, double-blind, phase 2/3 trial (NCT04840485) demonstrated a significant benefit of vunakizumab over placebo in active ankylosing spondylitis (AS) at week 16, with sustained improvements through 32 weeks. However, it remains unknown whether the effect of vunakizumab on AS varies according to disease course (DC). Here, we conducted a post-hoc analysis of this randomized, double-blind, phase 2/3 trial to assess the efficacy and safety of vunakizumab in patients with active AS stratified by DC (< 5 versus ≥ 5 years).

Methods: In the phase 2/3 trial, adult patients with active AS who had either an inadequate response, intolerance, or contraindication to non-steroidal anti-inflammatory drugs were enrolled. All patients in this study fulfilled the 1984 modified New York criteria for AS and also met the American College of Rheumatology classification criteria. Data for this analysis were obtained from those eligible patients who were randomly assigned to receive either vunakizumab 120 mg or placebo at weeks 0, 2, 4, 8 and 12; from week 16, all patients transitioned to treatment with vunakizumab 120 mg until week 32. The primary endpoint was the proportion of patients who met the Assessment of Spondyloarthritis International Society 20 (ASAS20) response criteria at week 16. Key secondary endpoints included ASAS40, ASAS5/6 and safety.

Table 1. ASAS response stratified by disease course

	Disease course of ≥ 5 years			Disease course of < 5 years		
	Placebo (n = 58)	Vunakizumab (n = 116)	OR (95% CI)[1]/Difference (95% CI)[2]	Placebo (n = 88)	Vunakizumab (n = 178)	OR (95% CI)[1]/Difference (95% CI)[2]

Results: A total of 440 patients were included in this analysis, of which 174 had a DC of ≥ 5 years (vunakizumab 120 mg, n = 116; placebo, n = 58) and 266 had a DC of < 5 years (vunakizumab 120 mg, n = 178; placebo, n = 88). At week 16, the ASAS20 response rates were 62.07% for vunakizumab versus 43.10% for placebo (OR 2.15, 95% CI 1.13 to 4.09, P = 0.0196) in patients with a DC of ≥ 5 years; and in patients with a DC of < 5 years, the corresponding rates were 67.98% versus 42.05% (OR 2.98, 95% CI 1.75 to 5.07, P < 0.0001). Moreover, patients switching from placebo to vunakizumab at week 16 showed improved ASAS20 at week 32 (62.50% for DC of ≥ 5 years; 66.20% for DC of < 5 years), which was comparable to those who continued on vunakizumab (68.10% and 78.09%, respectively). Similar improvements were also observed for ASAS40 and ASAS5/6 (Table 1). In terms of safety, during the 16-week period, 110 (94.83%) of 116 patients with a DC of ≥ 5 years in the vunakizumab group and 54 (93.10%) of 58 such patients in the placebo group had at least one treatment-emergent adverse event (TEAE); while among patients with a DC of < 5 years, TEAEs occurred in 164 (92.13%) of 178 patients and 82 (93.18%) of 88 patients, respectively. The overwhelming majority of TEAEs were mild to moderate, with the most common being upper respiratory infection (DC of ≥ 5 years: 31 [26.72%] for vunakizumab versus 20 [34.48%] for placebo; DC of < 5 years: 42 [23.60%] versus 20 [22.73%]). No treatment-related deaths were reported.

Conclusion: Vunakizumab 120 mg showed improved efficacy with a manageable safety profile in patients with active AS, irrespective of DC.

Statin Use for Primary Prevention of Atherosclerotic Cardiovascular Disease Among Patients with Systemic Lupus Erythematosus

Aakash V. Patel[1], Lingxiao Zhang[2], Emily S. Lau[3], Hyon K. Choi[4] and April Jorge[5], [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Harvard Medical School, Boston, [4]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA, [5]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiovascular disease (CVD) is the most common cause of mortality among patients with systemic lupus erythematosus (SLE). Statin medications play a crucial role for the primary prevention of atherosclerotic cardiovascular disease (ASCVD), but data characterizing statin usage among patients with SLE are scarce. We sought to identify patterns of statin use for primary prevention of ASCVD in patients with SLE.

Methods: We identified an SLE cohort from TriNetX, an electronic health record (EHR) database with patients from academic, community, and private medical centers across the United States. We included patients with SLE (≥2 ICD codes ≥30 days and ≤2 years apart) between January 2000 and August 2021. We utilized the 2018 American Heart Association Guideline on the Management of Blood Cholesterol and the Pooled Cohort Equation (PCE) to identify SLE patients with an indication for treatment with a moderate or high intensity statin for primary prevention of ASCVD (indications include a 10-year risk of ASCVD ≥7.5%, diabetes, or LDL ≥190 mg/dL. We also performed a variation of ASCVD risk estimation by

doubling the risk calculated by the PCE (modified PCE) to account for increased risk conferred by SLE. We assessed statin use patterns among eligible patients and examined factors associated with underutilization using multivariable logistic regression, adjusting for 10-year ASCVD risk.

Results: There were 21,926 SLE patients between ages 40-75 without prior ASCVD who underwent at least one ASCVD risk assessment with cholesterol and blood pressure monitoring **(Figure 1)**. After excluding 355 patients with contraindications to statin therapy (i.e., pregnancy and liver failure), 9,456 patients (43.8%) had an indication for a moderate or high-intensity statin. Of these, 5,039 (53.3%) received a statin. Among the 3216 patients with a PCE risk score ≥20% or LDL ≥190 mg/dL, 1303 (40.5%) never received a statin. Employing the modified PCE, an additional 2827 patients (13.1%) were eligible for a moderate or high-intensity statin, of whom 871 (30.8%) received a statin in primary prevention. Among those with an indication, Black individuals (adjusted OR [aOR] 1.40 [95% CI 1.27-1.54]) and patients below the age of 60 (aOR 2.09 [95% CI 1.90-2.30]) were more likely to receive a moderate or high-intensity statin, as were those with comorbidities such as diabetes (aOR 1.91 [95% CI 1.76-2.08]), hypertension (aOR 1.16 [95% CI 1.07-1.26]) and hyperlipidemia (aOR 1.91 [95% CI 1.75-2.08], **Table 1)**. There was no difference in statin use in the subset of patients with lupus nephritis (aOR 0.95 [95% CI 0.84-1.09]).

Conclusion: In this large EHR-based cohort of patients with SLE, 44% met criteria for a moderate or high-intensity statin for primary prevention of ASCVD, but only around half of eligible patients received a statin. These findings highlight the significant underutilization of statin therapy among patients with SLE, a population of individuals with enhanced risk for CVD.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease characterized by a wide spectrum of clinical manifestations, fatigue being one of them; it is quite frequent and it is found in up to 90% patients. Thus, understanding its determinants is important; this has not been well studied in Latin-American patients. The aim of this study is to determine the factors associated with fatigue in SLE patients from a Latin American cohort.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. * SE=standard error. Ref: Reference. SDI: SLICC/ACR Damage Index. CCI: Charlson's comorbidity index. MCS and PCS: mental and physical component summary measures of the SF-36, respectively.

Methods: Patients from a single-center prevalent Peruvian SLE cohort [the Almenara Lupus cohort] were included. Fatigue was assessed with the FACIT-Fatigue Scale, which has been validated in SLE and is frequently used. This 13-item questionnaire is based on the patients' experience over the previous 7 days; higher scores indicate less fatigue. Potentially associated factors were sex, age at diagnosis, ethnicity, educational level, relationship status (single or couple), socioeconomic status (SES), disease duration, disease activity (ascertained with the SLEDAI-2K), damage accrual (ascertained with the SLICC/ACR damage index), comorbidities (ascertained with the Charlson's comorbidity index), sicca symptoms, fibromyalgia, glucocorticoid dose, antimalarial and immunosuppressive drugs use, as well as the mental and physical component summary measurements of the SF-36 (PCS and MCS).

To determine the predictors of fatigue during the follow-up, generalized estimating equations (GEE) were used. Potential predictors were sex, age at diagnosis, ethnicity, educational level, relationship status, SES, disease duration, disease activity, damage, comorbidities, sicca symptoms, fibromyalgia, glucocorticoid dose, antimalarial and immunosuppressive drugs use, PCS and MCS. The multivariable models were done using a backward selection procedure with an alpha to stay in the model of 0.05.

Results: Four-hundred and one patients with 2228 visits were included and evaluated; 31 (7.7%) of the patients were male, 393 (98.0%) were Mestizo and their mean age at diagnosis was 35.1 (13.3) years. The mean FACIT score was 33.0 (10.8). In the multivariable analysis, the Afro-Latin American ethnicity, the PCS and the previous FACIT were associated with lower levels of fatigue, whereas having sicca symptoms and fibromyalgia were associated with higher levels of fatigue (Table 1).

Conclusion: In our SLE patients, the Afro-Latin American ethnic group, a higher PCS and the previous FACIT were associated with less fatigue; sicca symptoms and fibromyalgia were associated with more. Further studies are needed to evaluate these findings in other populations and seek better strategies to improve fatigue in SLE patients.

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The Type 1 & 2 SLE Model separates lupus disease activity into two groups: Type 1 (e.g. arthritis, rash, nephritis) and Type 2 SLE (e.g. widespread pain, fatigue, brain fog). A patient-reported outcome measure that accurately assesses Type 1 & 2 SLE activity would facilitate the monitoring of disease activity outside clinical settings. This study evaluates the utility of the LupusPRO in predicting Type 1 and Type 2 SLE activity.

Table 1. Cohort characteristics and LupusPRO domains across Type 1 & 2 SLE activity groups.

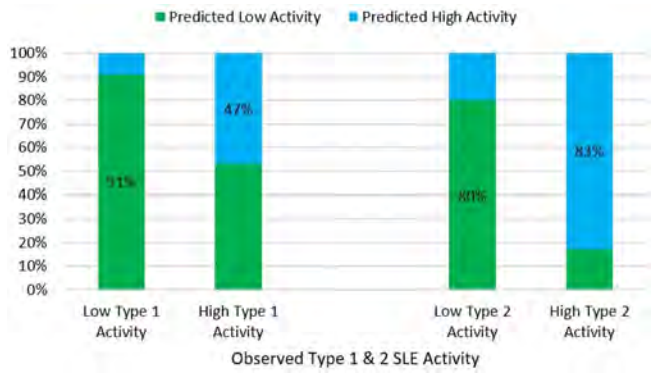

Figure 1. Observed Versus Predicted Type 1 & 2 SLE Activity.

Methods: Individuals meeting criteria for SLE were enrolled in a lupus registry. At routine visits, rheumatologists completed the SLEDAI and physician's global assessments (PGA) for Type 1 and Type 2 SLE activity. Patients completed the Polysymptomatic Distress Score (PSD) and LupusPRO, which consists of 10 health-related quality of life (HRQoL) and 4 non-HRQoL domains scored from 0 (worst) to 100 (best).

High Type 1 SLE activity was defined as SLEDAI ≥6, clinical SLEDAI ≥4, Type 1 PGA ≥1, or active nephritis. High Type 2 SLE activity was defined as PSD ≥8 or Type 2 PGA ≥1. Patients were categorized into 4 groups:

- Minimal SLE (low Type 1 and Type 2)
- Type 1 SLE (high Type 1 only)
- Type 2 SLE (high Type 2 only)
- Mixed SLE (high Type 1 and Type 2)

Median LupusPRO domain scores were compared across groups by the Kruskal–Wallis test. Logistic regression models, using all LupusPRO domains as predictors, estimated predicted probabilities for high Type 1 and high Type 2 SLE separately. We compared models' predicted probabilities with study definitions, calculated the proportion of correctly predicted outcomes, and calculated the Huberty's I index (>0.35 indicating predictive ability over chance)

Results: The LupusPRO was completed by 295 patients (mean age 44 years, 93% female, 59% Black). Among them, 36% had Minimal SLE activity, 11% Type 1 SLE activity, 29% Type 2 SLE activity, and 24% Mixed SLE activity. Differences in LupusPRO domain scores were observed across groups, with the Mixed SLE group having the lowest scores (Table 1). While scores were similar between the Type 2 SLE and Mixed SLE groups, lupus symptoms, lupus medications, emotional health and body image scores were significantly lower in the Mixed SLE group.

LupusPRO domains accurately predicted Type 2 SLE activity in 82% of patients (Huberty's I index = 0.64; Fig 1). Cognition, sleep and pain were key predictors of high Type 2 SLE activity. For Type 1 SLE activity, LupusPRO domains accurately predicted outcomes in 75% of patients (Huberty's I index = 0.46), with higher accuracy for low Type 1 activity (91%) than high Type 1 activity (47%). Among patients with high Type 1 SLE activity classified as low Type 1 activity, nearly half had active nephritis. Lupus symptoms, procreation and emotional health were significant predictors of high Type 1 SLE activity.

Conclusion: The LupusPRO effectively captures unique aspects of HRQoL and non-HRQoL that patients with SLE experience, particularly patients with active Type 2 SLE. While it was less able to predict active Type 1 SLE, due to small sample size or active lupus nephritis presenting asymptomatically, the LupusPRO offers valuable insights into patient experiences. Utilizing the LupusPRO can enhance the care provided to SLE patients, addressing their specific concerns and better targeting treatment strategies.

Factors Influencing Time to Diagnosis in Systemic Lupus Erythematosus: A Real-World Retrospective Analysis

Amiah Griffin, Pat Phisitkul, Sarah Green, Ashley Suh, Bryan Han, Jiaming Li, Catherine Mao and April Barnado, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Individuals with Systemic lupus erythematosus (SLE) face diagnostic delays that can lead to increased disease activity and organ damage. Using a large electronic health record (EHR)-based incident SLE cohort, we examined if demographic, clinical, and provider factors impact time to SLE diagnosis.

Methods: We identified potential SLE individuals using ≥ 4 instances of SLE ICD-10-CM codes (M32.1, M32.8, M32.9) from a de-identified EHR database. Chart review confirmed diagnosis by a specialist (rheumatologist, nephrologist, or dermatologist) and incident case status as newly diagnosed SLE at our institution. We examined age, sex, race, ethnicity, and insurance type closest to SLE diagnosis as well as time to SLE diagnosis, first outpatient provider seen at our institution, and first SLE-related billing code prior to SLE diagnosis. Time to SLE diagnosis was defined as time from first code for any condition to SLE diagnosis by a specialist. First outpatient provider was categorized as primary care, rheumatology, surgical specialties, or internal medicine subspecialties. SLE-related billing codes capture signs or symptoms from the SLE classification criteria but do not mention SLE in the code name and were grouped into positive ANA or other autoantibody, hematologic, neurologic, serositis, renal, skin, and joints. We calculated mean time from first SLE-related code to SLE diagnosis. We used descriptive statistics for cohort characteristics and Mann-Whitney U and Kruskal-Wallis tests for comparisons.

Table 1. Characteristics of Incident SLE individuals.

Characteristics	n = 976 % (n)
Sex	**(n = 976)**
Male	14% (132)
Female	86% (844)
Race	**(n = 949)**
White	70% (668)
Black	26% (246)
Other	4% (35)
Ethnicity	**(n = 834)**
Hispanic	8% (69)
Not Hispanic	92% (765)
Insurance	**(n = 975)**
Commercial	64% (623)
Medicaid	16% (150)
Medicare	11% (110)
Military	5% (49)
Uninsured (Private Pay)	4% (43)
Mean age at SLE diagnosis ± standard deviation	37 ± 18
EHR Duration* (years)	12 ±8
Time to SLE Diagnosis**(years)	5 ±6

*EHR (electronic health record) duration was defined as the time from the first ICD code to the last ICD code for any condition.
**Time to SLE diagnosis was time from first ICD code for any condition to a clinical SLE diagnosis by a specialist.

Table 2. Time to Diagnosis by Demographic and Clinical Characteristics.

Characteristics	Mean ± SD (years)	*p* value
Sex		
Female	5 ± 6	p = 0.60
Male	5 ± 6	
Race		
White	5 ± 6	p = 0.19
Black	5 ± 6	
Other	3 ± 6	
Ethnicity		
Hispanic	5 ± 6	p = 0.51
Not Hispanic	5 ± 6	
Insurance		
Commercial	4 ± 6	**p < 0.001**
Medicaid	5 ± 6	
Medicare	7 ± 7	
Military	2 ± 4	
Uninsured	6 ± 7	
Provider Specialty*		
Primary Care	6 ± 6	**p < 0.001**
Rheumatology	3 ± 5	
Surgical Specialties**	8 ± 6	
Internal Medicine Subspecialties***	6 ± 6	

*Provider specialty refers to the first outpatient encounter upon entry into the health system
Surgical Specialties: OBGYN, dentistry/oral surgery, neurosurgery, ophthalmology, orthopedics, otolaryngology, plastic surgery, sports medicine, general surgery, surgical oncology, urology *
***Internal Medicine Subspecialties: hematology, nephrology, neurology, allergy, autonomics, cardiology, endocrinology, gastroenterology, hepatology, infectious disease, oncology, pain management, pulmonary, psychiatry

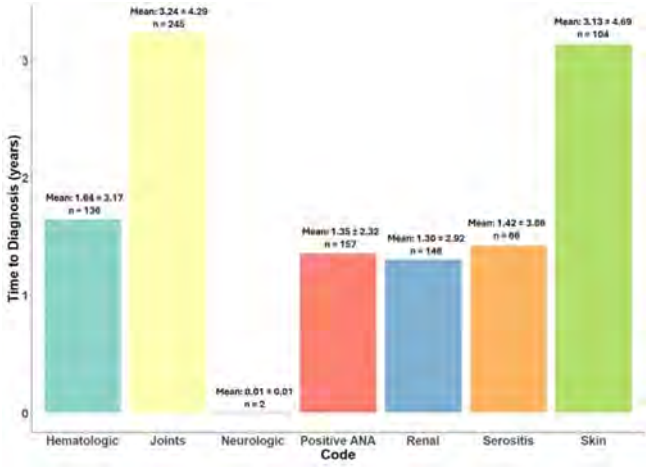

Figure 1. Time to SLE Diagnosis from first SLE-related billing code. We examined the first SLE-related billing code for individuals prior to SLE diagnosis. Mean time ± standard deviation from first SLE-related billing code to time of SLE diagnosis is labeled for the billing code categories. Billing codes were categorized into positive ANA/other autoantibody, hematologic manifestations (hemolytic anemia, anemia of chronic disease, pancytopenia, thrombocytopenia, leukopenia), neurologic (non-infectious encephalitis), serositis (pericarditis, pleurisy, pleural effusion), renal (nephritis, renal failure, proteinuria), skin (disorders or skin, alopecia, and dermatitis due to solar radiation), and joints (symptoms and disorders of joints and pain in joint).

Results: We identified 976 incident SLE individuals, predominantly female and White, with a mean time to SLE diagnosis of 5 ± 6 years (Table 1). Time to SLE diagnosis did not differ significantly by sex, race, or ethnicity (Table 2). Insurance status was significantly associated with time to diagnosis ($p < 0.001$). Individuals with military insurance had the shortest time to diagnosis (2 ± 4 years), and individuals with Medicare had the longest time (7 ± 7 years) (Table 2). Provider specialty at first outpatient visit was also significantly associated with time to SLE diagnosis ($p < 0.001$). Individuals seen first by rheumatologists had the shortest time to diagnosis (3 ± 5 years), while those seen by surgical specialties had the longest time (8 ± 6 years). The first SLE-related code was associated with time to SLE diagnosis ($p = 0.004$). Individuals with codes for encephalitis, renal disease (nephritis, renal failure, or proteinuria), positive ANA/other autoantibody, and serositis all had shorter times to diagnosis than individuals with first codes for hematologic abnormalities, skin findings, and joint pain (Figure 1).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In a large, real-world cohort at an academic medical center, time to SLE diagnosis was long with a mean time of 5 years. Time to SLE diagnosis varied by insurance, specialty of first provider seen, and clinical presentation. Ongoing studies are examining the trajectory of how SLE individuals interact with the healthcare system prior to SLE diagnosis. Our findings demonstrate that access to specialty care and insurance type can significantly shape the SLE diagnostic timeline and highlight areas to focus future interventions.

Renal Tubular Complement C9 Deposition is Linked to Tubulointerstitial Fibrosis and Progression to Chronic Kidney Disease in Lupus Nephritis

Angela Lu[1], Daming Shao[2], Ying Jin[1], Luis Chiriboga[3], Ming Wu[4], James Pullman[5], Anna Broder[6] and Shudan Wang[5], [1]Albert Einstein College of Medicine, Bronx, NY, [2]University of Chicago, Chicago, IL, [3]NYU Langone Medical Center, New York City, [4]Northwell Health, New Hyde Park, [5]Montefiore Medical Center, Bronx, NY, [6]Hackensack University Medical Center, Hackensack, NJ

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The complement system is known to play a central role in the pathogenesis of lupus nephritis (LN), one of the most severe manifestations of SLE. Emerging data suggest complement activation, particularly via membrane attack complex (MAC), mediates tubulointerstitial injury in LN. Studies have shown that tubulointerstitial damage leads to CKD progression in LN. Therefore, it is important to understand the mechanisms driving tubulointerstitial injury in LN to identify potential therapeutic targets. The objective of this study is to investigate C9 deposition, a part of the MAC, as a potential marker of tubulointerstitial injury and its association with chronic kidney disease (CKD) progression.

Methods: This retrospective cohort study included 30 LN patients who underwent kidney biopsies between February 2017 to November 2019 at an urban tertiary center. C9 deposition in proximal renal tubules was assessed via chromogenic immunohistochemistry on paraffin-embedded LN biopsy specimens stained with murine anti-human C9 antibody. C9 staining intensity was graded on a semi quantitative scale of 0 to 3 and categorized as present (1-3) vs absent (0). The percentage of staining in the tubules was also recorded. CKD progression was defined as $\geq$30% decline in estimated glomerular filtration rate (eGFR) within 5 years post biopsy, and those with stable or missing eGFR values were defined as non-progressors. Interstitial fibrosis/tubular atrophy (IFTA) was defined as $\geq$10% affected interstitium. Non-responders were defined as < 50% improvement in UPCR from baseline with no improvement in eGFR. CKD progression rates, treatment response, and IFTA were compared between C9 Positive (C9+) and C9 Negative (C9-).

Results: Among 30 LN patients, mean (SD) age was 34 (10.3) years, 23 (77%) were women, and 17 (57%) had proliferative LN (Class III, IV, III+V, and IV+V). Eighteen (60%) had tubular C9 deposition and 10 (33%) progressed to CKD. An example of an LN patient with tubular C9 stain is shown in Figure 1. Tubular C9 deposition was associated with IFTA: 71% in the C9+ group vs. 25% in the C9- group (p=0.016). LN patients with IFTA had greater C9 stain intensity (mean (SD) 1.0(0.6) vs 0.39 (0.56)) and percentage of tubules with C9 stain (14.67% (13.95) vs 5.36% (8.43)) as compared to LN without IFTA. Compared with C9- group, C9+ group had a lower median (IQR) urine-to-protein ratio (1.5 (0.9, 3.1) vs. 3.5 (2.2, 4.8) g/g,

Immunotherapy*^, n (%)	11 (37%)	7 (39%)	4 (33%)	>0.99
eGFR, mL/min/1.73 m2	75.57 [47.75, 104.25]	78.50 [35-120] [48.00, 106.75]	71.17 [53.75, 89.25]	0.35
Creatinine, mg/dL	0.90 [0.72, 1.43]	0.85 [0.72, 1.43]	1.0 [0.78, 1.40]	0.66
UPCR at biopsy (g/g)	2.32 [1.19, 4.15]	1.50 [0.90, 3.11]	3.45 [2.21, 4.82]	0.043*
UPCR at 6 mo (g/g)	0.75 [1.25, 4.26]	0.84 [0.90, 3.11]	0.70 [2.74, 5.12]	0.84
Serum C3 <70 mg/dL, n (%)	18 (60%)	8 (44%)	10 (83%)	0.058
Serum C4 <14 mg/dL, n (%)	19 (63%)	10 (56%)	9 (75%)	0.44
dsDNA ≤75 IU/mL, n (%)	10 (33%)	5 (28%)	5 (42%)	0.46
Non-responder at 6 mo, n (%)	12 out of 29 (41%)	9 out of 18 (50%)	3 out of 11 (27%)	0.27
Proliferative LN Class, n (%)	17 (57%)	10 (56%)	7 (58%)	0.82
Tubular Fibrosis (IFTA) <10%, n (%)	14 out of 29** (48%)	5 out of 17 (31%)	9 out of 12 (75%)	0.016*
Tubular Fibrosis (IFTA) ≥ 10%, n (%)	15 out of 29** (52%)	12 out of 17 (71%)	3 out of 12 (25%)	
Tubular inflammation none, n (%)	25 out of 29** (86%)	16 out of 17 (94%)	9 out of 12 (75%)	0.28
Tubular inflammation present, n (%)	4 out of 29** (14%)	1 out of 17 (6%)	3 out of 12 (25%)	

Legend: Tubular C9+ represents a stain intensity of 1-3, while Tubular C9- represents a stain intensity of 0. All continuous variables presented as median (IQR) unless otherwise specified. N (%) indicates "patient count (proportion of total N)".
*Significant p-value defined as $p < 0.05$. The Wilcoxon rank sum test and Fisher's exact test were used to assess continuous and categorical variables respectively.
**Missing tubular data for 1 patient, therefore N = 29
*^Mycophenolate mofetil, cyclophosphamide, tacrolimus, azathioprine, rituximab, voclopsorin, or belimumab

p=0.04) [Table 1]. Kaplan-Meier curves showed longer times to CKD progression in C9- group, with separation of the curves occurring after 2 years [Figure 2]. There was no difference in eGFR, serum creatinine, and treatment response at 6 months between the two groups.

Conclusion: This study demonstrates an association between C9 deposition in kidney tubules of LN patients with tubulointerstitial fibrosis. Patients with higher tubular C9 intensity trended towards shorter renal survival although not statistically significant, likely due to limited sample size. These findings highlight tubular MAC deposition as a potential marker for IFTA and CKD progression, underscoring the complement pathway as a potential therapeutic target for tubulointerstitial disease in LN.

Autoimmune Hemolytic Anemia in SLE: A Real-World National Cohort Study

Bana Shawareb[1], Muhannad Haddadin[1], lindsay Frumker[2], Keri Ann Pfeil[3], Meghan Gump[3], **Ansaam Daoud**[4] and Omer Pamuk[5], [1]Cleveland Clinic Akron General, Akron, OH, [2]Case Western Reserve University, Cleveland, [3]University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH, [4]Case Western Reserve University/ University Hospitals, Cleveland, OH, [5]University Hospitals Cleveland Medical Center/ Case Western Reserve University, Cleveland, OH

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune hemolytic anemia (AIHA) is a rare but serious hematologic manifestation of SLE. The prognostic implications of AIHA, particularly long-term mortality and organ involvement, remain poorly understood in real-world populations.

Methods: We conducted a multi-center, retrospective cohort analysis using the TriNetX research platform. Two cohorts were defined based on ICD-10 codes: SLE patients with AIHA and SLE without AIHA, selected via 1:1 propensity score matching across 59 variables, including demographics, comorbidities, and medication exposures. Outcomes were assessed using Kaplan-Meier survival methodology and risk remodeling. The primary outcome was all-cause mortality.

Results: Among 146,197 patients with SLE, 1,424 (0.97%) had AIHA. Before matching, the SLE+AIHA group was younger (mean age 39.5 ± 19.2 vs. 46.7 ± 17.3, p< 0.001), with higher proportions of males, non-White race, and Hispanic ethnicity. (Table 1) They also had a higher prevalence of antiphospholipid syndrome (9.7% vs. 3.7%, p< 0.001), end-stage renal disease (ESRD) (5.9% vs. 3.5%, p< 0.001), neutropenia, lymphocytopenia, and other cytopenias. (Table 1) Glucocorticoids,

B. Diagnosis

Variable	Before Matching - AIHA	Before Matching - Non-AIHA	Before Matching - p-value	After Matching - AIHA	After Matching - Non-AIHA	After Matching - p-value
Glomerular disease in SLE	144 (11.7%)	8,057 (5.9%)	<0.001	143 (11.7%)	123 (10.0%)	0.194
End stage renal disease	72 (5.9%)	4,784 (3.5%)	<0.001	72 (5.9%)	63 (5.1%)	0.426
Dependence on renal dialysis	37 (3.0%)	2,458 (1.8%)	0.002	37 (3.0%)	24 (2.0%)	0.092
Antiphospholipid syndrome	119 (9.7%)	5,076 (3.7%)	<0.001	117 (9.5%)	119 (9.7%)	0.891
Other venous embolism/thrombosis	114 (9.3%)	5,500 (4.0%)	<0.001	112 (9.1%)	95 (7.7%)	0.217
Immune thrombocytopenic purpura	94 (7.6%)	1,878 (1.4%)	<0.001	91 (7.4%)	91 (7.4%)	1

Table 2. Key medication use and lab characteristics in SLE Patients With vs Without AIHA before and after propensity matching

C. Medication Use

Medication	Before Matching - AIHA	Before Matching - Non-AIHA	Before Matching - p-value	After Matching - AIHA	After Matching - Non-AIHA	After Matching - p-value
Hydroxychloroquine	629 (51.1%)	57,678 (42.4%)	<0.001	628 (51.3%)	633 (51.6%)	0.840
Glucocorticoids	886 (72.0%)	73,152 (53.7%)	<0.001	882 (71.9%)	879 (71.7%)	0.893
Azathioprine	125 (10.2%)	6,635 (4.9%)	<0.001	124 (10.1%)	130 (10.6%)	0.691
Mycophenolate mofetil	210 (17.1%)	11,052 (8.1%)	<0.001	206 (16.8%)	201 (16.4%)	0.786
Mycophenolic acid	43 (3.5%)	2,918 (2.1%)	0.001	42 (3.4%)	42 (3.4%)	1
Mycophenolate (unspecified)	10 (0.8%)	347 (0.3%)	<0.001	10 (0.8%)	10 (0.8%)	1
Cyclophosphamide	91 (7.4%)	1,994 (1.5%)	<0.001	89 (7.3%)	80 (6.5%)	0.473
Methotrexate	52 (4.2%)	8,803 (6.5%)	0.001	52 (4.2%)	46 (3.8%)	0.536
Belimumab	10 (0.8%)	2,085 (1.5%)	0.041	10 (0.8%)	10 (0.8%)	1
Rituximab	114 (9.3%)	1,785 (1.3%)	<0.001	110 (9.0%)	85 (6.9%)	0.062
Anifrolumab	0 (0%)	92 (0.1%)	0.362	0 (0%)	10 (0.8%)	0.002
Dapsone	39 (3.2%)	1,024 (0.8%)	<0.001	38 (3.1%)	39 (3.2%)	0.908
Danazol	14 (1.1%)	70 (0.1%)	<0.001	14 (1.1%)	10 (0.8%)	0.412

D. Laboratory Characteristics

Lab	Before Matching - AIHA	Before Matching - Non-AIHA	Before Matching - p-value	After Matching - AIHA	After Matching - Non-AIHA	After Matching - p-value
Neutropenia	76 (6.2%)	2,347 (1.7%)	<0.001	74 (6.0%)	74 (6.0%)	1
Low C3 (<80 mg/dL)	420 (34.1%)	11,463 (8.4%)	<0.001	418 (34.1%)	260 (21.2%)	<0.001
Low C4 (<10 mg/dL)	294 (23.9%)	7,039 (5.2%)	<0.001	294 (24.0%)	174 (14.2%)	<0.001
dsDNA Ab (U/mL)	130.6 ± 503.1 (n=178)	81.3 ± 645.3 (n=14,585)	0.310	131.3 ± 504.5 (n=177)	213.7 ± 1248.0 (n=164)	0.419
Smith+RNP Ab (U)	1.0 ± 1.1 (n=10)	1.8 ± 2.2 (n=145)	0.218	1.0 ± 1.1 (n=10)	0.2 ± 0 (n=10)	0.042
Sjogren's A Ab (U/mL)	54.9 ± 134.4 (n=100)	29.6 ± 108.6 (n=7,172)	0.021	54.9 ± 134.4 (n=100)	42.8 ± 136.8 (n=87)	0.543
Sjogren's B Ab (U/mL)	31.0 ± 102.1 (n=101)	14.6 ± 64.9 (n=7,552)	0.013	31.0 ± 102.1 (n=101)	18.0 ± 66.1 (n=85)	0.315

MMF, CYC, and rituximab were more frequent in the AIHA group (p< 0.001 for all). (Table 2) Following matching (n=1,226 per group), cohorts were balanced across covariates.

Low complement levels remained significantly more frequent in the AIHA group, including low C3 (< 80 mg/dL: 34.1% vs. 21.2%) and C4 (< 10 mg/dL: 24.0% vs. 14.2%) (p< 0.001 for both) (Table 2). Rituximab use remained elevated in AIHA group after matching (9.0% vs. 6.9%, P=0.062). (Table 2) Although glomerular disease appeared more prevalent in the AIHA

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Mortality and Kaplan-Meier survival analysis in SLE Patients With vs Without AIHA before and after propensity matching

group before matching, this was attenuated after adjustment. Nephritis, ESRD, and dialysis did not differ significantly after matching.

Patients with SLE+AIHA exhibited significantly worse outcomes compared to matched controls. (Figure 1) Mortality was higher in the AIHA group (17.0% vs 7.7%), yielding a 9.3% absolute risk difference (95% CI: 6.7–11.9, $p < 0.001$), which is clinically meaningful. The risk ratio was 2.21 (95% CI: 1.76–2.79), and the odds ratio was 2.46 (95% CI: 1.90–3.18), indicating more than a twofold increased risk. Kaplan-Meier survival analysis at follow-up was 63% in the AIHA group vs. 84% in controls. Log-rank testing confirmed a significant difference ($\chi^2 = 15.89$, $p < 0.001$); hazard ratio was 1.64 (95% CI: 1.28–2.09, $p = 0.032$), reflecting a 64% higher mortality hazard in the AIHA group after accounting for survival duration.

Conclusion: In this national real-world cohort, AIHA was associated with significantly higher mortality risk and reduced long-term survival among SLE patients. These findings highlight AIHA as a prognostic marker of disease severity, supporting the need for early recognition and monitoring. Its association with low complement levels may further signal more aggressive disease phenotypes.

Abstract Number: 2383

The Age-Adjusted Charlson Comorbidity Index (CCI) Predicts All-Cause Mortality in Systemic Lupus Erythematosus (SLE) Patients: Data from the Almenara Lupus Cohort

Benny Rashuamán-Conche[1], Rocío Gamboa-Cárdenas[2], Victor Pimentel-Quiroz[3], Cristina Reategui-Sokolova[4], Claudia Elera-Fitzcarrald[4], Cesar Pastor-Asurza[5], Zoila Rodriguez-Bellido[6], Risto Perich-Campos[7], Graciela Alarcón[8] and Manuel Ugarte-Gil[9], [1]Hospital Guillermo Almenara Irigoyen, Lima, Lima, Peru, [2]Universidad Científica del Sur, Lima, Peru, [3]Universidad Científica del Sur, San Isidro, Peru, [4]Hospital Guillermo Almenara Irigoyen, Lima, Peru, [5]Hospital Nacional Guillermo Almenara Irigoyen, Lima, Pakistan, [6]Universidad Nacional Mayor de San Marcos, Lima, Peru, [7]Hospital Nacional Guillermo Almenara Irigoyen; Universidad Nacional Mayor de San Marcos, La Molina, Peru, [8]The University of Alabama at Birmingham, Oakland, CA, [9]Grupo Peruano de Estudio de Enfermedades Autoinmunes Sistémicas, Universidad Científica del Sur, Lima, Peru; Hospital Guillermo Almenara Irigoyen, EsSalud, Lima, Peru, Lima, Peru

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The CCI has been associated with adverse health-related outcomes in SLE-patients worldwide. Its modified version, the age-adjusted CCI (ACCI) has been associated with organ damage and mortality in Korean and Taiwanese SLE-patients cohorts. However, there are no studies addressing the impact of ACCI in mortality in Latin-American SLE cohorts. The aim of this study was to evaluate the ACCI as a predictor of mortality in Latin-American patients with SLE.

Table 1. Impact of the ACCI on mortality in SLE patients. *Adjusted for age at diagnosis, gender, ethnic group, socioeconomic status, years of education, tobacco use, disease duration, SLEDAI-2K, SLICC/ACR damage index, prednisone daily dose, antimalarial and immunosuppressive drugs use and the number of prescribed drugs. ACCI: Age-adjusted Charlson Comorbidity Index; HR: Hazard Ratio

	Unadjusted HR (95% CI)	*p* value	Adjusted* HR (95% CI)	*p* value
Main model				
ACCI score per 1.0 increase	1.442 (1.291-1.611)	<0.001	1.322 (1.083-1.615)	0.006
Alternative model				
ACCI score				
0	Ref.		Ref.	
1	1.907 (0.775-4.694)	0.16	1.965 (0.728-5.305)	0.183
2	3.447 (1.473-8.063)	0.004	2.640 (0.929-5.305)	0.068
3	4.144 (1.543-11.127)	0.005	2.838 (0.821-9.816)	0.099
4	6.502 (2.420-17.470)	<0.001	4.295 (1.030-17.913)	0.045
≥5	9.424 (3.904-22.747)	<0.001	5.246 (1.180-23.325)	0.029

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A secondary analysis was performed on the data from the Almenara Lupus Cohort. The follow-up period assessed was from January 2012 to March 2025. To enter this cohort, patients had to meet the ACR 1997 or the SLICC 2012 criteria set and to be older than 18 years of age at the baseline visit. Patients who had been diagnosed with other autoimmune disease, except Sjögren's or the antiphospholipid syndromes were excluded. Mortality was determined as the vital status according to the official information from the Peruvian Department of Health. ACCI scores were used to measure comorbidity status, excluding the point for connective tissue disease. It was calculated at baseline as a continuous variable. Unadjusted and adjusted Cox regression models were performed to assess the impact of ACCI on mortality. The model was adjusted for age at diagnosis, gender, ethnic group, socioeconomic status, years of education, tobacco use, disease duration, the SLEDAI-2K, the SLICC/ACR damage index, the prednisone daily dose, antimalarial and immunosuppressive drugs use and the number of prescribed drugs. In an alternative model, the ACCI was categorized as 0,1,2,3,4 and ≥ 5.

Results: Five-hundred and nine patients were included, 470 (92.3%) were women, their mean (SD) age at diagnosis was 35.0 (14.0) years, their disease duration at baseline was 6.7 (6.1) years, their mean (SD) ACCI was 1.4 (1.7) and their mean follow-up time was 8.5 (4.1) years. Fifty-seven (11.2%) patients died during the follow-up. A higher ACCI predicted mortality in both, the unadjusted [HR=1.442, (95% CI: 1.291-1.611; p≤0.001)] and adjusted analyses [HR=1.322, (95% CI: 1.083-1.615); p=0.006]. Main and alternative models are depicted in **Table 1**.

Conclusion: Higher ACCI scores predicted mortality after adjusting for potential confounders in a Latin-American SLE cohort. The active evaluation of comorbidities and their proper management will result in SLE patients having a better survival.

Abstract Number: 2384

Patient-Reported Quality of Life in SLE: Association with Biomarker-Derived Disease Activity Index (L-DAI) and hSLEDAI in a Prospective Cohort

Bernard Rubin[1], Rou Sore[1], Melissa Munroe[1], Daniele DeFreese[1], Adrian Holloway[1], Mohan Purushothaman[1], Yangfen Li[2], Hu Zeng[2], Uma Thanarajasingam[2], Judith James[3] and Eldon Jupe[1], [1]Progentec Diagnostics, Inc., Oklahoma City, OK, [2]Mayo Clinic, Rochester, MN, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systematic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by unpredictable disease activity. The Lupus Disease Activity Index (L-DAI) is a blood-based assessment informed by 10 immune biomarkers that objectively measures current disease activity, while the hybrid SLEDAI (hSLEDAI) is a clinician assessed measure of disease activity. This study evaluated the association between both L-DAI and hSLEDAI and patient reported quality of life (HRQol) in a small real-world community-based, prospectively followed SLE cohort.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective analysis from a small cohort of adults with classified SLE longitudinally and serially followed at the Mayo clinic from 2018 to 2021. L-DAI, hSLEDAI were collected quarterly for 12 months but clinicians were blinded to the L-DAI score throughout the study period. HRQol was assessed using the LupusPRO score (0-100 scale) at each visit. Linear regression was used to evaluate the association between HRQol and both L-DAI and hSLEDAI scores.

Results: Among 30 patients contributing to 145 visits, 27 (90%) were female and 3 (10.00%) were male. HRQol ranged from 28 to 100 (mean= 70.79 ± 16.34). In multivariable linear regression, both an increase in hSLEDAI (β = -0.89, p= 0.006) and an increase in L-DAI (β = -0.25, p= 0.020) were independently associated with a lower HRQol.

Conclusion: Our study demonstrated that both L-DAI and hSLEDAI were significantly associated with patient reported HRQol. In fact, an incremental increase in both L-DAI and hSLEDAI correlated with a decrease in patient reported quality of life. These findings highlight the utility of L-DAI and hSLEDAI in assessing disease activity and patient-reported quality of life measures. However, larger, more diverse patient cohorts are needed to validate these findings.

Abstract Number: 2385

The Presence of Avascular Necrosis in Patients with Systemic Lupus Erythematosus Undergoing Total Knee Arthroplasty is Not Associated with Worse Outcomes

Billy Kim[1], Ahmed Deeb[1], Douglas Mintz[1], Susan Goodman[2], Jose Rodriguez[2], Mark Figgie[2] and Jason Blevins[3], [1]Hospital for Special Surgery, New York, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [3]Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) patients seeking total knee arthroplasty (TKA) may present with secondary avascular necrosis (AVN) of the knee due to high-dose glucocorticoid use. Whether presence of AVN negatively impacts TKA outcomes in this high-risk population has not previously been studied.

Methods: A retrospective analysis of 184 knees (150 patients) with SLE undergoing TKA between 2015 and 2023 at a large academic institution was conducted. The cohort was stratified by the presence of AVN on preoperative X-ray and/or magnetic resonance imaging (MRI) when available. Imaging diagnosis was validated by an experienced musculoskeletal radiologist. Patient characteristics, clinical outcomes, and patient-reported outcome measures (PROMs) were compared between groups using univariable and multivariable analyses. Mean follow-up was 4.1 years (range: 0.1-8.5).

Results: AVN was present in 13% (n=23/184) of SLE knees. Patients with AVN were younger (P< 0.01) and had lower BMI than patients without AVN (P=0.05). Multivariable analyses demonstrated that younger age was associated with increased

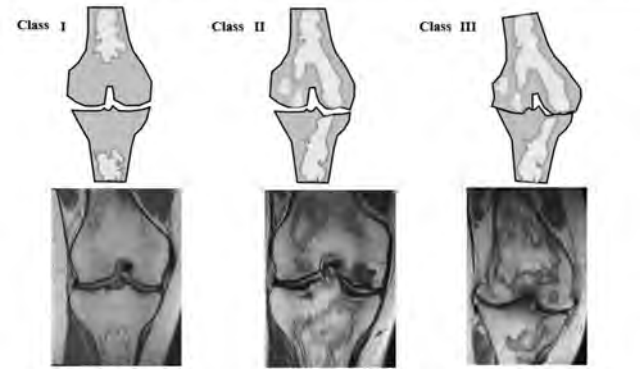
Class	Metadiaphyseal involvement	Articular Involvement (subchondral collapse, cartilage defect)	Deformity/Significant Bone Loss
I	+	-	-
II	+	+	-
III	+	+	+



MRI patterns of osteonecrosis inSLE patients with AVN

risk of 90-day readmission (P=0.03) and revision (P< 0.01). There were no significant differences in complication rates or postoperative PROMs between SLE patients with and without AVN (P >0.05). Based on osteonecrosis patterns on MRI, knee AVN was categorized into three sequential classes: I) primarily metadiaphyseal; II) metadiaphyseal with articular extension; III) progression with severe deformity or bone loss.

Conclusion: TKA outcomes in SLE patients with AVN are comparable to those without. Primary cemented implants provide durable results. In advanced stages of knee osteonecrosis, however, judicious preoperative evaluation is warranted, as significant bone deformities and defects may necessitate augments, cones, and/or stems.

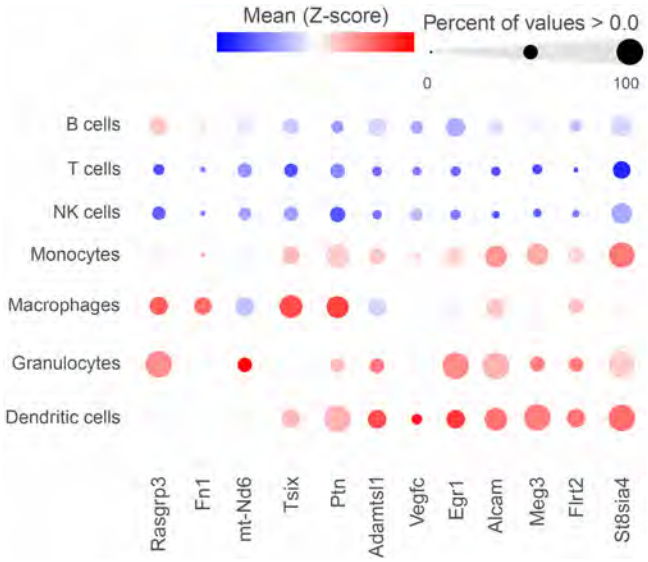
Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that causes inflammation in many of the body's tissues, including the heart. Recent studies attribute almost 50% of mortality in lupus patients to cardiovascular (CV) disease after the first 10 years. Myocardial inflammation is present in up to 40% of lupus patients. Understanding the pathogenic mechanisms that drive CV disease in SLE is essential for its management and for developing new therapeutic approaches. Given the importance of the membrane barrier function in preventing exposure of intracellular antigens to the extracellular space where they could act as autoantigens, compromised membrane repair may be a contributory mechanism to SLE pathogenesis.

We identified TRIM72, which is essential for membrane repair, as an autoantigen in myositis patients. Our current studies indicate this may be the case in lupus as well. Given the potential contribution of membrane repair in development of lupus myocarditis and the role of TRIM72 in membrane repair, we hypothesized that defective membrane repair leads to aberrant extracellular exposure of membrane repair proteins, such as TRIM72, and autoantibody generation which creates a positive feedback loop causing further exposure of intracellular antigens contributing to lupus myocarditis pathogenesis.

Methods: A custom TRIM72 antibody ELISA was used to quantify serum levels of TRIM72 antibodies in serum. Multiphoton confocal laser microscopy was used to measure the dynamics of membrane repair *in vitro*. snRNAseq of NZM2410 mouse hearts was performed on young and old mice. Partek™ Flow™ software was used to analyze the transcriptomic expression data.

Results: We demonstrate that anti-TRIM72 auto-antibodies were elevated in both SLE patient serum diagnosed with myocarditis and serum of NZM2410 mice with myocarditis. Murine cardiomyocyte membrane repair is significantly reduced by exposure to myocarditis positive SLE patient serum with high levels of TRIM72 antibodies but not to healthy control serum. Removal of TRIM72 antibodies from serum reduces this effect on membrane repair. Preliminary data demonstrate similar trends of lupus sera containing anti-TRIM72 antibodies on human cardiomyocytes. snRNAseq revealed that cardiomyocytes are reduced and fibroblasts increase as NZM2410 mice age. Specific CV disease pathways are enriched in cells of aged hearts of NZM2410 mice as compared to young mice. Genes linked to lupus disease pathology are differentially expressed in immune cells. Subcluster analysis of specific cell populations, e.g. cardiomyocytes, fibroblasts, etc. revealed several cell types and gene expression profiles associated with development of SLE myocarditis.



Transcriptomic analysis of cardiac tissue reveals multiple differentially expressed genes linked to lupus. A partial list of statistically significant differentially expressed genes in immune cells is shown.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: The plasma membrane repair protein TRIM72 is an autoantigen in SLE associated myocarditis and potentially contributes to disease pathogenesis. We demonstrate the presence of TRIM72 antibodies in SLE patients that can compromise membrane repair in cardiomyocytes in vitro. Ongoing studies will examine if these defects lead to membrane repair protein exposure to the extracellular space causing the production of autoantibodies which contribute to a vicious cycle that exacerbates SLE pathology.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The current Systemic Lupus Erythematosus Damage Index (SDI) is a robust instrument, but is limited by missing items, restricted applicability in pediatric patients, and outdated item definitions. A data-driven and expert/patient consensus-based project to develop a revised Systemic Lupus International Collaborating Clinics (SLICC)/ American College of Rheumatology (ACR), Damage Index (SDI) is underway supported by SLICC, ACR and the Lupus Foundation of America. Our objective was to report the item generation and item reduction phase results for developing a revised SDI.

Methods: Item generation included a literature review by Literature Review Groups and a Delphi exercise of international SLE experts and patients. Item reduction involved Delphi rounds where items with a median appropriateness score of $\leq$ 4 out of 9 were excluded. A 14-member Item Reduction Committee assessed the remaining items and removed those that did not reflect the damage construct, were excessively rare, or were not feasible to assess. The Clinical Domain Groups then refined the remaining items, and their definitions.

Results: The Delphi panel included 146 individuals from 35 countries. Item generation identified 226 initial candidate items. The Delphi exercise, review by the Item Reduction Committee and Clinical Domain Groups resulted in removal of 36, 126 and 25 items, respectively. This resulted in 39 items across 13 clinical domains. Eleven items from the original SDI, including chronic peritonitis, cranial neuropathy, mesenteric insufficiency, muscle atrophy or weakness, osteomyelitis, pancreatic insufficiency requiring enzyme replacement or with pseudocyst, pleural fibrosis, proteinuria, shrinking lung, skin ulceration (excluding thrombosis), and stricture or upper gastrointestinal tract surgery were removed. Several new items were proposed, such as growth failure/reduced final height and adrenal insufficiency. Sub-categorizing items based on severity or grade is proposed for 17 (43.6%) proposed items. Additionally, the Clinical Domain Groups developed definitions for each of the items, based on their clinical expertise, current evidence-based practice or specialty guidelines.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This data-driven and expert/patient consensus-based process has proposed 39 candidate items, some with sub-items, and with definitions for a revised SDI. Weighting of items and sub-items is now underway to increase the sensitivity and responsiveness of any new index.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) presents a highly heterogeneous clinical course and prognosis. In line with EULAR recommendations and treat-to-target (T2T) strategies, comprehensive assessment of disease activity, organ damage, and patient-reported outcomes (PROs) is essential to optimizing long-term patient care.

This study aimed to analyze the correlation between disease activity, organ damage, and PROs in a well-characterized cohort of SLE patients, providing insights into clinical management and functional outcomes.

Methods: We conducted an observational, cross-sectional study including the first 208 consecutive SLE patients assessed under a prospective Treat-to-Target (T2T) strategy from March 31, 2023, at a university hospital in Northern Spain.

Disease activity was measured using the SLE Disease Activity Index 2000 (SLEDAI-2K) and SLE-Disease Activity Score (SLE-DAS). Remission was defined according to DORIS criteria (clinical SLEDAI-2K = 0, Physician Global Assessment (PGA) = 0). Lupus Low-Disease Activity State (LLDAS) was defined as SLEDAI-2K ≤4, no disease activity in major organ systems, no new disease activity compared to previous evaluations, PGA ≤1, and prednisone ≤7.5 mg/day.

Organ damage was assessed using the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SLICC/ACR-DI, SDI). Patient-reported outcomes (PROs) included the Health Assessment Questionnaire (HAQ) and Lupus Impact Tracker (LIT).

Data are presented as percentages, mean±SD, or median [IQR], as appropriate. Correlations between HAQ, SDI, and remission criteria (DORIS and LLDAS) were analyzed to explore their interrelationship in clinical practice.

Table 2. A comparative table between remission according to DORIS, Lupus Low Disease Activity (LLDAS) and organ damage involvement and HAQ.

Total SLE patients, n= 208				
	Total	DORIS Remission N= 116	LLDAS N= 58	Non Remission / non LLDAS N= 34
SDI, score				
SDI=0, n (%)	117	61 (52.6)	37 (63.8)	19(55.9)
SDI=1, n (%)	38	21 (18.10)	10 (17.2)	7 (20.6)
SDI>2, n (%)	53	34 (29.3)	11 (19)	8 (23.5)
HAQ				
HAQ= 0-1, n (%)	151	100(86.2)	35(60.3)	16(47.1)
HAQ= 1-2, n (%)	50	13 (11.2)	21(36.2)	15(44.1)
HAQ >2, n (%)	9	3(2.6)	2 (3.5)	3 (6.8)

Results: We analyzed 208 SLE patients (86.5% women, mean age 46.9 ± 14.3 years). After a median follow-up of 145 [53–361] months, lupus nephritis was present in 60 (28.8%), corticosteroids were used by 88 (42.3%), and antimalarials by 164 (78.8%). At evaluation, 116 (55.7%) met DORIS remission criteria, while 58 (27.9%) were in LLDAS. Organ damage (SDI) was observed in 38 (18.2%) with SDI ≥1 and in 53 (25.4%) with SDI ≥2. Notably, 55.9% of non-remission patients had SDI = 0, indicating variability in disease progression. Among patients in remission, 86.2% had a HAQ score between 0 and 1, versus 47.1% of non-remission patients.

Conclusion: While 55.7% achieved DORIS-defined remission, nearly half had organ damage (SDI ≥1), highlighting a weak correlation between disease activity indices and organ damage. Concurrent assessment of both measures is essential. The stronger correlation between HAQ and SDI suggests PROs may better reflect disease burden than activity indices alone.

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: SLE is a systemic autoimmune disease that can present at different ages and with various multiorgan complications. In this study, we aimed to analyze the differences in characteristics in patients with older onset SLE (age of diagnosis >50) and younger onset SLE (age of diagnosis <49).

Methods: A retrospective cohort study was performed using TriNetX, a global federated health research network that provides access to electronic medical records across large health care organizations (HCOs). Data was used from 99 different

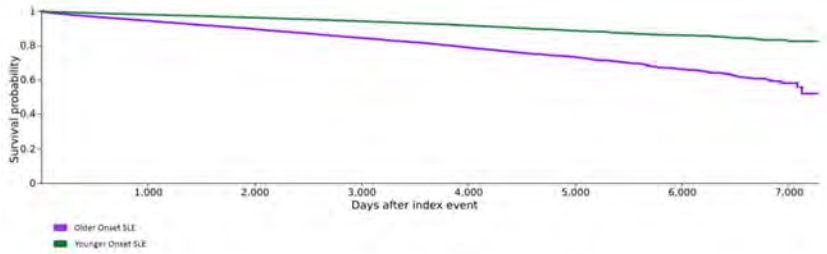

Figure 1. Kaplan-Meier Survival Analysis of Mortality in Older Onset SLE Patients vs. Younger Onset SLE Patients

HCOs. Adult patients (>18 years of age) were divided into two cohorts, older and younger onset SLE, based on age of SLE diagnosis (ICD-10: M32.9). 1:1 propensity score matching was performed using 58 different baseline patient characteristics, including demographics, comorbidities, medication usage, and serological profiles (Table 1 and Table 2). Kaplan-Meier survival analysis was performed to examine differences in mortality between both cohorts.

Results: 62,242 patients were included in the older onset SLE cohort and 85,011 patients were included in the younger onset SLE cohort before propensity score matching. After propensity score matching, 45,733 patients were included in the older onset SLE and younger onset SLE cohorts respectively.

Univariate analysis before matching showed several significant differences in characteristics between both cohorts (Table 1 and Table 2). After propensity score matching, the frequency of thrombocytopenia was higher in the younger onset SLE group compared to the older onset SLE cohort ($p < 0.001$), otherwise the frequency of SLE related comorbidities was not significantly different (Table 1). Patients in the younger onset SLE cohort had a higher frequency of positive anti-dsDNA ($p < 0.001$), positive anti-RNP ($p < 0.001$), and low complement C3 and C4 ($p < 0.001$) (Table 2). There were no statistically significant differences in the frequencies of medications used (Table 2).

Risk analysis showed that 4,658 (10.2%) of older onset SLE patients died and 1,896 (4.1%) of younger onset SLE patients died during the study period (7,000 days) (RR = 2.457, 95% CI 2.333, 2.587, p = < 0.001).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Survival analysis revealed that the older onset SLE group had a markedly lower survival probability at the end of the observation period (51.79%) compared to those diagnosed before age 49 (82.38%). The difference in survival between groups was statistically significant (log-rank test $\chi^2 = 1515.153$, $p < 0.001$). Cox proportional hazards modeling showed that older onset SLE was associated with a significantly increased risk of mortality (hazard ratio: 2.77; 95% CI: 2.63–2.92). The assumption of proportional hazards was met ($\chi^2 = 1.466$, $p = 0.226$), supporting the validity of the model (Figure 1).

Conclusion: This retrospective cohort study suggests that younger onset SLE patients are more likely to develop thrombocytopenia, otherwise have no significant difference in the examined comorbidities. Patients with younger onset SLE are also more likely to have positive anti-dsDNA, positive anti-RNP, and hypocomplementemia. Medications used between younger and onset SLE patients are not significantly different. Patients with older onset SLE have a significantly increased risk of mortality.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Growing evidence supports the role of chemical exposures as contributors to the development of Systemic lupus erythematosus (SLE)[1]. Several of the gene variants associated with SLE appear to be responsive to various environmental substances. We aimed to classify SLE-associated loci based on gene-chemical connection and to reveal potential exposure-based differences. We performed functional enrichment analysis, constructed polygenic risk scores (PRSs) and analyzed clinical phenotype associations.

Methods: A total of 155 genome-wide association study (GWAS) significant (p=5e-8) SLE single nucleotide variants (SNVs) were selected (based on European ancestry). Comparative Toxicogenomics Database (CTD[2]) was scanned for chemical exposure connection with these genes. A gene-chemical interaction analysis was performed. The top 1/3 of the genes with the highest number of gene–chemical connections were selected and denoted as total (TOT). Separately, we analyzed the number of interactions for endocrine-disrupting chemicals (EDCs)[3].

Scandinavian patients with SLE (n=1419), fulfilling ≥4 ACR-97 criteria, were genotyped by Illumina Global Screening Array. Clinical data was collected from charts. SLE environmental exposure weighted polygenic risk scores (PRSs) were developed including the TOT and EDC risk loci. Regression analysis compared the top quartile to the remaining individuals adjusting for sex and age. Functional enrichment was carried out using KEGG, TRRUS[4] and Reactome databases.

Results: In total, 19 of top genes identified in the CTD database were included exclusively in the TOT-PRS (including *IL7R* and *STAT4*), and 17 were specific to the EDC-PRS (including *ATXN2 and TYK2*). The highest number of interactions was observed for *IL10* (n=3169).

Pathway analysis showed enrichment of Toll-like receptor signaling in both groups (p=1.0e-4), while B-cell receptor signaling (p=1.6e-3) was enriched in TOT-PRS only.

Both scores were associated with higher risk of malar rash (OR 1.6, p=4.4e-8, TOT-PRS; OR 1.6, p=6.9e-8, EDC-PRS), nephritis (OR 1.7, p=8.1e-14, TOT-PRS; OR 1.6, p=9.2e-14, EDC-PRS) and serositis (OR 1.5, p=7.8e-7, TOT-PRS; OR 1.5, p=5.1e-7, EDC-PRS). No association was observed for discoid rash or arthritis (both p >0.05). Further, the PRSs showed association with thrombocytopenia (OR 1.1, p=0.02, TOT-PRS; OR 1.5, p=5.5e-3, EDC-PRS) and leukopenia/lymphopenia (OR 1.3, p=2.4e-4, TOT-PRS; OR 1.7, p=2.8e-5, EDC-PRS).

Conclusion: We demonstrated that classification of SLE loci based on gene-chemical connections can identify potential connections between selected risk genes and chemical compounds. A strong association between specific risk genes and a large number of chemical compounds suggests that these genes may be important targets when investigating the role of environmental exposures to risk for disease. Leveraging public functional gene-based information can also help to reveal exposome-associated mechanisms behind SLE clinical heterogeneity.

Background/Purpose: It has been reported that the presence of positive ANA in patients treated with TNF inhibitors (TNFi) could be associated with the development of new clinical symptoms of SLE. The aim of this study is to review the prevalence of positive ANA titers by immunofluorescence assay (IF-ANA) in patients with psoriasis (PSO) and PsA, as well as the associated risk of developing clinical symptoms of SLE after treatment with TNFi.

Methods: The study utilized the electronic medical record system to generate a list of patients who were diagnosed with PSO or PsA between 2014 and 2024. From this list, patients with a positive IF-ANA titer (>1:80) who were treated with TNFi were selected. A detailed chart review was then performed to identify those who developed drug-induced SLE-like symptoms following TNFi therapy.

Descriptive statistics were used to analyze demographic data (Table 1), and the Chi-square and Fisher's exact tests were employed to assess relationships between groups and binary outcomes.

Results: Over the ten-year period, 9,273 individuals were diagnosed with PSO or PsA. Among them, 1,171 patients were tested for IF-ANA, of whom 518 tested positive and 653 tested negative. Among the IF-ANA positive patients, 187 were treated with TNFi (Table 2). Some of these patients received more than one TNFi agent during the course of treatment. Notably, 20 patients developed IF-ANA positivity only after initiating TNFi therapy.

Based on clinical visit notes, 42 patients were suspected of developing drug-induced lupus. Among them, 7 reported worsening joint pain and fatigue, 17 developed worsening or new skin rashes, 3 patients had a significant increase in IF-ANA titers (>6,000), 2 patients developed new anti-dsDNA antibodies, and 1 patient developed anti-histone antibodies. Additional findings included transaminitis in 3 patients, a demyelinating disorder in 1 patient, and paresthesia in 4 patients. Four patients developed other symptoms, including one case each of pericarditis, allergic reaction, diverticular rupture, and pancytopenia (Table 3). Furthermore, 69 IF-ANA–positive patients did not respond to TNFi treatment.

Conclusion: The association between TNFi use and SLE-like symptoms remains a clinical concern. TNFi can elevate ANA titers in ANA-positive patients and may induce new ANA positivity in ANA- negative individuals (2). TNFi have been linked to drug-induced lupus, presenting with arthralgias, rashes, and serositis (1). Diagnosis typically requires symptom onset after TNFi initiation, one positive autoantibody (e.g., ANA or anti-dsDNA), and one non-serologic criterion such as rash (4).

Table 1. Demographics.

Demographics	N (%)
Female N (%)	148(74%)

Table 3. Chi-square statistics.

Patients with positive IF-ANA before and after TNFi		SLE-like symptoms		Positive IF-ANA		Worsening of joint pain		Worsening or new rash		Significant increase in IF-ANA titer		New positive anti-dsDNA antibody		New positive anti-histone antibody		Transaminitis		Demyelinating disorder		Paresthesia		Other symptoms	
		No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes
TNFi	Before	187	0	20	167	187	0	187	0	187	0	187	0	187	0	187	0	187	0	187	0	187	0
	After	145	42	0	187	180	7	170	17	184	3	185	2	186	1	184	3	186	1	183	4	183	4
Chi-square p-value		<0.0001		0.1239		0.0076		<0.0001		0.082		0.1562		0.3167		0.082		0.3167		0.0461		0.0461	
Fisher's exact test p-value		<0.0001		0.2286		0.0148		<0.0001		0.248		0.4987		1		0.248		1		0.123		0.123	

In our review, 20 of 187 patients developed new ANA positivity. Although ANA and anti-dsDNA positivity were low, SLE-like symptoms were statistically significant, with joint pain and rash being the most common. The 72% of affected patients were on adalimumab. Prior studies suggest higher lupus risk with adalimumab and infliximab, though all TNFi can induce ANA (1). Some patients may tolerate a different TNFi without recurrence (5). Proposed mechanisms include reduced CD44 expression, infection-induced autoantibodies, and a cytokine shift toward Th2 responses (3), possibly explaining variable risk across TNFi agents.

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Obesity, a prevalent condition, is known to exacerbate inflammation and could potentially influence the progression and severity of autoimmune diseases like Systemic lupus erythematosus (SLE). Despite this, limited research has explored the impact of obesity on disease activity and biomarkers in SLE patients. This retrospective study aims to investigate how obesity affects disease activity, as measured by the SLEDAI, and various biomarkers, and renal function, in SLE patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: Using data from Slicer Dicer (via EPIC) and Redcap, we analyzed 150 SLE patients at LSU Health Shreveport in 2021, divided into 78 obese (BMI ≥ 30 kg/m^2) and 72 non-obese (BMI < 30 kg/m^2) patients. We examined SLEDAI, WBC count with lymphocytes, anti-dsDNA, ANA levels, C3 and C4 levels, ESR, CRP, creatinine, lupus nephritis presence, LDL to HDL ratio, total HDL, and triglycerides. Results are presented as mean±SD. Statistical analyses were made using the unpaired Student's t-test, with $p< 0.05$ considered significant.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: This study enrolled 150 lupus patients: 136 females (90.7%), 14 males (9.3%); 123 African Americans (82.0%), 20 Caucasians (13.3%), 7 Hispanics (4.7%). Although anti-dsDNA and ANA interpretations were similar between obese and non-obese groups, obese patients demonstrated worse outcome with a higher trend of SLEDAI score compared to the non-obese group (10.8±7.8 vs 8.6±6.7). In addition, obese lupus patients showed significantly higher frequencies of more than two joints arthritis (95.83% vs 33.33%) and lupus rush (66.67% vs 25%) than the non-obese group. The increasing trend of CRP(70 mg/L+4.1 vs 29mg/L+0.69) and ESR level (41.1±27.4 mm/hr vs 37.1±33.5mm/hr) was found in the obese lupus patients compared to nonobese lupus patients, but didn't reach statistical significance. No difference was observed in triglyceride level, LDL: HDL ratio, WBC counts, creatinine level, and lupus nephritis between the obese group and the non-obese group. Surprisingly, we found that the obese group had significantly higher C3 levels (116±32.6 mg/dL) compared to the non-obese group (96.7±31.9 mg/dL) ($p < 0.001$). The C4 level was also higher in the obese group (28.4 ±26.3 mg/dL) than in the non-obese group (23.0±11.9 mg/dL).

Conclusion: Our results indicate that obesity in lupus patients is associated with elevated C3 levels, higher mean SLEDAI scores, and inflammation-related parameters, suggesting a potential link between obesity and worse outcomes in SLE. Other clinical and laboratory parameters (such as autoantibody, lupus nephritis) did not show significant differences, implying that obesity may not affect humoral immunity in SLE. Further research at the cellular and molecular levels on obese lupus patients will help us understand the impact of obesity on lupus progression and management.

Improving Clinical Outcomes In SLE Arthritis Trials: Post-Hoc Analysis Of A Prospective Intervention Study

Samuel Wood[1], Khaled Mahmoud[2], Md Yuzaiful Md Yusof[2], Philip Conaghan[2], Elizabeth Hensor[2] and **Ed Vital**[3], [1]University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]University of Leeds, Leeds, England, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Musculoskeletal (MSK) manifestations of SLE are the most frequently assessed domain in clinical trials. Optimal MSK assessment is contested; candidates include the binary or ordinal SLEDAI and BILAG, tender joint count (TJC), swollen joint count (SJC) and "active" joint counts, (either tender or swollen, or both).Ultrasound studies in SLE have identified imaging-only synovitis, such that the BILAG A/B criterion has a sensitivity of just 56% for US synovitis.

Our aim was to assess sensitivity and specificity of a set of candidate joint counts against US synovitis, as well as patient and US defined response to therapy.

Components of the LAMDA
Swollen joint count (66/68)
Physician musculoskeletal disease activity VAS (scored 0-100)
Patient reported musculoskeletal pain VAS (scored 0-100)
Erythrocyte Sedimentation Rate (ESR)

Components of the composite lupus arthritis and MSK disease activity (LAMDA) score.

Methods: We performed a post-hoc analysis of a multi-centre study [USEFUL; PMID: 33792659]. Patients with inflammatory arthralgia were assessed clinically and using US at 0, 2 and 6 weeks following single-dose intra-muscular glucocorticoid therapy.

Candidate joint sets were defined as: 68 TJC and SJC, 28 TJC and SJC, or 24 TJC and SJC (MCPs, PIPs, elbows, wrists). Joint counts were compared with weighted scatter plots and intraclass correlation coefficients (ICCs).

Participant-reported change was measured using a Likert scale (-7 to 7). For US response, changes in number of 'active' joints (grey scale ≥2 and/or power Doppler ≥1) were calculated. Spearman rank correlation measured associations between changes in the candidate joint counts, participant-reported changes and changes in the number of US active joints. Associations are also reported for the composite lupus arthritis and MSK disease activity score (LAMDA) (Table 2).

Results: Of 133 patients, 95% female and 62% European ancestry, 63% had ≥1 SJC at baseline. TJC and SJC had poor sensitivity (50.7% and 41.6% respectively), and TJC had lower specificity than SJC (60.7% and 91.4% respectively)(Table 1). Active "either" and active "both" almost exactly matched TJC and SJC respectively (Figure 1a-h).

In joint-by-joint analysis the most commonly swollen joints were MCPs 2-5.Tenderness was most common in MCP 2 and 3, wrist, shoulder and knee. Reduced joint counts were more strongly correlated with US-defined response than full joint counts (Figure 1i) but not with participant-defined response. Changes in TJCs correlated with participant-defined response and changes in SJCs with US-defined response but not vice-versa. LAMDA was modestly correlated with both response definitions.

Conclusion: (1) TJC and SJC have limited sensitivity for imaging-detected synovitis, but SJC has high specificity. (2) Active 'either' and 'both' joint counts almost exactly match TJC and SJC respectively and are therefore redundant. (3) Diagnostic accuracy of clinical assessment varies by joint area; shoulders and knees likely contribute little to assessment of joint inflammation and often have non-inflammatory pathology. (4) SJC is the most responsive measure of objective synovitis; SJC24 is the most responsive set for US response, but is not correlated with participant-defined response.

Given the relative insensitivity of SJC, and importance of patient defined response, the composite measure, LAMDA may be optimal in RCTs. Future work will evaluate these variables in randomised trials and define inclusion and response thresholds.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiovascular events are a significant source of morbidity and mortality in SLE patients, occurring more frequently than in the general population owing to immune dysregulation and chronic inflammation. While certain medications such as glucocorticoids may inherently increase cardiovascular risk, we hypothesize that non-glucocorticoid medications could potentially be associated with reduced cardiovascular risk.

Table 1. Patient Demographics

Variable	No MACE (N=319, 81%)	MACE (N=74, 19%)	P-Value
Age in years, Mdn (IQR)	49 (39, 61)	61.5 (50, 70)	<0.01
Sex			0.16
Male, n (%)	23 (7)	9 (12)

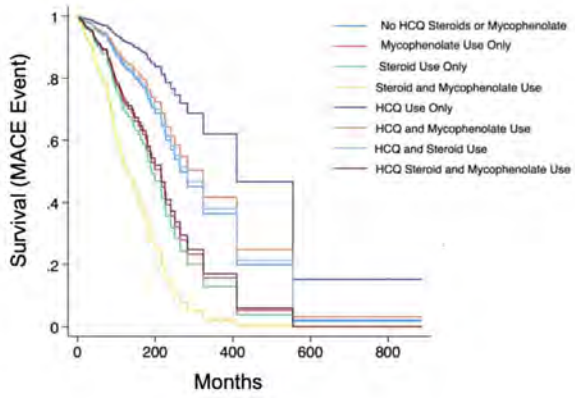
Figure 1. Cox Proportional Hazard Regression



Cox Proportional hazards regression model comparing combinations of hydroxychloroquine, corticosteroids, and mycophenolate versus survival-time for MACE. MACE: Major Adverse Cardiac Event (non-fatal myocardial infarction (MI), non-fatal stroke, unstable angina, hospitalization for heart failure, and/or all-cause death) HCQ: hydroxychloroquine

Methods: This is a retrospective cohort study utilizing data from a diverse, single health system in a major urban center in North America. We completed a survival analysis examining risk of major adverse cardiac events (MACE) defined by a 5-point MACE scale, with respect to immunosuppressant use. Survival time was measured from SLE diagnosis to event or last follow-up. Kaplan-Meier, log-rank test, and Cox proportional hazards models were used to compare survival curves. Model fit and assumptions were evaluated using Schoenfeld residuals and likelihood ratio tests. A final multivariable Cox regression analysis was developed using a backward regression approach including 7 final variables. Immunosuppressant medications were tested in individual models and statistically significant regimens were included in the final analyses.

Results: 393 patients were included. Demographics are listed in Table 1. Nineteen percent of participants experienced ≥1 MACE. These included stroke (42%), myocardial infarction (26%), heart failure hospitalization (21%), unstable angina requiring cardiac revascularization (11%), cardiovascular death (0%). Kaplan-Meier curves demonstrated a lower time to event in patients taking corticosteroids and mycophenolate (MMF), while patients taking hydroxychloroquine (HCQ) had a higher survival probability (Table 2, Figure 1). Log-rank test demonstrated statistical significance (p=0.03, 0.03, 0.03, respectively). Corticosteroid and MMF use were independently associated with increased risk of MACE (HR 2.02, 95% CI 1.21–3.37, p<0.01, and HR 1.82, 95% CI 1.14–2.92, p=0.01). Use of HCQ was associated with a reduced risk of MACE (HR 0.47, 95% CI 0.25–0.88, p=0.02) (Table 2, Figure 1). Other disease modifying anti-rheumatic drugs and biologic medications tested did not reach statistically significant conclusions.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Given the increased risk of cardiovascular events in SLE patients, identifying modifiable risk factors is crucial for pinpointing high-risk patients. While we expected non-corticosteroid immunosuppressants to be associated with reduced MACE, the opposite was true, except for HCQ. A major limitation of this study is unaccounted-for confounding variables including indication bias (i.e. patients with more severe SLE may receive stronger immunosuppression). Additionally, statistical power was limited for several classes of medications due to smaller numbers of patients using these treatments. As longitudinal databases expand, and biologics become more widely available, future studies should focus on evaluating the effects of specific biologic and DMARD therapies. Ultimately, developing models to assess cardiovascular risk in SLE patients will enhance outcomes and personalized care in the future.

Analysis of Histopathological Changes in the Placenta of Patients with Systemic Lupus Erythematosus

Bartira Melo[1], Elizabeth Avvad[2], Marcela lacerda[2], Nilson jesus[2], **Evandro Klumb**[2] and Guilherme Ramires de Jesus[3], [1]UERJ- Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [2]UERJ - Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [3]Universidade do Estado do Rio de Janeiro, Rio De Janeiro, Rio de Janeiro, Brazil

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is more frequent in women of reproductive age and pregnancy in these patients is considered as high risk. The inflammatory environment, with exacerbated activation of the complement system, formation, and tissue deposition of immune complexes promote placental histopathological changes that predispose to pregnancy complications. The objective of this study was to describe histopathological findings in the placentas of pregnant women with SLE and correlate them with adverse outcomes.

Methods: Patients with SLE (ACR criteria 1997) and singleton pregnancies, who received prenatal care at a tertiary hospital and delivered at the same institution, were included. They were divided in four groups: Group 1 – Preeclampsia (PE)/intrauterine growth restriction (IUGR); Group 2 – Active SLE (SLEPDAI $\geq$ 4); Group 3 – Systemic infection during pregnancy; Group 4 – patients without PE/IUGR, active SLE or infection. Histopathological analysis of the placentas was performed according to Amsterdan Placental Workshop Group Consensus Statement.

Results: Ninety-seven patients were included and histopathological study of the placenta was performed in all cases by blinded pathologists for pregnancy outcome. Adverse outcomes were observed in 49 (50.5%) pregnancies. PE/IUGR was the most frequent, being found in 28 (28.8%) patients. Disease activity during pregnancy was diagnosed in 23 (23.7%) cases and an episode of systemic infection was identified in 13 (13.4%) pregnant women. Fifteen women were analyzed in more than one group due to multiple events (e.g., PE/CIUR and SLE activity). Considering all patients, maternal vascular hypoperfusion abnormalities (MVHA) were the most frequent histopathological findings: 19 (19.6%) had moderate to severe major MVHA; 59 (60.8%) had mild major MVHA; and 83 (85.6%) presented minor MVHA. Patients in Group 2 (PE/IUGR) had more frequently moderate to severe major MVHA compared to the other groups (32.1% x 14.5%, p=0.047), while patients in

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Group 4 (no studied outcomes) had significantly less acute fetal vascular hypoperfusion abnormalities (FVHA) (14.3% x 33.3%, p=0.027). In both Groups 2 (active SLE) and 3 (systemic infection), the most common finding was minor MVHA (82.6% and 84.6%, respectively), but there was no statistical difference compared to the other groups. Significant risk predictors for the outcome PE/IUGR were absence of acute (FVHA) (p=0.025), presence of hematogenous infection (p=0.005), presence of small for gestational age (SGA) newborn (p< 0.0001), need for neonatal intensive care unit (p=0.002), lower gestational age at delivery (p=0.0003) and lower birth weight (p< 0.0001). No variable was a significant predictor for the outcome disease activity and systemic infection. Based on multivariate analysis, it was observed that SGA newborn (p< 0.0001) and hematogenous infection (p=0.015) were significant independent variables to predict the PE/IUGR outcome.

Conclusion: This study demonstrates that MVHA are commonly found in placentas of patients with SLE. Moderate to severe MVHA are more frequent in patients who develop PE/IUGR, which may be linked to the pathophysiology of these obstetric adverse outcomes.

A Machine Learning Algorithm Based on a 15-autoantibody Profile by a Novel Fully Automated Multiplexed Microarray Immunoassay for the Diagnosis of Autoimmune Connective Tissue Diseases

Gerber Gomez[1], Yipeng Cheng[2], Kristiana Nita[2], Michael Hausmann[3], Christian Fischer[1] and Yasemin Ataman-Önal[3], [1]Scientific & Medical Affairs, AliveDx Suisse SA, Eysins, Switzerland, [2]AliveDx, Edinburgh, United Kingdom, [3]AliveDx Suisse SA, Eysins, Switzerland

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Detection of relevant autoantibodies is key in the identification of autoimmune connective tissue diseases (CTD). The evaluation of multiple autoantibodies for extended serological profiling may improve the diagnosis of these conditions. We evaluated the diagnostic utility, in patients with CTD and disease controls, of machine learning classifiers based on the 15-autoantibody profile performed by a novel, single-use, multiplexed microarray immunoassay, used with its fully automated high-throughput proprietary system for simultaneous the detection of IgG autoantibodies directed to dsDNA, SS-A 60, TRIM21 (SS-A 52), SS-B, Sm, Sm/RNP, U1RNP, Jo-1, Scl-70, Centromere B, Chromatin, Ribosomal P, DFS70, RNAP III and CCP2.

Methods: De-identified sera from 475 patients diagnosed with autoimmune CTD in accordance with current guidelines [127 patients with systemic lupus erythematosus (SLE), 74 with systemic sclerosis, 76 with Sjögren's syndrome (SjS), 71 with idiopathic inflammatory myopathies, 54 with mixed CTD, 73 with rheumatoid arthritis] and 652 patients with other disorders, who served as disease controls were analyzed using the investigational MosaiQ AiPlex® CTDplus (AliveDx, Switzerland) assay. Classification models were developed using all 15 autoantibodies or a selected subset, employing the RandomForest algorithm (XGBoost and Logistic L1 L2 were also used). Diagnostic performance was evaluated by receiver operating characteristic (ROC) curve analysis.

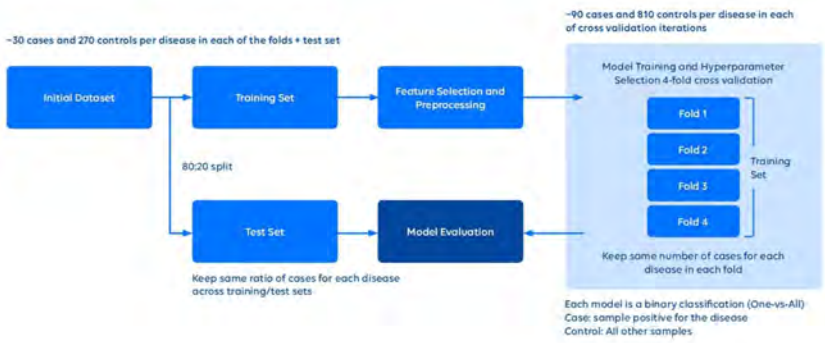

Figure 1. Model Pipeline

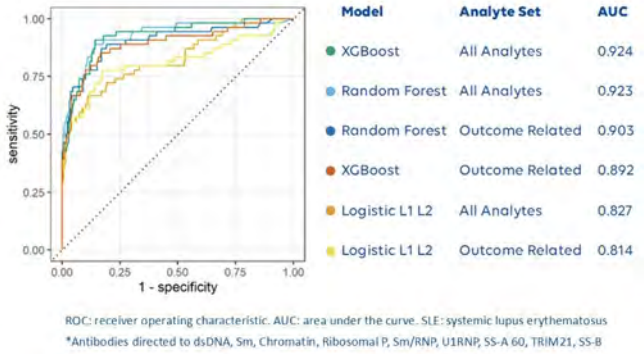

Figure 2. ROC Curves and AUCs - SLE: All 15 analytes vs. 9 Outcome-related analytes*

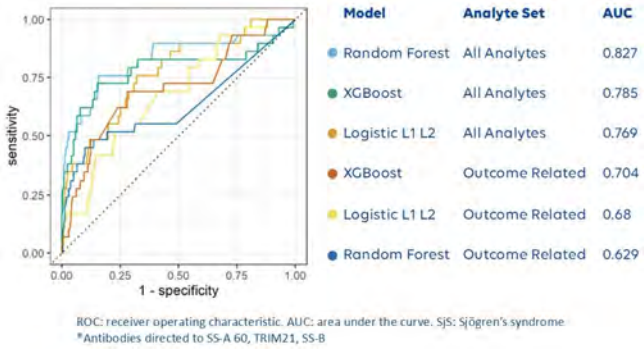

Figure 3. ROC Curves and AUCs - SjS: All 15 analytes vs. 3 Outcome-related analytes*

Results: A RandomForest classifier incorporating all 15 autoantibodies demonstrated robust performance in predicting SLE, achieving an area under the curve (AUC) of 0.92. In comparison, the individual SLE-specific markers dsDNA and Sm yielded lower AUCs of 0.68 and 0.60, respectively. For SjS, the 15-plex RandomForest classifier achieved an AUC of 0.83, outperforming a 3-plex RandomForest classifier based on SS-A 60, TRIM21, and SS-B autoantibodies, which had an AUC of 0.62. The individual AUCs for these markers were 0.63, 0.59, and 0.58, respectively. Similarly, for other CTDs, 15-plex classifiers consistently outperformed the individual disease-specific markers.

Conclusion: Multiplex autoantibody testing combined with machine learning algorithms has the potential to improve the diagnosis of autoimmune CTD.

Abstract Number: 2397

Analytical Performance of a Fully Automated Multiplexed Microarray Immunoassay for the Simultaneous Detection of Fifteen Autoantibodies Associated with Connective Tissue Diseases in a Reference Laboratory in Southern France

Guillaume Nardella[1], **Gerber Gomez**[2], Christian Fischer[2] and Claire Monat[1], [1]Inovie Labosud Provence, Specialized Autoimmunity Analyses, Marseille, France, [2]Scientific & Medical Affairs, AliveDx Suisse SA, Eysins, Switzerland

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoantibodies are key diagnostic markers in autoimmune connective tissue diseases (CTD). Conventional testing often requires multiple single-measurand assays, which can be labor-intensive and time-consuming. We evaluated the analytical performance of a multiplex microarray immunoassay (MosaiQ AiPlex® CTDplus; AliveDx, Switzerland) for the simultaneous detection of 15 autoantibodies associated with CTD, used with its fully automated proprietary platform, compared to routine methods in a reference laboratory.

Methods: A cohort of analytically characterized sera (572 reactive and 2,686 non-reactive) were included in the study. Reference methods included a multiplex bead-based immunoassay for most measurands, indirect immunofluorescence assay (IFA) for DFS70, and a chemiluminescence assay for CCP. Samples were tested with the investigational microarray immunoassay that detects IgG autoantibodies to dsDNA, SS-A 60, TRIM21 (SS-A 52), SS-B, Sm, Sm/RNP, U1RNP, Jo-1, Scl-70, CENP B, Chromatin, Ribosomal P, DFS70, RNAP III, and CCP. Performance was assessed using positive (PPA), negative (NPA) and overall percent agreement (OPA). Additionally, Cohen's kappa coefficient was calculated.

Results: The microarray immunoassay demonstrated substantial agreement with the reference methods (overall Cohen's kappa: 0.72), with total PPA of 86.6% (95% CI: 83.4, 89.3), total NPA of 92.3% (95% CI: 91.2, 93.3) and total OPA of 91.3%. Individual measurands showed PPA ranging from 59.1% (Sm) to 100% (TRIM21, Jo-1), and NPA ranging from 72.6% (Chromatin) to 100% (Sm, Jo-1, CCP). Notably, high kappa values for almost perfect agreement were observed for SS-A 60 (0.92), TRIM21 (0.85) Sm/RNP (0.97), and CENP B (0.87). Cohen's kappa values for substantial agreement were observed for dsDNA (0.72), SS-B (0.75) and Sm (0.73); whereas U1RNP (0.49), Scl-70 (0.41) and Ribosomal P (0.43) showed moderated agreement. Finally, kappa values for fair agreement were found for Chromatin (0.33) and CCP (0.34). No samples were available for RNAP III and thus, no comparison was made. Due to limited sample availability, results for Jo-1 (reactive, overall) and CCP (non-reactive, overall) should be interpreted with caution. Detailed results are shown in Table 1.

Conclusion: This fully automated multiplex microarray immunoassay demonstrated overall substantial agreement with established methods for the detection of CTD-associated autoantibodies, with particularly high concordance for key targets such as SS-A 60, Sm/RNP, and CENP B. Its ability to simultaneously detect multiple autoantibodies in a single, automated run may streamline the serologic evaluation and support more efficient clinical workflows in autoimmune diagnostics.

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Indirect immunofluorescence assay (IFA) on HEp-2 cells (HEp-2 IFA) remains a key tool in the diagnostic work-up of autoimmune connective tissue diseases (CTD). Traditionally performed manually, this method is labor-intensive, time-consuming, and subject to operator variability. While semi-automated and automated systems exist, there is still a need for fully automated platforms that integrate both slide processing and interpretation using computer-assisted image analysis. As a preliminary step in evaluating a novel fully automated IFA system (LumiQ®, AliveDx, Switzerland) in combination with the HEp-2 substrate Diagnostic Kit for ANA (investigational device), we assessed the analytical performance of the investigational device when used manually by a single operator, comparing results to historical IFA data from patients with suspected CTD.

Methods: Banked, de-identified human serum samples, previously manually characterized by the Mosaic Basic Profile (Euroimmun, Germany) (routine method) were included in the study. Samples were stored at -20°C for up to three months prior to being thawed for subsequent analysis with the investigational device. The study cohort consisted of 25 samples characterized as non-reactive and 60 samples characterized as reactive, with varying titers, covering a broad range of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

patterns, as per the International Consensus on ANA Patterns (ICAP). Samples were tested with the investigational device at a 1:80 screening dilution. The testing protocols for both investigational device and routine method were manually conducted following the manufacturer's instructions for use (IFU), with all readings performed by a single operator using a manual fluorescent microscope to reduce inter-operator variability. Results were interpreted based on categorical classifications (reactive / non-reactive), pattern identification, and the grading of reactive samples from 1+ to 4+ at the screening dilution. Positive (PPA), negative (NPA) and overall percent agreement (OPA) were calculated for sample status (reactive or non-reactive). For reactive samples, percent agreement of each individual IFA pattern and overall pattern agreement were determined. From the 60 ANA reactive samples, 20 samples were selected to determine the end-point titer. Dilutions were prepared of these samples +/- one titer step around the pre-characterized end point titer (EPT).

Results: PPA was 100% (95% CI: 94.0, 100), with all 60 historically reactive samples yielding reactive results by the investigational device. NPA was 100% (86.3, 100), with all 25 historically non-reactive samples yielding non-reactive results by the investigational device. The overall agreement between methods was 100% (95% CI: 95.7, 100). The pattern agreement was 100% (95% CI: 86.3, 100). The end point titration of 20 positive samples showed EPT agreement of 100% (95% CI: 83.2, 100).

Conclusion: The manual preparation and readings using the investigational device showed high concordance with historical characterization. Future studies evaluating the fully automated capabilities of this solution will allow for an expanded assessment of the performance of the device and platform.

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: During disease, ~50% of SLE patients develop lupus nephritis (LN), one of the most serious complication. Despite the best therapy, within 15 years, ~20% progress to renal failure (1). Diagnosis is based on urine protein-creatinine ratio and histology in renal biopsy; genetic factors are common, but penetrance is low, and the cause is unknown. A gut-kidney axis has been suggested. We therefore investigated pathogenetic urinary factors associated with host response to an implicated pathobiont in biopsy-proven patients.

Methods: Patients with SLE diagnosis met ACR criteria and had a SLE Disease activity scores. Urine protein-creatinine ratio was determined at the time of sample collection. As a marker of microbe-specific immune exposure, serum antibodies to cell wall lipoglycan (LG) in pathogenic strains of *Ruminococcus gnavus (RG)* were quantified by a

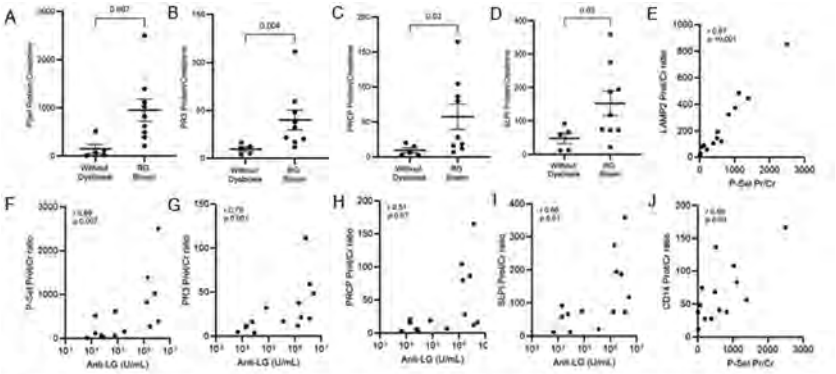

Figure 2. Urine from LN patients with RG gut blooms contains higher levels of A) platelet-associated P-selectin, B) neutrophil-associated proteinase 3 (PR3), C) endothelial cell-associated prolyl carboxypeptidase (PRCP), and D) phagocyte-associated secretory leukocyte protease inhibitor (SLP1). F-I) These urinary levels directly correlate with a patient's serum anti-RG lipoglycan (LG) levels. Within the urine, platelet-associated P-selectin levels also correlate with E) urinary mononuclear cell lysosomal-associated membrane protein 2 (LAMP-2) levels, and J) myeloid cell-associated CD14 levels.

standardized bead-based assay (2,3). Compared to active LN without dysbiosis, active LN with RG gut bloom and high anti-LG had elevated transcripts reflecting platelet (SPARC, SNCA, PROS1, PF4, PDGFA, MMRN1, EGF) and neutrophil activation (GATA1)(padj=2x10(-4))in whole blood(manuscript submitted). We therefore used the same proteomics assay as in AMP-sponsored high-dimensional discovery studies to detect self-proteins in urine to identify WHO class and activity of glomerular lesions by urine "liquid biopsy" (4). In contrast, we custom-designed multiplex arrays to detect 30 human proteins implicated in platelet-associated thrombo-inflammation and neutrophil extracellular TRAPs/NETosis, and in other immune pathways. By urine hybridization, antigens were detected, data normalized by creatinine levels.

Results: With this custom proteomics array, we tested urine of 14 LN at flare with coincident RG blooms and 6 LN patients at flare without bloom. For selected analytes (normalized to urine creatinine), significant increases were seen in urine of patients with gut dysbiosis (Figs. 1A-D). Analytes were proteins from platelets, neutrophils and endothelial cells. These data support the hypothesis that platelet & neutrophil-related pathways contribute to LN activity during RG blooms (Figs. 1A, B). Presence of these proteins in urine is positively associated with RG blooms, with significant correlations of platelet and neutrophil proteins with serum antibodies to RG lipoglycan (Figs. 1F, G). Findings were highly reproducible.

Hence, renal exposure to either the lipoglycan, or the induced antibodies to lipoglycan, may contribute to glomerular injury.

Conclusion: Our studies suggest that LN flares in patients with gut RG blooms are associated with peripheral platelet activation similar to that observed in patients with sepsis. In the affected LN patients, the level of urinary proteins from activated platelets, neutrophils, and endothelial cells documents underlying systemic immune activation, with release of proteases that likely injure the kidney. Taken together, these data indicate that intestinal expansions of the RG pathobiont can worsen LN flares through *thrombo-inflammation*. This previously unsuspected endotype of LN may be amenable to therapeutic interventions beyond the glucocorticoids and immunosuppressants commonly used to treat LN.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that potentially affects any organ. Pulmonary diseases (PD) are common in SLE and cover several different subtypes including, interstitial lung diseases (ILD), shrinking lung syndrome (SLS), pleural and airway diseases. PD are associated with increased morbidity and mortality. The main purpose of this study is to determine the prevalence of PD and subtypes of PD in SLE and to identify predictors of PD.

Methods: In a cross-sectional study we identified all adult patients with SLE in Region Southern Denmark diagnosed and classified with SLE according to the 2019 EULAR/ACR classification criteria and invited eligible patients. Participants' damage accrual was scored according to SLICC/ACR damage index.

To diagnose PD, the participants underwent:

- High-resolution computed tomography scan of the thorax (HRCT)
- Pulmonary function tests (PFT) - body plethysmography, diffusion tests, and six-minute walk test (6MWT)

PFT measures included: Forced expiratory volume in one second (FEV_1), forced vital capacity (FVC), FEV_1/FVC ratio, total lung capacity (TLC), diffusing capacity of the lung for carbon monoxide (DLCO). Participants were diagnosed with or without PD and classified according to subtype. We investigated associations between PD and subtypes of PD and risk factors with first univariate analyses, then significant associations were analyzed with multivariable regression analyses.

Table 1. Prevalence of pulmonary diseases and subtypes of pulmonary diseases among 185 patients with Systemic Lupus Erythematosus. PD – Pulmonary Diseases, ILD – Interstitial Lung Diseases, UIP – Usual Interstitial Pneumonia, NSIP – Non-Specific Interstitial Pneumonia, HP – Hypersensitivity Pneumonitis, LIP – Lymphoid Interstitial Pneumonia; OP – Organizing Pneumonia, SLS – Shrinking Lung Syndrome; COPD – Chronic Obstructive Pulmonary Diseases, % is the percentage of the total study population.

Types of PD	Selected subtypes of PD	Prevalence, no. (%)
PD		109 (59%)
ILD		22 (12%)
	UIP patterns	10 (5.4%)
	NSIP patterns	1 (0.54%)
	HP patterns	3 (1.6%)
	LIP	3 (1.6%)
	OP	1 (0.54%)
	Other	6 (3.2%)
SLS		1 (0.54%)
Pleural		35 (19%)
	Pleuritis	9 (4.9%)
	Pleuroparenchymal fibrosis	23 (12%)
	Other	3 (1.6%)
Airway		70 (38%)
	Asthma	1 (0.54%)
	Bronchiectasis	28 (15%)
	Bronchiolitis	3 (1.6%)
	COPD	8 (4.3%)
	Emphysema	20 (11%)
	Thickened airways	25 (14%)

Table 2. Prediction of any pulmonary disease and subtypes of pulmonary diseases in systemic lupus erythematosus by means of regression analyses. OR – Odds ratio, SDI - Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index, SDI, no PD - Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index without score from pulmonary diseases, APS – Anti-Phospholipid Syndrome, DLCO - Diffusing Capacity of the Lung for Carbon Monoxide, % - percentages of expected, low* - less than 80% of expected, TLC – Total Lung Capacity.

Predictor	Univariate analyses, OR (p-value)	Multivariate analyses, OR (p-value)
Any pulmonary diseases		
Age, years	1.05 (< 0.001)	1.08 (0.008)
SDI, Score 0-48	1.48 (< 0.001)	9.96 (< 0.001)
SDI, no PD, Score 0-43	1.31 (0.003)	0.0894 (< 0.001)
Interstitial lung diseases		
Age, years	1.06 (0.001)	1.07 (0.018)
SDI, Score 0-48	1.40 (0.001)	8.30 (0.001)
SDI no pd, Score 0-43	1.26 (0.015)	0.147 (0.002)
Pleural diseases		
SDI, Score 0-48	1.38 (< 0.001)	53.8 (< 0.001)
SDI no pd, Score 0-43	1.21 (0.020)	0.0179 (< 0.001)
APS	4.44 (< 0.001)	6.44 (0.041)
DLCO, %	0.975 (0.019)	1.12 (0.003)
DLCO low*	2.96 (0.017)	29.7 (0.003)
Airway diseases		
TLC low*	3.21 (0.010)	3.75 (0.036)

Results: We invited 318 patients with SLE and 185 (58%) participated. Participants were predominantly white (94%), female (87%), with a mean age of 52 years (standard deviance 14), a median disease duration of 15 years (interquartile range 5.7 to 24), and 54% had ever smoked. PD were diagnosed in 59% of the participants, of which 12% had ILD, 1% SLS, 19% pleural diseases, and 38% airway diseases (Table 1).

When predicting PD and subtypes of PD, ventilation parameters had low sensitivities ranging from 20% to 45%. DLCO was abnormal in 62% of all participants, including 46% of those without PD. Descriptions of HRCT scans were closely related to final diagnoses of PD, although some minor cystic changes and small nodules were insufficient to establish a diagnosis of PD. In univariate analyzes PD were significantly associated with decreased PFT measures such as decreased FEV_1, FVC, TLC, and DLCO, but not with measures from 6MWT. In univariable analyzes both ILD and pleural diseases were significantly associated with decreased FEV_1, FVC, TLC, and DLCO, while airway diseases associated with decreased FEV_1, FEV_1/FVC ratio, TLC, and DLCO. In multivariable logistic regression analyzes 12 variables had a significant association with PD or its subtypes (Table 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In a large, population-based study of PD in well-characterized patients with SLE, we identified PD in 59% of the cases. The most common manifestations were airway and pleural diseases, with ILD occurring in 12% of the patients. PFT alone contributed only to a limited extent to identification of patients with PD which was also true in multivariable analyzes. As PD are frequent and often treatable, diligent diagnosis is important.

Associations Between Serum Levels of Soluble Urokinase Plasminogen Activator Receptor (suPAR) and Activity and Chronicity Features in Diagnostic and Per-protocol Repeat Kidney Biopsies in Patients with Lupus Nephritis

Sandra Jagerback[1], Frederic Houssiau[2], Dionysis Nikolopoulos[3], Lina Wirestram[4], Julius Lindblom[5], Farah Tamirou[6], Christopher Sjowall[7] and **Ioannis Parodis**[8], [1]Karolinska Institutet, Stockhom, Stockholms Lan, Sweden, [2]CUSL, BRUSSELS, Belgium, [3]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, [4]Linköping University, Linköping, Sweden, [5]Karolinska Institutet, Stockholm, Sweden, [6]Cliniques universitaires Saint-Luc, Brussels, Belgium, [7]Linkoping University, Linkoping, Sweden, [8]Karolinska Institutet and Karolinska University Hospital, Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Serum levels of soluble urokinase plasminogen activator receptor (suPAR) have been associated with organ damage accumulation in patients with recent-onset systemic lupus erythematosus (SLE). In this study, we aimed to investigate serum suPAR levels in relation to lupus nephritis (LN), including activity and chronicity features in diagnostic and per-protocol repeat kidney biopsies.

Methods: Serum levels of suPAR from 23 well-characterised patients with LN (of whom 19 were incident cases) from the Cliniques Universitaires Saint-Luc, Brussels, Belgium (N=21) and the Karolinska University hospital, Stockholm, Sweden (N=2) were analysed using enzyme-linked immunosorbent assay (suPARnostic® AUTO Flex ELISA, ViroGates, Birkerød, Denmark) at the time of the diagnostic kidney biopsy and prior to commencement of immunosuppressant therapy for active LN, and twelve months after treatment initiation, at the time of a per-protocol repeat kidney biopsy. We also analysed levels of suPAR in serum samples from 15 healthy controls for the purpose of comparisons. The Spearman's rank correlation coefficient was used to compare levels of suPAR at baseline (BL) and month12 (M12) with serum levels of creatinine, estimated glomerular filtration rate (eGFR), urine protein-creatinine ratio (UPCR), Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) scores, extra-renal SLEDAI-2K scores (after exclusion of the renal descriptors), and renal histopathological features of activity or chronicity based on the National Institutes of Health (NIH) activity and chronicity index scores, at the same timepoints.

Results: At the time of active LN, patients had significantly higher suPAR levels compared to one year after treatment initiation (mean ± standard error: 5.37 ± 0.40 at BL versus 3.77 ± 0.20 at M12; 95% CI: 0.62–2.56; p=0.002), and compared with healthy controls (2.64 ± 0.25; BL vs HC: p< 0.001; M12 vs HC: p< 0.001; Figure 1). Furthermore, suPAR levels at BL

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

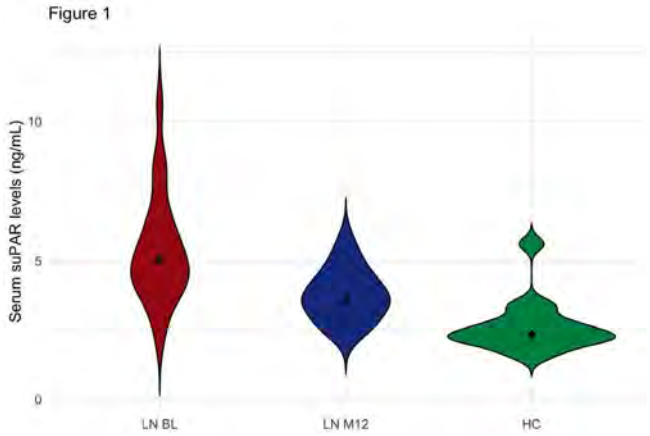

Figure 1.

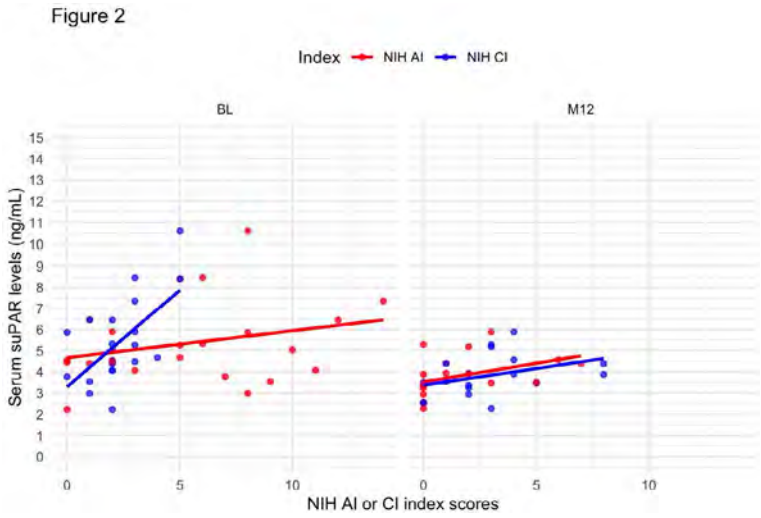

Figure 2

were not correlated with NIH activity index (AI) scores (rho=0.202; *p=0.368*), but a significant correlation could be seen at M12 (rho=0.595; *p*=0.007). In addition, suPAR levels were positively correlated with NIH chronicity index (CI) scores at BL (rho=0.541; *p*=0.008) and the same trend, although not significant, could be seen at M12 (rho=0.440; *p*=0.066; Figure 2). However, a moderate and statistically significant correlation was seen between baseline suPAR levels and NIH CI scores at M12 (rho=0.554; *p*=0.017).

Conclusion: In this cohort of LN with repeat kidney biopsies, serum suPAR levels were prominently elevated in patients with active LN compared with healthy individuals and compared to 12 months after initiation of treatment. Levels of suPAR were positively correlated with histopathological activity at month 12 from treatment initiation. An association with chronicity features was also seen at baseline, as well as a correlation between baseline suPAR levels and chronicity features at 12 months. These findings suggest that suPAR levels may prove useful as a biomarker for monitoring LN activity and an indicator of poor prognosis, warranting further investigation.

Abstract Number: 2402

High-Resolution Proteomic Profiling Validates BAFF Pathway Modulation and Reveals Novel Biomarker Signatures in Belimumab Treatment

Alexander Tsoi[1], Dionysis Nikolopoulos[2], Natalia Sherina[3] and **Ioannis Parodis**[1], [1]Karolinska Institutet and Karolinska University Hospital, Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden, [2]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, [3]Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, and Karolinska University Hospital, Stockholm, Stockholm, Stockholms Lan, Sweden

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Belimumab, a BAFF inhibitor, is an effective treatment for systemic lupus erythematosus (SLE), but biomarkers predicting treatment response remain elusive. We aimed to identify protein signatures associated with clinical response to belimumab.

Methods: We conducted a prospective observational study of patients with SLE initiating belimumab treatment. Samples were available at baseline (prior to treatment initiation; T0; N=69), month 3 (T1; N=63), and month 6 (N=69). Complete clinical data were available for 64 patients, who were finally included for analysis. Using NUcleic acid Linked Immuno-Sandwich Assay (NULISA) technology (1), we simultaneously measured 250 protein markers at each timepoint in normalised protein quantification units (NPQ). Clinical response was defined as a ≥4-point reduction in SLEDAI-2K score at T2. Mixed-effects models were employed to identify proteins associated with response and temporal changes, with false discovery rate (FDR) correction.

Results: The main effects analysis demonstrated a strong modulation of BAFF pathway proteins at T2, with TNFRSF13C (BAFF-R) showing significant reduction from baseline to month 6 (NPQ: T0 13.059, T2 12.220; $p < 0.001$). Similar decreases were observed in TNFRSF9 (CD137; NPQ: T0 11.269, T2 10.704; $p < 0.001$) and TNFRSF13B (TACI; NPQ: T0 12.713, T2

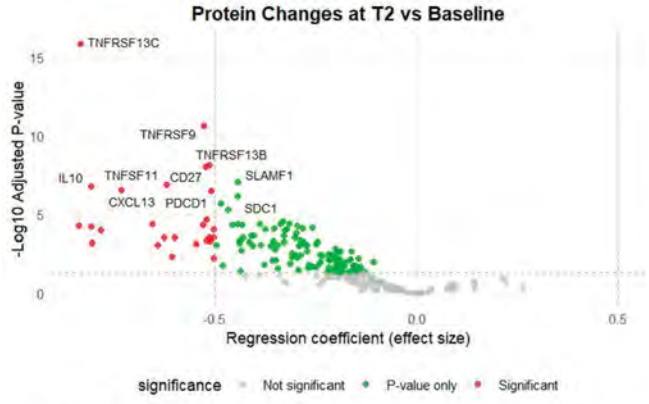

Figure 1. Protein changes following belimumab treatment.
Volcano plot showing protein expression changes at 6 months versus baseline. TNFRSF13C (BAFF-R), TNFRSF9 (CD137), and TNFRSF13B (TACI) show significant downregulation (p<0.001, FDR-adjusted) following treatment.

Figure 1

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

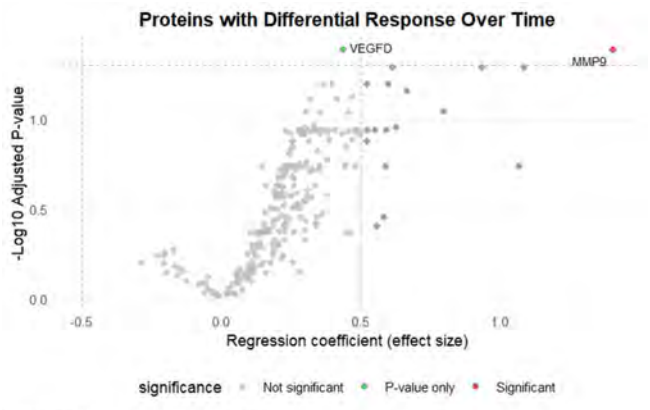

Figure 2

12.183; $p< 0.001$) with FDR-adjusted values (figure 1). Additionally, interaction analysis revealed distinct temporal patterns between responders and non-responders, with MMP9 and VEGFD showing significant treatment-response interactions at T2 (FDR-adjusted p=0.040 for both) (figure 2).

Conclusion: This high-resolution proteomic analysis provides molecular validation of belimumab mechanism of action through BAFF pathway modulation and identifies novel protein signatures associated with treatment response. The technical capabilities of NULISA enabled detection of both on-target drug effects as well as less well-described effects on other molecular targets, demonstrating its utility for biomarker discovery in SLE.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: SLE is clinically heterogeneous and associated with increased hospitalizations. However, it remains unclear which patient subgroups drive this excess in unplanned healthcare use. We aimed to determine 1) whether elevated hospitalization rates are concentrated among patients with LN or aPL, and 2) whether individuals with non-renal, aPL-negative SLE exhibit hospitalization risks comparable to the general population.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Incident SLE cases (1995–2018) from a 27-county region in the US Midwest were matched 1:2 to non-SLE comparators on age, sex, race/ethnicity, and county. SLE onset was defined by fulfillment of the 2019 EULAR/ACR criteria with follow-up starting after discharge if diagnosed during hospitalization. Using a time-dependent variable (**Figure**), patients contributed person-time to the **SLE state** (non-renal, aPL-negative) until developing LN or aPL positivity. The **aPL state** began at detection of lupus anticoagulant or IgG anticardiolipin/β2-glycoprotein-1 (≥40 GPL). The **LN state** began at biopsy confirmation or proteinuria ≥500 mg/day. Patients meeting both LN and aPL criteria were analyzed in the LN state.

The primary outcome was inpatient stays ≥24 hours. Follow-up continued until December 2023, emigration, or death. Conditional frailty models—adjusted for sex, age, white race, and smoking—compared admission hazards across SLE states vs. comparators; secondary models examined time-varying hazards post-discharge (0–30 days, 31 days–1 year, >1 year).

Table 1. Demographics, Baseline Disease Characteristics, Clinical Outcomes and Unplanned Hospitalizations of an Incident (1995-2018) Cohort of Patients with Systemic Lupus Erythematosus (SLE) and Matched non-SLE Comparators from 27 counties in the Midwest Region of the United States.*

Table 2. Inpatient Hospitalization Risk Estimates in Patients with Incident Diagnoses of Systemic Lupus Erythematosus (SLE), Positive Antiphospholipid Antibody Profile (aPL) and/or Lupus Nephritis (LN) in Relation to Matched non-SLE Comparators from 27 counties in the Midwest Region of the United States.*

Patient Group	First 30d Post-Diagnosis Period HR (95% CI)	Between 30d-1y Post-Diagnosis Period HR (95% CI)	After 1y Post-Diagnosis Period HR (95% CI)	Overall Adjusted HR (95% CI)
Non-SLE comparator	1 (reference)	1 (reference)	1 (reference)	1 (reference)
SLE State	1.82 (1.31-2.53)	1.54 (1.18-2.01)	1.43 (1.14-1.79)	1.51 (1.24-1.82)
aPL State	2.66 (1.61-4.37)	2.13 (1.38-3.28)	1.47 (0.96-2.26) †	1.85 (1.33-2.58)
LN State	3.78 (2.62-5.46)	2.72 (1.96-3.77)	2.19 (1.61-2.98)	2.59 (2.01-3.32)

*Results are adjusted for sex, age at baseline, white race, and ever smoking. 30d= 30 days, 1y= 1 year, HR= Hazard Ratio, 95% CI= 95% Confidence Intervals. †Result did not reach statistical significance.

Results: Among 326 SLE patients and 652 comparators (median age 46; 79% female; 81% non-Hispanic White), SLE patients had 829 admissions over 3,272 person-years, vs. 799 admissions over 6,654 person-years among comparators (**Table 1**). Of all the SLE patients, 86 transitioned to the LN state (25 were also aPL-positive) and 69 to the aPL state. In fully adjusted models, the SLE state was associated with a 51% higher hazard of hospitalization compared to controls (HR 1.51, 95% CI 1.24–1.82; $p < .001$). aPL state conferred an 85% increase (HR 1.85, 95% CI 1.33–2.58; $p < .001$), and LN state the greatest rise at 159% (HR 2.59, 95% CI 2.01–3.32; $p < .001$). Time-stratified analyses demonstrated peak risk in the first 30 days post-discharge—hazard ratios of 1.82 for SLE, 2.66 for aPL, and 3.78 for LN—with gradual attenuation thereafter (**Table 2**).

Conclusion: In this population-based cohort, patients with lupus nephritis demonstrated the greatest increase, those with antiphospholipid antibodies an intermediate rise, and non-renal, aPL-negative SLE the smallest—yet still substantial—elevation. These findings highlight the need for stratified risk assessment in SLE: while everyone with SLE is at increased risk of rehospitalization, the greatest attention—and potentially the most aggressive preventive strategies—should be directed toward those with LN and aPL.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystemic chronic disease characterized by a wide range of clinical and serological manifestations. It most commonly affects young women, with incidence and disease activity typically declining with age. As a result, data regarding the diagnoses of SLE in individuals ≥60 years of age (elderly onset SLE) is scarce. To better characterize elderly-onset SLE, a multi-racial cohort of SLE patients was analyzed.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: This analysis leverages a cohort of 1141 SLE patients who met SLE criteria by at least one method: American College of Rheumatology (ACR), Systemic Lupus Erythematosus International Collaborating Clinics (SLICC), and/or 2019 ACR/European League Against Rheumatism (EULAR) classification criteria. Lupus manifestations at the time of diagnosis were compared between elderly-onset SLE patients and those diagnosed at < 60 years old. An analysis of SLE presentation and diagnosis was conducted for elderly-onset SLE patients, including whether SLE diagnoses occurred during hospitalization, following referral to a rheumatologist, or through ongoing rheumatology clinic follow-up.

Results: Of 1141 patients with SLE, 90% were female and 10% were male. The racial and ethnic composition was as follows: 30% Black, 26% Hispanic, 22% White, 16% Asian, and 5% of unknown race/ethnicity. Within this cohort, 43 individuals were diagnosed at age ≥60 years (3.8%), while 1,098 were diagnosed at age < 60 years (96.2%). Additionally, there was a trend toward men being more likely to be diagnosed at age ≥60 years compared to those under 60 (19% vs. 10%, p=0.06). Among the 43 elderly-onset SLE patients, 9 were diagnosed between the ages of 65-69 and 10 were diagnosed at age ≥ 70, with the oldest being 82 years old. In this group, 28% had lupus nephritis (LN), with 6 patients later confirmed by a kidney biopsy. Compared to the remainder of the cohort, elderly-onset SLE patients exhibited significantly lower frequencies of malar rash at presentation (12% vs. 41%, p=0.0001), arthritis (33% vs. 69%, p ≤0.0001), and lupus nephritis (28% vs. 50%, p=0.004. (Table 1.) A majority of patients were diagnosed with SLE during hospitalization (47%), with 80% presenting with lupus-related complaints, and 20% presenting for SLE-unrelated issues (Table 2). The remaining diagnoses were made following referrals from a primary care physician or general rheumatologist (44%), with 11% of these referrals seeking evaluation for conditions other than lupus (Table 3).

Conclusion: This analysis identifies a distinct clinical profile in elderly-onset systemic lupus erythematosus (SLE). Despite immunosenescence, nearly 30% developed lupus nephritis (LN), with almost half diagnosed during hospitalization following severe symptom onset. Only one of 12 LN cases was referred by a rheumatologist for proteinuria; in most, renal involvement

Table 1. Lupus clinical criteria profile for elderly-onset patients and patients diagnosed <60 years of age

Lupus Criteria	Dx=60 y/o n=43	Dx<60 y/o n=1098	P-values

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The SLE Risk Probability Index (SLERPI), a clinical prediction model for systemic lupus erythematosus (SLE), was developed using machine-learning variable-selection techniques (Random Forest, LASSO). Its score reflects diagnostic certainty, ranging from unlikely to definite SLE. A dichotomous model that uses a cut-off > 7 points to distinguish SLE from non-SLE previously showed high specificity and sensitivity and excellent diagnostic performance in early SLE (disease onset < 5 years). This study aimed to (i) evaluate the dichotomous SLERPI's sensitivity, specificity, and likelihood ratios (LR) in a connective-tissue-disease cohort; (ii) correlate its score with SLE activity/damage indices; and (iii) assess its performance in early SLE, defined as disease duration < 5 years.

Table 1: Baseline Characteristics of Case and Control Groups (N=365)

Characteristic		Case Group (n=183)	Control Group (n=182)
Age in years, mean (SD)		38.9 (13.0)	53.6 (13.3)
Female, *n* (%)		169 (92.3)	154 (84.6)
Occupation, n (%)	Unemployed	52 (32.5)	45 (25.9)
	Employed	108 (67.5)	129 (74.1)
Ethnic group, n (%)	Mestizo	86 (50.3)	77 (47.2)
	Caucasian	52 (30.4)	59 (36.2)
	Other	33 (19.3)	27 (16.6)
Disease duration in months, median (IQR)		92 (37-150)	82.5 (38-151)
Less than 5 years from symptom onset, n (%)		61 (33.3)	64 (35.2)
General disease involvement, n (%)	Immunological	183 (100)	134 (73.6)
	Cutaneous	172 (94)	42 (23.1)
	Musculoskeletal	151 (82.5)	149 (81.9)
	Hematological	110 (60.1)	42 (23.1)
	Renal	103 (56.3)	4 (2.2)
	Constitutional	97 (53)	46 (25.3)
	Serosal	63 (34.4)	6 (3.3)
	Neurological	26 (14.2)	9 (4.9)
	Pulmonary	13 (7.1)	24 (13.2)
	Vascular	7 (3.8)	7 (3.8)
	Cardiac	5 (2.7)	2 (1.1)
	Gastrointestinal	2 (1.1)	2 (1.1)
SLEDAI, median (IQR)		2 (0-6)	-
SLICC-SDI score, median (IQR)		0 (0-1)	-
Current Treatment, n (%)	Glucocorticoids	71 (38.8)	61 (33.5)
	Hydroxychloroquine	158 (86.4)	35 (19.2)
	Mycophenolate mofetil	31 (17)	31 (16.9)
	Cyclophosphamide	8 (4.4%)	8 (4.4%)
	Methotrexate	13 (7.1)	96 (52.7)
	Leflunomide	1 (0.5)	16 (8.8)
	Sulfasalazine	-	2 (1.1)
	Azathioprine	-	11 (6)
	Cyclosporine	3 (1.7)	1 (0.5)
	tsDMARDs	-	4 (2.2)
	bDMARDs	8 (4.4)	21 (11.5)

Abbreviations: *SD = standard deviation; IQR = interquartile range; SLEDAI = Systemic Lupus Erythematosus Disease Activity Index; SLICC-SDI = Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index; tsDMARDs = targeted synthetic DMARDs; bDMARDs = biologic DMARDs;*

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2: Performance of SLERPI Classification Criteria (N=365)

Classification Criteria	Sensitivity % (95 % CI)	Specificity % (95 % CI)	LR (+) (95 % CI)	LR (–) (95 % CI)
ACR 1997	93.4 % (88.8–96.6)	90.1 % (84.8–94.0)	9.45 (6.08–14.67)	0.07 (0.04–0.13)
SLICC 2012	98.4 % (95.3–99.7)	87.9 % (82.3–92.3)	8.14 (5.50–12.05)	0.02 (0.01–0.06)
ACR/EULAR 2019	99.5 % (97.0–100.0)	89.0 % (83.5–93.2)	9.05 (5.98–13.69)	0.01 (0.00–0.04)
SLERPI	98.4 % (95.3–99.7)	87.9 % (82.3–92.3)	8.14 (5.50–12.05)	0.02 (0.01–0.06)

Abbreviations: CI = confidence interval; LR (+) = positive likelihood ratio; LR (–) = negative likelihood ratio; SLERPI = SLE Risk Probability Index.

Methods: In this multicenter, cross-sectional study, we included consecutive adults (≥18 years) with SLE (cases) and other systemic autoimmune diseases (controls). Exclusion criteria were active infections, active onco-hematologic disease, drug-induced lupus, and SLE overlap syndromes. We recorded sociodemographics, disease characteristics, activity/damage indices (SLEDAI, SLICC-SDI), and treatments. Three blinded evaluators independently classified patients as SLE/No SLE; unanimous agreement served as the gold standard. Expert opinion was compared with ACR 1997, SLICC 2012, ACR/EULAR 2019, and SLERPI criteria. Analyses included descriptive statistics, sensitivity, specificity, LR ±, and Spearman correlations. All sites obtained institutional review-board approval and complied with the Declaration of Helsinki.

Results: From seven centers, 365 patients were enrolled (183 cases, 182 controls). **Table 1** for characteristics. SLERPI showed 98.3 % sensitivity (95 % CI 95.3–99.7), 88 % specificity (95 % CI 82.3–92.3), LR+ 8.1 (95 % CI 5.5–12.0) and LR- 0.02 (95 % CI 0.006–0.06). Comparative performance versus other criteria is presented in **Table 2**. SLERPI scores correlated with SLEDAI ($r = 0.24$; $p = 0.001$) and SLICC-SDI ($r = 0.23$; $p = 0.002$). SLERPI was higher in patients with damage (20 [IQR 16.5–22]) than in those without (17 [IQR 13.5–21]; $p = 0.02$). In the early-SLE subgroup ($n = 125$; duration < 5 years), sensitivity was 96.6 %, specificity 87.9 %, LR+ 8.0, and LR- 0.04. Frequently used treatments among SLE cases were hydroxychloroquine (86.4 %), glucocorticoids (38.8 %), and mycophenolate mofetil (17 %).

Conclusion: SLERPI demonstrated diagnostic accuracy in this multicenter cohort comparable to SLICC 2012 criteria. Although correlations with activity and damage indices were modest, the SLERPI score was significantly higher in patients with established damage. Diagnostic accuracy remained high in early SLE (disease duration < 5 years). SLERPI may serve as a rapid screening tool for SLE, particularly when serological testing is delayed.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systematic lupus erythematosus (SLE) is an autoimmune disease with prognostic challenges due to its cyclic diversity. Artificial intelligence and machine learning (ML) has emerged as a powerful tool for analyzing multifactorial SLE data. This systematic review aims to investigate the current use of ML in predicting clinical outcomes and stratifying SLE patients.

Methods: A comprehensive search of PubMed, Scopus, Web of Science, and the Cochrane Library was conducted for studies published up to May 2025 evaluating the use of machine learning for stratifying SLE patients and determining prognosis. Extracted data included study design, country, recruitment period, sample size, ML application and algorithms, study aims, inclusion criteria, and main results.

Results: Seventeen studies applying machine learning to 16,483 SLE patients were included, with 81% of participants being female. The majority of studies (58.8%) originated from the USA. Random Forest was the most frequently used algorithm (41.1%), followed by recurrent neural networks and support vector machines. Main applications included predicting disease activity/flares, lupus nephritis, hospitalization risk, and molecular subtypes. Model performance, assessed by area under the ROC curve in nine studies, ranged from 0.595 to 0.9375. Sensitivity and specificity, reported in three studies, ranged from 0.75 to 82.1 and 0.75 to 89.6, respectively.

Conclusion: Machine learning demonstrates strong performance in analyzing complex SLE datasets, enabling accurate prediction of prognosis, disease activity, hospitalization risk, and treatment response. These models consistently outperform traditional approaches, supporting more personalized care and clinical decision-making for SLE patients across diverse clinical scenarios.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: One common and clinically important form of systemic lupus erythematosus (SLE) is neuropsychiatric systemic lupus erythematosus (NPSLE). This systematic review and meta-analysis aimed to assess the prevalence, regional disparities, and moderators of seven neurological syndromes in adult-onset SLE, as defined by the criteria of the American College of Rheumatology 1999 (ACR1999).

Methods: PubMed, Scopus, Web of Science, and the Cochrane Library were searched for English-language studies (April 1999–April 2024) reporting on CNS neurological syndromes in adults (>18 years) using the 1999 ACR Case Definitions and including at least 30 patients. Pediatric studies, commentaries, case reports/series, and reviews were excluded. Methodological quality was assessed with the Newcastle-Ottawa Scale. Pooled prevalence with 95% confidence intervals (CIs) was calculated, heterogeneity was evaluated using the I-squared (I^2) test, and publication bias was assessed with Egger's test. Subgroup and meta-regression analyses for moderator and geographic effects were performed using R and a random-effects model.

Results: A total of 25 studies comprising 16,989 patients were included. The mean weighted age was 38.64 years, and 81.1% were female. The median Systemic Lupus International Collaborating Clinics/ACR-damage index (SDI) score at enrollment was 1.1 (range: 0.29–1.7). The most common syndromes were headache (25%, 95% CI [15, 36]), seizures (9%, 95% CI [5, 13]), and cerebrovascular disease (CVD) (9%, 95% CI [5, 13]). In contrast, syndromes such as aseptic meningitis, myelopathy, chorea, and demyelinating syndromes were rare (1%, 95% CI [0, 0.01]). Headache was most prevalent in African populations (55%), followed by Asians (22%), Europeans (19%), and Latin Americans (9%). Seizures were highest among Latin Americans (17%), followed by Asians (13%), Africans (8%), the USA (7%), and Europeans (3%). CVD was most frequent in Asians (13%), then Latin Americans (11%), Europeans (7%), and Africans (3%). Age at SLE diagnosis was not a significant moderator for headache (p=0.59) or CVD (p=0.81), though it showed a trend toward an inverse effect on seizures (p=0.09). Disease duration was not a significant moderator for seizures (p=0.12), but it trended inversely with headache (p=0.07) and CVD (p=0.08). Female gender did not significantly influence headache (p=0.5), seizures (p=0.4), or CVD (p=0.5). Renal involvement was also not a significant moderator for any of the three (headache p=0.76, seizures p=0.87, CVD p=0.81). Substantial heterogeneity and publication bias were present.

Conclusion: Neurological CNS symptoms, as defined per the ACR 1999 criteria, in adult-onset SLE vary significantly. Aseptic meningitis, myelopathy, and chorea were rare, while headaches, seizures, and cerebrovascular disease were most common. Common modifiers like age, sex, disease duration, and renal involvement showed some trends but did not consistently affect syndrome occurrence. Clear regional disparities were noted.

Abstract Number: 2408

Direct Medical Cost Burden of Cutaneous Lupus Erythematosus (CLE): A Comparison with Psoriasis, Atopic Dermatitis, and a General Population

Joseph F Merola[1], Catherine Mak[2], Tiange Tang[2], Tricia Li[2], Margaret K Moseley[2], Janine Gaiha-Rohrbach[2] and Feng Zeng[2], [1]Department of Dermatology and Department of Medicine, UT Southwestern Medical Center, Dallas, TX, [2]Biogen, Cambridge, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is an autoimmune disease primarily manifesting in skin that can significantly impact patients' quality of life. Current understanding of the direct healthcare cost of CLE is limited. This study was conducted to understand the direct costs of CLE compared with psoriasis, atopic dermatitis (AD), and a general patient population.

Table 1. Selected baseline characteristics of CLE, AD, psoriasis, and general patients

	CLE (N=3,714)	Psoriasis (N=90,133)	AD (N=83,589)	General patients (N=67,221)
Age at index year, mean (SD)	59.5 (15.4)	57.5 (16.8)	57.5 (19.6)	57.9 (19.1)
Age group, n (%)				
18–34	276 (7.4)	10,834 (12.0)	14,336 (17.2)	10,473 (15.6)
35–49	735 (19.8)	17,666 (19.6)	13,633 (16.3)	11,791 (17.5)
50–64	997 (26.8)	22,596 (25.1)	16,317 (19.5)	13,626 (20.3)
65–75	1,119 (30.1)	25,427 (28.2)	20,906 (25.0)	16,684 (24.8)
≥75	587 (15.8)	13,610 (15.1)	18,390 (22.0)	14,647 (21.8)
Sex, n (%)

Estimate (SE)	5,060.13 (354.41)	5,635.62 (336.57)
P-value	***	***
Comparison:	**CLE vs General**	
	No comorbidities controlled	**Comorbidities controlled**
	Total direct cost	Total direct cost
Estimate (SE)	12,403.23 (384.13)	9,949.09 (364.13)
P-value	***	***

All costs are from 2023 and are in US dollars
*** P<0.001; ** P<0.01; * P<0.05; absent asterisk denotes P>0.05
AD, atopic dermatitis; CLE, cutaneous lupus erythematosus; SE, standard error

Methods: Data from January 1, 2016, to December 31, 2023, were extracted from the Optum® de-identified Clinformatics® Data Mart. Patients with CLE or psoriasis were identified by at least two relevant International Classification of Disease-9/10 (ICD-9/10) diagnosis codes, with at least one code from a dermatologist. Patients with AD had at least one relevant ICD-9/10 code and an additional claim of asthma or allergic rhinitis. The general patient cohort was a 1% random sample of those without a diagnosis of CLE, psoriasis, or AD. The index date was the first diagnosis date for each of the CLE, psoriasis, and AD cohorts. The index date for the general patient cohort was randomly assigned to simulate the index date distribution of the other cohorts. Eligible patients were at least 18 years old on the index date. Direct costs were calculated as the sum of post-index annualized all-cause utilizations, including outpatient, medications, and hospitalization. Linear regressions with propensity score weighting assessed the cost difference across cohorts. Patient demographics were balanced across different cohorts after propensity score weighting.

Results: The study identified 3,714 CLE, 90,133 psoriasis, 83,589 AD, and 67,221 general patients (**Table 1**). The CLE cohort had a higher mean age (59.5 years), and higher percentage of female (78.5%) and Black (16.2%) patients than other cohorts. In the CLE cohort, 60.0% had systemic lupus erythematosus (SLE); in the psoriasis cohort, 18.6% had psoriatic arthritis. The CLE group showed similar Charlson Comorbidity Index scores and depression and anxiety rates to the psoriasis and AD cohorts, but higher than the general population.

Regression models unadjusted for comorbidities showed that patients with CLE had significantly higher total direct healthcare costs than those with AD ($5,060, $P < 0.001$) and the general cohort ($12,403, $P < 0.001$) (**Table 2**). The CLE annualized total cost was slightly higher than psoriasis, reaching significance ($945, $P < 0.01$). After comorbidity adjustment, the CLE costs remained significantly higher than the general population and AD, while the total cost difference between CLE and psoriasis became non-significant (**Table 2**).

Conclusion: Adults with CLE, with or without SLE, had comparable comorbidity rates to AD and psoriasis, and higher than the general population. This CLE cohort had substantially higher excess total costs than AD and the general population, and similar total cost to the psoriasis cohort. The significant healthcare costs in this population underscore health policy and societal challenges, emphasizing the need for improved management and expedited research efforts to advance therapeutic options.

Cutaneous Lupus Activity Investigator's Global Assessment——Revised (CLA-IGA-R) Content Validity: Cutaneous Lupus Erythematosus (CLE) Patient Qualitative Study

Joseph F Merola[1], Weihong Yang[2], Qianyun Li[2], Helen Doll[3], Jason Randall[3], Catherine Barbey[4] and Feng Zeng[2], [1]Department of Dermatology and Department of Medicine, UT Southwestern Medical Center, Dallas, TX, [2]Biogen, Cambridge, MA, [3]Clinical Outcomes Solutions, Folkestone, Kent, United Kingdom, [4]Biogen, Baar, Switzerland

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The Cutaneous Lupus Activity Investigator's Global Assessment-Revised (CLA-IGA-R) is an emerging clinician-reported outcome measure for severity of Cutaneous Lupus Erythematosus (CLE) disease activity, developed with clinician input. It consists of three separate items ('Erythema', 'Other morphologic characteristics' [edema, scale, and secondary change], and 'Follicular activity').[1] Qualitative interviews with patients are an important step in assessing the content validity of a measure. The objectives of this concept elicitation study were to qualitatively explore the lived experience of the condition from the patient's perspective and to confirm whether all key signs experienced by patients with CLE are captured by the CLA-IGA-R.

Methods: In total, 15 US participants with a clinical diagnosis of CLE were invited to take part in a qualitative, semi-structured, face-to-face interview. The interview lasted approximately 60 minutes and focused on spontaneously reported signs, symptoms, and impacts of CLE. Key topics not spontaneously discussed were then probed by the interviewer. All interviews were audio recorded and transcribed verbatim; transcripts were then coded and subjected to thematic analysis by two independent researchers. Saturation analysis was performed by dividing the 15 participants into three equal sets.

Results: Participants had an average age of 43.8 (range 24–59) years. They included Black/African American (53.3%; n=8), White (26.6%; n=4), Asian/Asian American (6.6%; n=1), and multiracial (13.3%; n=2) individuals, and most were non-Hispanic (73.3%; n=11). Most were women (86.7%; n=13). Half of the participants had been diagnosed with CLE for at least 10 years, and most reported mild or moderate CLE symptom severity. Six participants had a diagnosis of subacute CLE (SCLE) and eight were diagnosed with chronic CLE (CCLE), including five with discoid lupus.

Red, pink, or purple skin (erythema) was discussed by all 15 participants; 13 reported this spontaneously (**Table 1**). Erythema was described as typically being the first sign of a lupus rash, which was then shortly followed by dry, ashy, or scaly skin (scale: n=13; mentioned spontaneously by 9 participants); this was sometimes followed by swelling, swollen, or bumpy skin (edema) (n=12). Open wounds (n=11) and skin crusting/scabbing (n=8) were associated with more severe rashes and typically occurred at the end of the rash. Little blisters were reported by less than half of participants (n=6). Participants also

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Frequency of reported skin-related lupus concepts during participant interview

Skin-related lupus signs of disease activity	Total (N=15)		
	Total	Spontaneously reported	Mentioned upon questioning
Skin-related lupus signs, n			
Red, pink, or purple skin (Erythema)	15	13	2
Dry, ashy, scaly skin (Scale)	13	9	4
Skin swelling, swollen or bumpy areas (Edema)	12	2	10
Open wounds (Erosion)	11	3	8
Crusting and scabbing after open wounds (Crusting)	8	1	7
Blistering (Vesicles)	6	2	4
Sores in mouth (Mucous membrane sores)	11	2	9
Signs of skin damage,* n			
Scarring	7	7	0
Symptoms,* n			
Hair loss	14	6	8
Skin pain	9	8	1
Itch	7	6	1

*The aim of the interview was to identify signs of CLE activity. Topics relating to signs of disease damage and symptoms were not probed during the interview. However, as these were spontaneously mentioned by participants, they have been included in the results

reported experiencing both current and previous hair loss on the scalp due to CLE (n=14). Saturation was supported as no skin-related lupus signs were introduced within the last group of interviews.

Conclusion: The findings from this qualitative analysis reveal the participants with CLE experienced a wide range of skin-related lupus signs. The key signs and symptoms experienced by participants (erythema, scale, edema, open wounds, crusting, and hair loss [hair loss is the downstream effect of follicular activity]) are captured in the CLA-IGA-R. These data support the content validity of the CLA-IGA-R, and thus its use as a measure of CLE disease activity.

Background/Purpose: Polygenic risk scores (PRS) quantify an individual's genetic susceptibility to diseases by integrating genotype data across multiple loci. However, conventional PRS are limited in capturing the biological context of risk variants. Here, we applied a novel approach, cell-type PRS (csPRS) and pathway-specific PRS (psPRS), to assess genetic risk variants related to specific immune pathways associated with lupus nephritis (LN) phenotypes in childhood-onset SLE (cSLE).

Methods: The study cohort included 192 patients diagnosed with SLE before the age of 18, recruited from the University of Texas Southwestern Medical Center. Demographic and clinical phenotypes were collected during routine clinic visits. A total of 952 SLE risk variants were utilized based on an autoimmune multi-ancestry meta-GWAS. Using chromatin accessibility data, the variants were categorized by immune cell type - B cells, T cells, monocytes, and NK cells - and, using KEGG pathway annotation, the variants were grouped into four biological pathways - BCR, TLR, JAK-STAT, and MAPK. csPRS and psPRS were calculated using a high-performance PRS model (Pruning + Thresholding; p-value threshold: 5×10^{-4}; AUC > 0.7). To evaluate differences in csPRS and psPRS based on the presence of LN and classes (class I/II, proliferative [III, IV, III+V, IV+V], and membranous), ANOVA followed by post-hoc analysis were performed to assess group-wise differences. Overlap of SNP sets between pathways and immune cell types was visualized using R. Pearson correlation coefficients were calculated to assess the relationship between csPRS and psPRS.

Results: The majority of cSLE patients (63.5%) were classified genetically as admixed ancestry, followed by African ancestry (19.7%). There was no difference in overall PRS between patients with and without LN. Further analysis comparing csPRS and psPRS across LN classes showed that patients with proliferative LN had numerically higher T cell PRS than those with class I/II LN, while MAPK psPRS was significantly elevated in the proliferative group ($p = 0.016$). To assess the combined contribution of specific immune cell types and pathways, an integrated PRS was calculated. T cell + MAPK PRS revealed a significant difference between class I/II and proliferative LN ($p = 0.021$). To ensure the result was not driven by overlapping variants, the two SNPs shared between the T cell and MAPK sets were removed prior to computing the integrated score. Notably, there was no significant correlation between T cell and MAPK PRS.

Conclusion: This study demonstrated the heterogeneity of genetic risk across immune pathways in cSLE. Applying csPRS and psPRS, we identified distinct immunogenetic signatures that may underlie differences between class I/II and proliferative LN, reflecting potential immunopathological distinctions between LN histologic subtypes. Expanding this approach in larger, ancestrally diverse cohorts will be essential to validate findings and improve patient stratification into biologically meaningful endotypes. Ultimately, this framework may inform the identification of key immune pathways driving disease phenotypes and support the development of targeted therapies in cSLE.

Table 1. Baseline Characteristics of cSLE Patients (n=192)

Sex: n (%)	
Female	163 (84.8)
Age at diagnosis (years): median (IQR)

Class I, II	22 (11.4)
Proliferative LN (Class III, IV, III+V, IV+V)	87 (45.3)
Membranous LN (Class V)	13 (6.8)

Ancestry was determined using ADMIXTURE analysis. Patients were assigned to a specific ancestry group if their first principal component (PC1) exceeded an 80% threshold; otherwise, they were classified as admixed.

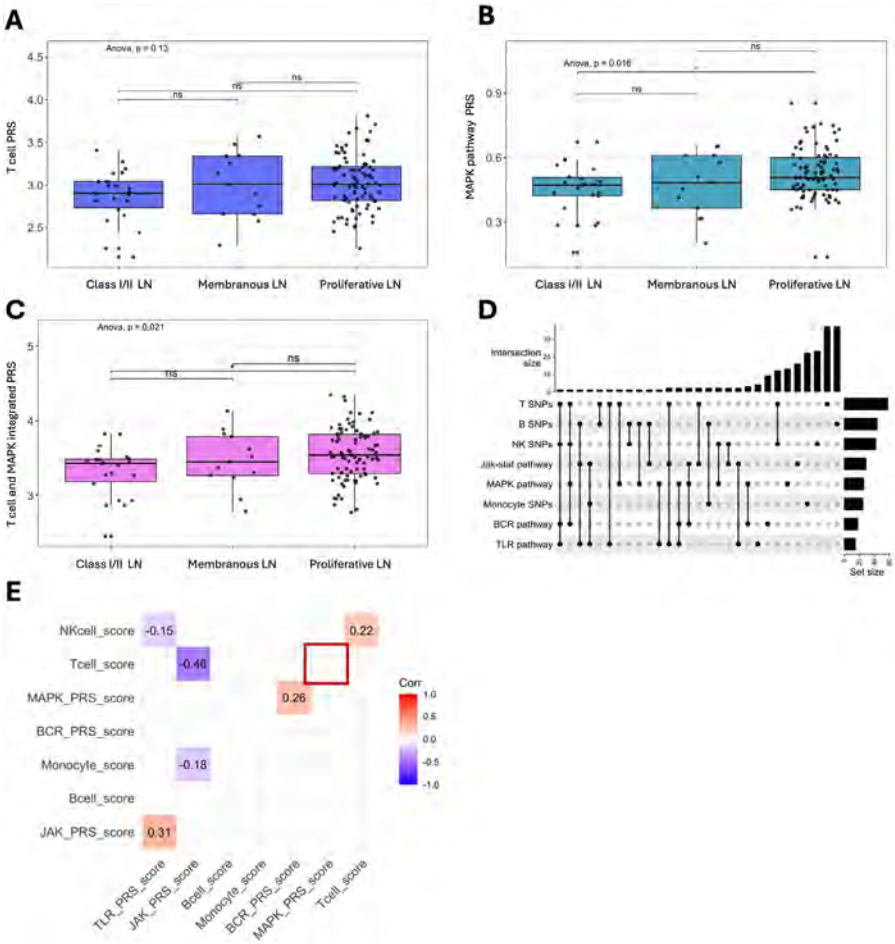
Comparison of csPRS and psPRS in cSLE patients with and without lupus nephritis, using t-test. (A) Immune csPRS (B cell, monocyte, NK cell, and T cell) in cSLE patients with lupus nephritis (n=122) versus those without lupus nephritis (n=70). (B) psPRS (BCR, JAK-STAT, MAPK, and TLR signaling pathways) in the same patient groups.



Comparison of csPRS and psPRS across lupus nephritis classes. Lupus nephritis classes were grouped as class I/II, proliferative lupus nephritis (classes III, IV, III+V, IV+V), and membranous lupus nephritis (class V) (A) T cell PRS was compared across lupus nephritis classes using ANOVA followed by post-hoc tests. (B–C) MAPK PRS and the integrated T cell + MAPK PRS were analyzed using the same approach as described for T cell PRS. (D) SNP set overlaps across pathways and immune cell types were visualized using an UpSet plot in R. "Set Size" indicates the number of SNPs in each category (e.g., T cell, B cell, MAPK, TLR), while "Intersection Size" shows the number of SNPs shared between sets. Intersections represent overlapping SNPs or pathways between sets, with each intersection corresponding to a shared subset. (E) Pearson correlation coefficients were calculated to the relationship between csPRS and psPRS. * indicates $p \leq 0.05$; ns indicates not statistically significant.

The 2019 EULAR/ACR and 2012 SLICC Classification Criteria for SLE Should Be Applied with Caution as Diagnostic Criteria

Luca Mazzoleni[1], Francesca Crisafulli[2], Md Yuzaiful Md Yusof[3], Aamir Aslam[4], Andrew Barr[5], Lesley-Anne Bissell[6], Shouvik Dass[5], Jack E Arnold[7], Ed Vital[8], Franco Franceschini[9] and Porntip Intapiboon[10], [1]University of Brescia, Brescia, Italy, [2]ASST Spedali Civili and University of Brescia, Brescia, Italy, [3]University of Leeds, Leeds, United Kingdom, [4]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [5]Leeds teaching hospitals- NHS trust, Leeds, United Kingdom, [6]Leeds Teaching Hospitals NHS Trust, Leeds, England, United Kingdom, [7]Leeds Institute of Rheumatic & Musculoskeletal Medicine, Leeds, United Kingdom, [8]University of Leeds, Leeds, England, United Kingdom, [9]University of Brescia, Brescia, Brescia, Italy, [10]Prince Of Songkla universitiy, Tambon Kohong, Thailand

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: To assess the 2012 SLICC and 2019 EULAR/ACR classification criteria performance as diagnostic criteria in two cohorts of ANA-positive patients clinically suspected of having CTDs.

Methods: An observational study of 286 ANA-positive, treatment-naïve patients with CTD-related symptoms (≤1 year) was conducted. The 2012 SLICC and 2019 EULAR/ACR criteria were assessed at enrollment (T0) and during a 3-year follow-up. T1 was defined as the visit when patients met classification criteria or their last follow-up. Anonymized charts from T0 and T1 were reviewed by four independent consultants to assess diagnoses and treatment decisions.

Results: At T1, consultants diagnosed SLE in 29 patients (10.14%). The 2012 SLICC criteria were met in 38 patients (13.29%) and the 2019 EULAR/ACR in 39 (13.64%). 6 patients (2.1%) were diagnosed with SLE despite not meeting either classification criteria, while 18 participants (6.29%) met at least one classification criterion but were not diagnosed with SLE by a consultant. Among these 18 patients, consultants recommended hydroxychloroquine monotherapy in 7 cases, immunosuppressive therapy alone in 6, a combination of the two in 1, and no treatment in 4.

Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy at T1 of the 2019 EULAR/ACR and 2012 SLICC SLE criteria are reported in table 1.

Table 1. *Comparison of Sensitivity, Specificity, Positive predictive value, Negative predictive value, Accuracy between 2012 SLICC and 2019 EULAR/ACR criteria*

	2012 SLICC	2019 EULAR/ACR
Sensitivity (95% CI)	75.86% (57.89–87.78)	79.31% (61.61–90.15)
Specificity (95% CI)	93.77% (90.13–96.13)	93.77% (90.13–96.13)
Positive predictive value (95% CI)	57.89% (42.19–72.15)	58.97% (43.42–72.92)
Negative predictive value (95% CI)	97.18% (94.29–98.6)	97.57% (94.8–98.88)
Accuracy (95% CI)	91.96% (88.22–94.58)	92.31% (88.63–94.87)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: In a diagnostic setting, the criteria are less effective than in a classification context and should therefore be applied with caution. They are more useful for ruling out SLE rather than confirming it, given their moderate sensitivity and PPV, but high specificity and NPV.

Evolving Trends in Pulmonary Arterial Hypertension among Systemic Lupus Erythematosus Patients: A Nationwide Analysis

Maria Romero Noboa[1], Faria Sami[2], Almurtada Razok[3] and Shahzad Ahmed Sami[4], [1]University of Alabama at Birmingham, Birmingham, AL, [2]The University of Alabama at Birmingham, Birmingham, AL, [3]John H Stroger Jr Hospital of Cook County, Chicago, IL, [4]DCH Regional Medical Center, Birmingham

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a rare manifestation of Systemic Lupus Erythematosus (SLE) with increased morbidity and mortality. It has historically been underdiagnosed in SLE patients due to nonspecific symptoms and overlap with other conditions but has recently come into light as an important SLE associated complication due to increased awareness. This study aims to analyze yearly trends in PAH and its types in SLE population in the U.S. as well as in-hospital mortality.

Methods: We performed a retrospective review of annual trends in PAH among SLE patients using the National Inpatient Sample (NIS) from 2016 - 2020. Hospitalizations with SLE were identified using ICD-10 codes and cases with a concurrent PAH diagnosis were included. We examined the baseline demographic characteristics and inpatient mortality rate. Yearly trend in PAH among SLE patients was analyzed. Trends across various WHO groups of PAH in SLE patients were also

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Yearly trends of PAH with and without SLE

Figure 2: Yearly trends of SLE with PAH by WHO GROUP

Figure 3: Yearly in-hospital mortality trend in SLE with PAH

compared. Statistical analysis was performed on STATA 7, with P-value less than 0.05 was considered statistically significant.

Results: A total of 41,445 hospitalizations with concurrent SLE and PAH were identified between 2016 and 2020. Most patients were females (89.4% in 2020) and by 2020, white race comprised 39.9%, African Americans 37.9%, Hispanic 13.2% and Asian 8.9%. Mean age increased from 54.5 years in 2016 to 57.4 years in 2020. Overall, yearly hospitalizations of SLE with PAH increased substantially from 200 in 2016 to over 12,000 by 2018 ($p < 0.001$). (Figure 1) This was also seen according to WHO groups of PAH, especially for Group 5 (Figure 2). There was a significant increase in comorbidity burden, with the proportion of patients with a CCI ≥4 increasing from 6.8% in 2016 to 77.2% in 2019. Comorbidities with notable uptrend included congestive heart failure (CHF) (47.5% to 63.1%, $p = 0.001$), hyperlipidemia (20.0% to 35.9%, $p = 0.005$),

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and protein-energy malnutrition (PEM) (7.5% to 11.8%, p = 0.005). Despite rising complexity, in-hospital mortality was 5.0% in 2016 and continued like this to 2020 with 4.9% (p = 0.249). (Figure 3) Mean length of stay (7.3 days in 2016 vs 7.2 in 2020) and Total Hospital Charges ($86,676 in 2016 and $96,961 by 2020) remained stable. However, rates of adverse in-hospital events increased, including mechanical ventilation (MV) (2.5% to 8.1%, p =0.004), acute myocardial infarction (AMI) (5.0% to 7.5%, p = 0.001), acute respiratory failure (ARF) (12.5% to 16.6%, p = 0.001), and pulmonary embolism (PE) (0% to 2.1%, p =0.019). There was no change in the trend for sepsis, acute kidney injury (AKI), need for pressors, or cerebrovascular accident (CVA).

Conclusion: Hospitalizations of SLE patients with PAH increased significantly from 2016 to 2020, with an uptrend in comorbidities including CHF, hyperlipidemia and PEM. There was an increase in-hospital events including MV, AMI, ARF and PE. Despite this rise in complexity and events, mortality and healthcare utilization remained similar from 2016 to 2020. These findings highlight the evolving clinical profile of SLE patients with more frequent PAH diagnosis over time, and underscores the need for targeted interventions to improve outcomes in patients with SLE-related PAH.

Hydroxychloroquine and Adverse Cardiovascular Outcomes in Pregnant Patients with Systemic Lupus Erythematosus

Mariana Gonzalez-Treviño[1], Ashley L Ciosek[1], Genessis Maldonado[1], Catherine Deffendall[2], Tania Ruiz[1], Tracy Frech[1] and Rashmi Dhital[3], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN, [3]Vanderbilt University Medical Center, Brentwood, TN

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is a medication used in SLE during pregnancy. An adverse effect of HCQ includes cardiotoxicity. Hormonal changes during pregnancy may trigger SLE cardiomyopathy. The objective of this study was to examine the association of HCQ use during pregnancy with new onset adverse cardiovascular (CV) outcomes during pregnancy and postpartum in subjects with SLE.

Methods: In this study, we used the Synthetic Derivative, a de-identified copy of the EHR containing billing codes and clinical data spanning 1989-2024. We identified pregnant subjects with SLE and CV outcomes using ICD-9/ICD-10 codes for 1) SLE, 2) labor/delivery, and 3) heart failure (HF)/peripartum cardiomyopathy or CPT codes for cardiac MRI. Charts were manually reviewed by a physician to ascertain SLE clinical diagnosis and pregnancy (inclusion criteria). Subjects without SLE, pregnancy prior to SLE, onset of HF prior to pregnancy, and pregnancies terminating < 20 weeks were excluded. Demographic and clinical characteristics, HCQ use during pregnancy, immunosuppressive therapy (IST), and maternal complications were abstracted. Medical records were reviewed from conception until six months after delivery to identify new onset adverse CV outcomes (HF, arrhythmias, valvular disease, pericarditis, Cor pulmonale) during pregnancy and postpartum. Comparisons were made using Mann-Whitney U test for continuous variables and Fisher's exact test or X^2-test for categorical variables, as appropriate.

HCQ use prior to pregnancy, n (%)	5 (50%)	14 (60.9%)	0.70	12 (54.5%)	7 (63.6%)	0.71
HCQ use during pregnancy, n (%)	5 (50%)	12 (52.2%)	1	11 (50%)	6 (54.5%)	1
HCQ dose at delivery (mg/day), median (IQR)	350 (225–400)	350 (200–400)	0.87	400 (200–400)	300 (225–375)	0.54
IST use during pregnancy, n (%)	7 (70%)	8 (34.8%)	0.13	14 (63.6%)	1 (9.1%)	**0.001**
Glucocorticoid use during pregnancy, n (%)	8 (80%)	13 (56.5%)	0.67	14 (63.6%)	4 (36.4%)	0.06
Glucocorticoid dose at delivery (mg/day), median (IQR)	20 (8.1–52.5)	10 (5–17.5)	0.05	17.5 (5–20)	7.5 (3.1–13.7)	0.08
Aspirin use during pregnancy, n (%)	7 (70%)	13 (56.5%)	0.70	13 (59.1%)	7 (63.6%)	1
LMWH use during pregnancy, n (%)	1 (10%)	5 (21.7%)	0.64	3 (13.6%)	3 (27.3%)	0.39

CV, cardiovascular; HCQ, hydroxychloroquine; IST, immunosuppressive therapy; LMWH, low molecular weight heparin; SLE systemic lupus erythematosus.
[a]Adverse CV outcomes during pregnancy and postpartum included HF (n=6), valvular disease (n=1), arrhythmia (n=1), Cor pulmonale (n=2)
[b]Maternal complications included preeclampsia (n=11), eclampsia (n=1), peripartum infections (n=2), postpartum hemorrhage (n=3), gestational HTN (n=6), and gestational DM (n=2). Some subjects presented more than one maternal complication.

Results: Of 131 identified cases, we included 33 pregnant subjects with SLE. Median (IQR) age at delivery was 27 (24–31) years. Seventeen (51%) of them were taking HCQ during pregnancy. Those on HCQ during pregnancy were more likely to have received IST (64% vs 25%, p=0.04) and aspirin (82% vs 37%, p=0.01) during pregnancy, and had lower median glucocorticoid (GC) dose at delivery (10 vs 20 mg/day, p=0.04). Demographic and clinical characteristics are shown in **Table 1**. Ten (30%) subjects developed new onset CV outcomes during pregnancy and/or the postpartum period, whereas 23 (70%) didn't have cardiac complications during the follow-up period. Half (n=5) of the subjects with adverse CV outcomes received HCQ during pregnancy (**Table 2**). All five adverse CV outcomes in the HCQ group were HF, one of whom had peripartum cardiomyopathy with recovery of myocardial function in the postpartum period without HCQ discontinuation. Twenty-two (66.7%) patients developed maternal complications, of whom 50% (n=11) were on HCQ during pregnancy. The use of HCQ was similar between individuals with or without adverse CV outcomes and maternal complications (**Table 3**). Those with adverse CV outcomes had shorter SLE duration (2 vs 5 years, p=0.03). Individuals with maternal complications were younger at delivery (26 vs 32 years, p=0.008), had higher rates of preterm birth (77% vs 27%, p=0.009), positivity of dsDNA antibody (95% vs 40%, p=0.002), and IST use (63% vs 9%, p=0.001).

Conclusion: In this study, there was no difference in adverse CV and maternal outcomes with or without the use of HCQ among pregnant individuals with SLE. Those with adverse outcomes had shorter SLE duration, were younger, and had more exposure to IST, suggesting higher SLE disease activity.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

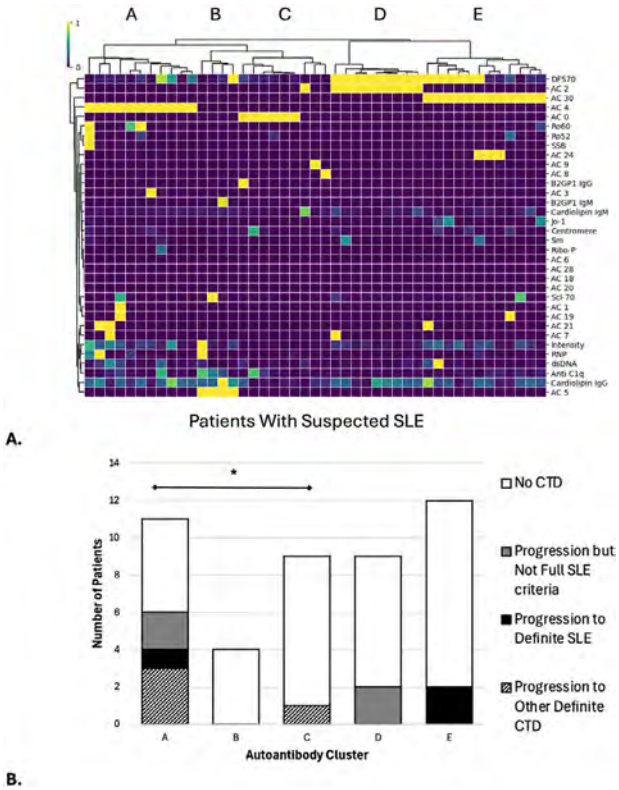

Figure 1. A) Five autoantibody clusters identified based on baseline samples of 45 samples of suspected SLE (left to right): Cluster A (n=11) AC-4 nuclear speckled pattern with the greatest autoantibody reactivity including anti-RNP, anti-dsDNA, and anti-Ro60/SSA, Cluster B (n=4) nuclear large speckled pattern, Cluster C (n=9) mostly no autoantibodies, Cluster D (n=9) monospecific anti-DFS70 antibody with dense fine speckled (AC2) pattern, and Cluster E (n=12) nuclear speckled with mitotic plate staining (AC-30). The ANA patterns were classified according to the most recently updated International Consensus on ANA Patterns recommendations and performed on Indirect immunofluorescence assay (IFA) using HEp-2 substrate (NovaLite,Werfen, San Diego, USA). In accord with the manufacturers' directions, a positive test was defined as a titer of >=1:80. IFA results (titres and patterns) were initially read by an automated digital IFA microscope (NovaView, Werfen) and then validated by technologists with >15 years of experience. SLE-related antibodies and anti-DFS70 antibodies were performed on the Aptiva® Connective Tissue Disease Essential kit, a fully automated multi-analyte system using particle-based multi-analyte technology (Werfen, San Diego, USA). IgG and IgM anti-cardiolipin and IgG and IgM anti–β2-glycoprotein-1 (β2GP1) and anti-C1q antibodies were performed using an ELISA (Werfen, San Diego, USA). B) Cluster A (AC-4 nuclear speckled pattern and high autoantibody reactivity) had the largest number of patients with disease progression +/- definite SLE or other CTD at follow-up. *denotes a significant difference in proportion of patients who had disease progression +/- definite SLE or other CTD at follow-up (Cluster A vs. C, diff. 43.43%, 95%CI 0.08%-0.79%).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Background/Purpose: Up to a third of those with suspected SLE progress to definite SLE; however, reliable predictive markers for disease progression remain unknown. Previously, we developed a Lupus Lymphocyte Activation Score (LLAS) based on key cell subsets (transitional B cells, age-associated B cells, plasmablasts, Tph cells, and Tfh cells) observed in those with or at risk of developing SLE (Horisberger, 2024). Here we examined the relationship between autoantibody profiles, including anti-dense fine speckled 70 (DFS70) antibodies, as well as sialic acid binding Ig like lectin 1 (SIGLEC1, a surrogate marker for type I interferon), LLAS, and SLE development among those with suspected disease.

Methods: Blood samples were collected from 45 patients with new onset (< 3 yrs) suspected SLE at Brigham and Women's Hospital Lupus Center. At baseline, subjects did not meet SLE classification criteria and received prednisone < 10mg/day and no immunosuppressants. Using baseline samples, SIGLEC1 was measured by flow cytometry on a subset of patients (n=20) and a comprehensive autoantibody profile on all patients: ANA by indirect immunofluorescence assay on HEp-2 cells and patterns classified according to the International Consensus on ANA Pattern anti-cell (AC) nomenclature, SLE-related autoantibodies, including anti-DFS70 by a fully automated multi-analyte system using particle-based multi-analyte technology, and anti-C1q and anti-phospholipid antibodies by ELISA. To examine patterns of autoantibodies, we used hierarchical clustering and investigated their relationships with disease progression, LLAS, and SIGLEC1 levels.

Results: Of 45 patients, 36 had multiple visits with a mean follow-up of 13.6 months. In follow-up, 3 patients were diagnosed with SLE and met 2012 SLICC or 2019 EULAR/ACR criteria; 4 were diagnosed with or suspected of new dermatomyositis or Sjögren's syndrome. We identified 5 clusters of suspected SLE patients based on autoantibody profiles (Fig. 1A, B). Cluster A (AC-4 nuclear speckled with multiple autoantibody reactivity including anti-RNP, -dsDNA, -anti-Ro60/SSA) was more likely progress or develop a CTD including SLE (OR 1.94, 95%CI 0.42-3.46) than others (Fig. 2A), particularly compared to Cluster C (no autoantibodies) (diff. 43.43%, 95%CI 0.08%-0.79%). Cluster A also had significantly

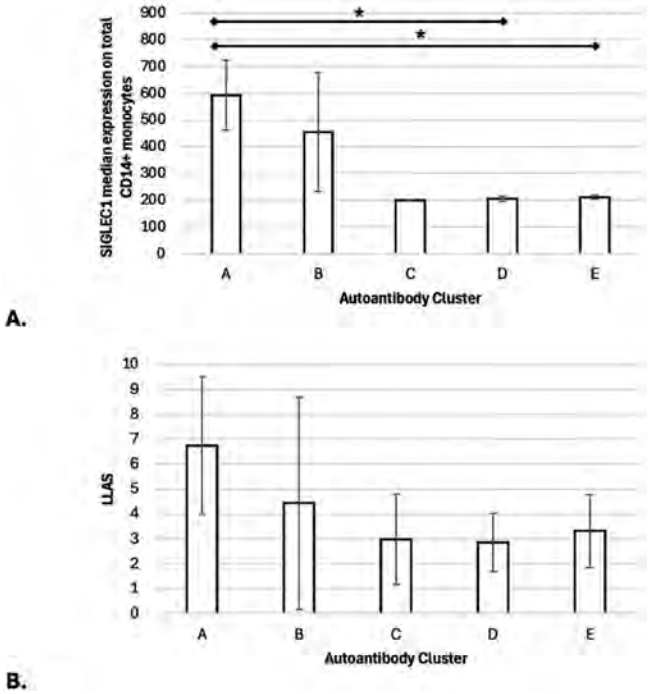

Figure 2. Autoantibody clusters of suspected SLE patients and their A) median SIGLEC1 expression on total CD14+ monocytes (n=20 patients selected sequentially based on enrolment date). *Cluster A (n=5) had higher median SIGLEC1 expression compared to Cluster D (n=5) and Cluster E (n=6). Of note, there are no error bars for cluster C (n=1) as there was only one patient with SIGLEC1 level. Cluster B had 3 patients with SIGLEC1 measurements. B) Lupus Lymphocyte Activation Score (LLAS) (n=45) was not statistically different among different autoantibody clusters.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

higher median SIGLEC1 expression on total CD14+ monocytes vs. Cluster D (monospecific antiDFS70 with AC2, diff. 388.00, 95%CI 86.78-689.22) and Cluster E (AC30, diff. 382.97, 95%CI 116.30-649.64). There was no difference in LLAS by autoantibody cluster (Fig. 2B).

Conclusion: Autoantibody profile characterized by nuclear speckled with multiple autoantibody reactivity, including anti-RNP, -dsDNA, and -Ro60/SSA, was predictive of CTD development. Although based on a smaller sample size, this cluster also had higher baseline SIGLEC1 vs. those with monospecific DFS70 antibodies or no autoantibodies. Further analysis will assess whether LLAS, SIGLEC1, and autoantibodies are complementary, and when combined, could enhance the prediction of SLE development.

Abstract Number: 2415

Evaluating the Readability and Comprehension of Patient Education Materials for Systemic Lupus Erythematosus (SLE) Available Online

Nagoor Shaik, Ugochukwu Nweke and **Meenakshi Jolly**, Rush University, Chicago

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic multisystemic autoimmune disease that had multidimensional adverse effects on patients lives, and preferentially inflicts young women, specially of color. Patient education materials (PEMs) help patients understand their condition and manage it better. However, these materials frequently exceed the reading ability of the general population, posing challenges for individuals with limited health literacy. The National Institutes of Health (NIH) and the American Medical Association (AMA) recommend that PEMs be written at or below a 6th-grade reading level.

We aimed to evaluate the readability and comprehension of SLE-related PEMs available online from both nonprofit and for-profit organizations.

Methods: We analyzed the SLE PEMs from four nonprofit organizations (American College of Rheumatology-ACR, Lupus Foundation of America-LFA, Lupus Research Alliance-LRA, and Lupus Society of Illinois-LSI) and three for-profit companies (Aurinia, AstraZeneca, and GlaxoSmithKline). Readability and comprehension scores were calculated using six standard tools, and group-level comparisons were performed using one-way ANOVA followed by Tukey's post-hoc analysis. A p-value of ≤0.05 was considered significant.

Results: The average Flesch–Kincaid Grade Level and Flesch Reading Ease scores across all patient education materials (PEMs) were 10.05 ± 0.7 and 52.68 ± 4.1, respectively. On average, materials from nonprofit organizations had a Flesch–Kincaid Grade Level of 10.3 ± 0.8 and a Reading Ease score of 51.1 ± 4.9, whereas for-profit organizations had a slightly lower Grade Level of 9.9 ± 0.4 and a higher Ease score of 54.3 ± 2.6. These differences were not statistically significant

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Readability and Comprehension of SLE Patient Education Materials

Readability Index	ACR (NPO)	LFA (NPO)	LRA (NPO)	LSI (NPO)	All NPO	Aurinia (FPO)	AstraZeneca (FPO)	GSK (FPO)	All FPO	p-value
Flesch–Kincaid Grade Level	10.6 ± 0.5	9.1 ± 0.4	10.5 ± 0.6	11.2 ± 0.4	10.3 ± 0.6	9.5 ± 0.4	9.9 ± 0.3	9.8 ± 0.2	9.9 ± 0.4	0.514
Flesch–Kincaid Ease Score	49.8 ± 2.2	58.3 ± 3.1	50.5 ± 2.6	45.6 ± 2.0	51.1 ± 4.9	55.7 ± 3.0	53.1 ± 2.4	54.2 ± 2.1	54.3 ± 2.6	0.198
Gunning Fog Index	12.0 ± 0.6	10.8 ± 0.5	11.7 ± 0.7	12.5 ± 0.5	11.7 ± 0.8	11.3 ± 0.7	12.2 ± 0.6	12.0 ± 0.5	11.8 ± 0.6	0.138
SMOG Index	10.8 ± 0.4	9.6 ± 0.3	10.5 ± 0.5	11.0 ± 0.4	10.5 ± 0.6	10.2 ± 0.5	10.7 ± 0.4	10.6 ± 0.3	10.5 ± 0.4	0.223
Coleman–Liau Index	12.5 ± 0.5	11.0 ± 0.6	12.1 ± 0.4	12.8 ± 0.7	12.1 ± 0.7	11.7 ± 0.6	12.0 ± 0.5	11.9 ± 0.4	11.9 ± 0.5	0.310
Automated Readability Index	10.2 ± 0.3	9.0 ± 0.4	9.8 ± 0.5	10.5 ± 0.6	9.9 ± 0.7	9.3 ± 0.5	9.8 ± 0.4	9.7 ± 0.3	9.6 ± 0.4	0.445

This table presents the mean readability scores (± SD) for materials from nonprofit and for-profit organizations, calculated using six standard readability indices. Reported p-values represent the results of one-way ANOVA tests comparing average scores across all NPO and FPO organizations for each index.

Abbreviations: FKGL - Flesch–Kincaid Grade Level, FRES – Flesch Reading Ease Score, GFI – Gunning Fog Index, SMOG – Simple Measure of Gobbledygook, CLI – Coleman-Liau Index, ARI – Automated Readability Index, NPO-Non Profit Organization, FPO-For profit Organization, SD – Standard Deviation

(p = 0.51 and 0.20respectively). However significant within-group differences were observed. Among nonprofit organizations, PEMs from the Lupus Foundation of America (LFA) had the best reading and comprehension metrics: (Flesch–Kincaid Grade Level of 9.1 ± 0.4 and a Reading Ease score of 58.3 ± 3.1), as compared to ACR (10.6 ± 0.5, 49.8 ± 2.2), LRA (10.5 ± 0.6, 50.5 ± 2.6), and LSI (11.2 ± 0.4, 45.6 ± 2.0) (p < 0.01). Among for-profit organizations, reading and comprehension levels for PEMs from Aurinia were significantly better in reading and comprehension (Flesch Kincaid Grade level 9.5 ± 0.4 and Reading Ease score of 55.7 ± 3.0), than AstraZeneca (9.9 ± 0.3, 53.1 ± 2.4) and GSK (9.8 ± 0.2, 54.2 ± 2.1) (both p < 0.001).

Conclusion: Most SLE patient education materials online (from both nonprofit and for-profit organizations) are written at or above 10th grade level. These findings highlight the urgent need to improve the reading and comprehension of patient education resources to better assist individuals in understanding and managing their health.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: We reported partial direct healthcare costs associated with damage accrual in the SLICC Inception Cohort (Barber M. Arthritis Care Res 2020;72:1800). We have supplemented this data by querying a cohort subset on all healthcare use and lost time in paid/unpaid labour and now provide complete direct and indirect costs (DC, IDC) for the full cohort, stratified by damage.

Methods: Between 1999 and 2011, SLE patients from 31 centres in 10 countries were enrolled in the SLICC Inception Cohort within 15 months of diagnosis. Damage (SLICC/ACR Damage Index [SDI]) and limited healthcare use (hospitalizations, medications, and dialysis) were collected annually to July 2022. Starting in 2015, 18 sites collected supplemental economic data annually (physicians, non-physician healthcare professionals, emergency room, laboratory tests, radiological/other procedures, outpatient surgeries, help obtaining medical care, and lost time in paid/unpaid labour).

DC were calculated by multiplying each health resource by its corresponding 2024 Canadian unit cost. Total IDC included: 1) absenteeism (time lost from paid labour because of illness), 2) presenteeism (degree of patient self-reported productivity impairment in paid/unpaid labour, based on a visual analogue scale), and 3) opportunity costs (additional time patients would be working in paid/unpaid labour if not ill). Opportunity costs were calculated as the difference between time patients reported working versus that worked by an age, gender, and geographic-matched general population in paid/unpaid labour. IDC from paid/unpaid labour were valued using age-and-gender-specific wages from Statistics Canada. Multiple imputation was used to predict missing costs for patients in the full cohort who provided only limited economic data for all observations.

At each assessment, patients were assigned to one of six damage states (SDI = 0, 1, 2, 3, 4, >= 5) and annual costs, both unimputed and including imputations, were stratified by SDI. Means and 95% CIs were compared.

Table 1. Participant Characteristics

Characteristics	Full Cohort (n=1694)	Cohort Subset (n=766)
Baseline		
Female, %	88.8	89.7
White race and ethnicity, %	48.9	41.4
Age at diagnosis (years), mean	34.8	33.0

Total Costs	**32252**	**46854**	**48360**	**62606**	**69381**	**86138**

*Other includes non-physician healthcare professionals, emergency room visits, outpatient surgeries, and help obtaining medical care
**Opportunity costs for paid labour for patients with an SDI = 0 are negative because these patients reported working more than the matched general population.

Figure 1. Annual imputed complete direct, indirect, and total costs (in 2024 Canadian dollars) for the full cohort, stratified by SDI (n = 15,106 observations)

Results: 1694 patients (88.8% female, 48.9% White, mean age at diagnosis 34.6 years) were followed a mean of 10.5 years. Of these 1694 patients, 766 (89.7% female, 41.4% White, mean age at diagnosis 33.0 years) completed the supplemental economic questionnaire **(Table 1)**. Their mean disease duration at the time of this questionnaire was 10.9 years and this subset provided economic data a mean of 3.5 years.

Among the subset completing the supplemental questionnaire, on average, IDC, primarily from unpaid labour, accounted for 81.2% of total costs **(Table 2)**. For the full cohort, annual DC and IDC increased with increasing SDI (SDI = 0: total costs $35,417 [95%CI $32,563, $38,271]; SDI >= 5: total costs $95,149 [95%CI $86,178, $104,119]) **(Figure 1)**.

Conclusion: Patients with the highest versus the lowest SDI incurred complete DC that were 6.0-fold and IDC 2.1-fold higher. Even patients with no or minimal damage still experienced considerable IDC. IDC exceeded DC, on average, by

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: Systemic autoimmune rheumatic diseases (SARD) are a heterogeneous group of disorders marked by the presence of antinuclear antibodies (ANA), commonly detected by HEp-2 cell-based indirect immunofluorescence (IIF). The dense fine speckled (DFS) antinuclear antibody (ANA) pattern, caused by anti-DFS70 antibodies, is often misunderstood due to reported low association with SARD and presence in healthy individuals. Some studies suggest presence of isolated anti-DFS70 antibodies exclude SARD. Given the limited data from the Indian subcontinent and the large volume of ANA IIF tested, this study aims to estimate the prevalence and clinical associations of anti-DFS70 antibodies in sera tested for ANA without well defined disease, in nonrheumatic disease controls and in SARD patients.

Methods: Sera from SARD patients, those without a well-defined disease, and from non-rheumatic disease controls displaying a DFS IIF pattern, were further investigated using an anti-DFS70 ELISA and Line Immunoassay (LIA). ANA IIF was performed utilising HEp-20-10 based IIF.

Results: The DFS IIF pattern was observed in 82 out of 32,285 (0.25%) sera from referrals for undefined disease, 2 out of 350 (0.57%) in SARD sera and 1 out of 250 (0.4%) non-rheumatic disease controls. ELISA anti-DFS70 was positive in 74 of 82 (90%) undefined disease sera, 54 of 350 (15.4%) SARD sera and in 1 of 1 (100%) non-rheumatic disease control sera. Anti DFS70 LIA was positive in 74 of 82 (90%) undefined disease sera, 20 of 350 SARD sera(5.7%) and in 1 of 1 (100%) non-rheumatic disease control sera. There was almost perfect agreement (kappa value = 0.861) between anti-DFS70 ELISA and LIA in the routine ANA referral group. In SARD,anti-DFS70 ELISA positivity was significantly associated with higher prevalence of SLE (87% vs. 67.6%; p = 0.0033) and lower prevalence of RA (1.9% vs. 15.2%; p = 0.0040). Mean DFS ELISA titres in SLE patients with LIA positivity (n=14) were higher (3.38±1.61) compared to those negative for anti-DFS70 antibodies in LIA (1.55±0.63).SLE patients with positive anti-dsdna were significantly more likely to be anti-DFS70 ELISA positive (p=0.0001).SLE patients who tested positive for anti-DFS70 by ELISA had significantly higher disease activity, with a median SLE Disease Activity Index (SLEDAI) score of 16 (range: 10–23), compared to 10 (range: 5–15) in ELISA-negative patients (p = 0.01)Renal involvement significantly correlated with anti-DFS70 positivity in SLE patients; p=0.014.

Table 1: Comparison of DFS IIF, Anti-DFS70 ELISA, LIA, and Monospecific Results Across Study Groups

Group	Total Patients	DFS IIF Positive (n, %)	ELISA Positive (n, %)	LIA Positive (n, %)	Monospecific Anti-DFS70 (n, %)
SARD Patients	350	2 (0.57%)	54 (15.4%)	20 (5.7%)	3 (15% of LIA^{+}) (All in UCTD)
Routine ANA Referrals	32,285	82 (0.25%)	74 (90.2% of DFS IIF^{+})	74 (90.2% of DFS IIF^{+})	55 (74.3% of LIA^{+})
Controls	250	1 (0.4%)	1 (100% of DFS IIF^{+})	1 (100% of DFS IIF^{+})	1 (100% of LIA^{+})

Table 2: Demographic and Clinical Characteristics – (SARD Group)

Parameter	***Value (n=350)***
Mean Age (years)	29.7 ± 11.8
Female Sex	313/350 (89.4%)
Diagnosis Distribution	
- Systemic Lupus Erythematosus (SLE)	247 (70.5%)
- Rheumatoid Arthritis (RA)	46 (13.1%)
- Undifferentiated CTD (UCTD)	35 (10%)
- Systemic Sclerosis (SSc)	15 (4.3%)
- Sjögren's Syndrome	3 (0.9%)
- Antiphospholipid Syndrome (APS)	1 (0.3%)
- Anti-Synthetase Syndrome (ASS)	1 (0.3%)
- Mixed CTD (MCTD)	1 (0.3%)
- Myositis	1 (0.3%)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 3: Distribution of anti-DFS70 positivity by ELISA and LIA in various SARD (n=54)

Diagnosis	Anti-DFS70 ELISA positive(n)	Anti-DFS70 LIA positive(n)	Monospecific anti-DFS 70 antibodies in LIA -n(%)
SLE	47	14	0
RA	1	1	0
UCTD	4	4	3 (75)
SSc	1	1	0
APS	1	0	0

Monospecific anti-DFS70 antibodies in LIA were observed only in UCTD (3/4;75%), and none of the other SARD patients

Conclusion: When the DFS-IIF pattern is seen in sera with monospecific anti-DFS antibodies (as tested in line immunoassay), SARD is less likely. Significant concordance between ELISA and Line immunoassay is noted for detecting anti-DFS70 antibodies. Anti-DFS70 antibodies, when present in SARD , coexist with other disease-associated antibodies and hence do not produce DFS IIF pattern. In SARD patients, anti-DFS70 ELISA positivity was significantly associated with SLE, higher disease activity (SLEDAI), anti-dsdna positivity, and renal involvement, while being inversely associated with RA.

ORF1p Expression Correlates with STING Activation and IFN Signatures in SLE Nonlesional Skin

Mehrnaz Gharaee-Kermani[1], Svenja Henning[2], John LaCava[3], Tomas Mustelin[4] and J. Michelle Kahlenberg[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Groningen, Groningen, Groningen, Netherlands, [3]Rockefeller University, New York City, NY, NJ, [4]University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Type I interferons (IFNs) are elevated in the skin and blood of patients with systemic (SLE) and cutaneous (CLE) lupus erythematosus. Upregulation of type I IFNs in non-lesional keratinocytes promotes myeloid activation and cell death in response to ultraviolet light, an important trigger for skin and systemic disease flares. The reasons for chronic type I IFN upregulation in non-lesional SLE remain under-explored but are important targets for disease flare prevention. Here, we examined upregulation of the protein ORF1p, which occurs with de-repression of LINE-1 elements, in conjunction with markers of STING activation and type I IFN signatures in non-lesional SLE skin biopsies.

Methods: Non-lesional skin biopsies were obtained from the upper thigh of 40 patients with SLE and were examined via bulk RNA sequencing and immunohistochemistry (IHC) for ORF1p and phosphorylated (activated) STING. IHC was scored for number of positively staining cells across the basal epidermis within10 field of view at 20x magnification. Expression of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

ORF1p was correlated with clinical data of patients. Interferon scores using 138 epidermal specific genes regulated by type I IFN exposure was calculated as previously reported.

Results: Healthy control skin biopsies had very low levels of ORF1p expression with no subject having >1 positive cell per field at 20 X magnification (mean 0.395, SD 0.258). SLE patients, on the other hand, exhibited significantly higher expression of ORF1p (mean 16.018, SD18.510). There was a strong correlation between staining for ORF1p and phospho-STING in the basal epidermis (R^2=0.871, p< 0.0001). Type I IFN scores were significantly increased in SLE patients who had an average of $\geq$10 cells stained for ORF1p per field (mean of < 10 cells -12.070, SD 76.931; mean of $\geq$ 10 cells 151.080, SD 158.163; p=0.020). Evaluation of clinical data found a correlation between ORF1p epidermal staining and points on the EULAR/ACR classification criteria for SLE (R=0.55, p=0.002). No differences were noted in ORF1p positivity based on use of hydroxychloroquine, history of skin disease, or CLASI activity.

Conclusion: ORF1p staining is increased in non-lesional skin of SLE patients and correlates strongly with the activation of STING in the epidermis and the presence of an interferon signature in the skin. SLE patients with the most widespread disease exhibit the highest ORF1p expression. Further research is needed to determine if ORF1p upregulation (and the preceding de-repression of LINE1 elements) is a cause or consequence of type I IFN signaling in SLE skin. This understanding will lead to novel therapies to treat type I IFN-driven disease.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Antinuclear antibody (ANA) and SLE-related autoantibody testing are integral parts of SLE screening, diagnosis, and monitoring. However, these tests rely on access to phlebotomy for blood sample collection and a lab that can receive and perform these assays in a timely manner. This is a challenge for patients living in remote areas, including Indigenous populations and African countries, where SLE is likely underdiagnosed. Here, we investigated the performance of ANA and SLE-related autoantibody tests on dried blood spots (DBS) as a more resource-efficient and minimally invasive alternative for patients.

Methods: Patients with SLE meeting the 2012 SLICC or 2019 ACR/EULAR criteria or rheumatoid arthritis (RA) meeting the 2010 ACR/EULAR criteria as disease controls were enrolled from a single tertiary care centre. Serum was collected by both venipuncture and DBS at the same visit. DBS cards were subsequently stored under four conditions: 1) 25°C (room temperature) for one week, 2) 25°C for 4 weeks, 3) 4°C for one week, and 4) 4°C for 4 weeks. For each condition, ANA was

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

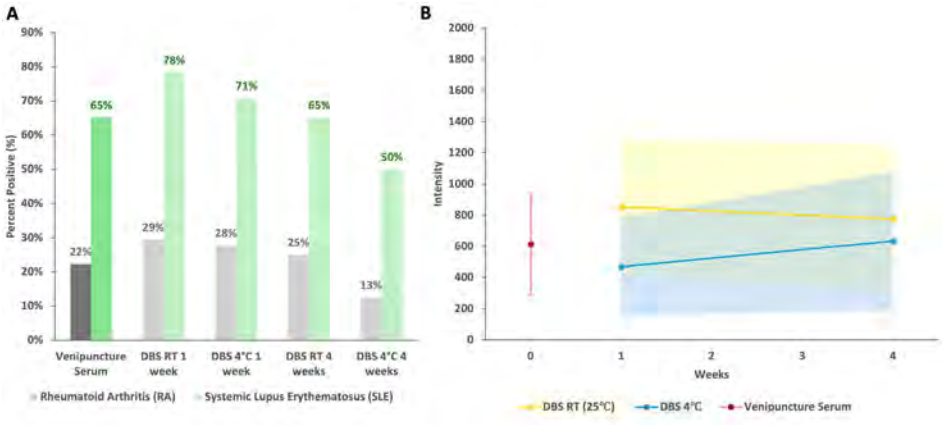

Figure 1. Venipuncture vs. DBS for A) ANA positivity (>=1:80) using indirect immunofluorescence on HEp2 substrate, stratified based on diagnosis (RA vs. SLE). There was no significant difference between venipuncture vs. DBS for all storage conditions; B) ANA titre over time (31 patients for 25°C, 30 patients for 4°C) represented by intensity level measured by an automated digital IFA microscope (NovaView, Werfen). Mean titres ± 95% confidence interval (CI) for 25°C were not significantly different after 1 week (853.68 ± 438.80) vs 4 weeks (776.00 ± 466.01) (McNemar paired chi-square test, p=0.554). Similarly, there were no significant differences for 4°C after 1 week (469.67 ± 315.6) vs. 4 weeks (634.27 ± 442.57) (p=0.321).

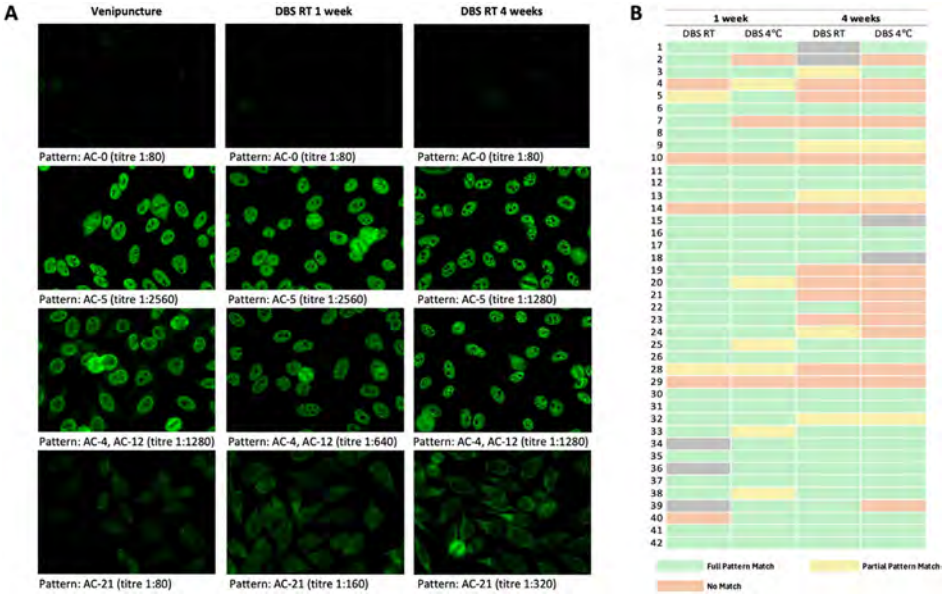

Figure 2. Venipuncture vs. DBS for A) ANA pattern, examples of ANA images shown and B) comparing pattern agreement under 4 different conditions. There was highest agreement at week 1, regardless of temperature condition. RT=room temperature. Full pattern match refers to identical pattern(s) between venipuncture and DBS. Partial pattern match refers to when there are multiple ANA patterns on venipuncture and at least one of those patterns matches a DBS pattern, but not all. No match refers to no patterns agree on venipuncture vs. DBS.

performed using an indirect immunofluorescence assay (IFA) on HEp-2 substrate (NovaLite,Werfen, CA). ANA patterns were classified according to the most recently updated International Consensus on ANA Patterns recommendations. Per manufacturers' directions, a positive test was defined as a titer of >=1:80. SLE-related antibodies (anti-U1-RNP, -histone, Jo-1, -ribosomal P, -Sm, -Sm-RNP, -Scl70, -PmScl, -centromere B, -PCNA, -Ro52/TRIM21, -Ro60/SSA, and -La/SSB) were performed on Connective-13 profile (addressable laser bead immunoassay by Theradiag, positive >80 AU/mL) and anti-dsDNA by ELISA (Werfen, CA, positive >300 IU/mL). We compared the ANA (titres and patterns) and autoantibody titres between venipuncture vs. DBS under the different storage conditions.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. SLE-related autoantibodies and correlation between venipuncture and DBS titres (1 week stored at room temperature shown only). All autoantibodies were analysed using Connective-13 profile (addressable laser bead immunoassay by Theradiag, positive >80 AU/mL) except for anti-dsDNA which was analyzed using ELISA (Werfen, CA, positive >300 IU/mL). Pearson correlation was used to evaluate the concordance of autoantibody titres.

	Correlation Coefficient (r)	p value
U1-RNP	0.964	<0.001
Histone	0.391	0.011
Jo-1	0.910	<0.001
Ribosome	0.869	<0.001
Sm	0.983	<0.001
Sm-RNP	0.998	<0.001
Scl-70	0.585	<0.001
PMScl	0.774	<0.001
CENP-B	0.911	<0.001
PCNA	0.869	<0.001
Ro-52	0.981	<0.001
SSA Ro60	0.985	<0.001
SSB	0.991	<0.001
ds-DNA	0.679	<0.001

Results: 42 patients were enrolled (24 SLE, 18 RA). There was no statistical difference in the frequency of ANA positivity between venipuncture vs. DBS under all four storage conditions for SLE and RA controls (Fig1A). The ANA titres as indicated by intensity level measured using the automated digital IFA microscope (NovaView, Werfen) did not change significantly from week 1 to 4 at 25°C and 4°C. Most ANA patterns were the same between venipuncture and DBS after 1 week at both 25°C (79.5%) and 4°C (71.4%) (Fig2). There were more discrepancies in ANA pattern between venipuncture and DBS after 4 weeks for both 25°C (57.5%) and 4°C (52.5%). The correlation between venipuncture vs. DBS SLE-related autoantibodies was moderate to strong for most, except for anti-dsDNA, anti-histone, and anti-Scl70 antibodies (Table 1). Specifically, the correlation for anti-dsDNA was r=0.68 ($p< 0.001$).

Conclusion: In the study, we demonstrated that DBS performance is comparable to venipuncture for ANA and SLE-related autoantibody testing. Antibody titre did not vary significantly over time or with temperature variation. This highlights the sustainability of DBS as a potential screening test in under-resourced populations.

Background/Purpose: Systemic lupus erythematosus (SLE is an autoimmune disease that attacks different organs. There have been reports of hyperglycemic hyperosmolar syndrome (HHS) from steroid use in SLE and insulin resistance in SLE, which results in DKA. However, the exact incidence and outcomes of DKA/HHS are unknown.

Methods: This population-based retrospective cohort study utilizes data from the National Inpatient Sample (NIS) database for the period 2021-2022. Patients hospitalized with DKA and HHS based on ICD-10 were identified. Patients were stratified into groups with and without SLE. The primary outcome is the incidence of patients with DKA/HHS and SLE. Secondary outcomes include mortality rate, length of stay (LOS), cost of hospitalization and risk of developing

Results: The study included 315435 DKA patients, 95290 HHS patients, and 246427 SLE patients. The incidence of DKA and HHS in SLE is 0.3% and less than 0.01%, respectively. Table 1 summarizes the characteristics of the patients, Table 2 and Table 3 summarize primary and secondary outcomes of interest.

DKA patients with SLE were predominantly women (86.43% vs 49.32%, p< 0.01) with younger age (52.93=-1.02 vs 57.20 vs 1.02; p< 0.01) with no difference in racial distribution compared to non-SLE. They were more likely to have diabetes with complications (48.57% vs 37.10%. p=0.049) and long-term steroid use (8.57% vs 0.74%, p< 0.01), but less likely to have renal disease (17.4% vs 35.00%, p< 0.01%) as co-morbidities compared to those without SLE. No difference in the average LOS and the cost of hospitalization was observed. DKA patients with SLE had a significantly higher risk of developing AHRF (aOR=1.67, 95% CI 1.01-2.76, p=0.045). No significant increased risk of mortality (aOR=1.7, 95% CI 0.86-3.36, p=0.13) and risk of other in-hospital outcomes were detected.

HHS patients with SLE demonstrated no significant difference in gender, age, and racial distribution. They were more likely to have essential hypertension (50.0% vs 23.16%, p=0.04), insulin use (50.0% vs 21.41%, p=0.02), and long-term steroid use (5.88% vs 0.78%, p< 0.01) as co-morbidities compared to those without SLE. No difference in the average LOS and the cost of hospitalization was observed. HHS patients with SLE had a significantly lower risk of developing AKI (aOR=0.25, 95% CI 0.10-0.64, p< 0.01). No significantly increased risk of other in-hospital outcomes was detected.

Conclusion: DKA patients with SLE had a higher risk of developing AHRF, while HHS patients with SLE have a higher risk of AKI without significant difference in mortality, LOS and cost.

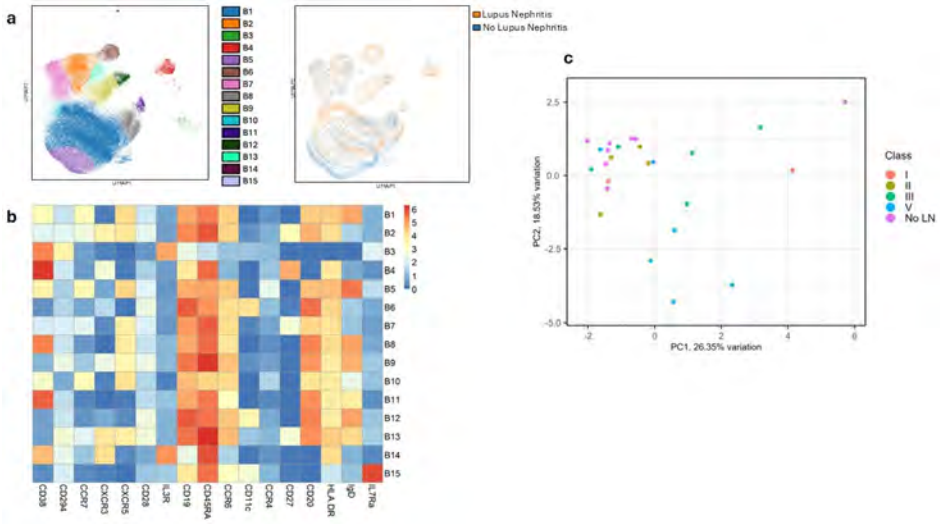

Figure 1. B cell clusters in LN and Non LN cases. (A): Uniform Manifold Approximation and Projection (UMAP) dimension reduction visualizing the different B cell clusters (top left) and the differences in their density (top right) (B): Marker expression in each of the B cell clusters (C): PCA based on B cell clusters colored by biopsy histology.

Background/Purpose: Autoreactive B cell populations play a key role in the pathogenesis of lupus nephritis (LN). Therefore, it is hypothesized that dysregulation in the B cell compartment may be an early indicator of kidney involvement in SLE. The AMP-AIM lupus nephritis study was initiated to identify molecular drivers of kidney disease in SLE patients with minimal proteinuria (considered "early" disease). Accordingly, this study leveraged CyTOF performed at the time of a kidney biopsy in AMP-AIM to characterize alterations within the B cell lineage between LN and non-LN cases and within LN disease classes.

Methods: Twenty-five patients fulfilling diagnostic criteria for SLE with a urine protein creatinine ratio between 0.25 – 0.49 without a history of LN but an additional risk factor for LN including active sediment and/or serologies were enrolled in AMP-AIM. Whole blood was collected at the time of their kidney biopsy and stained at the point of collection on the same day using the Maxpar Direct Immune Profiling Assay (MDIPA), a comprehensive panel of 30 markers to capture the broad immune phenotype of the samples. The samples were stabilized and shipped to a central location where data were captured

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Four B cell clusters differentiate LN and non LN (A): Boxplots showing the four B cell clusters significantly different between Non LN and LN cases. LN is further divided into mesangial, membranous, and proliferative histology. P-values for Non LN vs LN and membranous vs proliferative are reported (B): Heatmap showing the expression of each cluster in all cases.

using the CyTOF XT platform. Low-quality events were excluded with FlowCut and cells were gated to include only the B cell lineage. Dimension reduction and clustering were performed using ClusterX. All pairwise comparisons were made with the Wilcoxon rank-sum test.

Results: Table 1 shows the clinical characteristics of the patients with and without LN at biopsy. ClusterX captured a total of 15 clusters within B cells (Figure 1A & 1B). Two clusters, both CD11c positive, were elevated in LN vs non-LN cases (Figure 2). One was IgD positive (B12) and the other was IgD negative (B6) (p=0.023 and p=0.0024 respectively). A naïve B cell cluster characterized as CXCR3 positive and CXCR5 positive (B9) was also expanded in LN compared to non-LN cases (p=0.0048). Surprisingly, elevated frequencies for all three clusters were seen in class V compared to class III (B6, p=0.18; B9, p=0.052; B12, p=0.082) (Figure 2). An additional CXCR5 and CCR7 positive naïve B cell cluster (B5) was also significantly elevated in class V compared to class III (p=0.034). These differences were also reflected in hierarchical clustering of the samples (Figure 2B).

Conclusion: Whole blood profiling at the point of collection, which likely reduced artifactual findings compared to prior studies which have relied on PBMCs, yielded several differences between LN and non-LN cases at the time of biopsy. These data suggest B cell dysregulation may be detected "early" in kidney involvement in SLE patients, especially with class V histology.

Whole blood profiling at the point of collection, which likely reduced artifactual findings compared to prior studies which have relied on PBMCs, yielded several differences between LN and non-LN cases at the time of biopsy. These data suggest B cell dysregulation may be detected "early" in kidney involvement in SLE patients, especially with class V histology.

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disorder characterized by multi-organ involvement and variable clinical manifestations. Recurrent clinical patterns suggest distinct phenotypes, where cluster analysis of autoantibodies could identify prognostic subtypes. The objective of this study is to define and describe serological clusters and their clinical-epidemiological characteristics, as well as their association with comorbidities, disease activity measures, severity, and damage.

Methods: Descriptive, observational, and multicenter study including SLE patients from the Spanish Registry RELESSER (includes a cross-sectional phase and a prospective phase with annual visits over four consecutive years). Gower distance was used for cluster analysis.

Results: A total of 1,740 patients from the cross-sectional phase and 718 from the prospective phase were included. Four serological clusters were identified. Cluster 1 ((negative for extractable nuclear antigen); 44.5% of the patients) was characterized by lower frequency of vasculitis (6.6%), leukopenia (49.1%) and lymphopenia (48.0%). Cluster 2 (positive antiphospholipid antibodies; 12.24%) was represented by higher frequency of high blood pressure (35.5%) as well as hemolytic anemia (13.5%), thrombocytopenia (39.9%), vasculitis (12.5%), visual disturbances (9.1%) and higher use of immunoglobulins (10.3%) and oral anticoagulants (39.0%). Cluster 3 (positive anti-Ro/anti-La; 26.7%) had the lowest frequency of lupus nephritis (24.9%). Patients from cluster 4 (positive anti-Sm/anti-RNP; 16.55%) were younger at disease onset (median age of 29.2 years) and had the highest frequency of lupus nephritis (38.5%), leukopenia (66.0%), lymphopenia (62.2%), hypocomplementemia (89.5%), myositis (5.6%) and cutaneous manifestations. Besides, they had a higher frequency of osteoporosis (11.0%) and severe infections (26.4%) and a higher use of glucocorticoids (93.5%), azathioprine (42.0%), cyclophosphamide (25.5%) and mycophenolate mofetil (24.0%).

Regarding disease activity assesed by SLEDAI (Systemic Lupus Erythematosus Disease Activity Index), at visit 1 of the prospective phase, patients in cluster 4 had the highest scores: 2.5 ± 3.4. After 4 years of follow-up, no differences were observed between clusters.

Mycophenolic acid, n (%)	18 (2.5%)	3 (1.6%)	14 (3.3%)	10 (3.7%)	45 (2.8%)	0.463
Antimalarials, n (%)	612 (82.6%)	155 (77.1%)	379 (88.6%)	252 (90.3%)	1398 (84.8%)	<0.001
Immunoglobulins, n (%)	22 (3.0%)	20 (10.3%)	19 (4.5%)	12 (4.4%)	73 (4.5%)	<0.001
Rituximab, n (%)	54 (7.3%)	19 (9.5%)	41 (9.6%)	22 (8.0%)	136 (8.3%)	0.496
Acetylsalicylic acid, n (%)	217 (34.7%)	127 (69.8%)	133 (34.7%)	79 (32.4%)	556 (38.7%)	<0.001
Oral anticoagulants, n (%)	83 (12.0%)	78 (39.0%)	57 (13.4%)	40 (14.5%)	263 (16.1%)	<0.001

Concerning damage assessed by SLICC/ACR DI (Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index), patients in cluster 2 exhibited the highest scores at visit 1: 1.9 ± 2.3. After 4 years of follow-up, a significant increase was observed across all clusters ($p < 0.001$), with differences between clusters persisting at the end ($p=0.049$).

Regarding severity (Katz index), patients in cluster 4 had the highest scores at visit 1: 5.2 ± 2.0. The differences persisted after follow-up ($p=0.005$).

As for mortality, 21 deaths were recorded: 5 in cluster 1 (1.7%), 6 in cluster 2 (5.5%), 6 in cluster 3 (2.9%) and 4 in cluster 4 (3.3%), with no significant differences between clusters ($p=0.427$).

Conclusion: In our cohort, the serological profile constitutes a crucial factor for the clinical stratification of patients and predicting their prognosis.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Early recognition and treatment of juvenile systemic lupus erythematosus (jSLE) improves outcomes and prevents disease-related mortality. This study examines the contributions of clinical factors (e.g. disease severity) and sociodemographic variables (e.g. neighborhood disadvantage, distance to care) to diagnostic delays.

Methods: This retrospective chart review included jSLE patients evaluated by the Division of Pediatric Rheumatology at Indiana University (IU) from Jan 2017 – Sept 2023. Participants were diagnosed before age 18 years and fulfilled the 1997 American College of Rheumatology (ACR) or Systemic Lupus Collaborating Clinics (SLICC) criteria for SLE (Figure 1). Time to diagnosis (TTD) was treated categorically: acute (< 4 weeks), subacute (5-12 weeks), and chronic (>12 weeks). Bivariate analyses were performed using Spearman correlation models and Wilcoxon-Kruskal-Wallis tests and multivariable analyses were performed using Generalized Linear Models, using SAS v9.4 (Figure 2).

Results: In bivariate analysis, the following clinical variables at diagnosis were associated with shorter TTD: neuropsychiatric symptoms (p=0.02), organ damage (p=0.04), pulse-dose corticosteroids (p=.01), and hospitalization (p=0.01). Higher disease activity at diagnosis, measured by SLEDAI-2K score, was associated with a trend towards shorter TTD when treated categorically, and this association reached significance when TTD was analyzed as a continuous variable (p= 0.04) (Figure 3). Renal disease was not associated with TTD.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Exclusion Criteria

In bivariate analysis, private health insurance was associated with a longer TTD (p=0.04), while age, race, ethnicity, preferred language, urbanization level, distance to care, and ADI showed no association.

In multivariable analysis including all variables with p< 0.10 plus age and sex, only the presence of neuropsychiatric symptoms remained independently associated with a shorter TTD (p = 0.02).

Conclusion: Neuropsychiatric symptoms, organ damage, pulse steroid use, and hospitalization at diagnosis were associated with shorter diagnostic intervals, suggesting that more severe presentations may prompt faster evaluation. Private health insurance was associated with a longer time to diagnosis, potentially reflecting differences in healthcare access or referral patterns. Race, ethnicity, distance to care, and area-level deprivation index were not significantly associated with diagnostic delays. The lack of association may reflect the single-center design, which could limit variability in access to care and sociodemographic representation. While several clinical variables were associated with a shorter TTD in the bivariate analysis, only neuropsychiatric symptoms remained significant in the multivariate analysis. The diminished effects of the other clinical variables suggest either mediating or confounding effects which will be explored in further analysis. The study findings underscore the complex interplay between disease severity and healthcare system factors in influencing diagnostic timelines for pediatric lupus.

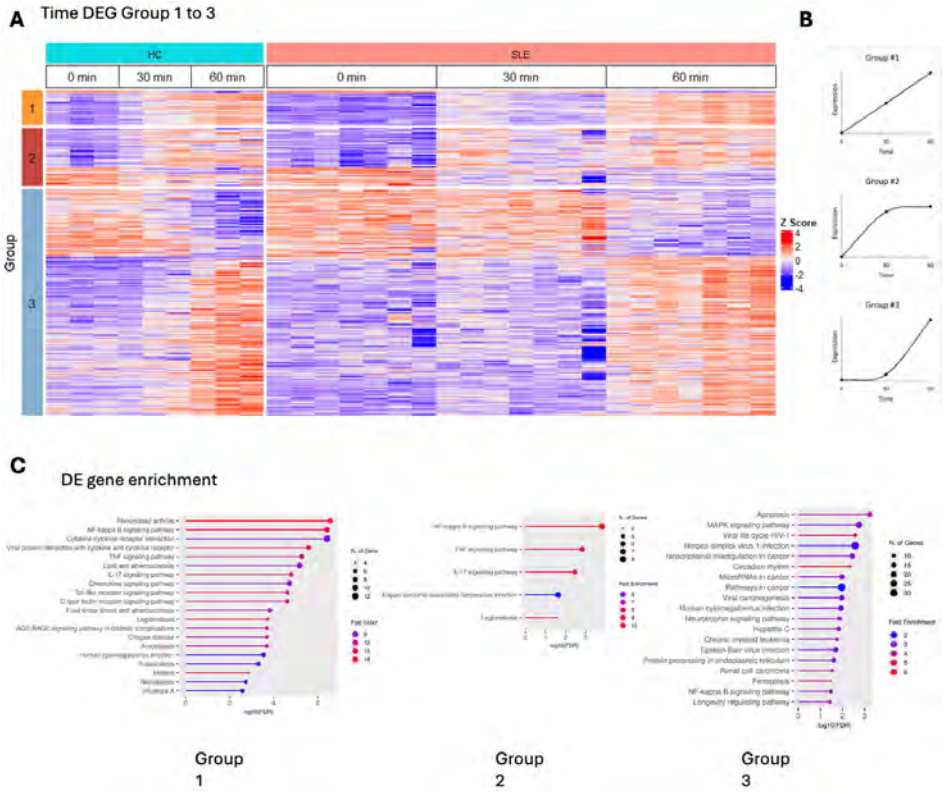
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by dysregulation of the adaptive and innate immune systems. Neutrophils, key players in innate immunity, significantly contribute to SLE pathogenesis. This study aimed to identify transcriptomic differences in neutrophils from SLE patients and healthy individuals, analyze ex vivo adaptation in gene expression dynamics, and evaluate the impact of chimeric antigen receptor (CAR)-T cell therapy on neutrophil transcriptomic profiles.



Heatmap of temporal transcriptomics in neutrophils and pathway enrichment analysis. (A) Heatmap displaying temporal transcriptomics of neutrophils categorized into three groups:(1) sustained changes from time 0 to 60 minutes, (2) changes from time 0 to 30 minutes followed by stabilization, and (3) changes only between 30 and 60 minutes. (B) Graphic Conceptualization of the 3 groups. (C) KEGG pathway enrichment analysis identifies key pathways impacted by time progression, including NF-κB activation, TNF signaling, and apoptosis, in neutrophils from both groups.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Clustered heatmap of intrinsic DEGs. Heatmap showing expression patterns of intrinsic DEGs categorized into seven clusters including interferon-related, Rho GTPase, cytoskeleton, DNA damage repair, ribosome, and long non-coding RNA (lncRNA). The "other" cluster includes genes with no clear pathway enrichment.

Longitudinal transcriptomic analysis post-CAR-T cell therapy. Heatmap visualizing intrinsic DEG expression in an SLE patient undergoing CAR T-cell therapy across baseline (two pre-treatment time points) and eight post-treatment time points. Samples from three healthy individuals serve as controls. Red arrowhead indicates day 0 (CAR T-cell infusion) and black arrowhead marks when the patient discontinued all immunosuppressive medications.

Methods: We utilized negative selection for neutrophil isolation from seven SLE patients and three healthy individuals. RNA sequencing was performed to assess transcriptomic differences between neutrophils from SLE and healthy individuals, ex vivo transcriptional dynamics over 60 minutes, and responses to lipopolysaccharide (LPS) stimulation. Additionally, longitudinal transcriptomic data from an SLE patient undergoing KYV-101 anti-CD19 CAR-T cell therapy were evaluated.

Results: We identified 258 differentially expressed genes (DEGs) consistently distinguishing SLE neutrophils from healthy controls regardless of the ex vivo culture duration; these genes spanned multiple clusters, enriched in upregulation of interferon-related and DNA damage repair genes, and downregulation of ribosomal protein genes. Differential expression (DE) analysis for ex vivo adaptation revealed shared activation pathways, such as NF-κB and apoptosis, across time in neutrophils from both patients and healthy individuals. LPS stimulation highlighted overlapping inflammatory responses, demonstrating retained functional capacities in SLE neutrophils. Following CAR-T cell therapy of an SLE patient, the neutrophil transcriptomic profile realigned with healthy control characteristics, with most gene clusters approaching normalcy by three months post-treatment.

Conclusion: Neutrophils in SLE exhibit intrinsic, disease-specific transcriptomic alterations but also share certain ex vivo adaptation dynamics with healthy individuals across diverse biological pathways. Notably, anti-CD19 CAR-T cell therapy demonstrates a profound ability to reset neutrophil gene expression toward healthy patterns by three months post-treatment, despite targeting B cells rather than neutrophils directly. These findings provide insights into SLE pathogenesis and highlight potential therapeutic strategies targeting both adaptive and innate immunity.

Physical Activity Patterns and Health-Related Quality of Life in Middle-Aged and Older Adults with Systemic Lupus Erythematosus

Sarah Lieber[1], Neha Nagpal[1], Julia Nguyen[2], Ashley Chung[2], Dongmei Sun[1], Iris Navarro-Millan[3], M. Carrington Reid[4] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Weill Cornell Medicine, Hospital for Special Surgery, Poughkeepsie, NY, [4]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The benefits of physical activity are well established in older adults in the general population. Among older adults with rheumatic and musculoskeletal diseases, including systemic lupus erythematosus (SLE), physical activity has been associated with improved health-related quality of life [1]. However, the extent to which this relationship may be similar for sedentary behavior or impacted by SLE disease severity is not well understood. We sought to characterize the association of physical activity and sedentary behavior with patient-reported outcome measures and self-reported disability in middle-aged and older adults with SLE.

Methods: Adults ≥50 years with validated SLE were enrolled in a single-center cross-sectional study. Sociodemographic and disease features were self-reported. Patient-reported outcomes, disability status, and physical activity and sedentary behavior were ascertained using PROMIS-29, Valued Life Activities, and International Physical Activity Questionnaire surveys, respectively. Associations between physical activity and sedentary behavior and health-related quality of life domains were assessed using linear regression and adjusted for age, race, ethnicity, SLE duration, and SLE disease activity and organ damage.

*Adjusted for age, race, ethnicity, SLE duration, disease activity, and organ damage

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Participants (N=80) were primarily female (95.0%) with mean age and SLE duration of 63.2 (standard deviation [SD] =8.5) and 23.1 (SD=14.5) years, respectively. Physical activity was associated with multiple health-related quality of life domains in unadjusted analyses, but after adjustment for covariates, only the association of physical activity with fatigue (ß coefficient -206.74, 95% confidence interval [CI] [-337.11, -76.36], $p < 0.01$) and social roles (ß coefficient 253.42, 95% CI [127.12, 379.72], $p < 0.01$) remained significant. Sedentary behavior was not significantly associated with any aspect of health-related quality of life pre- or post-covariate adjustment.

Conclusion: In this cross-sectional study of middle-aged and older adults with SLE, physical activity was associated with less fatigue and greater social engagement. Physical activity may have favorable effects on fatigue and social engagement in this growing population of patients.

Kidney-Specific Four-Protein Index Outperforms Conventional Measures for Detecting Early Kidney Damage in Lupus Nephritis and Diabetic Kidney Disease

Sepehr Taghavi[1], Ines Silva[2], Jacob Vasquez[3], Vasileios Kyttaris[4], Tyler O'Malley[5] and Mike Nerenberg[6], [1]Exagen Inc, Escondido, CA, [2]Exagen, Carlsbad, CA, [3]Exagen, Inc., Vista, CA, [4]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, [5]Exagen, Vista, CA, [6]Exagen, DEL MAR, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Early detection of renal involvement in diabetic kidney disease (DKD) and lupus nephritis (LN) is critical but remains challenging. Conventional renal biomarkers (serum creatinine, eGFR, albuminuria) are often insensitive to subclinical damage and rise late in disease. We identified four kidney-specific plasma proteins (uromodulin [UMOD], myo-inositol oxygenase [MIOX], heparanase [HPSE], and AREL1) linked to distinct renal processes: tubular transport, metabolic stress, extracellular matrix remodeling, and immune signaling. We hypothesized that an index combining these mechanistically distinct markers could detect early renal pathology in DKD and LN, outperforming conventional measures.

Methods: Plasma UMOD, MIOX, HPSE, and AREL1 were measured by immunoassay in three patient cohorts: 1) biopsy-confirmed active LN (n=31), compared to SLE without active proteinuria (n=31) and matched apparently healthy volunteer controls (AHV, n=31), ; 2) early-stage type 1 DKD obtained from the NIH-sponsored PERL study (n=49, mean eGFR=66 mL/min/1.73m^2); and 3) late-stage type 2 DKD obtained from the FIND study (n=50, mean eGFR≈21 mL/min/1.73m^2). The latter two cohorts were compared to matched AHVs (total AHVs=99). Logistic regression models using these four biomarkers were trained to distinguish DKD and LN from matched AHVs, generating DKD and LN indices (predicted probabilities). ROC analyses compared biomarker indices against eGFR, including comparisons of early DKD stratified by iohexol-

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. determined GFR (iGFR), cystatin C, and albuminuria. AHV versus LN were stratified by urinary protein-to-creatinine ratio (UPCR). Data from PERL and FIND were provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases.

Results: The LN Index strongly differentiated LN from AHVs (AUC=1.00) and from non-proteinuric SLE (AUC=0.99), significantly outperforming eGFR (AUC=0.27 for LN vs AHV, AUC=0.48 for LN vs non-proteinuric SLE). The DKD Index robustly discriminated both early DKD (PERL, AUC=0.92) and late DKD (FIND, AUC=0.97) from AHVs, surpassing eGFR performance (AUC=0.81 early DKD, AUC=0.94 late DKD). Subgroup analyses demonstrated superior sensitivity of biomarker

Table 1. Demographic and Clinical Characteristics of Study Cohorts
Demographic and clinical features of subjects included in the analysis. The cohorts consist of apparently healthy volunteers (AHV) matched to lupus nephritis (LN; biopsy-confirmed) and diabetic kidney disease (DKD), early-stage DKD from the PERL study (type 1 diabetes, mean eGFR 66 mL/min/1.73 m²), late-stage DKD from the FIND study (type 2 diabetes, mean eGFR 21 mL/min/1.73 m²), and patients with systemic lupus erythematosus (SLE) without active proteinuria. The distribution of sex, race, mean age, serum creatinine, and eGFR values are summarized for each group.

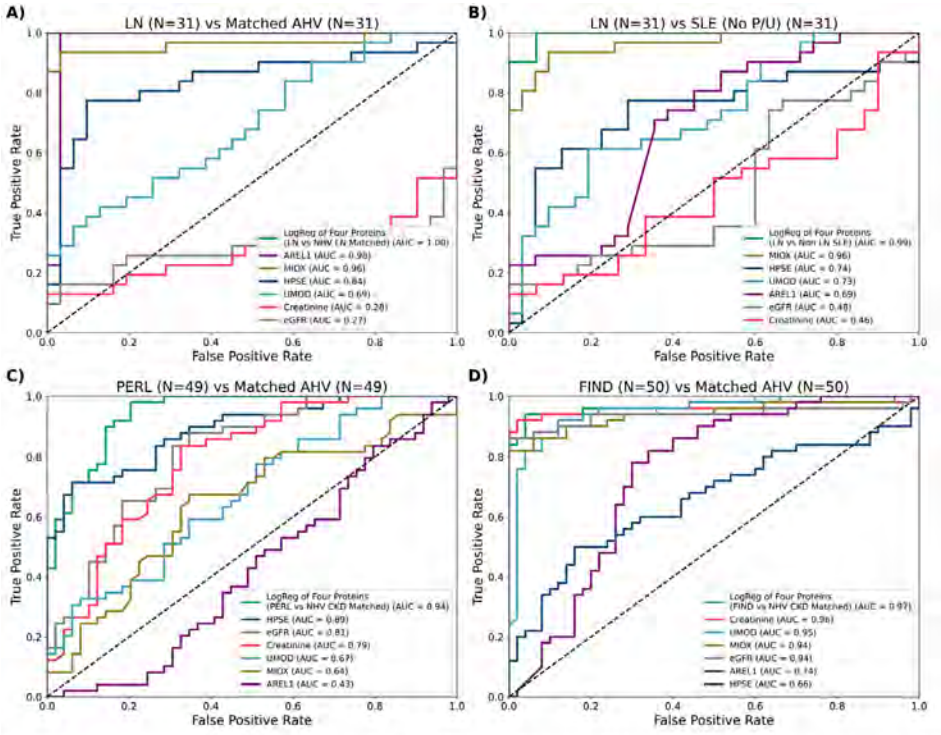

Figure 1. Receiver Operating Characteristic (ROC) Curve Analysis of Biomarker Performance. ROC curves evaluating the diagnostic accuracy of individual kidney-specific biomarkers (UMOD, MIOX, HPSE, AREL1), a combined logistic regression index (Four-Protein Index), and conventional measures (creatinine, eGFR) for distinguishing: (A) biopsy-confirmed lupus nephritis (LN) from matched apparently healthy volunteers (AHVs); (B) biopsy-confirmed LN from patients with systemic lupus erythematosus (SLE) without active proteinuria; (C) early-stage type 1 diabetic kidney disease (DKD; PERL cohort) from matched AHVs; and (D) late-stage type 2 DKD (FIND cohort) from matched AHVs. The Four-Protein Index consistently showed superior performance compared to eGFR and creatinine across all comparisons, demonstrating its robust utility for detecting kidney damage in both LN and DKD.

Figure 1. Receiver Operating Characteristic (ROC) curve analysis of biomarker performances

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Comparative analysis of eGFR and biomarker-derived indices (DKD index, LN index) across various kidney damage stratifications. Subgroups were defined as follows: Chronic Kidney Disease (CKD) stages using eGFR (panel A–B) as Stage 1 (≥90), Stage 2 (60–89), Stage 3 (30–59), and Stages 4/5 (<30 mL/min/1.73m²). Panels C–H illustrate comparisons within the PERL cohort (early DKD) stratified by iohexol-measured GFR (iGFR, high ≥60, low <60 mL/min/1.73m²), cystatin C levels (normal <1 mg/L, abnormal ≥1 mg/L), and albuminuria via albumin-to-creatinine ratio (normal <30 mg/g, abnormal ≥30 mg/g). Panels I–J show LN cohort subgroup analysis stratified by urine protein-to-creatinine ratio (UPCR; low <0.5, high ≥0.5 g/g). Across subgroups, biomarker-derived indices demonstrated significantly higher discriminatory power and earlier sensitivity in detecting renal involvement compared to eGFR alone. Statistical significance is indicated as follows: *p<0.06; **p<0.01; ***p<0.001. Effect sizes are denoted by rank biserial correlation: small (|r| ≤ 0.3), moderate (0.3 < |r| ≤ 0.5), and high (|r| > 0.5).

indices compared to eGFR for detecting early kidney damage defined by iGFR, cystatin C, or albuminuria in DKD. The LN index also outperformed UPCR in LN, while eGFR values mostly remained in the normal range.

Conclusion: A plasma biomarker index combining UMOD, MIOX, HPSE, and AREL1 detects DKD and LN with high sensitivity and specificity, identifying organ damage earlier and more clearly than standard measures. These kidney-specific proteins capture distinct pathophysiologic axes of renal damage, supporting their use as early, disease-specific indicators of nephropathy in diabetes and lupus. Such a multi-marker approach could improve timely diagnosis and monitoring of renal involvement beyond conventional tests.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is a chronic autoimmune disease marked by skin lesions that can vary in appearance and severity. Subacute cutaneous erythematosus (SCLE), acute cutaneous erythematosus (ACLE), and chronic cutaneous erythematosus (CCLE) make up the CLE categories and CCLE may be further subtyped.

Table 1. Dyspigmentation & Scarring Scores Across CLE Categories & CCLE Subtypes

CLE Categories & CCLE Subtypes	*Median Dyspigmentation [Q1, Q3]*	*Dyspigmentation p-value*	*Median Scarring [Q1, Q3]*	*Scarring p-value*	*Dyspigmentation & Scarring Correlation r-value*	*Dyspigmentation & Scarring Correlation p-value*
ACLE (41)	3 [2,4]	0.0163	0 [0,0]	p<2.2e-16	0.123	.298
SCLE (130)	8 [2,12]		0 [0,0]		0.158	0.517
CCLE (329)	8 [4,12]		4 [1,7]		0.590	5.56e-34
DLE (293)	8 [4,14]	8.17e-4	5 [2,7]	4.14e-10	0.544	5.61e-24
LET (20)	1 [0,2.5]		0 [0,0.5]		0.132	0.0819
Panniculitis (12)	4 [2,4]		2 [2,6]		0.671	.017
Chilblain (4)	3 [2.5,3.5]		0 [0, 0.25]		-0.087	0.728

Key: CLE = cutaneous lupus erythematous, ACLE = acute cutaneous lupus erythematous, SCLE = subacute cutaneous lupus erythematous, CCLE = chronic cutaneous lupus erythematous, DLE = discoid lupus erythematous, LET = tumid lupus erythematous, Q1 = first quartile, Q3 = third quartile. Values for median dyspigmentation and median scarring correlate to Cutaneous Lupus Erythematous Disease Area and Severity Index damage score dyspigmentation and scarring aspects respectively. P-values in columns in columns three and five represent differences in dyspigmentation and scarring across CLE categories and CCLE subtypes using the Kruskal-Wallis test. R-values represent correlations between dyspigmentation and scarring across CLE categories and CCLE subtypes using the Spearman's rank-order correlation test.

Figure 1

Figure 1. Comparison of median dyspigmentation and scarring scores across Cutaneous Lupus Erythematosus Categories. Dunn-Bonferroni post-hoc test run to analyze pairwise comparisons following Kruskal-Wallis test. CLE = cutaneous lupus erythematosus, ACLE = acute cutaneous lupus erythematous, SCLE = subacute cutaneous lupus erythematous, CCLE = chronic cutaneous lupus erythematous.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

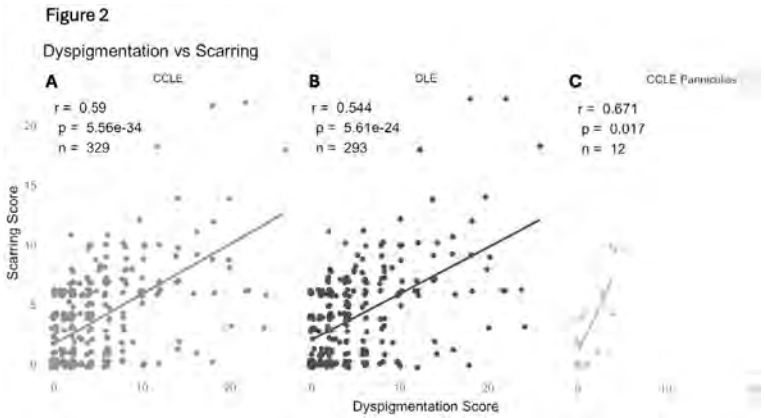

Figure 2. Correlation of scarring and dyspigmentation in Cutaneous Lupus Erythematosus Categories & Subtypes. Spearman's rank-order correlation between scarring and dyspigmentation scores for each patient visit where dyspigmentation was highest. (A) CCLE (B) DLE (C) Panniculitis. r = Spearman's rank correlation coefficient, CCLE = chronic cutaneous lupus erythematous, DLE = discoid lupus erythematous.

While dyspigmentation and scarring are recognized as complications of discoid lupus erythematosus (DLE), no studies have investigated scarring and dyspigmentation across all the CLE categories and subtypes.

Methods: To better characterize dyspigmentation and scarring in CLE, we conducted a cross-sectional review of our IRB-approved CLE database at the University of Pennsylvania. Patients were divided by category and CCLE subtype. Dyspigmentation and scarring were quantified using components of the CLE Disease Area and Severity Index damage (CLASI-D) score. Data on dyspigmentation and scarring were captured from the patient visit where dyspigmentation was highest. The Kruskal-Wallis test was used to compare dyspigmentation and scarring scores across CLE categories and CCLE subtypes. A Post-hoc Dunn analysis was used to check for pairwise comparisons between groups. The Spearman's rank-order correlation test was used to assess the correlations between dyspigmentation and scarring.

Results: A total of 500 patients were included in the study. Dyspigmentation and scarring significantly differed between CLE categories and CCLE subtypes ($p < .01$). Across categories, CCLE had the highest medians for dyspigmentation and scarring. Across CCLE subtypes, DLE had the highest medians for dyspigmentation and scarring. Dyspigmentation and scarring were significantly positively correlated in CCLE, DLE, and LE Panniculitis ($p < .01$).

Conclusion: Our findings show that scarring and dyspigmentation do not necessarily correlate in CLE except for CCLE as a whole and the CCLE subtypes of DLE and LE panniculitis. These CLE categories and CCLE subtypes are known to have higher rates of long-lasting disease damage. Dyspigmentation and scarring correlation differences highlight the importance of accurate assessment and documentation of both elements of damage. Our results reflect important differences in the CLE categories and CCLE subtypes which may be helpful for clinicians and patients as they navigate the course of the disease.

Table 2. REACH program adherence rates and acceptability ratings

Table 2. REACH program adherence rates and acceptability ratings (mean likelihood to recommend out of 10) with 95% confidence intervals*

	REACH Peer Coaching Intervention	REACH App Control	All Participants
Adherence	n=13	n=16	n=29
REACH Program Completion Rate	84.6% (55.6–96.4%)	93.8% (69.8–99.1%)	89.7% (73.6–96.4%)
Mean Educational Module Completion Rate	92.3% (77.2–100.0%)	81.9% (64.5–99.2%)	86.6% (74.9–98.2%)
Mean Weekly Physical Activity Log Completion Rate	64.2% (40.4–87.9%)	56.8% (39.4–74.2%)	60.1% (46.0–74.2%)
Mean Weekly Mood/Energy Check-In Completion Rate	96.8% (93.9–99.8%)	82.3% (67.9–96.7%)	88.8% (80.5–97.2%)
Mean Weekly Patient-Reported Outcome Survey Completion Rate	93.0% (87.1–98.8%)	85.9% (76.4–95.5%)	89.1% (83.2–95.0%)
Acceptability	n=12	n=15	n=27
Educational Modules	8.42 (7.57–9.27)	8.00 (6.74–9.26)	8.19 (7.41–8.97)
REACH App	7.50 (6.36–8.64)	6.93 (5.57–8.29)	7.19 (6.29–8.09)
REACH Peer Coaching	7.42 (5.89–8.95)	n/a	n/a
REACH Program	8.42 (7.64–9.20)	6.80 (5.65–7.95)	7.52 (6.74–8.30)

*Adherence rates are calculated for the 29 participants who had completed data collection at the time of submission. Acceptability rates are calculated for the 27 participants who submitted 12-week surveys.

Background/Purpose: Fatigue is a highly prevalent and debilitating symptom affecting up to 90% of individuals living with systemic lupus erythematosus (SLE). Despite its significant impact, fatigue remains difficult to treat due to its complex, multifactorial origin, including behavioral and psychosocial factors. While physical activity interventions have shown promise in reducing SLE-related fatigue, they often fail to address these multiple factors and have been limited by their in-person format. The aim of this study is to evaluate the feasibility and preliminary efficacy of the Restore Energy, Activity Can Help (REACH) mobile health (mHealth)-enabled peer coaching intervention for fatigue in SLE.

Methods: Individuals meeting 2019 ACR SLE classification criteria were enrolled in this open-label pilot randomized controlled trial. Participants were randomized to the REACH mHealth-enabled peer coaching intervention or the REACH mHealth application (app)-only control arm. Participants in the intervention arm were paired with trained coaches with lived SLE experience who supported participants through a 12-week structured program promoting physical activity facilitated by the REACH app. Program feasibility was assessed via enrollment and adherence rates, and acceptability was evaluated with participant net promoter scores. Preliminary efficacy of the intervention was examined by comparing Fatigue Severity Scale (FSS) scores between arms at 12 weeks using ANCOVA. All participants were interviewed for feedback at program completion.

Results: Thirty-three of 43 eligible individuals screened enrolled (76.7% enrollment rate), with a mean baseline FSS score of 5.6 (SD 0.8) (Table 1). In the 29 participants in whom data collection has been completed to date, 26 finished the program (completion rate 89.7%) (Table 2). Program adherence rates were high, especially in the peer coaching arm, in which mean completion rates of educational modules, weekly check-ins and patient-reported outcome surveys were over 90% (Table 2). At 12 weeks, mean FSS scores were 0.8 (95% CI 0.2 to 1.5) lower in the coaching arm than the app-only arm, and a clinically meaningful improvement of ^{3} 0.6 was achieved in 75% of participants in the coaching arm vs. 40% in the app arm. Likelihood to recommend the program and its individual components were higher in the coaching arm than the app-only arm (Table 2). Participants in both arms shared that the program was impactful, citing improvements in self-efficacy and increased self-awareness and self-regulation facilitated by the accountability and motivation provided by both the peer coach and the REACH app. (Table 3).

Conclusion: The REACH peer coaching intervention was feasible and demonstrated promising preliminary efficacy for reducing fatigue in SLE. Participants in the coaching arm showed greater improvement in fatigue, with a higher proportion achieving a clinically meaningful benefit than in the app-only arm. Participant engagement and satisfaction were high. These

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 3. Impact of REACH program: thematic analysis of participant interview feedback

Feature	Theme	Participant quote
REACH program overall	Self-efficacy	"It's given me more confidence, and it's made me feel like it's achievable to set exercise goals for myself... It helped me to reinforce the idea that I can make small choices and small changes." – ID 4, Peer Coaching Participant
		"I do think that it has solidified that moving my body does, in fact, help with my fatigue. I know that I have been told by providers previously, 'move around a little bit more, Get some exercise and that might help you.' But I think being held more accountable in keeping track of my own exercise, or even just doing a little bit more than I usually do did solidify to me like this is something that is controllable." – ID 5, App-only Participant
	Relationship to movement/intrinsic motivation	"I started off with next to nothing movement-wise, only what was required for work, what was required for me to take care of my home, and things that I absolutely had to do. Exercise or activity beyond that really wasn't even on my radar. And so, in weeks 4 or 5, I recognized I want to go exercise and do activity. And that was really a moment for me where I was like, 'Wow! This is really impactful.'" – ID 13, Peer Coaching Participant
	Self-awareness/self-regulation	"I'm the type of person with my lupus, I don't really listen to my body as much as I should. So sometimes I know I'm tired, and I just need to get this one thing done. 'Body, just let me get this one thing done', and then I'm dead to the world the next day. But I noticed when I did listen to my body, I did feel better." – ID 33, App-only Participant
Peer coaching	Empathy/social support	"It is really heartwarming to talk to someone who is dealing with the same issues, and who really understands and really knows what I'm feeling. Sometimes it's even hard for me to describe to my doctor what I'm dealing with." – ID 15, Peer Coaching Participant
		"I was able to talk about what I was going through with someone who also understood what I was going through. So that was a really nice part of it– that community part that I was looking for. If I started experiencing a new problem, and I wasn't sure if it was lupus connected, it gave me a person to be able to talk to about it." – ID 38, Peer Coaching Participant
	Motivation/encouragement	"She kept me motivated; she kept me encouraged. And I think it was also a good balance. Sometimes I get disappointed because I really wanted to do this, but I physically couldn't do it. And she helped me switch my mindset around it, which was helpful because then she would somehow encourage me to try again." – ID 19, Peer Coaching Participant
Educational modules	Validation	"Even though I knew about the spoon theory, in my head reading, and then I read it out loud, and I started to cry. Because it was just so true that people really don't understand. We don't look sick... I thought that that was just so instrumental in helping people explain to other people, you know sometimes I can. Sometimes I can't... It just hit home." – ID 3, Peer Coaching Participant
	Informational	"I really thought the readings were helpful. I got a lot of information that I didn't know about. Nobody told me anything about lupus before. You know [the doctors] just tell me 'you have lupus' but they don't explain to you what the illness is about. The readings gave me a lot of information, and I got to know more about it." – ID 10, App-only Participant
REACH app	Accountability/motivation	"[The app] was an accountability partner. It added a layer of motivation, and it was results oriented. I got to see what I was doing and what I wasn't doing." – ID 43, App-only Participant
	Reflection	"The initial 'how do you feel today?' It gives you a moment to stop, reflect, and acknowledge how you feel and move on. Sometimes I'm like 'okay you know what this is a bad week and it's okay', and then next week I'm like 'okay you know what this is a better week'." – ID 19, Peer Coaching Participant
	Self-monitoring/self-regulation	"Having documentation of feeling fatigued, sleep, activity is helpful to understand the trends of how we feel over time. Sometimes we think we are doing very well one day, but then to see there were actually many days we were not well is helpful to understanding if we need to change something in our health or lifestyle to actually feel better." – ID 17, App-only Participant

findings support the potential of mHealth-enabled peer coaching to address behavioral and psychosocial drivers of fatigue in SLE and warrant further evaluation in larger trials.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Mechanisms driving cognitive impairment (CI) in systemic lupus erythematosus (SLE) remain poorly understood; conflicting results exist regarding the relationship between CI and disease activity. NIH Toolbox for Assessment of Neurological and Behavioral Function (NIHT) is widely utilized to monitor CI in conditions like Alzheimer's disease and long COVID, yet few reports address its value in measuring CI in SLE. Further, the relationship between NIHT's subdomains and SLE disease activity has yet to be explored. We hypothesize that NIHT can effectively characterize CI in persons with and without active SLE and help clarify if disease activity contributes to poor cognitive performance. A secondary aim is to identify serum and cerebrospinal fluid (CSF) biomarkers mediating immune-related neuropathology.

Methods: Cross-sectional data were analyzed from adult patients enrolled in our ongoing study of immune-mediated mechanisms of neuropsychiatric SLE. Eligible participants met 4 of 11 ACR 1997 or 3 of 11 ACR 1997 with SLICC 2012 criteria for SLE and did not have concurrent autoimmune or neurologic diseases, active or chronic infections, GFR< 60, liver enzymes >3× ULN, or sodium imbalance. Cognitive performance was assessed by the clinically validated Montreal Cognitive Assessment (MoCA), reported as total score, and a targeted NIHT battery, reported as age-adjusted standard scores. SLEDAI-2K≥6 defined moderate-high disease activity; SLEDAI-2K< 6 indicated low-moderately active or inactive disease. Note, only one participant scored for a neurological SLEDAI-2K descriptor. Descriptive statistics summarized demographic and clinical characteristics. Spearman correlations assessed relationships between continuous variables. Associations between continuous and categorical variables were assessed via Wilcoxon rank sum tests.

Results: Our sample included 22 female patients with SLE free of concurrent autoimmune or neurologic disease with mean (SD) age of 33.8 (11.8) years and disease duration of 8.9 (6.0) years (Table 1). Patients with moderate-high disease activity scored lower on the Dimensional Change Card Sort and Rey Auditory Verbal Learning Tests for executive function and delayed auditory-verbal memory, respectively, compared to those with inactive or low-moderate disease activity (Table 2,4). SLEDAI subcomponent scores did not associate with altered CI subdomains (Table 3). Yet, low circulating complement C4 correlated with worse delayed auditory-verbal memory. Findings were independent of demographic, patient-reported, clinical, and other lab characteristics (Table 2,4). MoCA did not differentiate groups, highlighting NIHT's superior sensitivity.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The NIHT is a domain-specific, sensitive tool for detecting CI in SLE, outperforming the MoCA. Higher SLEDAI, but not subcomponent, scores correlate with executive function and memory impairments, supporting a role for generalized inflammation, and potentially C4, in SLE-related CI. Here, we advance the field by exploring the link between SLE disease activity and CI of domains essential for daily functioning and expanding immune profiling of serum and CSF to clarify the neuroimmune basis of these deficits.

Bone marrow- activity on 18F-FDG PET/CT as a Predictor of Hematologic Manifestations in Systemic Lupus Erythematosus

Sungwon Ko[1], Young-Eun Kim[1], Soyoon Yoon[2], Soo Min Ahn[1], Ji Seon Oh[1], Yong-Gil Kim[1], Chang-Keun Lee[3], Bin Yoo[1], Dong Yun Lee[4] and Seokchan Hong[1], [1]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, Seoul, Republic of Korea, [2]Department of Nuclear Medicine, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Department of Rheumatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Seoul, Republic of Korea, [4]Department of Nuclear Medicine, University of Ulsan College of Medicine, Seoul, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Fluorine-18 fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT) is a noninvasive imaging modality widely used to assess inflammatory activity in various autoimmune and hematologic disorders. The bone marrow (BM), as the site of hematopoiesis, may play a key role in the pathogenesis of systemic lupus erythematosus (SLE). This study aimed to investigate whether BM metabolic activity on PET/CT is associated with hematologic manifestations and to assess its potential as a predictive biomarker in SLE.

Methods: We retrospectively analyzed patients with SLE who underwent ^{18}F-FDG PET/CT imaging at baseline and had available follow-up data for at least 6 months. Patients with malignancy were excluded. BM FDG uptake was quantified using standardized uptake values (SUV), and the BM-to-liver ratio (BLR) was calculated using both SUVmax and SUVmean. Hematologic manifestations were defined as leukopenia, anemia, and/or thrombocytopenia. Associations between BLR indices and hematologic involvement were assessed using Pearson correlation and multivariable logistic regression adjusted for age, sex, and comorbidities. Receiver operating characteristic (ROC) curve analysis was conducted to evaluate predictive performance.

Results: Among 76 patients with SLE (median age 48.0 years; 86.0% female), 21 (27.6%) exhibited baseline hematologic abnormalities. Median BM SUVmax and SUVmean were 2.40 (SD, 0.65) and 1.65 (SD, 0.50), respectively. Median BLRmax and BLRmean were 1.58 (SD, 0.52) and 1.10 (SD, 0.41), respectively. Both BLRmax and BLRmean were positively correlated with baseline hematologic involvement ($r = 0.282$, $p = 0.014$ and $r = 0.264$, $p = 0.021$, respectively). Elevated baseline

	Total (n=76)	
Baseline characteristics		
Age (years, median [IQR])	48.0	30.0–60.3
Female, no. (%)	65	86.0
BMI (kg/m², median [IQR])	22.8	20.6–26.8
Comorbidities		
Hypertension	16	21.0
Diabetes	6	7.9
Chronic kidney disease	7	9.2
Laboratory data		
C3 (mg/dL, median [IQR])	69.4	45.4–110.1
C4 (mg/dL, median [IQR])	13.8	6.7–23.7
Anti-dsDNA (IU/mL, median [IQR])	7.5	3.9–21.1
ESR (mm/hr, median [IQR])	30	18–63
CRP (mg/dL, median [IQR])	0.6	0.1–3.3
SLEDAI	6	3–12
SLE involvement		
Constitutional	42	55.3
Renal	25	32.9
Hematological	21	27.6
Mucocutaneous	11	14.5
Musculoskeletal	10	13.2
Neurologic	9	11.8
Pulmonary	8	10.5
Cardiac	4	5.3
PET profile		
Liver SUVmean (mean, SD)	1.56	0.27
Bone marrow SUVmax (mean, SD)	2.40	0.65
Bone marrow SUVmean (mean, SD)	1.65	0.50
SLR max (mean, SD)	1.47	0.48
SLR mean (mean, SD)	1.12	0.38
BLR max (mean, SD)	1.58	0.52
BLR mean (mean, SD)	1.10	0.41

Baseline characteristics of patients with systemic lupus erythematosus who underwent 18F-FDG PET/CT.

BLR values were independently associated with the development of hematologic abnormalities at 6 months (adjusted ORs: 1.57 [95% CI: 1.15–2.13] for BLRmax and 1.42 [1.10–1.83] for BLRmean; both $p < 0.01$). ROC curve analysis yielded an AUC of 0.76 for BLRmax in predicting future cytopenia, with an optimal cut-off value of 1.8 (sensitivity 78%, specificity 72%).

Conclusion: Increased BM-metabolic activity relative to the liver on PET/CT is associated with both initial and subsequent hematologic manifestations in patients with SLE. BLR, particularly BLRmax, may serve as a noninvasive imaging biomarker for predicting hematologic involvement, underscoring a potential role of the BM in SLE pathophysiology.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a common, complex inflammatory autoimmune disease in which dysregulation of both innate and adaptive immune responses has been implicated in disease pathogenesis. Leukopenia is a common hematologic manifestation in SLE, yet the mechanisms remain incompletely defined. Our published data show that anti-Ro autoantibodies can bind neutrophil surface proteins and potentially fix complement leading to leukopenic conditions. Additionally, the Duffy null genotype (ACKR1 rs2814778-CC), enriched in individuals of African and Arab ancestry, is associated with low neutrophil counts. Therefore, we investigated whether this Duffy null genotype, combined with autoantibody-mediated neutrophil targeting, contributes to more severe leukopenia and worse immunologic outcomes in SLE.

Methods: DNA from subjects who met the ACR classification criteria were obtained from the Oklahoma Medical Research Foundation (OMRF) Lupus Family Registry and Repository (LFRR). These subjects were genotyped for ACKR1 (rs2814778-CC) using biallelic discrimination assays. We analyzed the subjects corresponding clinical and serologic data and stratified them by autoantibody status and Duffy genotype (ACKR1 CC vs. CT/TT). Finally, we assessed white blood cell (WBC) counts across these groups. Statistical analysis was performed using the Kruskal-Wallis test to assess significant differences in WBC counts among stratified subgroups.

Results: WBC counts were lowest among SLE patients who were both anti-Ro or anti-dsDNA positive and Duffy antigen negative (*ACKR1*-CC genotype) compared to autoantibody negative/Duffy antigen positive (*ACKR1*-TT/CT genotype) SLE subjects. Additionally, subjects that were both anti-dsDNA positive and Duffy null had a significant decrease in WBC compared to subjects with anti-dsDNA antibodies and Duffy positive. These findings suggest an additive or synergistic effect of anti-dsDNA autoantibodies and Duffy null status on the severity of leukopenia.

Conclusion: Our previously published data support a model in which autoantibodies (anti-Ro60) directly contribute to leukopenia in SLE by binding neutrophil surface proteins and subsequently fixing complement. The current findings suggest this effect is amplified in subjects with the Duffy null genotype. These results highlight the importance of integrating ancestry-specific genetics (such as Duffy null genotype) and immunologic factors into our understanding of SLE pathogenesis and personalized care strategies.

Abstract Number: 2433

The Clinical Utility of a Multianalyte Lupus Risk Score Incorporating Cell-bound Complement Activation Products: A Systematic Evaluation

Vasileios Kyttaris[1], Sepehr Taghavi[2], Clayton Nagle[3], Christine Schleif[3], Brittany Partain[4] and Tyler O'Malley[5], [1]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, [2]Exagen Inc, Escondido, CA, [3]Exagen, Carlsbad, CA, [4]Exagen, Boston, MA, [5]Exagen, Vista, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Timely SLE diagnosis and treatment are critical to preventing irreversible organ damage and preserving quality of life. However, conventional biomarkers often underperform in patients presenting with non-specific signs and symptoms. We systematically evaluated a multianalyte assay panel (MAP) index incorporating cell-bound complement activation products (CB-CAPs) to address this diagnostic gap.

Methods: We analyzed biomarker data from multiple clinical studies (2011–2024), comprising 1,208 SLE patients meeting 1997 ACR criteria, 667 healthy controls, and 1,234 autoimmune rheumatic disease and chronic pain controls. CB-CAPs were measured by semi-quantitative flow cytometry and reported as net mean fluorescent intensity. Autoantibodies were measured by ELISA and complement C3 and C4 were measured by immunoturbidimetry. Diagnostic odds ratios (DOR), likelihood ratios (LR+/-), and sensitivities were calculated. Sensitivity comparisons between the MAP index, and conventional markers (anti-dsDNA, anti-Smith, and complement C3/C4) were performed within the SLE cohort using McNemar's test. Sensitivity odds ratios were calculated from discordant pairs, with p-values adjusted using the Benjamini-Hochberg method. Effect sizes were expressed as the difference in sensitivities with corresponding 95% confidence intervals.

Results: The SLE cohort was predominantly female (62%), mean age 43.5 (±14.1) years, and mostly White (40%) [Table 1]. The MAP index consistently outperformed conventional biomarkers across both healthy and disease control comparisons. Against healthy controls, MAP achieved the highest diagnostic odds (DOR = 101.6), compared to CB-CAPs alone (DOR = 55.1), anti-dsDNA/Smith antibodies (DOR = 36.2), and complement C3/C4 (DOR = 7.9) [Figure 1A]. Against autoimmune and chronic pain controls, MAP maintained superior performance (DOR = 22.3), exceeding that of anti-dsDNA/Smith (DOR = 20.3), CB-CAPs (DOR = 13.7), and complement (DOR = 9.1) [Figure 1B]. The MAP index yielded the highest positive likelihood ratio (LR+ = 32.7) and strongest rule-out utility (LR– = 0.3), outperforming all individual markers. Sensitivity comparisons within the SLE group revealed significantly higher odds of MAP positivity versus anti-dsDNA (OR = 24.8), anti-Smith (OR = 1382.0), and CB-CAP subsets (ORs = 17.3–19.0), all with adjusted p-values < 0.001 and moderate-to-large effect sizes (sensitivity differences = 0.31-0.57) [Figure 2A]. Integration of the MAP index identified 24% more SLE cases than conventional markers alone and reduced the proportion of patients testing negative for all biomarkers from 36% to 28% (Figure 2B-C). Overlap analysis confirmed MAP captured unique diagnostic information beyond traditional serologies and complement levels.

Conclusion: Systematic analysis demonstrates the MAP index integrating CB-CAPs improves lupus diagnostic precision. With unique utility for both rule-in and rule-out decisions, particularly in cases of intermediate lupus probability, the MAP index addresses critical diagnostic gaps. Robust performance across diverse patient populations further supports its clinical generalizability and practical value for enhancing lupus management.

Pre-test vs post-test probability curves demonstrate diagnostic performance of the Multianalyte Assay Panel (MAP) index, CB-CAPs, and conventional biomarkers (anti-dsDNA or anti-Smith antibodies, and serum complements C3 or C4) for distinguishing SLE patients (N=1208) from (A) healthy controls (AHV, N=667) and (B) autoimmune/chronic pain controls excluding AHV (N=1234). The MAP index showed the highest diagnostic odds ratio (DOR = 101.6 vs AHV; DOR = 22.3 vs other controls) and best rule-out utility (LR− = 0.3 in both comparisons). MAP also achieved the highest LR+ against AHV (32.7), while anti-dsDNA or anti-Smith antibodies had the highest LR+ (12.6) against other controls. CB-CAPs, presented as a separate biomarker category, consistently outperformed individual conventional markers but trailed the MAP index across all metrics.

Figure 1. Pre-test vs. post-test probability for SLE figures comparing MAP index to CB-CAPs and conventional markers

Sensitivity for SLE Comparison	Odds Ratio [95% CI]	Adjusted p-values (Benjamini-Hochberg)	Effect Size (Sensitivity Diff) [95% CI]
MAP Index vs anti-Smith Positive	1382.00 [86.35, 22118.03]	<0.001	0.57 [0.54, 0.60]
MAP Index vs anti-dsDNA Positive	24.76 [15.25, 40.22]	<0.001	0.33 [0.31, 0.36]
MAP Index vs BC4d Positive	19.00 [12.25, 29.47]	<0.001	0.31 [0.28, 0.34]
MAP Index vs EC4d Positive	17.33 [11.76, 25.55]	<0.001	0.37 [0.34, 0.39]
Either CB-CAPS Positive vs anti-Smith Positive	12.66 [9.10, 17.61]	<0.001	0.37 [0.34, 0.40]
MAP Index vs Either CB-CAPS Positive	6.77 [4.91, 9.32]	<0.001	0.21 [0.18, 0.23]
Either CB-CAPS Positive vs Either C3 or C4 Low	5.22 [4.06, 6.72]	<0.001	0.25 [0.22, 0.28]
Either CB-CAPS Positive vs anti-dsDNA Positive	2.16 [1.76, 2.66]	<0.001	0.13 [0.10, 0.16]

Figure 2. (A) The MAP Index shows significantly higher sensitivity for SLE compared to conventional markers, particularly anti-Smith (Δ = 0.57). All comparisons are statistically significant (adjusted p < 0.001).

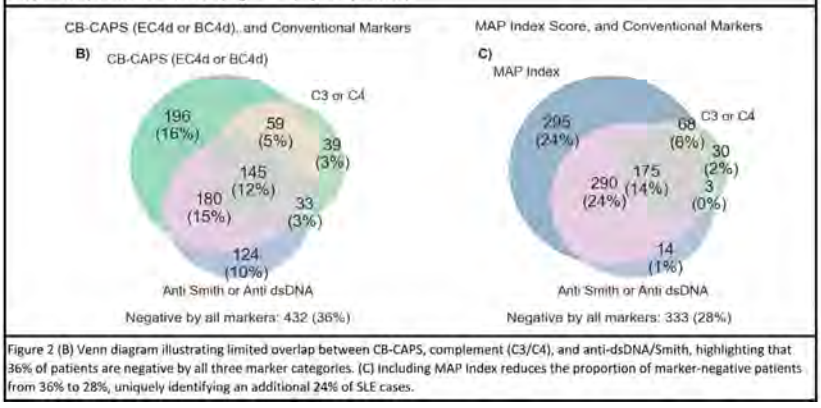

Figure 2 (B) Venn diagram illustrating limited overlap between CB-CAPS, complement (C3/C4), and anti-dsDNA/Smith, highlighting that 36% of patients are negative by all three marker categories. (C) Including MAP Index reduces the proportion of marker-negative patients from 36% to 28%, uniquely identifying an additional 24% of SLE cases.

Figure 2. Sensitivity for SLE comparison between MAP, CB-CAPs and conventional biomarkers

Specificity of Cell-bound T Cell Biomarkers (TC4d, TIgG, TIgM) in Differentiating SLE from ANA-Associated Rheumatic Diseases

Vasileios Kyttaris[1], Sepehr Taghavi[2], Clayton Nagle[3], Christine Schleif[3], Brittany Partain[4] and Tyler O'Malley[5], [1]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, [2]Exagen Inc, Escondido, CA, [3]Exagen, Carlsbad, CA, [4]Exagen, Boston, MA, [5]Exagen, Vista, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: We previously validated T Cell-bound C4d (TC4d), T Cell-bound IgG (TIgG), and T Cell-bound IgM (TIgM) biomarkers, demonstrating high sensitivity and specificity for differentiating systemic lupus erythematosus (SLE) from apparently healthy volunteers (AHVs) and other autoimmune rheumatic diseases (ARDs). The current study aims to further evaluate the specificity of these biomarkers in distinguishing SLE from other suspected anti-nuclear antibody (ANA)-associated ARDs within a large cohort.

Methods: Three cohorts were analyzed: 71 clinically diagnosed SLE patients meeting the 2019 ACR/EULAR classification criteria; 162 AHVs; and 31,221 subjects from a de-identified population undergoing autoimmune testing (Jan–Apr 2025). Suspected ARDs were identified based on autoantibody levels exceeding ten times the diagnostic assay cutoffs (anti-CCP for RA; anti-Ro52, anti-Ro60, and anti-SSB/La for Sjögren's syndrome; anti-centromere protein B for limited scleroderma; anti-Scl-70 for diffuse scleroderma; and anti-Jo-1 for myositis) and negative for anti-dsDNA and anti-Smith antibodies. Semiquantitative flow cytometry was used to measure cell-bound TC4d, TIgG, and TIgM, reported as median fluorescence intensity (MFI). Autoantibody measurements utilized ELISA or enzyme linked fluorescent assay (ELFA) methods per kit recommendations (ThermoFisher, Phadia). Biomarker distributions, sensitivity, specificity, likelihood ratios (LRs), and diagnostic odds ratios (DORs) were assessed at thresholds achieving 95% specificity vs. AHVs, 95% specificity vs. ARDs, and 99% specificity vs. ARDs. Mann-Whitney U tests evaluated significant differences.

Results: SLE patients (N = 71) had a mean (SD) age of 42.6 (9.8) years, were predominantly female (83.1%), ANA IFA-positive (83.1%), and ANA ELISA-positive (97.2%). Suspected ARD groups included RA (N = 648), Sjögren's (N = 140), limited scleroderma (N = 366), diffuse scleroderma (N = 26), and myositis (N = 22) [Table 1]. At thresholds providing 95% specificity vs. AHVs, the T Cell biomarkers showed specificities of 87.5% (TC4d), 87.3% (TIgG), and 83.5% (TIgM) for differentiating SLE from ARDs (Table 2). Sensitivity for SLE at 95% specificity for SLE vs. ARD was 64.8% (TC4d), 54.9% (TIgG), and 36.6% (TIgM). At thresholds providing 99% specificity vs. ARDs, sensitivities ranged from 11% to 28%. The DORs at 95% specificity vs. AHVs were 24.1 (TC4d), 16.3 (TIgG), and 7.3 (TIgM). Median TC4d, TIgG, and TIgM levels were

Table 1. Demographic characteristics

	SLE	AHV	Suspected RA	Suspected Sjögren's	Suspected Limited Scleroderma	Suspected Diffuse Scleroderma	Suspected Myositis

Table 2. Performance characteristics

Biomarker	Specificity level	Sensitivity for SLE (%)	Specificity vs. ARD (%)	LR+	LR-	DOR
TC4d	95% vs. AHV	77.5% (66.0-86.5%)	87.5% (85.5-89.3%)	6.2	0.3	24.1
TC4d	95% vs. suspected ARDs	64.8% (52.5-75.8%)	94.9% (93.5-96.1%)	12.8	0.4	34.4
TC4d	99% vs. suspected ARDs	28.2% (18.1-40.1%)	98.9% (98.2-99.4%)	26.0	0.7	35.9
TIgG	95% vs. AHV	70.4% (58.4-80.7%)	87.3% (85.3-89.1%)	5.5	0.3	16.3
TIgG	95% vs. suspected ARDs	54.9% (42.7-66.8%)	94.8% (93.4-96.0%)	10.6	0.5	22.4
TIgG	99% vs. suspected ARDs	25.4% (15.8-37.1%)	98.9% (98.2-99.4%)	23.4	0.8	31.1
TIgM	95% vs. AHV	59.2% (46.8-70.7%)	83.5% (81.3-85.6%)	3.6	0.5	7.3
TIgM	95% vs. suspected ARDs	36.6% (25.5-48.9%)	94.9% (93.5-96.1%)	7.2	0.7	10.8
TIgM	99% vs. suspected ARDs	11.3% (5.0-21.0%)	98.9% (98.2-99.4%)	10.4	0.9	11.6

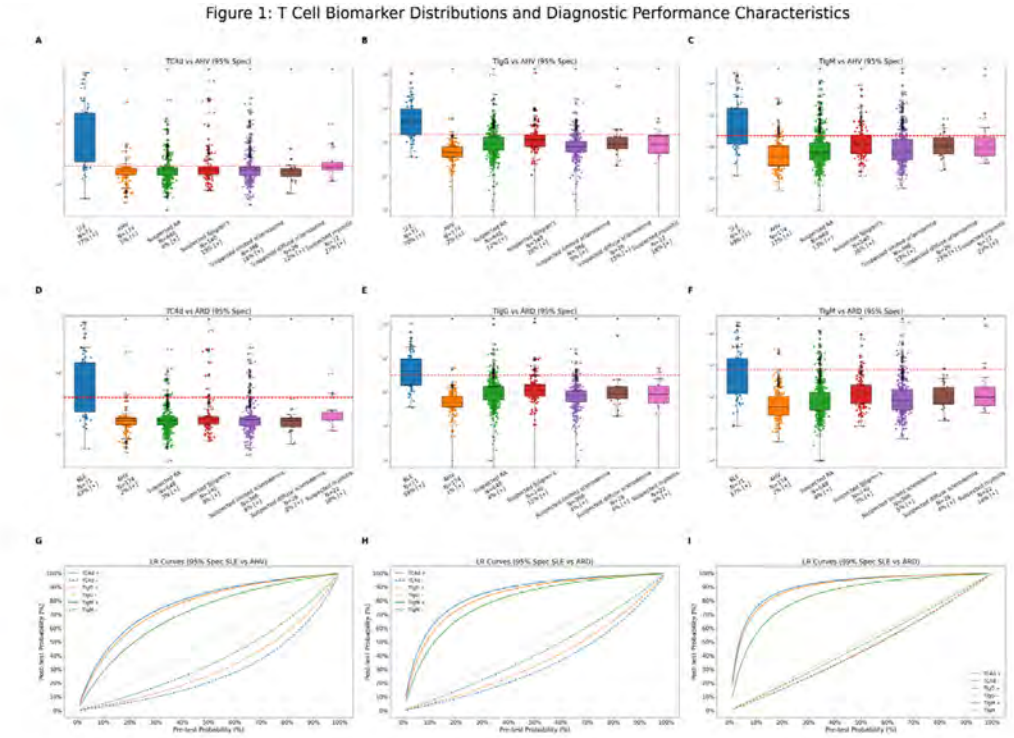

Figure 1. Biomarker distributions and diagnostic performances at varying levels of specificity for SLE

significantly higher in SLE patients compared to all other ANA-associated ARDs (Figure 1A-F, $p < 0.01$). At a moderate pre-test probability for SLE (30%), the post-test probabilities following a positive TC4d result were 72.7% (95% specificity vs. AHVs), 84.5% (95% specificity vs. ARDs), and 91.8% (99% specificity vs. ARDs) [Figure 1G-I]. Conversely, negative TC4d results reduced the post-test probability to 9.9%, 13.7%, and 23.7%, respectively.

Conclusion: Cell-bound TC4d, TIgG, and TIgM exhibit robust specificity for differentiating SLE from other ANA-associated ARDs. The availability of multiple threshold levels allows flexible clinical application, enhancing diagnostic decision-making through optimized rule-in or rule-out approaches.

Abstract Number: 2436

Preload deficiency as a treatable cause of fatigue and exercise intolerance in SLE

Yoo Jin Kim[1], Phebe Ismail[1], Michelle Petri[2], Jennifer Lee[1], Luigi Adamo[3] and Andrea Fava[1], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Timonium, MD, [3]Johns Hopkins Unviersity, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2377–2436) Systemic Lupus Erythematosus – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Fatigue and exercise intolerance affect over 90% of patients with SLE, often persisting despite inactive disease and disrupting quality of life. Yet, the underlying mechanism remains poorly defined, and treatment options are limited. We report a detailed evaluation and therapeutic response in a series of ten women with SLE and disabling fatigue and exercise intolerance, identifying preload deficiency as a potential and treatable contributor.

Methods: A prospective cohort study of ten women with SLE who experienced exercise intolerance and fatigue was conducted as part of the Hopkins Lupus Cohort. All patients underwent extensive cardiopulmonary evaluation, including laboratory tests, transthoracic echocardiography (TTE), cardiac MRI, continuous cardiac monitoring, coronary CT, quantitative autonomic testing (QAT), and cardiac pulmonary exercise testing (CPET). A subset of these patients underwent right heart catheterization (RHC) with exertion.

Results: The median age was 41. All patients had no anemia, renal, or pulmonary dysfunction. TTE, cardiac MRI, continuous cardiac monitoring, and coronary CT were unremarkable, indicating no structural, coronary, or conduction abnormalities. QAT identified postural orthostatic tachycardia syndrome (POTS) in 2 patients. However, all demonstrated impaired aerobic capacity (peak VO_2 < 80% predicted) on CPET, with low anaerobic thresholds and elevated resting heart rates, indicating cardiovascular limitation to exercise. Jugular venous pressure (JVP) was < 5 cm H_2O in all cases, suggesting **preload deficiency**, a condition of inadequate augmentation of right-sided filling pressures during exertion. To confirm, five patients underwent RHC with exertion, all demonstrating preload deficiency defined as failure to increase right atrial pressure with exercise (ΔRAP< 5.5). Pro-BNP was undetectable in all, consistent with inadequate right atrial filling and suggesting its potential utility as a biomarker.

Patients were advised to increase fluid (128 oz/day) and sodium intake (>5g/day) and use compression garments. Ivabradine was introduced in a subset of patients with persistent symptoms, high resting heart rates, marked exertional tachycardia, or limited fluid/sodium tolerance. All patients reported significant symptomatic improvement. One patient, previously nearly bed-bound, returned to school and completed a doctoral degree.

Conclusion: Reduced peak VO_2 and anaerobic thresholds have been described in SLE. Our findings suggest that **preload deficiency**—a reversible cardiovascular abnormality—may underlie this impairment in selected patients, offering a previously unrecognized but treatable cause of exercise intolerance. Undetectable pro-BNP may serve as a biomarker of preload deficiency in this population, warranting further study. Recognition of this phenotype may enable effective, low-risk interventions and offer a mechanistic target for future studies aimed at defining the prevalence and pathophysiology of preload deficiency in SLE.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, multi-system autoimmune disease with heterogenous presentation. Most patients with SLE report fatigue or brain fog, which often does not respond well to standard SLE therapies. As such, even patients with well-controlled SLE often continue to have debilitating fatigue. Bupropion is a combined dopamine/norepinephrine reuptake inhibitor used in the treatment of depression. Unlike most alternative antidepressants, bupropion has a stimulating effect, and has been shown to be effective for cancer-associated fatigue. Providers at the University of North Carolina (UNC) at Chapel-Hill Rheumatology and Nephrology clinics have been prescribing bupropion off-label for the treatment of lupus-associated fatigue for several years. The purpose of this study is to better understand patient acceptability, tolerability, and response to bupropion as a treatment for lupus-associated fatigue.

Methods: We identified patients with a lupus ICD-10 code (M32.X or L93.X), who received care at the UNC Rheumatology or Nephrology clinics and were prescribed bupropion 11/2019-10/2024. Data was manually reviewed and extracted from the electronic medical record (EMR) to confirm SLE diagnoses and to identify patients who started bupropion in this timeframe for fatigue, brain fog, poor concentration, low energy, or lack of motivation/apathy. Baseline demographic characteristics, SLE activity, mental health comorbidities, medications, and response to bupropion treatment were collected. Descriptive statistics, including means, standard deviations, and frequency distributions, were calculated.

Results: Data extraction has been completed for 34 EMRs. Mean follow-up was 2.5 yrs. The median age was 45, approximately 56% of patients identified as Black or African American, and 97% female. Over half (52%) of patients had SLEDAI-2K < 4 suggestive of low lupus disease activity. Depression (53%) and anxiety (29%) were frequent comorbidities. Thirty-two percent reported improvement in energy, fatigue, concentration, low motivation/apathy, or mood during the follow-up period. Forty-one percent currently have an active prescription for bupropion and remain on this medication. The most frequent reasons for bupropion cessation include side effects (24%), lack of efficacy (18%), and loss of initial efficacy (6%). The most frequently reported side effects included insomnia (26%), headache (12%), rash (6%), anxiety (6%), and tremor (6%).

Other	1 (2.9%)
Taking bupropion at final visit	14 (41%)

n (%)

Conclusion: Bupropion may be an efficacious treatment for SLE-associated fatigue and other cognitive symptoms with few side effects. Planned next steps include assessment of outcomes of interest in all eligible patients and utilization of efficient machine learning tools for validation, in order to reduce any errors and bias introduced by human data extraction.

SGLT2 Inhibitors in SLE: Impact on Pulmonary Hypertension, Mortality, and Renal Outcomes

Ahmad Alomari[1], Asim Khanfar[2], Miguel Rodriguez[3] and Diala Alawneh[4], [1]UCF- North Florida hospital, Gainesville, FL, [2]Rochester General Hospital, Rochester, NY, [3]SIMED Rheumatology, Gainesville, FL, [4]University of Florida, Gainesville, FL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose:

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease linked to significant morbidity, including pulmonary hypertension (PH). While SGLT2 inhibitors are known for cardiovascular and renal benefits, their impact on PH in SLE remains underexplored. This study assesses the association between SGLT2 inhibitor use and reduced risks of PH, mortality, and other cardiopulmonary outcomes in SLE patients.

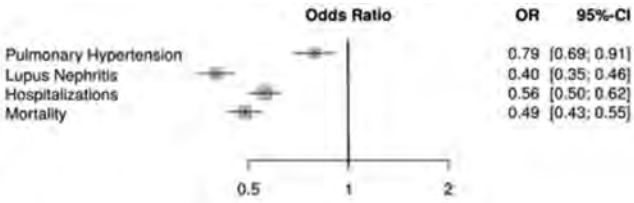
Table 1: Summary of primary and secondary outcomes with odds ratios and p-values.

Outcome	Number of Patients with Event (%)		Odds Ratio (95% CI)	P Value
	SLE with SGLT2i	SLE without SGLT2i		
Pulmonary Hypertension	368 (5.70%)	484 (7.10%)	0.79 (0.69–0.91)	0.001
Mortality	437 (5.80%)	843 (11.20%)	0.49 (0.43–0.55)	<0.001
Hospitalizations	753 (27.90%)	1,254 (40.80%)	0.56 (0.50–0.63)	<0.001
Lupus Nephritis	322 (4.90%)	863 (11.40%)	0.40 (0.35–0.46)	<0.001

Values are n (%) unless otherwise indicated.
SLE: Systemic Lupus Erythematosus.
SGLT2i: Sodium-glucose cotransporter 2 inhibitor



Forest plot summarizing odds ratios and 95% CIs for all primary and secondary outcomes.

Methods: This retrospective cohort study utilized the TriNetX Research Network to identify two cohorts of SLE patients—those prescribed SGLT2 inhibitors and non-users—between August 1, 2014, and August 1, 2024. SLE patients were identified using ICD-10 codes. Outcomes, including pulmonary hypertension (PH), mortality, hospitalizations, and lupus nephritis, were also defined using ICD-10 codes and additional codes available on the TriNetX platform. Data analysis was performed in January 2025.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Propensity score matching (PSM) in a 1:1 ratio was applied to achieve balanced baseline characteristics between the two cohorts, including demographics, steroid use, comorbidities, and SLE-specific laboratory markers. Following matching, outcomes were compared between the two groups over a follow-up period of five years. Statistical analysis was conducted using Cox proportional hazards models for time-to-event outcomes, Kaplan-Meier survival curves for visualizing survival differences, and log-rank tests to assess statistical significance between the matched cohorts.

Results: After propensity score matching, 7,556 patients were included in each cohort, ensuring balanced demographics (mean age: 61 years, 80% female, 46% White). SGLT2 inhibitor use was associated with a significantly lower incidence of pulmonary hypertension (PH) (5.7% vs. 7.1%; OR: 0.79, 95% CI: 0.69–0.91; $p < 0.001$).

All-cause mortality was reduced in the SGLT2i group (5.8% vs. 11.2%; OR: 0.49, 95% CI: 0.43–0.55; $p < 0.001$), and hospitalizations were less frequent among SGLT2i users (27.9% vs. 40.8%; OR: 0.56, 95% CI: 0.50–0.63; $p < 0.001$). Additionally, SGLT2i use was associated with a significantly lower incidence of lupus nephritis (4.9% vs. 11.4%; OR: 0.40, 95% CI: 0.35–0.46; $p < 0.001$).

Conclusion: SGLT2 inhibitors were significantly associated with reduced risk of PH, mortality, lupus nephritis, and other cardiopulmonary complications in SLE patients. These findings support the potential role of SGLT2 inhibitors as an adjunctive therapy in SLE management. Prospective studies are warranted to confirm these results.

Abstract Number: 2439

Belimumab Versus Mycophenolate Mofetil in Lupus Nephritis: A Real-World Comparative Analysis

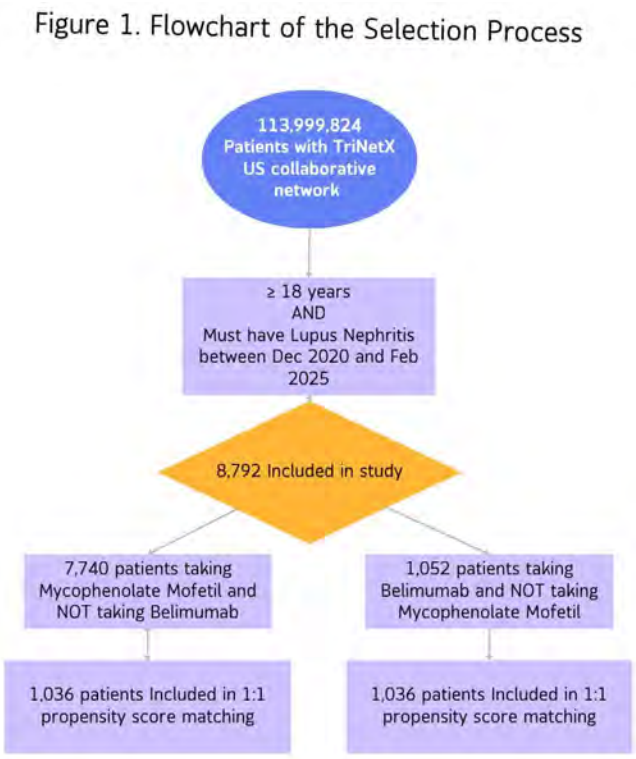
Ahmad Alomari[1], Nikita Shah[2], Miguel Rodriguez[3] and Diala Alawneh[4], [1]UCF- North Florida hospital, Gainesville, FL, [2]UCF/HCA Florida North Florida Hospital, Gainesville, FL, [3]SIMED Rheumatology, Gainesville, FL, [4]University of Florida, Gainesville, FL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE), often leading to chronic kidney disease (CKD) and end-stage renal disease (ESRD). Belimumab, a B-lymphocyte stimulator (BLyS) inhibitor, was FDA-approved for LN in 2020, offering a targeted approach to reduce B-cell activity. This study aims to compare renal outcomes in LN patients treated with Belimumab versus Mycophenolate Mofetil (MMF) using real-world data, providing insights into their relative effectiveness and safety.

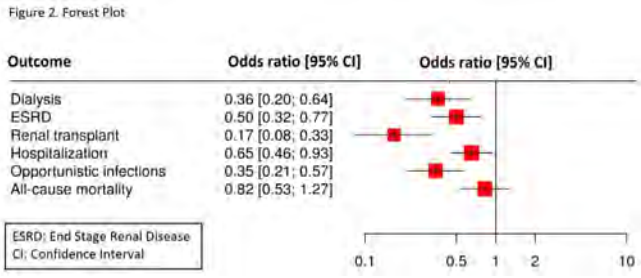
Methods: This multicenter retrospective cohort study utilized data from the TriNetX network, comprising electronic health records from 104 healthcare organizations. Adult patients (≥18 years) with lupus nephritis (LN) were identified using ICD-10 codes. Two cohorts were defined: patients receiving Belimumab (n=1,052) and those receiving mycophenolate mofetil (MMF) (n=7,740) between December 2020 and February 2025. To eliminate potential confounding, patients receiving concurrent use of both Belimumab and MMF were excluded from the analysis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Outcome	Number and percentage of events		Odds Ratio (95% CI)	P Value
	Belimumab (N, %)	MMF (N, %)		
Dialysis	17 (1.7%)	45 (4.7%)	0.36 (0.28–0.45)	<0.001
ESRD	33 (3.5%)	60 (6.8%)	0.50 (0.36–0.68)	0.001
Renal Transplant	10 (1.0%)	55 (5.6%)	0.17 (0.09–0.31)	<0.001
Hospitalization	71 (21.0%)	89 (29.0%)	0.65 (0.47–0.89)	0.02
Opportunistic Infections	22 (2.3%)	61 (6.3%)	0.35 (0.23–0.53)	<0.001
All-Cause Mortality	39 (3.8%)	47 (4.5%)	0.82 (0.61–1.10)	0.38

Comparative Outcomes in Belimumab vs. MMF for Lupus Nephritis



Propensity score matching (PSM) was applied to adjust for demographics, comorbidities, and laboratory values, achieving balanced baseline characteristics between the two groups. Outcomes were compared between the matched cohorts over a follow-up period of five years. The primary outcomes were end-stage renal disease (ESRD), dialysis, and renal transplant. Secondary outcomes included opportunistic infections, hospitalization, and all-cause mortality.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: After propensity score matching, 1,036 patients were included in each group. The Belimumab cohort had significantly lower odds of dialysis (OR 0.36, 95% CI 0.28–0.45, p < 0.001), ESRD (OR 0.50, 95% CI 0.36–0.68, p = 0.001), and renal transplant (OR 0.17, 95% CI 0.09–0.31, p < 0.001) compared to MMF. Additionally, Belimumab was associated with reduced hospitalization (OR 0.65, 95% CI 0.47–0.89, p = 0.02) and fewer opportunistic infections (OR 0.35, 95% CI 0.23–0.53, p < 0.001). No statistically significant difference was observed in all-cause mortality (OR 0.82, 95% CI 0.61–1.10, p = 0.38).

Conclusion: This real-world analysis suggests that Belimumab may provide superior renal outcomes compared to MMF in lupus nephritis, with reduced risks of dialysis, ESRD, and renal transplant. The findings support the potential of Belimumab as an alternative or adjunct to conventional therapy. Further prospective studies are necessary to confirm long-term efficacy and safety.

Abstract Number: 2440

Effect of Cenerimod on Four Main Clinical Items of SLEDAI-2K Score in SLE Patients in a Phase 2b Study

Anca Askanase[1], **Bruno Flamion**[2], Ouali Berkani[2] and Cecile Dubois[2], [1]Columbia University Medical Center, New York, NY, [2]Viatris Innovation, Allschwil, Switzerland

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Cenerimod is a selective $S1P_1$ receptor modulator that has the potential to reduce the abnormal immune response seen in Systemic lupus erythematosus (SLE) thereby leading to decreased disease activity and improved clinical outcomes for patients.

In a recent multicenter, randomized, double-blind, placebo-controlled phase 2b trial (CARE study, NCT03742037), the efficacy, safety, and tolerability of four doses of cenerimod (0.5 mg, 1 mg, 2 mg, and 4 mg) was compared to placebo in adults with moderate-to-severe SLE who were receiving standard of care background therapy. The primary endpoint was the change from baseline in mSLEDAI-2K scores from baseline to month 6. Cenerimod 4 mg is currently being investigated for the treatment of SLE in two 1-year treatment phase 3 trials (NCT05648500 and NCT05672576).

This post-hoc analysis of the CARE study was performed to compare the monthly changes (improvements) in four individual SLEDAI-2K items from baseline over 6 months between cenerimod 4 mg and placebo. These four main clinical items are: arthritis, rash, alopecia, and mucosal ulcers that are clinically significant manifestations of SLE. Arthritis affects around 82.6% of patients, rash is seen in approximately 69.2% of patients, alopecia affects about 58.2% of patients and mucosal ulcers occur in about 32.5% of patients.

Methods: The SLEDAI-2K values were measured on a monthly basis. Proportions of patients with each of the four selected SLEDAI-2K items improvements were calculated by treatment group and visit only for the cenerimod 4 mg and the placebo arm. Improvement was defined as a reduction vs baseline score.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

SLEDAI-2K item	Group	Patients with involvement at baseline n (%)	Patients with improvement from baseline, n (%) Month 1	Month 2	Month 3	Month 4	Month 5	Month 6
Arthritis	Cenerimod 4 mg	83 (97.6)	5 (6.0)	14 (16.9)	22 (26.5)	25 (30.1)	27 (32.5)	33 (39.8)
	Placebo	84 (97.7)	7 (8.3)	12 (14.3)	19 (22.6)	20 (23.8)	30 (35.7)	32 (38.1)
Rash	Cenerimod 4 mg	74 (87.1)	5 (6.8)	11 (14.9)	13 (17.6)	18 (24.3)	20 (27.0)	20 (27.0)
	Placebo	72 (83.7)	4 (5.6)	8 (11.1)	15 (20.8)	20 (27.8)	23 (31.9)	20 (27.8)
Alopecia	Cenerimod 4 mg	60 (70.6)	1 (1.7)	2 (3.3)	5 (8.3)	12 (20.0)	16 (26.7)	19 (31.7)
	Placebo	62 (72.1)	0	2 (3.2)	4 (6.5)	6 (9.7)	5 (8.1)	7 (11.3)
Mucosal Ulcers	Cenerimod 4 mg	39 (45.9)	8 (20.5)	15 (38.5)	18 (46.2)	25 (64.1)	29 (74.4)	27 (69.2)
	Placebo	44 (51.2)	8 (18.2)	6 (13.6)	17 (38.6)	20 (45.5)	21 (47.7)	20 (45.5)

≥5% greater improvement with Cenerimod vs placebo | ≥10% greater improvement with Cenerimod vs placebo | ≥5% greater improvement with placebo vs Cenerimod | ≥10% greater improvement with placebo vs Cenerimod

Proportions of patients with improvement in individual SLEDAI-2K items

Results: At baseline, involvement of individual SLEDAI-2K items was well balanced between cenerimod 4 mg and placebo arm. Numeric treatment differences ≥10% favoring cenerimod 4 mg were seen at months 4-6 for alopecia and months 2–6 (except month 3 which showed improvement of ≥5%) for mucosal ulcers. (Table 1).

Conclusion: This post-hoc analysis provided insights to the trends in improvements of four individual SLEDAI-2K clinical components when patients were treated with cenerimod 4 mg dose for 6 months. There was no obvious difference in arthritis or rash scores vs placebo. However, as compared to placebo, better early improvement was seen in alopecia (from month 4) and mucosal ulcers (from month 4) until month 6. The ongoing confirmatory Phase 3 program OPUS (NCT05648500 and NCT05672576) will further evaluate the safety and efficacy of 4 mg cenerimod in adults with SLE.

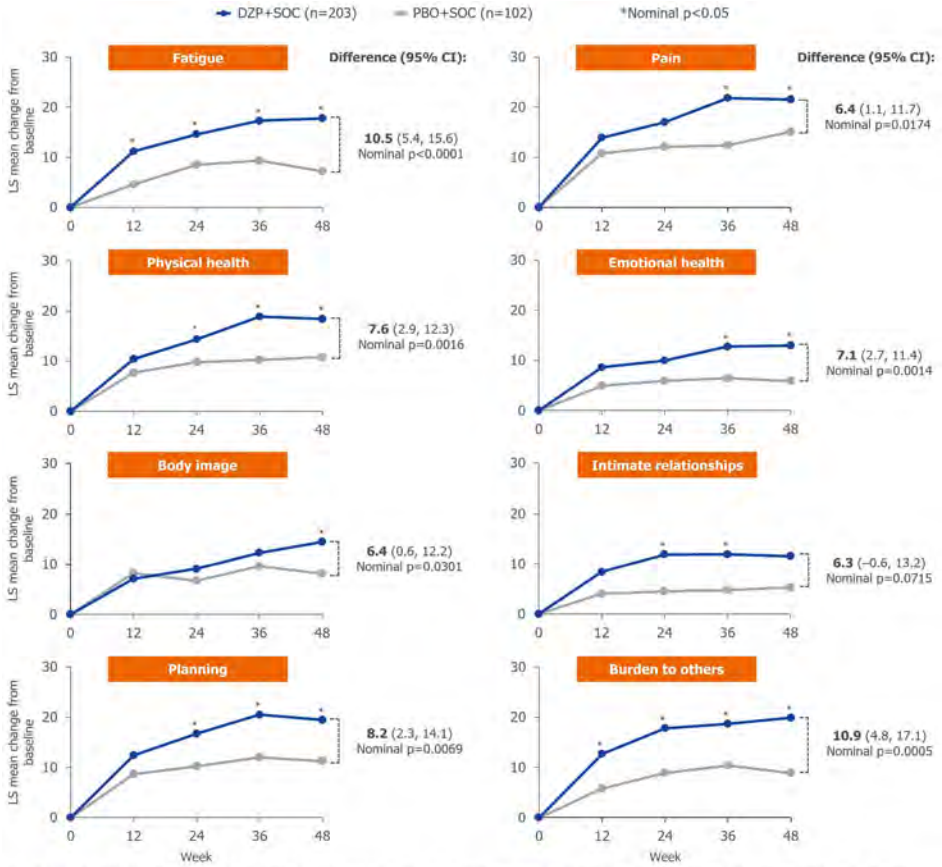
Table. Baseline LupusQoL domain scores

	DZP+SOC n=203	PBO+SOC n=102
LupusQoL domain scores, mean (SD)		
Fatigue	52.4 (25.6)	52.6 (24.5)
Pain	52.8 (26.1)	53.7 (25.9)
Physical health	54.2 (23.6)	55.8 (22.3)
Emotional health	66.1 (21.7)[a]	69.0 (19.9)
Body image	63.0 (24.0)[b]	64.3 (27.3)[c]
Intimate relationships	58.3 (32.4)[d]	60.0 (32.6)[e]
Planning	58.1 (29.5)	58.1 (29.3)
Burden to others	52.1 (28.3)	54.0 (27.7)

Full analysis set. [a] n=202; [b] n=184; [c] n=94; [d] n=174; [e] n=91.
DZP: dapirolizumab pegol; LupusQoL: Lupus Quality of Life; PBO: placebo; SD: standard deviation; SOC: standard of care.



Full analysis set; MMRM. All p-values are nominal and were not controlled for multiplicity. Higher LupusQoL scores correspond with better HRQoL. The LS mean, difference between DZP+SOC and PBO+SOC, 95% CIs, and p-values were computed using a MMRM.
CI: confidence interval; DZP: dapirolizumab pegol; HRQoL: health-related quality of life; LS: least square; LupusQoL: Lupus Quality of Life; MMRM: mixed model for repeated measurements; PBO: placebo; SOC: standard of care.

Figure. LS mean change from baseline in LupusQoL domain scores by visit

Background/Purpose: SLE imposes significant disease burden and diminishes health-related quality of life (HRQoL); improvement of HRQoL is therefore a key treatment goal in SLE.[1,2] Dapirolizumab pegol (DZP) is a novel CD40L inhibitor with broad modulatory effects on SLE immunopathology;[3,4] it consists of a polyethylene glycol (PEG)-conjugated antigen-binding fragment (Fab'), which lacks an Fc domain. In the phase 3 PHOENYCS GO trial (NCT04294667), the primary end-point was met; DZP plus standard of care (DZP+SOC) resulted in significantly higher rates of BILAG-based Composite

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Lupus Assessment (BICLA) response vs placebo (PBO)+SOC at Week (Wk) 48.[5] We report the impact of DZP on HRQoL as measured by LupusQoL, completed by patients, in PHOENYCS GO.

Methods: PHOENYCS GO, a 48-wk, randomized, double-blind, PBO-controlled trial, included patients aged ≥16 years with moderate-to-severe, active SLE characterized by persistently active or frequently flaring/relapsing-remitting disease activity despite stable SOC medication (antimalarials, glucocorticoids and/or immunosuppressants). Patients were randomized 2:1 to intravenous DZP 24 mg/kg+SOC or PBO+SOC every 4 wks.

HRQoL outcomes were measured using LupusQoL, a patient-reported outcome based on responses on a 5-point Likert scale to 34 items across 8 domains.[1] Each domain score ranges from 0 to 100; higher scores indicate better HRQoL. The least square (LS) mean change from baseline in LupusQoL domain scores at Wk 12, 24, 36, and 48 are reported.

Results: In total, 97.6% (203/208) of patients receiving DZP+SOC and 95.3% (102/107) receiving PBO+SOC had LupusQoL responses available at any visit. Baseline LupusQoL scores were comparable between the treatment groups (**Table**).

Patients receiving DZP+SOC demonstrated consistently greater improvements from baseline over time in LupusQoL scores across all domains compared with PBO+SOC (**Figure**). Patients receiving DZP+SOC reported greater improvements in the 'Fatigue' and 'Burden to others' domains at all assessed visits compared with those receiving PBO+SOC, as of Wk 12 (all nominal $p < 0.05$). Additionally, greater improvements were reported for patients receiving DZP+SOC compared with PBO +SOC in the 'Physical health' and 'Planning' domains at Wks 24, 36, and 48, in the 'Pain' and 'Emotional health' domains at Wks 36 and 48, in the 'Intimate relationships' domain at Wks 24 and 36, and in the 'Body image' domain at Wk 48 (each nominal $p < 0.05$).

Conclusion: Improvements in HRQoL were greater in patients treated with DZP+SOC compared with PBO+SOC across all LupusQoL domains, starting at the earliest time point (Wk 12) for some domains. These data, along with the previously reported significant improvements in overall disease activity,[5] support the potential of DZP as a valuable treatment option in SLE to improve HRQoL.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by aberrant B cell activation and autoantibody production. CD19-targeted chimeric antigen receptor (CAR) T-cell therapy induces a short, deep B cell depletion and showed promising clinical efficacy in patients with refractory SLE. However, it is poorly understood how the B cell system evolves after reconstitution and whether pathogenic immune phenotypes reemerge.

Methods: 18 patients with active, refractory SLE (15 with lupus nephritis) received autologous CD19-CAR T-cell therapy. Longitudinal, high dimensional phenotyping of blood B cells was performed using spectral flow cytometry. B cells were analyzed before therapy (N = 18), at first reappearance (N = 14) and at early (3-6 months, N = 10), late (12+ months, N = 10) and long-term (median 24 months) reconstitution. B cells from 10 healthy donors were included as control.

scRNA-Seq was performed at baseline and early reconstitution.

Results: Patients with active SLE showed aberrant B cell subsets and frequencies, including an increase in circulating plasmablasts and IgD– CD27– double negative (DN) memory B cells. CAR T cell therapy led to transient depletion of CD19+ B cells in all patients. After a median follow up of 17 (range: 3 – 36) months, B cells had reconstituted in 14/18 (78%) of patients. B cells recovered between 28 to 420 (mean: 169) days after CAR T, with a transient increase in immature B cells during reconstitution. At reconstitution and 6 months thereafter, the new B cell compartment consisted predominantly of CD20+ IgD+ CD27– naïve B cells. Accordingly, all other subsets, including switched and unswitched memory B cells and circulating plasmablasts were reduced. HLA-DR expression was decreased after reconstitution, indicating reduced stimulation. Surprisingly, IgD– CD27– double negative (DN) and Tbet+ age associated B cells (ABCs), reappeared one year after CAR-T cell therapy. However, fresh DN cells consisted almost exclusively of CXCR5+ CD11c– Tbet– DN1 cells, whereas disease associated CD11c+ CXCR5– Tbet+ DN2 cells stayed reduced, constituting less than 5% of peripheral CD19+ B cells. This was confirmed by identification of DN2 cells in scRNA-Seq showing reduced frequencies after therapy.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Concordantly, new switched memory B cells, which slowly reappeared after a mean of 12 months after therapy, were mostly CXCR5+, while CXCR5– switched memory B cells were not accumulated. New plasmablasts were rarely detected (< 1% of CD19+ cells) and displayed substantially reduced activation ($CD95^{low}$ $HLA\text{-}DR^{low}$). Frequencies of atypical B cell subsets remained low and indistinguishable from healthy individuals even at late follow-up.

Conclusion: Deep B cell depletion, as mediated via CD19-CAR T cell therapy, profoundly remodels the B cell compartment. New B cells appear to predominantly repopulate from $CXCR5^{+}$ cells, suggesting less utilization of extrafollicular B cell maturation pathways. Accordingly, new B cells display overall reduced activation levels, while disease-associated DN2 cells, atypical B cell subsets and activated plasmablasts remained cleared long after reconstitution. These changes indicate a deep and durable reset of adaptive immunity even long after B cell reconstitution.

Abstract Number: 2444

Hydroxychloroquine-Induced Retinopathy in Systemic Lupus Erythematosus: Predictors of Progression Following Drug Discontinuation

Emily Gutowski[1], Jessica Dai[2], Erin Carter[3], Brooke Cohen[4], Jill Buyon[5], Chung-E Tseng[6], Mala Masson[7], Amit Saxena[5], H Michael Belmont[8], Joseph Colcombe[6], Yasha Modi[3], Carol Lee[6] and Peter Izmirly[9], [1]New York University Grossman School of Medicine, Brooklyn, NY, [2]New York University Grossman School of Medicine, Tenafly, NJ, [3]New York University Grossman School of Medicine, New York, NY, [4]Yale Physician Associate Program, New Haven, CT, [5]NYU Grossman School of Medicine, New York, NY, [6]New York University Grossman School of Medicine, New York, [7]NYU Langone Health, New York, [8]NYU School of Medicine, New York, NY, [9]New York University Grossman School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is a cornerstone of systemic lupus erythematosus (SLE) management, but long-term use carries the risk of retinopathy. While prior studies have identified risk factors for HCQ-induced retinopathy and described varying degrees of progression even after drug discontinuation, existing literature is limited by small sample sizes. We aimed to characterize a cohort of SLE patients with confirmed HCQ retinopathy to identify factors associated with progression after discontinuation.

Methods: We queried an urban multi-ethnic lupus cohort (all ACR/SLICC or EULAR criteria longitudinally followed) for patients who had evidence of HCQ-induced retinopathy and identified 59 of 1,530 with documented retinopathy diagnoses. Of these, 28 had records available to confirm the onset of retinopathy and at least one ophthalmology follow-up to assess for progression. We conducted a chart review of these 28 patients and captured cumulative HCQ exposure, ophthalmologic screening adherence, and SLE activity preceding and following drug cessation. Ophthalmology notes were reviewed to assess for stability or progression of OCT imaging and/or Humphrey Visual Fields after discontinuation.

Table 1. Demographic characteristics of cohort.

Sex		N (%)
	Female	26 (93%)
	Male	2 (7%)
Race		
	White	13 (46%)
	Asian	9 (32%)
	Black	5 (18%)
	Other	1 (4%)
Ethnicity		
	Non-Hispanic	9 (32%)
	Hispanic	19 (68%)

Factor	Progressed	Did not progress	P-value
Age (years)	Mean: 60.3 Median: 61	Mean: 49.7 Median: 50	**0.033**
Cumulative HCQ exposure (g)	Mean: 2033.7 Median: 1365.0	Mean: 1329.6 Median: 1204.5	0.704 (NS)
Duration of HCQ therapy (years)	Mean: 13.67 Median: 13	Mean: 13.87 Median: 16	0.949 (NS)
Ophthalmology visit interval	≤1 year: 87.5% >1 year: 12.5% Unknown: 0%	≤1 year: 53.3% >1 year: 13.3% Unknown: 33.3%	0.176 (NS)
SLEDAI-2K score	Mean: 2.3 Median: 3.0	Mean: 2.5 Median: 2.0	0.885 (NS)
SLICC Damage Index	Mean: 3.8 Median: 3.0	Mean: 3.8 Median: 3.0	0.501 (NS)

Results: Among 28 patients with confirmed HCQ retinopathy, 13 (46%) were White, 9 (32%) Asian, 5 (18%) Black, and 1 (4%) other; 9 patients (32%) identified as Hispanic; 26 (93%) were female. The average age at diagnosis was 53.3 years. The mean cumulative HCQ exposure across all patients with retinal toxicity was 1,827 g (SD 1,442 g) over a mean of 14.0 years (SD 8.1). Most patients (57%) were seeing ophthalmology at least yearly, while a smaller proportion (18%) had screening lapses preceding their diagnosis. At diagnosis of retinopathy, the mean SLEDAI-2K score was 2.3, and the average SLICC Damage Index was 3.13.

Retinal toxicity progressed in 35% of patients despite drug discontinuation. Patients who progressed were significantly older than those who did not (60.3 vs 49.7 years, p = 0.033). No statistically significant associations were found between retinopathy progression and race, ethnicity, cumulative HCQ exposure, duration of therapy, SLICC Damage Index, SLEDAI-2K or ophthalmology screening interval.

Conclusion: In this SLE-specific cohort with confirmed HCQ-induced retinopathy, retinal toxicity progressed in a third of patients despite HCQ discontinuation. There was a significant association between age and retinopathy progression despite equivalence of cumulative dosing and ophthalmologic screening intervals. These findings support the consideration of more frequent monitoring in older patients.

Abstract Number: 2445

Achievement of Treat to Target Measures with Upadacitinib in Patients with Systemic Lupus Erythematosus: Phase 2 Randomized Sleek Clinical Trial Results

Eric Morand[1], Joan Merrill[2], Martin Aringer[3], Zahi Touma[4], Richard Furie[5], Karim Masri[6], Christopher Saffore[7], Ling Cheng[8] and Ronald van Vollenhoven[9], [1]Centre for Inflammatory Diseases, Monash University and Monash Health, Melbourne, Victoria, Australia, [2]Oklahoma Medical Research Foundation, Oklahoma City 73104, OK, [3]University Medical Center, Dresden, Germany, [4]University of Toronto, Toronto, ON, Canada, [5]Division of Rheumatology, Northwell Health, Great Neck, NY, [6]AbbVie Inc., North Chicago, IL, [7]AbbVie Inc., waukegan, IL, [8]AbbVie, North, IL, [9]Department of Rheumatology, Amsterdam University Medical Centre, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

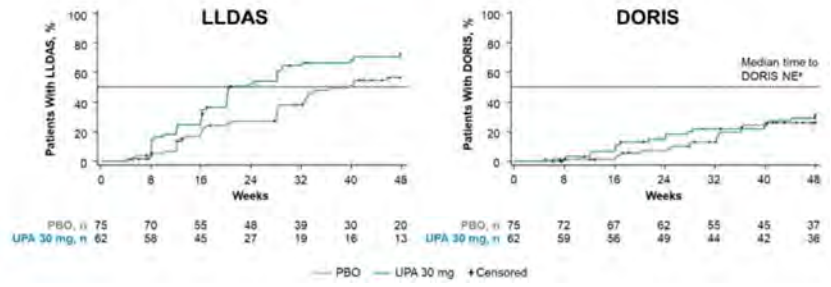
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Achievement of treat-to-target measures Lupus Low Disease Activity State (LLDAS) and Definition of Remission in SLE (DORIS) has been associated with improved outcomes and quality of life in patients with systemic lupus erythematosus (SLE).[1,2] Upadacitinib (UPA), an oral, selective JAK inhibitor, reduced SLE disease activity in the phase 2, randomized, double-blind SLEek study (NCT03978520) of adults with moderately to severely active SLE.[3] In this post hoc analysis of SLEek, we evaluate the achievement of LLDAS and DORIS with upadacitinib (UPA) monotherapy (30 mg) vs placebo (PBO).

Methods: LLDAS was defined as meeting a clinical SLE Disease Activity Index 2000 (SLEDAI-2K) score ≤ 4, absence of SLE disease activity in major organ systems, no new disease activity, by clinical criteria including SLE Disease Activity Index 2000 (SLEDAI-2K) score ≤ 4, no major organ activity, a Physician Global Assessment (PhGA) score ≤ 1, glucocorticoid (GC) dose ≤ 7.5 mg/day, and stable maintenance doses of standard immune-modulating drugs. In this analysis, DORIS was defined as meeting a clinical SLEDAI-2K score of 0, PhGA score < 0.5, GC ≤ 5 mg/day, and stable maintenance doses of standard immune-modulating drugs but with stricter criteria. Data were reported based on nonresponder imputation incorporating multiple imputation for missing data due to COVID-19. Between-group differences were adjusted using the Cochran-Mantel-Haenszel test and Cox proportional hazard model; adjustments were made for SLEDAI-2K score at screening (<

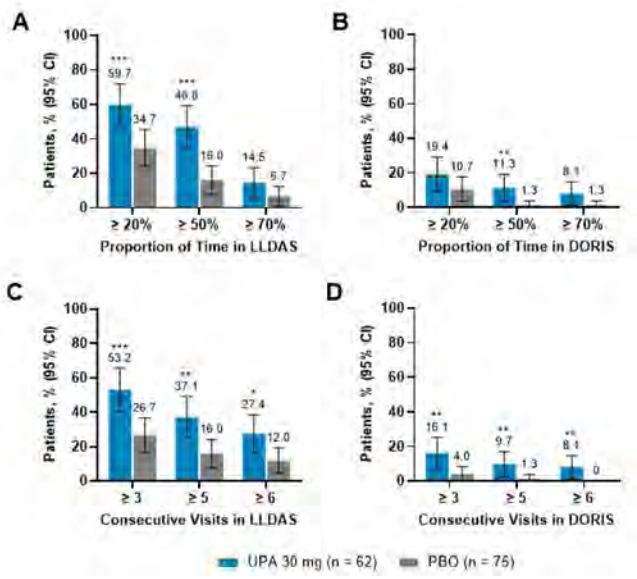
Figure 1. Time to First Reaching LLDAS or DORIS



DORIS, Definition of Remission in SLE; LLDAS, Lupus Low Disease Activity State; NE, not estimable; PBO, placebo; SLE, systemic lupus erythematosus; UPA, upadacitinib. Horizontal dashed lines are located at 50% on the y-axis. Vertical dashed lines represent the median time to first response for each treatment group. aThe median time to reach DORIS could not be estimated due to < 50% of participants reaching DORIS at any time point for either treatment group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 2. Cumulative Time in (A) LLDAS and (B) DORIS and Sustained Consecutive Monthly Visits in (C) LLDAS and (D) DORIS



DORIS, Definition of Remission in SLE; LLDAS, Lupus Low Disease Activity State; PBO, placebo; SLE, systemic lupus erythematosus; UPA, upadacitinib. *P < .05; ** P < .01; *** P < .001 vs placebo.

10 or ≥ 10), baseline GC dose (< 10 mg or ≥ 10 mg), baseline immunosuppressant use (yes or no), and baseline IFN score (high, low, or not applicable). No multiplicity adjustments were applied; all P values are nominal.

Results: Data were included from 137 patients (UPA 30 mg, n = 62; PBO, n = 75; female: 96.4%, White: 56.2%). Rates of achievement of LLDAS and DORIS, respectively, with UPA vs PBO at week 48 were 50.0% vs 24.0% (P < 0.001) and 19.4% vs 9.3% (P = 0.063). Median time to first achievement of LLDAS was shorter with UPA vs PBO (20.4 vs 39.9 weeks; HR [95% CI]: 2.0 [1.2, 3.2]; P = 0.005); median time to DORIS could not be estimated due to < 50% of patients achieving DORIS at any time point (**Figure 1**). Cumulative % of time spent in LLDAS and DORIS was greater with UPA vs PBO; LLDAS: LS mean [95% CI]: 28.9% [19.8, 38.1] vs 12.5% [4.6, 20.5]; P = 0.001; DORIS: 9.1% [3.4, 14.7] vs 3.0% [–1.9, 8.0]; P = 0.051. Higher proportions of patients were in LLDAS or DORIS for various cumulative proportions of time with UPA vs PBO, and the proportions of patients who sustained LLDAS or DORIS for ≥ 3, ≥ 5, and ≥ 6 consecutive monthly visits were higher with UPA vs PBO (P < 0.05 for all; **Figure 2**).

Conclusion: Patients with SLE who received UPA achieved higher rates of LLDAS and DORIS, had a shorter time to first LLDAS, spent more cumulative time in LLDAS and DORIS, and experienced more consecutive visits in these states versus PBO. These data support the potential benefit of UPA in achieving stringent SLE treat-to-target measures.

Use of Voclosporin in Pediatric Patients: A Summary of Available Data from Post-marketing Reports

Eugenia Chock[1], Ankana Daga[2], Tasim Begum[3], Kathryn Dao[3] and Michelle Dardeno[3], [1]Yale School of Medicine, New Haven, CT, [2]Boston Children's Hospital, Boston, MA, [3]Aurinia Pharmaceuticals Inc., Rockville, MD

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Lupus nephritis (LN) is common in pediatric patients with systemic lupus erythematosus (SLE), with more than 50% developing renal manifestations, typically within the first 2 years. Treatment options for this patient population have been inadequately studied.[1]

Voclosporin is approved for use in adult patients with active LN. The Phase 3 AURORA studies showed that in patients ≥18 years, adding voclosporin to MMF and low-dose glucocorticoids yielded significant reductions in proteinuria with no unexpected safety signals associated with up to 3 years of treatment.[2,3]

The safety and efficacy of voclosporin in patients < 18 years old has not been established. A study in the pediatric population is ongoing (Voclosporin in Adolescents with Lupus Nephritis [VOCAL; NCT05288855]). There have been reports of off-label voclosporin use in patients < 18 years captured in Aurinia's global safety database as part of post-marketing spontaneous safety surveillance. Our objective was to summarize the post-marketing experience with voclosporin in the pediatric population.

Table 1. Summary of Serious Adverse Events

Serious reported adverse events*, n (%)	18/93 (19%)
Hospitalization	14
Reason unknown, after voclosporin initiation	2
Reason unknown, before voclosporin initiation	1
Reason unknown, unknown timing in relation to voclosporin	1
High creatinine and full blood count decreased	1
Asthma attack	1
High blood pressure	1
Sepsis	1
High potassium	1
Kidney problems	1
Lupus flare	1
Lupus flare, acute kidney injury, and COVID-19	1
Liquid retention	1
Urinary tract infection	1
Medically Significant	4
Renal failure	1
Stills disease	1
Seizure	1
Chronic kidney disease and hydrocephalus	1

*Events described as reported and entered in the Aurinia Global Safety Database.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Data included in this analysis were collected up until January 21, 2025, from the Aurinia Global Safety Database, which contains spontaneous, post-marketing reports of pediatric use. Post-marketing safety data are collected via a passive surveillance system with limitations, including possible underreporting, biased or incomplete reporting, and difficulties in attributing an adverse event (AE) to any specific drug. Use of voclosporin in patients < 18 years is considered an off-label use and is tracked in the safety database even in the absence of associated AEs. Data from the ongoing VOCAL study are not included in this analysis.

Results: As of January 21, 2025, 93 reports of pediatric use of voclosporin (in 70 unique patients) had been received, the majority from the US. Patients ranged in age from 7 to 17 years old and were mostly female. The most common indication for voclosporin was LN (83.8%). In most cases, the dose of voclosporin administered was the approved adult dose (23.7 mg twice daily; 57/93 reports). The duration of use of voclosporin was not consistently reported; where reported, the duration ranged from several weeks to 1 year, 9 months. In total, 44 of the 93 (47%) individual reports of pediatric use did not include any associated AEs following the initiation of voclosporin other than off-label use and other non-health-related events (ie. therapy interrupted, missed dose, insurance issue). Of the individual reports of pediatric use with associated AEs, 18 were considered to be serious (Table 1). There were no particular trends in the AEs reported. Data on kidney biopsies and concomitant medications were not consistently available.

Conclusion: Due to the limited number of reports and incomplete nature of spontaneous reporting, the emerging safety profile of voclosporin in pediatric patients requires further investigation, although no new safety signals were detected. Additional research is needed to better characterize the use of voclosporin in this population.

SLE disease course (ref.≥7 years)	0.282	0.108-0.735	***0.010***	0.136	0.011-1.730	0.124	0.481	0.037-6.249	0.576
Total B lymphocytes % (ref. ≥9%)	2.185	0.848-5.635	0.106	0.289	0.024-3.543	0.332	0.132	0.011-1.646	0.116

Methods: A prospective cohort of SLE treated with belimumab was established, with record assessments every 3 months after baseline and every 6 months after 12 months of belimumab infusion. Patients' baseline clinical data, SLE disease assessment data, and treatment regimens were collected, and latent class trajectory modeling was used to identify the trajectory of change in patients' SLE Disease Activity Index 2000 (SLEDAI-2K) scores during the follow-up period and multinomial logistic regression analyses were used to assess the baseline clinical characteristics associated with each group.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 169 patients with SLE with belimumab were enrolled in the study, including 155 females (91.7%). The median age of patients at baseline was 34 years, and the median duration of SLE was 7 years. The baseline SLEDAI score of the enrolled patients was 7.8±5.1. Three different SLEDAI-2K score change trajectories were identified through trajectory modeling: 24.3% in the rapid improvement group, 71.0% in the slow improvement group, and 4.7% in the disease fluctuation group. Of the three groups, patients in the disease fluctuating group were more likely to have renal involvement (*P*=0.012) and had the highest baseline urinary protein quantification (*P*=0.000), compared to the slow improvement group, and patients in the slow improvement group had the lowest baseline prednisone dose of the three groups (*P*=0.000). Using multinomial logistic regression analysis, it was found that SSA antibody positivity was more closely associated with patients in the slow improvement group (OR 25.738, *P*=0.041) or the rapid improvement group (OR 33.679, *P*=0.026) compared to patients in the fluctuating group.

Conclusion: SLEDAI-2K changes in SLE patients treated with belimumab can be divided into three different response trajectory groups: the rapid improvement group, the disease fluctuating group, and the slow improvement group. Early initiation of belimumab in patients with active SLE may enhance their therapeutic response and improve their prognosis. In patients with lupus nephritis, regular follow-up can help detect disease recurrence at an early stage and reduce the overall risk of disease damage.

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rituximab (RTX) has been commonly used for the treatment of patients with severe or refractory systemic lupus erythematosus (SLE), yet real-world data concerning RTX as the first-line treatment in newly diagnosed moderate-to-severe SLE patients is lacking.

Methods: We conducted a retrospective cohort study using a newly diagnosed (< 3 months) hospitalized Systemic Lupus Inception Cohort (hSLIC) at our center between 1 April 2013 and 1 September 2022. All patients were followed up for at least 12 months or until death. The cohort included patients on RTX (n=104) as the first-line treatment and those on conventional immunosuppressants (IS) (n=154) as comparators. Propensity score-based inverse probability of treatment weighting (IPTW) was used to minimize possible confounding factors. Primary outcome analyses included attainment of modified lupus low disease activity state (mLLDAS) and remission, by 12 months. Secondary outcomes focused on mortality, major flare rates, and the incidence of adverse events of interest, i.e., major infections.

Results: After IPTW, 76.0%/50.5% of RTX-treated patients achieved mLLDAS/remission versus 45.8%/9.7% in the conventional IS group during 12 months follow-up, respectively (p=0.005 and p< 0.001). Sensitivity analyses with renal or neuropsychiatric lupus removal and timeline breakout (pre versus post November 2019) confirmed the robustness of RTX's

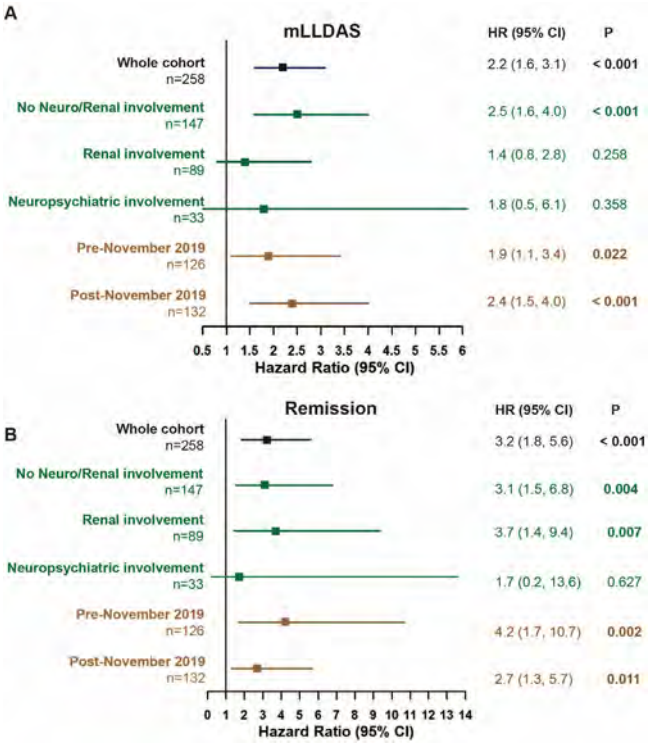

Figure 2. Treat-to-target outcomes. Attainment of mLLDAS (A) and remission (B) within 12 months in the whole cohort and sensitivity analyses (rituximab versus conventional immunosuppressants group). The model was adjusted for age, gender and maximum prednisone dosage. Pre-November 2019 (no COVID-19 exposure): Patients who completed their 12-month follow-up before November 2019. Post-November 2019 (COVID-19 exposure): Patients who completed their 12-month follow-up after November 2019. CI: Confidence interval; mLLDAS: modified lupus low disease activity state; SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index 2000. Neuro: Neuropsychiatric; HR: Hazard ratio. At 12-month, follow-up data were missing for 12 out of 258 patients (4.6%) (3 in the RTX group and 9 in the conventional IS group). The last observation carries forward (LOCF) method was employed to address the missing data in the endpoint assessment by 12-month.

efficacy in achieving mLLDAS and remission outcomes. Additionally, the incidence of major infections was similar between the two groups (12.5% vs. 8.4%, p=0.288).

Conclusion: In patients with newly diagnosed moderate-to-severe SLE, upfront treatment with RTX was associated with improved clinical outcomes compared to conventional immunosuppressive therapy, in terms of achieving low disease activity or remission by 12 months.

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Neuromyelitis optica spectrum disorder (NMOSD) can coexist with systemic lupus erythematosus (SLE) and Sjögren's syndrome (SS). Due to overlapping clinical presentations and the rarity of these conditions, specific treatment strategies for acute-phase NMOSD with SLE (NMOSD/SLE) and NMOSD with SS (NMOSD/SS) are lacking. This study aimed to investigate the clinical characteristics, treatment and prognosis of patients with NMOSD/SLE and NMOSD/SS.

Methods: This retrospective descriptive study utilized the Diagnosis Procedure Combination (DPC) database, a nationwide inpatient database in Japan. We identified patients with NMOSD (ICD-10 codes, G360) between 2010 and 2023. Patients were categorized into three groups: NMOSD alone, NMOSD/SLE and NMOSD/SS. We extracted clinical data during hospitalization and compared patient characteristics, treatments and outcomes between these groups.

Results: A total of 8,029 patients were included: NMOSD alone (n=7,507), NMOSD/SLE (n=217), and NMOSD/SS (n=305). The median age was 55 years and 76% were female. NMOSD/SLE patients had a higher burden of comorbidities compared to those with NMOSD alone or NMOSD/SS. The treatment regimen included more frequent use of plasma exchange and cyclophosphamide, and a wider use of immunosuppressive agents in NMOSD/SLE patients. The percentage of plasma exchange were: NMOSD alone 31.1%, NMOSD/SLE 44.2%, NMOSD/SS 36.1% (p< 0.001). The percentage of intravenous cyclophosphamide administration were: NMOSD alone 0.4%, NMOSD/SLE 4.1%, NMOSD/SS 2.3% (p< 0.001). The percentage of rituximab administration were: NMOSD alone 0.4%, NMOSD/SLE 1.4%, NMOSD/SS 0.3% (p=0.056). The most common disease-modifying antirheumatic drug was azathioprine (NMOSD alone 11.3%, NMOSD/SLE 46.1%, NMOSD/SS 18.7%, p< 0.001), followed by tacrolimus, cyclosporine, and mycophenolate mofetil. Crude in-hospital mortality was 1.3%. There was no significant difference in in-hospital mortality across all groups; however, NMOSD/SLE patients had better activities of daily living scores and were more likely to be discharged to home. The proportion of patients with a Barthel index of 100 (total independent) in the three groups were: NMOSD alone 57.7%, NMOSD/SLE 60.8%, NMOSD/SS 50.2% (p=0.006). The percentage of discharge to home were: NMOSD alone 74.1%, NMOSD/SLE 83.4%, NMOSD/SS 69.2% (p=0.001).

Conclusion: Although NMOSD/SLE patients had a greater burden of comorbidities, they received a broader range of treatments during the acute phase and showed favorable outcomes in terms of functional status and discharge to home.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Anifrolumab is a biologic recently approved for systemic lupus erythematosus (SLE), with efficacy shown in trials, but data from real-world practice remain limited. The aim of this registry is to evaluate the effectiveness and safety of anifrolumab at 3 and 6 months (m) in SLE patients under real-life routine care in Spanish rheumatology centers.

Methods: Multicenter, observational, ambispective study including SLE patients (2019 EULAR/ACR criteria) from 28 centers, treated with anifrolumab and followed at baseline, 3, and 6m. Clinical, lab, and treatment data were collected. Disease activity (SLEDAI-2k, SLE-DAS, PGA), damage (SLICC/ACR/DI), remission (DORIS-21), low disease activity (LLDAS), acute-

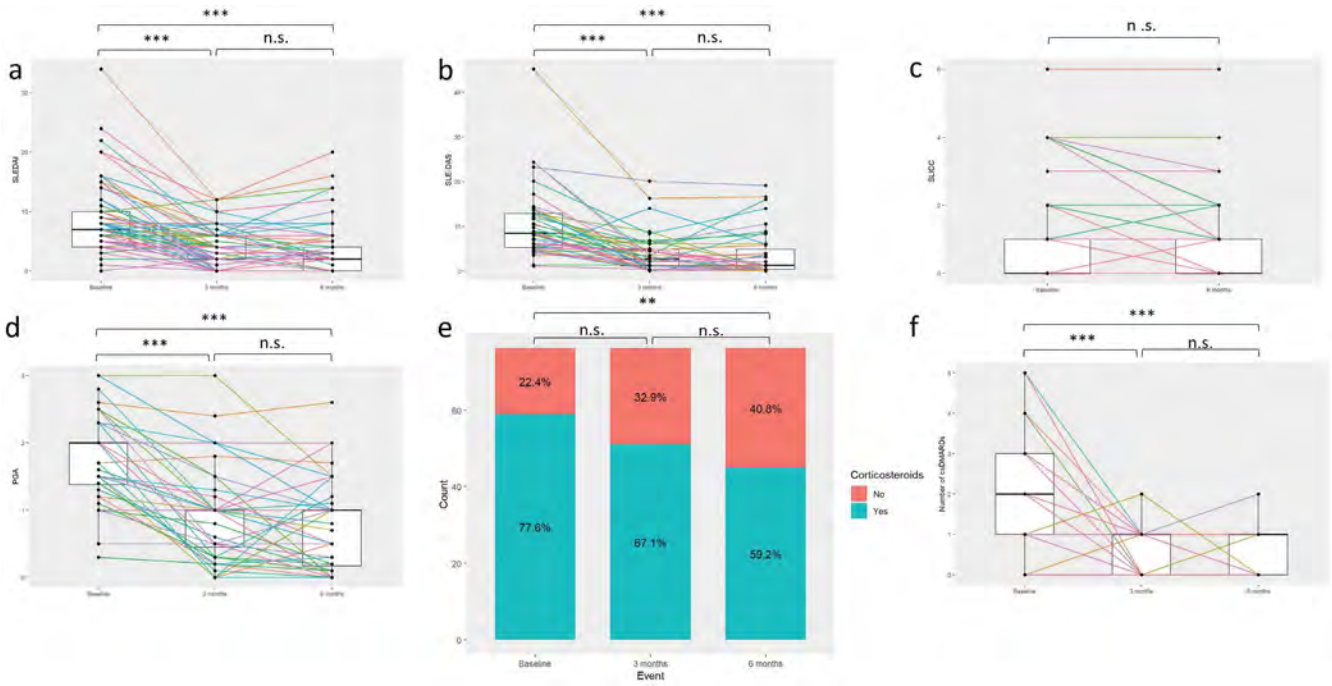

Figure 1: Statistically significant differences in disease indices between the baseline visit and the visits at 3 and 6 months after the start of anifrolumab. p-values significance level: n.s.: > 0.5; * < 0.05–0.01; ** < 0.01–0.001; *** < 0.001. a): SLEDAI – Systemic Lupus Erythematosus Disease Activity Index (n = 77); b) SLE-DAS – Systemic Lupus Erythematosus Disease Activity Score (n = 43); c) SLICC – Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (n = 73); d): PGA – Physician Global Assessment (n = 52); e) Glucocorticoids yes/no (n = 76); f) Number of disease modifying antirheumatic drugs with anifrolumab (n = 76).

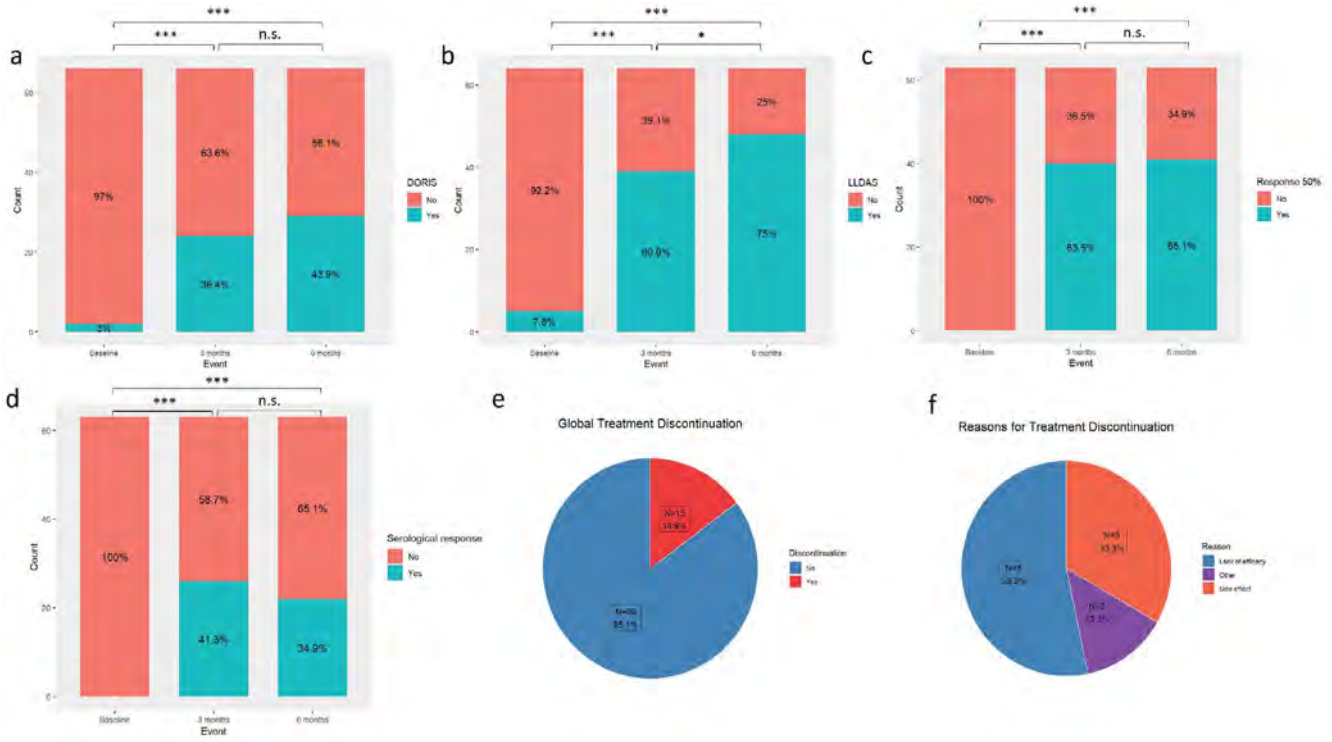

Figure 2: Statistically significant differences in response indices and discontinuation between baseline and the visits at 3 and 6 months after the initiation of anifrolumab. p-values significance level: n.s.: > 0.5; * < 0.05–0.01; ** < 0.01–0.001; *** < 0.001. a) DORIS – Definition of Remission in Systemic Lupus Erythematosus (n = 66); b): LLDAS – Lupus Low Disease Activity State (n = 64); c): 50% response (n = 63); d) Serologic response (n = 63); e) Treatment discontinuation; f) Reasons for treatment discontinuation.

phase reactants (CRP, ESR), response to treatment and medication changes were assessed. Efficacy and security comparisons across visits were done using Friedman's test (adjusted by Holm's method) and Cochran's Q with McNemar's test (Bonferroni correction) for binary outcomes.

Results: Among 133 patients, 100 completed the 3-month visit and 82 the 6-month visit. Median age was 49 years (IQR ±17), and time from diagnosis was 31 years (±16); 87.9% were female, 77.3% Caucasian and 14.4% Hispanic; 56.5% were currently employed and 19.8% were active smokers. Significant improvements at 3 and 6m compared with the baseline visit were observed in SLEDAI, SLEDAS, PGA, the percentage of patients in remission DORIS-21 and in low disease activity (LLDAS), and the number of concomitant disease modifying antirheumatic drugs, and in those receiving glucocorticoids 6m after initiation of anifrolumab vs. the basal visit (Fig. 1-2). Flare counts significantly dropped from 2 (±2) at baseline to 0 (±0 at 3m and ±1 at 6m). Response rates were: physician's criteria 77.1% at 3m and 75.7% at 6m; 50% response in 63.5% and 65.1%; 20% response in 83.6% and 74.5%; serological response in 41.3% and 34.9% (all p = not significant) (Fig. 2).

Discontinuation occurred in 5/95 patients (5%) before 3m and 10/72 (12.2%) between 3–6m. Fourteen hospital admissions (10.5%) occurred during those 6m: 5 due to SLE activity, 2 to infections, 3 to both SLE activity and infection and 4 to other reasons. Five (3.8%) patients presented a COVID-19 and 4 (3%) a herpes zoster infection since anifrolumab onset. One new case of depression and 2 new psychotropic treatments were noted. None of the patients died since starting anifrolumab. There were no differences in either SDI at baseline vs. 6m (0 ± 1 vs. 0 ± 1), or anti-dsDNA titers, C-reactive protein levels or glucocorticoid dose among any of the 3 visits.

Conclusion: In real-life clinical practice, anifrolumab improved multiple SLE activity measures at 3 and 6 months, with a substantial proportion of patients achieving LLDAS or DORIS-defined remission, along with reduced flare rates and background immunosuppressive use, and no new major safety concerns.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Photosensitivity lowers quality of life in patients with cutaneous lupus erythematosus (CLE) and puts patients with systemic lupus erythematosus (SLE) at risk of systemic disease flare. Janus kinase (JAK) inhibitors can reduce Type I interferons (IFNs) in the skin, where they are important drivers of photosensitivity. In addition, JAK inhibitors can interrupt neutrophil NETosis, a potentially important cell population in CLE. We thus examined the impact of JAK blockade in patients with a history of CLE.

Methods: We conducted a proof-of-concept mechanistic study in patients with a history of CLE, either in isolation or with associated SLE. Participants underwent phototesting with 0, 10, 20, 30, 40, 50, 60, 70 and 80 mJ/cm^2 UVB prior to initiation of a 3-week course of 11 mg XR tofacitinib PO daily followed by repeat phototesting after drug completion. Biopsies were taken from unexposed skin, the initial minimal erythema dose (MED) site and from the site corresponding to the next highest UVB dose (MED+1) from initial and follow-up phototesting for mechanistic studies. The primary endpoint was the change in percentage of UVB-induced apoptotic epidermal cells from Day 1 (pre-treatment) to Day 26 (post-treatment). Safety and disease activity metrics were assessed.

Results: Seven patients were enrolled and 6 patients completed the study. Participant data can be seen in Table 1. A single grade 2, unrelated adverse event (AE) was reported and no participant withdrew due to an AE. The mean change in percent of apoptotic epidermal cells following tofacitinib treatment was -17.03% (SD 8.355). Analyses of secondary outcomes

None	2 (28.6)

Note: Percentages are based on the number of participants with evaluable data.
[1] Participants may be counted more than once if they were taking more than one type of lupus medication at baseline

comparing pre vs. post tofacitinib showed no change in MED, no change in CLASI activity and damage scores, and no change in SLEDAI. A varied response to tofacitinib was observed within and across participants in gene transcripts via bulk RNA sequencing for UVB-mediated cutaneous gene expression for *IL6, IFNB, IFI44, TNFA, IL1B*, and *CXCL9*. However, single cell spatial transcriptomics revealed that following tofacitinib treatment, there was a significant decrease (FDR $\leq$1.0E-03) in UVB-induced type I IFN-regulated genes in many cell populations, including keratinocytes and fibroblasts, and a reduction in genes regulating antigen presentation and cytotoxic T cell activation in myeloid cells, such as *SIGLEC1, CCL5, CD1C, CD207, MX1*, and *IFI44L*. All patients demonstrated a significant reduction from baseline in PMA-stimulated production of neutrophil extracellular traps (NETs) from circulating neutrophils following administration of tofacitinib, and there was a trend towards decreased neutrophil staining in the UVB-treated skin as well.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: A 3-week course of tofacitinib was well-tolerated and reduced epithelial apoptosis after UVB exposure in patients with a history of CLE. Single cell resolution spatial transcriptomics identified cell-specific inflammatory gene reductions in the presence of tofacitinib following UVB exposure. The principal limitation of the trial was the small sample size. Additional studies are needed to investigate whether JAK inhibition is a viable strategy for reduction of photosensitivity and prevention of UVB-mediated skin and systemic disease flares.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) and anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV) are autoimmune conditions characterized by B cell activation, autoreactivity, and autoantibody production. CAR-T therapy has emerged as a promising strategy to deplete autoreactive B cells and induce sustained remission. This study

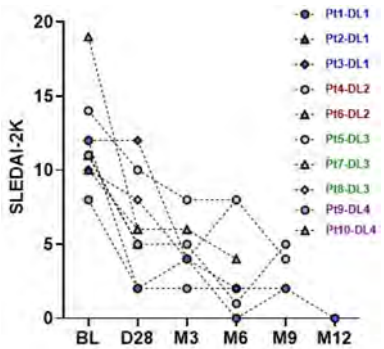

Figure 1. SLEDAI-2K score

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. CAR-T cells

evaluates the safety, efficacy and cellular kinetics of CTA311, a CD19 targeted "off-the-shelf" universal CAR-T product, in patients with active autoimmune disease.

Methods: Patients received a single administration of CTA311 treatment at 4 dose levels (DLs): DL1 as 0.2 $\times 10^6$ CAR+T cells/kg, DL2 as 1×10^6 CAR+T cells/kg, DL3 as 3×10^6 CAR+T cells/kg, DL4 as 6×10^6 CAR+T cells/kg following lymphodepletion with cyclophosphamide (300mg/m^2/day×3) and fludarabine (30 mg/m^2/day×3). Clinical activity assessments include disease activity scores (SLEDAI-2K) and Physician's Global Assessment (PGA).

Results: As of April 30, 2025, eleven patients (10 SLE and 1 AAV) received CTA311 at various doses, DL1 (n=3), DL2 (n=2), DL3 (n=3), and DL4 (n=3). Ten (91%) patients were female, median age 31 (range 25-55) years, median disease duration 6 (range 1-23) years. All had previously been treated with steroids and immunosuppressants, and 6 patients received biological agents (3 telitacicept, 1 belimumab, and 2 both).

Treatment was well tolerated; CRS events occurred in 82% (n=9), all low grade (G) (7 G1 and 2 G2). No neurotoxicity was reported. Transient lymphodepletion-related cytopenia (< 28 days) were observed in all patients. Three patients experienced infections deemed to be treatment related (1 pt with pneumonia (G3) and CMV reactivation (G1), 1 pt with fungal infection (G2), and 1 pt with infection NOS (G1)), which all completely resolved within 2 months.

Preliminary efficacy indicated reductions in SLEDAI-2K and PGA accompanied by improvements in autoantibodies, C3, and proteinuria. All 10 patients achieved a Systemic Lupus Erythematosus Responder Index-4 (SRI-4) response, and Lupus Low Disease Activity State (LLDAS) was attained in 4 patients. Two patients achieved DORIS remission. The AAV patient's BVAS score improved from 8 at baseline to 0 at M3 and M4. However, patient resurgence of mild arthritis) M6. All patients discontinued immunosuppressants and decreased/stopped steroid (≤10 mg/d).

PK analysis revealed median peak expansion (C_{max}) of 93,679 (range 84-1,091,116) copies/ug DNA approximately 7-11 days post-infusion. Complete B cell depletion was observed by Day 4 post-infusion and persisted for about 1-3 months. In pts that achieved dsDNA Ab eradication, the Ab remained undetected up to 12 months, and ongoing, despite B-cell recovery.

Conclusion: Preliminary data suggest favorable safety, CAR-T cell expansion, B cell depletion and promising efficacy of CTA311 in B cell-mediated autoimmune diseases. Ongoing follow up and enrollment in additional indications will provide insights into long-term safety and efficacy.

Background/Purpose: LN develops in ~40% of patients with SLE and is associated with increased risk of morbidity, including end-stage kidney disease, and mortality. Belimumab, a B-cell modulator that targets the central immunopathogenic pathway in SLE by selectively inhibiting B-lymphocyte stimulator, has been shown to prevent organ damage progression in SLE and preserve kidney function in LN. This study evaluated whether belimumab is associated with a protective effect and lower risk of progression to LN among patients with SLE versus standard of care (SOC) in real-world clinical practice, by comparing time to initiation of LN therapy.

Methods: A retrospective, longitudinal cohort study (GSK Study 217533) was conducted using claims linked with electronic health record data from the Optum Market Clarity database. Index was defined as the date of initiation of belimumab or SOC (immunosuppressant [IS, except for use in LN initial therapy], intravenous glucocorticoids [GCs], or oral GC escalation to ≥20 mg/day prednisone-equivalent) between Jan 1, 2017, and Mar 31, 2023. The unit of analysis was treatment episode and patients could be included in both study cohorts if they received both belimumab and SOC during the study period. Patients were ≥18 years old with an SLE diagnosis and had ≥12 months continuous enrollment pre-index. Those with LN diagnosis or LN induction therapy prior to the index date were excluded. Initiation of LN induction therapy served as a proxy for incident LN and was defined as earliest use of: subcutaneous belimumab 400 mg once-weekly for four doses; voclosporin; cyclophosphamide (either monotherapy or combined with MMF or azathioprine); high-dose MMF. For each treatment episode, the observation period spanned from index to the earliest of: end of continuous enrollment, end of data availability, death, or treatment switch. Time to initiation of LN induction therapy was assessed using a Cox proportional hazards (PH) model with a robust (Huber-White sandwich) variance estimator, weighted by average treatment effect among the treated weights (ATT-weights) based on propensity-score, and with covariates that remained imbalanced after weighting included in the model for a doubly robust approach.

Results: In total, 1408 belimumab and 74,288 SOC patients were included and contributed 3727 belimumab and 3621 SOC treatment episodes to the analysis. Prior to weighting, belimumab patients were younger (median age 47 vs 53 years) and more likely to have moderate (53.5% vs 31.0%) than mild (18.9% vs 42.9%) SLE severity and a greater number of SLE treatment types at baseline. ATT-weighted baseline characteristics (**Table**) were similar between treatment cohorts. The number of IS, oral GC, and antimalarial therapies remained imbalanced after weighting and were further adjusted in the Cox PH model. Patients receiving belimumab had a significantly lower hazard of initiating LN induction therapy versus SOC (hazard ratio [95% CI]: 0.77 [0.62, 0.95]).

Conclusion: Belimumab use was associated with a lower risk of initiating LN induction therapy versus SOC among patients with SLE, suggesting a potential renal protective effect through which belimumab may prevent progression to LN.

Abstract Number: 2454

Longitudinal Analysis of B cell Remodeling in Systemic Lupus Erythematosus Following iPSC-Derived CAR T-cell Therapy

Jonatan Tuncel[1], Trever Greene[2], Nicholas Brookhouser[2], Sandeep Kothapally Hanok[1], Seth Peng[1], Alison O'Conor[1], Parastoo Fazeli[3], Jennifer Medlin[4], Cara Bickers[2], Kelsea Hubka[1], Allison Aguilar[1], Wei Zhao[1], Kyla Omilusik[1], John Goulding[1], Tom Lee[2], Jode Goodridge[2], Marie Hu[5], Veronika Bachanova[5], Jeffrey Miller[6], Matthew Lunning[7], Rebecca Elstrom[2], Debra Zack[1], Vaneet Sandhu[2], Bahram Valamehr[8] and Lilly Wong[8], [1]Fate Therapeutics, San Diego, [2]Fate Therapeutics, Inc., San Diego, [3]UMN, ST PAUL, MN, [4]University of Nebraska Medical Center, Omaha, NE, [5]University of Minnesota, Minneapolis, [6]University of Minnesota, Minneaspolis, MN, [7]University of Nebraska Medical Center, Omaha, [8]Fate Therapeutics, Inc., San Diego, CA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Autologous chimeric antigen receptor (CAR) T-cell therapy is an exciting new potential therapy for autoimmune diseases but limited in scope of application by logistical complexity and cost of treatment. Furthermore, autoimmune patients will benefit from CAR T cell protocols that omit intensive conditioning chemotherapy (CCT) and integrate with their existing treatments. Here, we report 3-12 month follow-up data from our ongoing Phase I trial of FT819, an off-the-shelf iPSC-derived CD19-targeted CAR T-cell therapy, for the treatment of B-cell mediated autoimmune diseases (NCT06308978). FT819 is engineered to improve the safety and efficacy of CAR T cell therapy and incorporates a novel 1XX CAR signaling domain that extends T cell effector function without causing exhaustion. The CAR transgene is integrated into the T cell receptor (TCR) alpha constant locus to promote uniform CAR expression and enhance potency, with bi-allelic disruption of TCR expression to completely prevent graft-versus-host disease.

Methods: All patients enrolled to date were treated with FT819 for moderate to severe systemic lupus erythematosus (SLE) and either received fludarabine-free CCT (bendamustine or cyclophosphamide) or received no CCT and continued their standard-of-care therapy. Blood samples were collected at protocol-specified timepoints for B cell analysis.

Results: At baseline, patients had a mean SLEDAI score of 16 and reduced proportions of naïve B cells compared with healthy controls (HC, 60.2% vs 70.2%), increased proportions of pathogenically associated double-negative (DN) B cells (18.4% vs 8.7%), and circulating plasmablasts (PB, 8.2% vs 2.0%). Clonal architecture, as determined by sequencing of the BCR heavy chain, showed an increase in class-switched BCRs (73.1% vs 45.8%), larger clone sizes (12.3% vs 6.5% of total reads assigned to the top 10 clones), and a less diverse repertoire (Shannon index: 7.5 vs 8.7). Following treatment in patients receiving CCT, and concurrent with the overall resurgence in total B-cell numbers (6-12 mo), proportions of PB and DN B cells returned to the range observed in HC, while naïve B cells expanded to a proportion higher than that seen in HC. Moreover, the average proportion of large clones fell by 73.2%, with 87% of pre-treatment dominant clones absent by 6 months. Repertoire diversity increased from 6.2 to 9.2, and IgG/IgA fractions dropped by 42.6% while IgM rose 2.5-fold. Importantly, these measures paralleled the reduction in SLEDAI in these patients. In the patient treated with FT819 in the absence of CCT, we observed an overall minor reduction in PB (3.3% vs 2.9%) and DN B cells (33.3% vs 25.8%), but no change in naïve B cells at month 3 follow-up. Additionally, we observed a shift toward IgM positivity that, together with observed improvement in SLEDAI, may suggest ongoing rejuvenation of the B-cell compartment.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Collectively, these findings demonstrate that FT819 can remodel the B-cell compartment toward a naïve and more diverse repertoire, even without CCT, supporting immune reset as a mechanism of clinical remission. This trial is actively enrolling, and updated patient data will be included at the time of presentation.

Abstract Number: 2455

Lupus Intervention Fatigue Trial: Preliminary Analysis of Baseline Data

Justin Arnold[1], Linda Ehrlich-Jones[2], Dominique Kinnett-Hopkins[3], Linda Van Horn[4], Grace Whiteford[4], Lutfiyya muhammad[5], Jing Song[6], Joan Chmiel[7], Rowland Chang[5], Pamela Semanik[7], Anh Chung[8], Daniel Erickson[4], Christie Bartels[9] and Rosalind Ramsey-Goldman[5], [1]Northwestern Feinberg School of Medicine, Chicago, IL, [2]Shirley Ryan AbilityLab, Aurora, IL, [3]University of Michigan, Ypsilanti, MI, [4]Feinberg School of Medicine, Chicago, [5]Northwestern University Feinberg School of Medicine, Chicago, IL, [6]Northwestern University Feinberg School of Medicine, Worthington, MN, [7]Feinberg School of Medicine, Chicago, IL, [8]Northwestern University, Chicago, [9]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is associated with persistent fatigue. Physical activity (PA) & dietary intake are potential modifiable behaviors that can reduce fatigue in people with SLE. The Lupus Intervention Fatigue Trial, LIFT (NCT02653287), a 12-month, phase II randomized, parallel-group, single-blind study compared motivational interviewing counseling targeting PA & diet with an education-based control program to reduce SLE fatigue. We also assessed neighborhood conditions measured by the Area Deprivation Index (ADI), as a potential factor impacting PA & diet.

Objectives: Present baseline descriptive results of LIFT participants. Assess associations between ADI and PA/diet intake.

Methods: LIFT criteria included age ≥18 yrs, English proficiency, walk household distances, BMI 18–40 kg/m^2, and meeting ACR or SLICC classification criteria for SLE. Accelerometers worn for 7 consecutive days during waking hours captured daily PA: sedentary < 100 counts/min, light PA (LPA) 101–2019 counts/min, and moderate-to-vigorous PA (MVPA) ≥2020 counts/min. Weekly MVPA=daily MVPA average x 7. Diet intake assessed via 24-hour recall from Nutrition Data System for Research (NDSR) generated Healthy Eating Index (HEI) total score (0-100) & food group scores 0-5 or 0-10) with higher scores being healthier. ADI derived from participants' 9-digit ZIP codes (higher ADI values indicate more deprivation, for 17 socioeconomic indicators). Patient-Reported Outcomes (PROs) used Fatigue Severity Score (FSS) & PROMIS measures for Fatigue, Pain Interference, Depression, Anxiety, Sleep Disturbance and Related Impairment, & Physical Function. Descriptive statistics were calculated; Spearman correlations used to assess associations between PA, or HEI and ADI.

Table 1. Baseline Characteristics of LIFT Participants (n=167)	
Patient Characteristics	
Age (years), mean (SD)	43.5 (13.0)
Sex, Female (n, %)	152 (91%)
Race (self-reported) (n, %)	
Asian	16 (9.6%)
Black or African American	54 (32.3%)
White	87 (52.1%)
Other/Unknown	9 (5.4%)
Ethnicity (n, %)	
Hispanic or Latino	25 (25%)
Not Hispanic or Latino	136 (81.4%)
Not Reported	6 (3.6%)
Education Level (n, %)	
High School Diploma/GED	9 (5.4%)
Some College	23 (13.9%)
2-Year College Degree	16 (9.6%)
4-Year College Degree	55 (33.1%)
Masters' Degree	42 (25.3%)
Doctoral Degree	12 (7.2%)
Professional Degree	9 (5.4%)
Unknown	1
BMI (kg/m^2), mean (SD)	27.1 (5.1)
Disease Measures	
SLICC DI Score, mean (SD)	1.2 (1.6)
SLEDAI Total Score, mean (SD)	2.9 (3.1)
SLEDAI <6 (n, %)	135 (81%)
SLEDAI >= 6 (n, %)	32 (18%)
Patient-Reported Outcomes	
Fatigue Severity Score (FSS), mean (SD)	4.3 (1.5)
PROMIS-Fatigue, mean (SD)	59.0 (9.0)
PROMIS-Pain Interference, mean (SD)	53.8 (9.9)
PROMIS-Depression, mean (SD)	50.4 (8.7)
PROMIS-Anxiety, mean (SD)	53.8 (9.0)
PROMIS-Sleep Disturbance, mean (SD)	52.6 (8.5)
PROMIS-Sleep Related Impairment, mean (SD)	54.2 (8.9)
PROMIS-Physical Function, mean (SD)	48.7 (7.6)

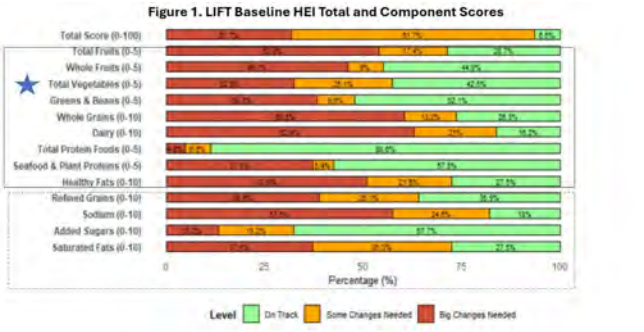
BMI=Body Mass Index; SLICC DI=Systemic Lupus International Collaborating Clinics Damage Index (range 0-53); SLEDAI=Systemic Lupus Erythematosus Disease Activity Index (range 0-105); FSS=Fatigue Severity Score (range 1-7);PROMIS measures (range 10-100, mean [SD] for US population 50 [10]); higher scores for all measures mean worse symptoms except for Physical Function where a lower score is better functioning

Table 2. Baseline Physical Activity (PA) Measures and Neighborhood Resources (ADI); Correlations Between PA and ADI in LIFT Participants (n=167)			
ADI Rank/Average PA Daily Minutes	**Mean (SD)**	**Spearman Correlation Between ADI and PA**	**P-value**
ADI	34.7 (21.4)	NA	NA
Sedentary	582.8 (92.8)	0.09	0.252
LPA	242.2 (75.5)	-0.08	0.299
MVPA*	**19.8 (19.4)**	**-0.20**	**0.009**
Total PA	262.3 (83.4)	-0.13	0.113

ADI=Area Deprivation Index; NA=not applicable; LPA=light physical activity; MVPA=moderate-vigorous physical activity; ***32.5% of LIFT participants met US guidelines of ≥150 minutes/week of MVPA**

Results: Baseline demographics, disease characteristics, PRO's, and HEI for 167 LIFT participants are shown in Table 1; Figure 1. Most participants had low disease activity, low damage scores, low total HEI score (poorer diet quality), and high FSS & PROMIS-Fatigue scores. Most participants lived in less deprived areas, ADI [mean 34.7 (21.4)]. Only 32.5% of participants met U.S. guidelines for PA (≥150 MVPA min/week); MVPA min/week was negatively correlated with ADI suggesting persons living in higher ADI deprivation areas had lower average MVPA minutes (Table 2). Recommended changes based on HEI score are in Figure 1. Modest statistical association was found between ADI (high) and total vegetable intake (low), rho=-0.15, p= 0.049.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Items within dashed box indicate one should eat less from food category, items within solid line indicate one should eat more from food category. Starred item indicates significant relationship between ADI and total vegetable intake, p=.049

Conclusion: Preliminary LIFT baseline data suggest despite low disease activity, LIFT participants have significant fatigue, 1/3rd meet PA guidelines (>150 mins/week of MVPA); lower HEI total and food group scores suggest need for improved diet quality. Mean MVPA minutes/week and total vegetable intake were negatively correlated with ADI rank showing those in higher ADI areas were less physically active and had poorer diet quality. Follow-up analyses will assess change in fatigue between baseline & 6 month visit to compare the intervention and control groups. Tailored interventions to address individual & contextual barriers may be needed to improve PA & HEI impact on fatigue.

Abstract Number: 2456

Predictors of Real-World Remission in Patients with SLE Initiating Belimumab in the USA

Aarat M Patel[1], Renee L. Gennarelli[2], Temitope Bello[2], Ali Bonakdar[2] and **Karen Worley**[3], [1]GSK, US Medical Affairs, Durham, NC, [2]Cencora, Real-World Evidence, Conshohocken, PA, [3]GSK, Global Real-World Evidence & Health Outcomes Research, Collegeville, PA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The Definition Of Remission in SLE (DORIS) criteria were developed to align SLE remission definitions.[1,2] Post hoc analyses of clinical trial data demonstrated that belimumab (BEL) plus standard therapy (ST) increases the proportion of patients with SLE in DORIS remission compared with placebo plus ST.[3] As real-world SLE remission data for patients in the USA initiating BEL are scarce and there is a lack of clarity on characteristics of patients achieving remission, this retrospective, observational cohort study (GSK Study 222161) explored predictors of remission in this patient population.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

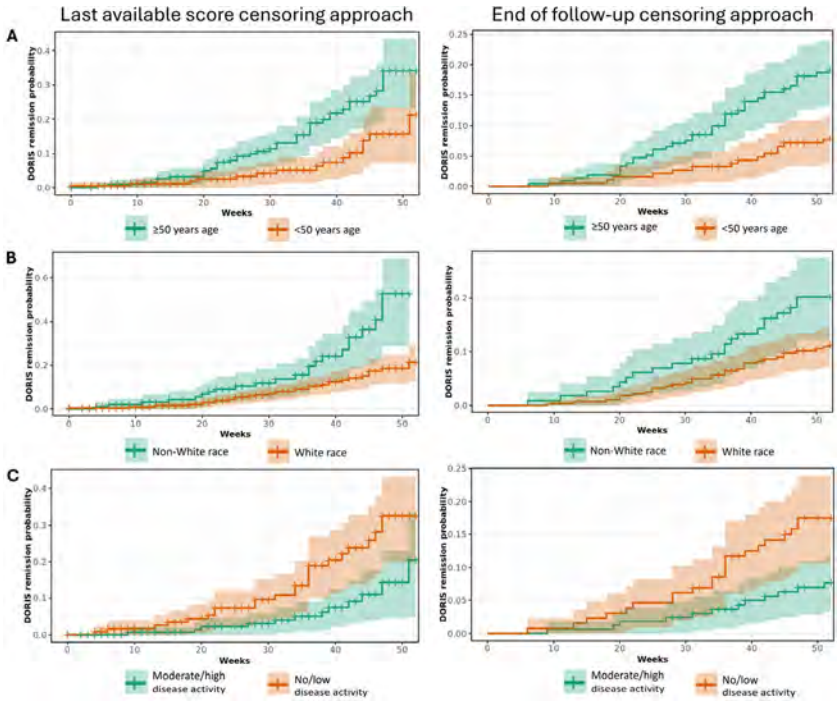

Figure 1. Unadjusted probability estimates of achieving real-world SLE remission (per DORIS proxy) stratified by (A) age, (B) race, and (C) baseline SLEDAI disease activity, as assessed by two censoring approaches. Shaded areas represent confidence bounds.

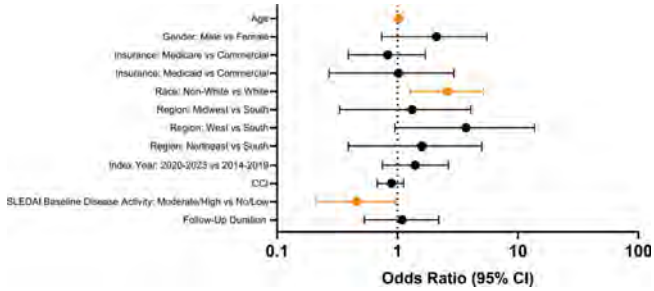

Figure 2. Logistic regression model with real-world SLE remission (per DORIS proxy) by 52 weeks as the event, and baseline patient demographics and clinical characteristics as covariates. Note: No/low disease activity per SLEDAI is not necessarily a complete measure of disease status, as all patients were determined by their physician to need initiation of a new therapy (biologic). CCI, Charlson Comorbidity Index.

Methods: Study period: Jan 1, 2013, to May 31, 2024. Data were derived from the OM1 PremiOM SLE dataset (OM1, Boston, MA, USA). Eligible patients had ≥1 BEL pharmacy/medical encounter during the identification period (Jan 1, 2014, to Oct 31, 2023). Real-world SLE remission was defined per DORIS proxy (SLEDAI/estimated SLEDAI score=0 [no disease activity]; Physician's Global Assessment [PGA] < 2 on the numeric rating scale; prednisone equivalent dose ≤5 mg/day) and assessed up to 52 weeks post-BEL initiation. Kaplan–Meier estimates were used to assess the probability of achieving remission. Two censoring approaches assessed estimate robustness: 1) last available score – earlier of latest available SLEDAI or PGA score in the follow-up period and end of follow-up; 2) end of follow-up – earlier of 52 weeks post-index (first BEL receipt), last activity date, or date of data cutoff. Patient demographics and clinical characteristics associated with remission were identified in a prespecified exploratory analysis using a logistic regression model with remission as the dependent variable; odds ratio (OR), 95% confidence intervals (CI) and p-values were calculated.

Results: Of 398 patients, 94% were female and 71% White, with a mean (standard deviation) age of 51 (14) years at index. Unadjusted probability estimates showed patients aged ≥50 years (vs < 50 years), non-White patients (vs White) and those with no/low (vs moderate/high) disease activity had a slightly higher probability of achieving remission; however, estimates

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

differed by censoring approach and confidence bounds overlapped (**Figure 1**).The adjusted model showed that older patients were significantly more likely to achieve remission by 52 weeks than younger patients (for each year of age OR: 1.03 [95% CI: 1, 1.06], p=0.0248; **Figure 2**). Patients of non-White race were significantly more likely to achieve remission than White patients (2.57 [1.27, 5.19], p=0.0092). Patients with moderate/high disease activity at baseline were significantly less likely to achieve remission than those with no/low disease activity (0.46 [0.21, 0.96], p=0.0378).

Conclusion: Predictors of real-world SLE remission with BEL include non-White race, older age, and no/low baseline disease activity. The association between minimal disease activity and higher remission rates supports the benefit of initiating belimumab treatment earlier in the course of disease.

No discontinuation, n (%)	4/18 (22)	/
Time of belimumab discontinuation before conception (median in months [min-max])	/	4 [2-10]

maternal, embryo-fetal and neonatal outcomes in patients with SLE, exposed to belimumab during the year preceding pregnancy, according to whether treatment was continued or not at time of conception.

Methods: Data were collected from: (1) the GR2 study, a French prospective cohort of pregnancies in women with autoimmune diseases involving 76 centers, (2) the French Teratology Information Service (CRAT) and (3) a national call for observations from the French Rheumatism and Inflammatory Club (CRI). Eligible participants were pregnant women aged ≥ 18 years with SLE according to the 2012 SLICC criteria, treated with belimumab within the year prior conception. Patients were stratified based on belimumab continuation (beli+) or discontinuation (beli-) at conception. Maternal disease activity, obstetrical complications and adverse embryo-fetal and neonatal outcomes were evaluated.

Results: A total of 32 pregnancies from 31 mothers were recorded between March 2016 and December 2024 across 19 French centers (n=19 from the GR2, n=8 from the CRAT and n=5 from the CRI) including 18 pregnancies in beli+ and 14 in beli-. Their characteristics are described in Table 1 and their exposure to belimumab in Table 2.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Among the 32 pregnancies, 25 resulted in 26 live births including 14 in beli+ and 12 (1 twin pregnancy) in beli-. Pregnancy losses (n=7) included 5 miscarriages (3 in beli+ and 2 in beli-), 1 in utero fetal death due to intervillositis (beli-) and 1 voluntary abortion for non-medical reasons (beli+).

Obstetrical complications occurred in 13/32 pregnancies (9 beli+, 4 beli-), including 3 maternal infections (2 beli+, 1 beli-), 2 preeclampsia (1 beli+, 1 beli-), 2 intrauterine growth restrictions (1 beli+, 1 beli-), 1 small for gestational age (beli +), 1 placenta abruption (beli-), 1 gestational diabetes (beli+), 1 postpartum hemorrhage (beli+) and/or 7 preterm deliveries (5 beli+, 2 beli-). No congenital malformations were identified.

Mild to moderate lupus flares occurred during 8/32 pregnancies (25%, 4 beli+, 4 beli-), at a median gestational age of 10 weeks [5-21] and in 6 during the year post-partum (2 beli+, 4 beli-).

Of the 26 live births, most neonates (n=18, 72%, 1 missing data) had normal Apgar scores. Three neonates (beli+) required hospitalization due to neonatal asphyxia (n=1) and prematurity (n=2). One neonate was suspected of congenital CMV infection (beli +).

No atypical infections were reported within the first year of life of the children in either group.

Conclusion: Adverse maternal and fetal outcomes were observed in both groups, but no specific risk was identified with belimumab continuation at time of conception or during pregnancy. No malformation was reported.

Obecabtagene autoleucel (obe-cel), a CD19-targeting Autologous Chimeric Antigen Receptor T-cell Therapy (CAR T) with a fast off-rate binding domain, in Patients (pts) with Severe, Refractory Systemic Lupus Erythematosus (srSLE): Preliminary Results from the Phase I CARLYSLE Study

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Pts with srSLE have limited remaining treatment options and represent a population with an unmet need. CD19 CAR Ts have potential for deep depletion of the B-cell lineage, including plasmablasts. Obe-cel is an autologous CD19-directed CAR T with a fast off-rate binding domain designed to reduce immunotoxicity, approved in adult relapsed/refractory B-cell acute lymphoblastic leukemia. We report initial safety and preliminary efficacy results from the single-arm, open-label, dose-finding, Phase I CARLYSLE study (NCT06333483).

Methods: Eligible pts (12–65 years old) had a diagnosis of SLE based on the 2019 EULAR/ACR criteria and a ≥8-point SLEDAI-2K score at screening with ≥1 major SLE-related organ involvement, and were refractory to multiple prior standard-of-care SLE medications. Immunosuppressants were tapered off prior to apheresis. Following lymphodepletion with fludarabine (3×25 mg/m^2) and cyclophosphamide (1x1,000 mg/m^2), obe-cel was administered as a single starting target dose of 50×10^6 (±20%) CAR T-cells. Primary endpoints: incidence of dose limiting toxicities (DLTs) within 28 days of infusion; frequency of adverse events. Secondary endpoints included: SLEDAI-2K; PGA; pharmacokinetics (PK); autoantibody and biomarker levels over time.

Results: As of 17 Mar 2025, seven pts had been enrolled and six had been infused with obe-cel with up to 8 months of follow up. At baseline, all infused pts had severe, refractory, active SLE (SLEDAI-2K score range: 15–28). All infused pts had class III or IV lupus nephritis; four also had class V. Four pts had elevated serum creatinine and an estimated glomerular filtration rate of < 60 mL/min/1.73m^2; six pts had elevated urinary protein-creatinine ratio. Pts were refractory to B-cell targeting agents and immunosuppressants (median: 5 prior medicines; range: 5–6). No DLTs or immune effector cell-associated neurotoxicity syndrome (ICANS) were observed. Three pts experienced Grade (Gr) 1 cytokine release syndrome (CRS) with no Gr ≥2 CRS. Transient hypertension was observed in five pts. All pts had Gr ≥3 neutropenia. Infections were transient and manageable; no life-threatening infections were observed. A ≥10 point reduction in SLEDAI-2K scores was seen in the four pts who had ≥3 months of follow up and all non-renal manifestations completely resolved within 3 months. Steroid doses were tapered to ≤10mg/day post obe-cel infusion; no other SLE medications were administered. Three of six pts had a complete renal response (CRR) at last follow-up, one at Month 1 (M1) and two at M3. Complement C3 normalized and anti-double-stranded DNA antibody decreased in all six pts by M1 compared with baseline levels. PK data indicated robust CAR T-cell expansion; peak expansion was reached at a median of 10 days. Three pts had ongoing CAR T-cell persistence at last follow-up.

Conclusion: Initial findings from the ongoing CARLYSLE study of obe-cel in srSLE show a manageable safety profile, with no DLTs, ICANS or Gr ≥2 CRS. SLEDAI-2K score reduction and clinical benefit were observed in all pts, including three pts who had a CRR. Despite the short follow up and small number of pts, initial findings are promising; further research is warranted. Updated data will be presented at the conference.

Abstract Number: 2459

Hydroxychloroquine Discontinuation in Systemic Lupus Erythematosus: A Retrospective Cohort Study with 3-Year Follow-Up

Milena Delai[1], Rachel Simon[1], Eduardo Mantovani Cardoso[2] and Vasileios Kyttaris[3], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center, Boston, [3]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Hydroxychloroquine (HCQ) plays an important role in the immunomodulation of Systemic Lupus Erythematosus (SLE), reducing the risk of flares and overall mortality. However, long-term HCQ use is associated with retinal toxicity, a common reason for discontinuation. The incidence, risk factors, and characteristics of SLE flares post HCQ discontinuation remain unclear. This study aims to identify markers that predict SLE flares in patients who discontinue HCQ.

Methods: Retrospective cohort of adult patients who met the 1997 American College of Rheumatology criteria for SLE and discontinued HCQ at a single center between 2012 and 2023. The index visit was the closest (within 3 months) to HCQ discontinuation, and the follow-up was 36 months from the index visit. Flares were assessed using the SLE Disease Activity Index (SLEDAI) flare rate instrument. We compared variables between patients who experienced flares and those who remained flare-free. Variables a priori identified as potential predictors were analyzed using a Cox regression model.

Results: 42 patients were included in this cohort. The mean age of patients was 50 years, 95% were female, 43% self-identified as White, 33% as Black. The mean duration of SLE was 15.7 years, with the mean HCQ dose before discontinuation being 4 mg/kg/day. The main reason for discontinuation was retinal toxicity (56%). At the index visit, 28% of patients had low complement levels, 39% were positive for anti-dsDNA, 55% were on immunosuppressive or biological treatment, and 26% were using prednisone at baseline (Table 1).

A little over half of the patients flared during the follow-up period. In the first year after HCQ discontinuation, 12 patients (28.6%) flared, while 15 patients (35.7%) flared in the second year, and 14 patients (37.8%) flared in the third year. Five patients were lost to follow-up after 24 months.

Clinical SLEDAI score (mean ± SD)	0.8±2.5	0.3±0.7	1

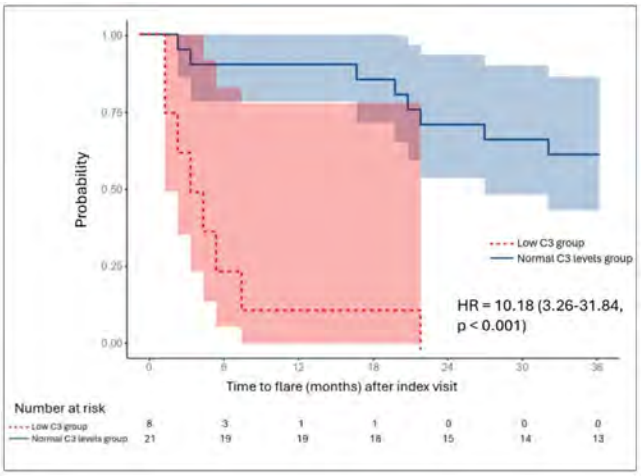

Figure 1: Kaplan-Meier survival analysis stratified by Complement C3 levels (log-rank p-value < 0.001) and Univariate Cox regression analysis with Hazard Ratio (HR).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The comparison of baseline variables between the 21 patients who experienced at least one flare (of any severity) with 19 flare-free patients over the 36 months showed that patients with any flare had lower complement (50% vs. 7%, p = 0.011) and lower mean C3 levels (91.1 ± 20.1 vs. 124.7 ± 27.5 mg/dL, p = 0.001) at the index visit (Table 2).

Kaplan-Meier curve showed that patients with low C3 levels flared more often and sooner than patients with normal C3 at baseline (log-rank p-value < 0.001). Univariate Cox regression analysis revealed that patients with low C3 levels at the index visit had a hazard ratio (HR) of 10.18 (95% CI: 3.26-31.84, p < 0.001) for any flare during follow-up, compared to patients with normal C3 levels (Figure 1).

Conclusion: In this cohort of 42 patients with SLE who discontinued HCQ, 21 patients (50%) experienced at least one flare over the 3 years. All patients with low C3 at baseline flared within the first 24 months, and low C3 was significantly linked to an increased risk of flares, especially in the first year. The use of immunosuppressants or glucocorticoids at the index visit was not associated with flare occurrence during follow-up. These findings suggest that monitoring C3 levels may help identify those at higher risk of complications after HCQ discontinuation. Further studies are needed to develop strategies for flare prevention in this setting.

Comparative Efficacy of Belimumab, Anifrolumab, and Rituximab in SLE: A Retrospective Analysis of Serological and Clinical Outcomes

Pablo Martínez Calabuig[1], Jorge Juan Fragío Gil[2], Roxana González Mazario[3], Laura Salvador Maicas[4], Mireia Sanmartin Martínez[4], Iván Jesús Lorente Betanzos[4], Amalia Rueda Cid[4], Juan José Lerma Garrido[4], Isabel Martínez Cordellat[4], Isabel Balaguer Trull[4], Berta Gómez Correas[4] and Cristina Campos Fernández[3], [1]Hospital General Universitario de Valencia, Spain/ Uversidad Catolica de Valencia San Vicente Martir, Valencia, Spain, Ontinyent, Spain, [2]Hospital General Universitario, Valencia, Spain, [3]Hospital General de Valencia, Valencia, Spain, [4]Hospital General Universitario de Valencia, Valencia, Comunidad Valenciana, Spain

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multisystem involvement and fluctuating activity. Biologic therapies such as Belimumab, Anifrolumab, and Rituximab offer new options for moderate-to-severe or refractory SLE, though comparative data remain limited. This study describes baseline clinical features and compares serologic outcomes over 12 months.

Methods: We conducted a retrospective study of SLE patients meeting 2019 ACR/EULAR criteria treated with Belimumab, Anifrolumab, or Rituximab between 2010–2025 at a university hospital. Clinical data and analytical parameters (anti-dsDNA, C3, C4, hemoglobin, leukocytes, lymphocytes, platelets, creatinine, eGFR) were collected. Linear mixed-effects models assessed treatment, time, and their interaction.

Table 1. Treatment and clinical manifestations of SLE patients

Table 1.	SLE PATIENTS (N=65)
TREATMENT	
ANIFROLUMAB, N (%)	17 (26.2)
MEDIAN TREATMENT DURATION, MONTHS	6
BELIMUMAB, N (%)	39 (60.0)
MEDIAN TREATMENT DURATION, MONTHS	18
RITUXIMAB, N (%)	9 (13.8)
MEDIAN TREATMENT DURATION, MONTHS	14
CLINICAL MANIFESTATIONS	
CUTANEOUS, N (%)	42 (64.6)
ARTICULAR, N (%)	59 (90.8)
ALOPECIA, N (%)	13 (20.0)
ORAL ULCERS, N (%)	20 (30.8)
NEUROPSYCHIATRIC MANIFESTATIONS, N (%)	33 (50.8)
SEROSITIS, N (%)	26 (40.0)
HEMATOLOGIC MANIFESTATIONS, N (%)	52 (80.0)
GASTROINTESTINAL INVOLVEMENT, N (%)	9 (13.8)
RENAL INVOLVEMENT, N (%)	23 (35.4)

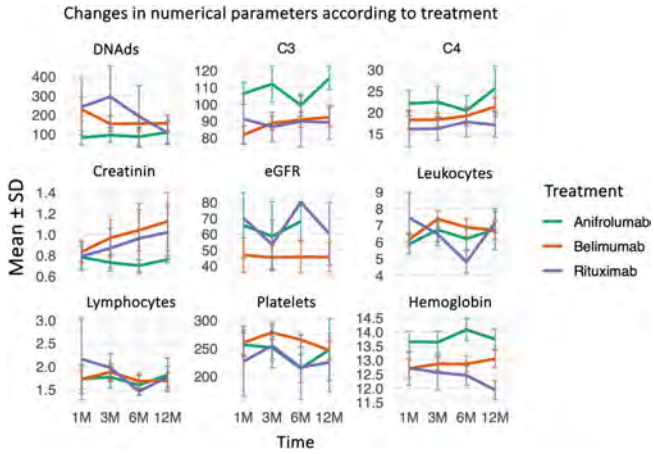

Image 1. Changes in numerical parameters according to treatment.

Results: A total of 65 patients were included (mean age at diagnosis: 36.1 years; 90.8% female). The most frequent baseline manifestations were articular (90.8%), hematologic (80.0%), or cutaneous (64.6%). Biologic therapies included Belimumab (60.0%), Anifrolumab (26.2%), and Rituximab (13.8%) (see Table 1&2).

Therapeutic survival at 12 months was 69.2% for Belimumab, 64.7% for Anifrolumab, and 66.7% for Rituximab. Most discontinuations were due to infections or lack of efficacy. Corticosteroids were used in 88%, 78%, and 83% of Belimumab, Anifrolumab, and Rituximab cases, respectively, with median initial prednisone doses of 7.5, 5, and 10 mg/day.

A significant inter-treatment difference was observed for complement C3 levels ($p=0.032$), with Anifrolumab achieving significantly higher C3 levels than Belimumab at month-1 ($p=0.0091$) and month-3 ($p=0.0097$), suggesting faster complement recovery. Rituximab, did not show significant improvements in C3 levels at any time point (see Image 1).

For anti-dsDNA, overall treatment effect was not statistically significant ($p = 0.13$), though time had a significant impact ($p=0.01$). Belimumab showed a significant intra-group reduction in anti-dsDNA between month 1 and month 12 ($p=0.0058$), while Rituximab was associated with persistently elevated levels.

No statistically significant differences were found between treatments in complement C4 levels ($p=0.26$), although a marginally significant treatment-by-time interaction ($p=0.063$) suggests a possible trend toward different temporal profiles among therapies.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 2. Baseline Analytical Characteristics of Patients with SLE

	SLE patients n= 65
Baseline hemoglobin, mean (SD)	12.86 (1.79)
Baseline leukocytes, mean (SD)	6.61 (2.72)
Baseline lymphocytes, mean (SD)	1.49 (0.84)
Baseline platelets, mean (SD)	265.10 (88.41)
Baseline C3, mean (SD)	88.29 (26.93)
Low C3, n (%)	25 (43.1)
Baseline C4, mean (SD)	17.52 (9.78)
Low C4, n (%)	28 (48.3)
Baseline anti-dsDNA, mean (SD)	180.49 (229.11)
Baseline creatinine, mean (SD)	0.86 (0.56)
Baseline eGFR, mean (SD)	81.12 (20.06)
Baseline hematuria, n (%)	5 (8.3)
Baseline proteinuria, n (%)	11 (18.3)

For the remaining analytical parameters no statistically significant differences were observed.

Conclusion: Anifrolumab demonstrated superior early improvement in C3 complement levels, suggesting a rapid modulation of immune activation, while Belimumab was associated with a significant reduction in anti-dsDNA titers over 12 months, indicating effective serologic control over time. Although C4 and anti-dsDNA levels showed trends toward inter-group differences, these were not statistically conclusive in between-treatment comparisons. Rituximab-treated patients, exhibited persistently elevated anti-dsDNA levels and less consistent complement normalization.These findings support individualized SLE treatment based on serologic response and organ involvement.

Background/Purpose: Systemic lupus erythematosus (SLE) therapies elicit distinct transcriptional responses, yet a subset of patients fails to achieve clinical remission. To guide precision repurposing, we applied a transcriptome-driven strategy to identify compounds that either mimic the molecular effects of standard therapies or reverse gene expression profiles associated with treatment resistance.

Methods: Paired whole-blood transcriptomes from 31 SLE patients treated with rituximab (n=8), belimumab (n=13), or cyclophosphamide (n=10) were analyzed to define drug-specific signatures (absolute $\log_2$FC > 0.58, $p < 0.05$). A "refractory SLE" signature was derived by comparing gene expression at 6 months between responders and non-responders. Signatures were queried against L1000CDS^2 and CMAP2 databases to identify compounds that replicate or reverse these transcriptional patterns. Drug-gene interactions were explored using the DGIdb database.

Results: Transcriptional mimics of standard therapies were largely drug-specific, reflecting distinct modes of action. Rituximab's signature aligned with mTOR blockers (everolimus, dactolisib), PI3K inhibitors (PIK-75, ZSTK474), JAK2 inhibitors (fedratinib) and agents downregulating the p38-MAPK pathway (OXA). Belimumab's mimics included BCL-2 and ERK inhibitors (FR180204). Cyclophosphamide's replicants entailed JNK and NETosis-targeting agents. For refractory SLE, inverse transcriptional alignment was accomplished by several mechanistically diverse compounds including HSP90 inhibitors (geldanamycin, tanespimycin), tyrosine kinase inhibitors (dasatinib, lapatinib), and ferroptosis inducers (CX-5461) Notably, proteasome inhibitors (bortezomib, carfilzomib, ixazomib) emerged as promising agents based on gene interaction mapping, implicating plasma cells in treatment-resistant disease course.

Conclusion: Our analysis delineates molecular correlates of therapeutic response and identifies candidate drugs capable of emulating molecular effects of standard SLE therapies or reversing gene expression patterns associated with treatment failure, offering a framework for drug repurposing in difficult-to-treat SLE.

Achieved the target	1	10%
Required dose reduction	0	0.0%

Figure 1

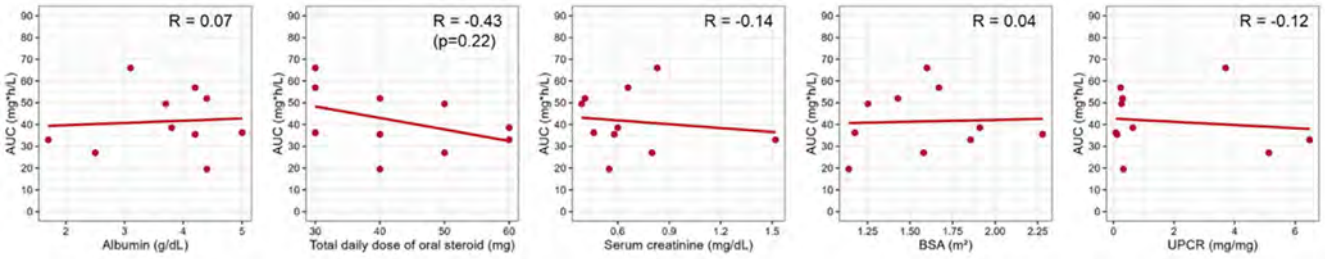

Figure 2

Background/Purpose: The safety and effectiveness of MMF for the treatment of LN have been tested in adult and pediatric patients. MMF, a prodrug, is rapidly converted to the active moiety *mycophenolic acid (MPA)* and is recommended as an immunosuppressive medication for active pediatric LN treatment, usually at a dose of 600 mg/m^2 body surface area (BSA) twice daily (max 3 gram/day). It has been suggested that an area under the concentration-time curve ($AUC_{0\text{-}12h}$) of MPA at $\geq$60-70 mg*h/L is best for reducing proteinuria in LN while levels < 30 mg*h/L are considered ineffective. This is currently being tested in a randomized clinical trial in pediatric LN (PLUMM, NCT05538208). The *objectives* of this analysis were to evaluate (1) the MPA exposures ($AUC_{0\text{-}12h}$) that are achieved with routine dosing of MMF in pediatric LN patients, and (2) associations of MPA exposures with kidney parameters [serum creatinine, albumin, and protein:creatinine ratio (UPCR)] and prednisone use.

Methods: Pediatric patients with biopsy-proven active LN who participated in the PLUMM trial and were on stable therapeutic doses of MMF underwent abbreviated pharmacokinetic profiling (PK; at trough, 20 minutes, 1 hour, and 3 hours) at study entry, using Volumetric Absorptive Microsampling Combined with Mass Spectrometry (PMID: 40132640). MPA exposure was estimated using an established algorithm (PMID: 26143647) and related to kidney parameters and oral prednisone use.

Results: PK profiles were analyzed in 10 enrolled patients receiving stable twice daily doses of MMF for at least 4 days. The median weight and BSA were 56.3 kg and 1.59 m^2, respectively, and the median MMF-dose was 2 g/day, resulting in a median MPA-exposure of 37.4 mg*h/L. There were 2 patients achieving ineffective (< 30) MPA exposures and only 1 patient achieved an MPA exposure considered optimal (Figure 1). Serum creatinine, albumin, UPCR, and BSA were all unrelated to MPA exposure. Conversely, there was a moderately strong inverse relationship (r=–0.43) to prednisone dosage (Figure 2). Data from additional patients enrolled in the PLUMM trial will be shown as they become available.

Conclusion: Current BSA-based dosing of MMF seems to generally result in suboptimal MPA exposure, limiting effective reduction of proteinuria in pediatric LN. Our findings confirm that MPA exposure is negatively associated with daily prednisone dosing (PMIDs: 12164891, 21982386). Given the limited sample size, further studies with larger cohorts are necessary. The impact of precision dosing on clinical outcomes will be evaluated after the completion of the PLUMM study.

Allogenic Anti- CD19 CAR-T Cells Induce Remission in Refractory Systemic Lupus Erythematosus

Chunnei Yang[1], Chuanyin Sun[2], Binghe Tan[3], Chao Hu[1], Liyan Wan[2], Changling Xie[3], **Qian Tan**[3], Mingyao Liu[3], Jin Lin[2], Bing Du[3] and Hongyan Tong[1], [1]Department of Hematology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China (People's Republic), [2]Department of Rheumatology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China (People's Republic), [3]BRL Medicine Inc., Shanghai, Shanghai, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease associated with significant morbidity and mortality. The treatment approach for SLE primarily involves immunomodulation and immunosuppression. However, these drugs have considerable toxicity and are not effective in all patients. Autologous CD19-targeted CAR-T therapies has been explored in several autoimmune diseases and reported promising efficacy in recent studies. In this study, a healthy donor-derived, multiplex genome-edited allogeneic CD19-targeted CAR-T product (BRL-303) was developed for refractory autoimmune diseases patients. Here we report the efficacy and safety profile of BRL-303 in treating patients with systemic lupus erythematosus (SLE).

Methods: This is an investigator-initiated trial evaluated the safety and efficacy of BRL-303 in adult patients with refractory autoimmune diseases (NCT05988216). Participants were screened and underwent lymphodepletion chemotherapy with cyclophosphamide (300 mg/m^2, day -5 to -4) and fludarabine (25 mg/m^2, day -5 to -3), then BRL-303 infusion at day 0 with a dose level of 1×10^6 cells/kg. For Patient SLE-04, the CAR-T cells were directly infused without lymphodepletion. After BRL-303 infusion, each patient underwent safety and efficacy assessment according to protocol.

Results: As of March 16, 2025, 4 patients with refractory systemic lupus erythematosus have been treated. These patients were unable to control disease progression despite treatment with corticosteroids and various immunosuppressants. After BRL-303 infusion, CAR -T cells in all subjects were significantly expanded. Notably, Patient SLE-03 &SLE-04 exhibited the most robust CAR-T cell expansion, with peak CAR copy numbers reaching 13,680 copies/μg on day 14 and 33,171 copies/μg on day 10 post-infusion, respectively . CAR-T cells remained detectable in all patients at 3 months. With expansion of BRL-303, B cells in peripheral blood of patients reached deep and persistent depletion about 1∼3 months. After BRL-303 infusion, all subjects met the Systemic Lupus International Collaborating Clinics (SLICC) criteria for a sustained response (SRI-4) and achieved a SELENA-SLEDAI score of zero and a PGA score<1 at 3 to 6 Months. Moreover, all subjects showed a significant decrease in serum ds-DNA and increase in complements (C3 and C4) within one month. Meanwhile, proteinuria also resolved in all subjects. Importantly,SLE-01 discontinued all immunomodulatory and immunosuppressive medications,

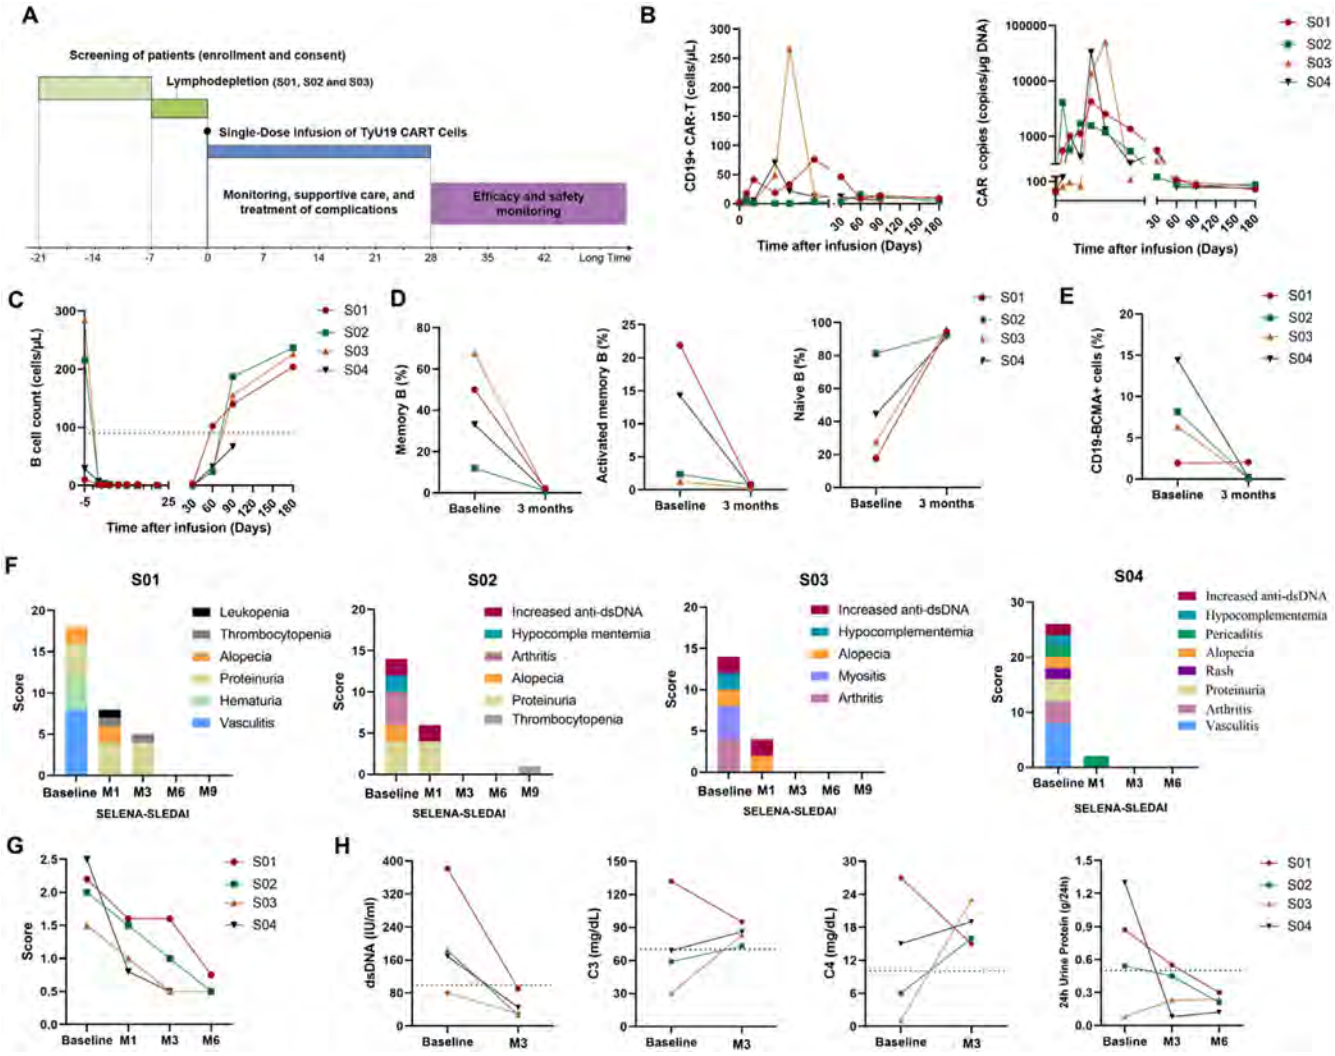

Figure 1. Study process diagram and Effects of BRL-303 for SLE patient (A, Therapeutic timelines; B, BRL-303 detected by flow and qPCR; C, Absolute B cells value; D and E, Changes in the numbers of memory B cells (CD21+CD27+), activated memory B cells (CD11c+CD21lo), naïve B cells (CD21+CD27–) and CD19-BCMA+ plasma cells in PBMC at 3 months after infusion; F and G, SELENA-SLEDAI and PGA change before and after BRL-303 treatment; H, SLEDAI-2K Score changs; C, Serological and 24h urine protein changes)

including glucocorticoids, at 3 months, achieving drug-free remission, while other patients require low-dose glucocorticoid maintenance therapy (≤5mg). All of them developed grade 1 CRS for 2 or 3 days, no ICANS and GvHD observed.

Conclusion: Overall, SLE subjects treated with BRL-303 achieved significant clinical remission, with a controllable safety profile, offering a potential paradigm shift for SLE patients who are refractory to currently available treatments. Further observation of SLE and more autoimmune disorders treated with BRL-303 are ongoing in our study.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Deep B cell depletion has been confirmed to be the main mechanism for complete clinical response of SLE patients. We analyzed the peripheral blood of SLE patients in an in-vitro assay and found that CD47 was expressed in all B cell subtypes especially in plasmablasts which are CD20 negative. IMC-002 (IMM0306) is a mAb-Trap targeting CD20 and CD47, which has been demonstrated to have robust B cells depletion activity in phase I clinical trial for patients with non-

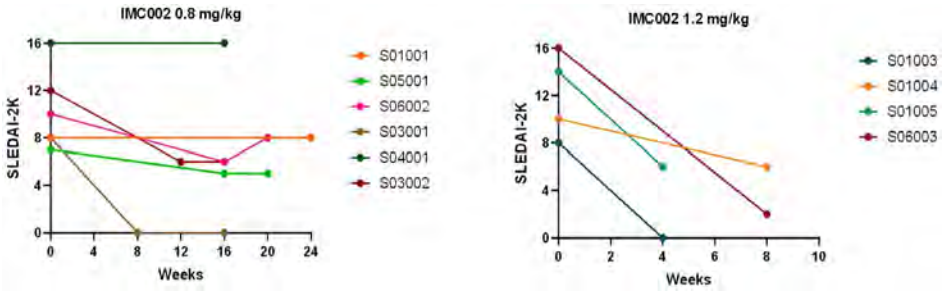

Figure 1. SLEDAI-2K evaluation from first dose to the latest visit at the time of data cutoff

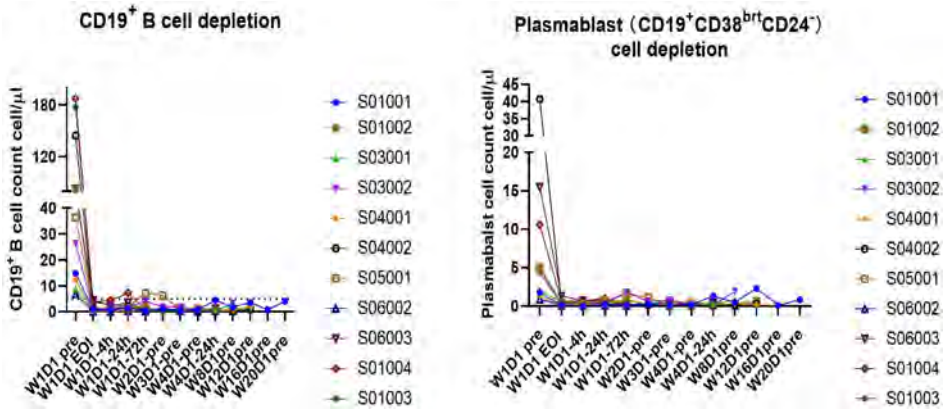

Figure 2. B lymphocyte depletion from first dose to latest available data at the time of data cutoff

hodgkin's lymphoma. This study aims to investigate the treatment of IMC-002 on safety, SLE disease activity measures, proteinuria responses and multiple biomarkers in SLE patients who had not previously responded to standard of care.

Methods: As of 14th Apr. 2025 (cut-off date), 11 patients who completed 4-weeks administration (once weekly) of IMC-002 and at least one SLEDAI-2K evaluation in Phase 1b were included in this analysis, 7 patients in 0.8mg/kg dose cohort were followed up for 16-24 weeks, 4 patients in 1.2mg/kg dose cohort were followed up for 4-8 weeks. Moderate to severe active SLE was defined as Class A manifestations in one or more organ systems and/or Class B manifestations in two or more organ systems and SLEDAI≥6, ANA or Anti-dsDNA positive. The efficacy endpoint was SLE Responder Index-4 (SRI-4) evaluation for every 12 weeks in Phase 1b. Other efficacy assessments included BILAG-2004, SLEDAI-2K, PGA and laboratory tests (24-hour urine protein, anti-dsDNA antibody, C3/C4 and IgG/IgA/IgM, B cells count, etc.)

Results: By the data cut-off date, in the 0.8 mg/kg dose cohort, 2 out of 7 patients reached SRI-4 at Week 12, and all patients did not reach 24-week SRI-4 evaluation time; in the 1.2 mg/kg dose cohort, all patients did not reach 12-week SRI-4 evaluation time. 4 patients (57.1%) in the 0.8 mg/kg dose cohort and 4 patients (100%) in 1.2 mg/kg dose cohort showed SLEDAI-2K improvement by≥4 with PGA decrease; 1 patient SLEDAI-2K scored from 8 (baseline) to 0 (W8) in the 0.8 mg/kg dose cohort and 1 patient from 8 (baseline) to 0 (W4) in the 1.2 mg/kg dose cohort (Figure 1). All patients had improvements or no changes in BILAG-2004, and no PGA score worsening in all patients except 1 patient had 0.4 increasement. The 24-hour urine protein were significantly decreased by 32% $\sim$ 62% from baseline during the administration period in all the 5 patients with proteinuria≥0.5g/24h at baseline. Anti-dsDNA antibody in all patients (6/6) showed a significant decrease trend. C3/C4 recovered to normal in 75% patients (3/4) with low complement at baseline. Complete deletion (defined as less than 5 cells/μL) of CD19+ B cells and plasma blasts in all 11 patients was achieved from end of injection (EOI) to latest visit time (up to W20) (Figure 2).

Conclusion: Results of this study suggest that treatment with IMC-002 is effective across multiple organ systems in patients with active SLE. IMC-002 showed deep and persistent B cell depletion in active SLE patients.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: GC012F (AZD0120) is a CD19/B cell maturation antigen (BCMA) dual-targeting chimeric antigen receptor T-cell (CAR-T) developed on the novel FasTCAR-T platform with next-day manufacturing, designed to improve depth and duration of B-cell depleting response. We present interim results here from a dose escalation investigator initiative trial (IIT) (NCT05858684) to evaluate the safety and efficacy of GC012F CAR-T cell therapy in resetting humoral immunity in patients with refractory systemic lupus erythematosus (SLE).

Methods: Ten patients with refractory SLE (SLEDAI-2K score range 8-20) were enrolled in this investigator-initiated, open-label, single-center Phase I study. All patients received a single infusion of autologous CD19-BCMA dual chimeric antigen receptor (CAR) T cells at one of three different dose levels following preconditioning with fludarabine and cyclophosphamide. The primary endpoint was safety and tolerability, assessed by the percentage of subjects experiencing dose-limiting toxicity (DLT) within 28 days and the percentage of subjects reporting adverse events (AEs) within 12 weeks. Efficacy was assessed using the SLE Responder Index (SRI-4), the Definition of Remission in SLE (DORIS) criteria and renal response rate. Safety parameters, including cytokine release syndrome and infections, were systematically recorded and evaluated.

Results: The median follow-up duration was 448.5 days (range, 336-612 days), with a mean duration of B-cell aplasia of 126 days (range, 84–168 days). All patients achieved an SRI-4 response in week 24. Five patients met DORIS remission by week 24, six by week 36 and week 48. All patients discontinued immunosuppressive drugs during the follow-up period. One patient experienced a disease flare at week 40. Four patients exhibited residual proteinuria, and repeat kidney biopsies were performed in three of them. The biopsy results primarily showed persistent fibrosis and podocyte injury, with resolution of acute inflammation, significant reduction in immune complex deposition, and absorption or dissipation of electron-dense deposits. No DLTs were observed. Six patients experienced grade 1 CRS, and one patient experienced grade 2 CRS. No cases of immune effector cell-associated neurotoxicity syndrome (ICANS) or grade ≥3 CRS were reported. Other common AEs included hematologic abnormalities, hypogammaglobulinemia, and infections. No fatal adverse events occurred.

Conclusion: GC012F CAR-T cell therapy was well tolerated and demonstrated high efficacy in patients with refractory SLE. A multicenter phase1/2 study (NCT06530849) is ongoing to further evaluate the safety and efficacy of GC012F in a broader range of patients with SLE.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Zetomipzomib (zeto), a selective immunoproteasome inhibitor, has previously shown anti-inflammatory activity in patients (pts) with SLE and LN in the open-label MISSION study. The PALIZADE trial (NCT05781750) was a global Phase 2b, multi-center, randomized (1:1:1), controlled double-blind study comparing the efficacy and safety of weekly subcutaneous administration of zeto 30 mg or 60 mg with placebo (pbo) in pts with active LN (Class III, IV ± V) on background standard of care therapy of MMF or equivalent plus corticosteroids. An Independent Data Monitoring Committee recommended pausing enrollment and dosing following 4 fatalities (1 - pbo, 2 - 30 mg arm, 1 - 60 mg arm) and additional nonfatal treatment-emergent serious adverse events (TESAE) that showed a common pattern of symptoms or proximity to dosing. PALIZADE was subsequently terminated early by the sponsor for strategic business reasons.

Methods: Planned enrollment was 279 pts, including 249 pts with Class III or IV ± V LN and 30 pts with pure Class V with a planned duration of 52 weeks of treatment and a primary endpoint at Week (W) 37. At the time of termination (October 2024), 84 patients (74 with Class III or IV ± V LN) were enrolled with mean treatment duration of 16.7 weeks. All enrolled pts were included in the safety analysis, and 39 pts with proliferative LN who reached W25 for 24-hour urine protein creatinine ratio (UPCR) evaluation were included in the efficacy analysis. No pt completed the full 52 weeks of treatment.

Table 1. PALIZADE Adverse Events (Safety Population), N=84

	Zeto 30 mg N=27 n (%)	Zeto 60 mg N=29 n (%)	Placebo N=28 n (%)
Participants with at least 1 Treatment Emergent Adverse Event (TEAE)	23 (85.2)	25 (86.2)	17 (60.7)
Treatment Emergent Serious Adverse Event	5 (18.5)	8* (27.6)	3 (10.7)
Deaths	2 (7.4)	1 (3.4)	1 (3.6)
Most common TEAEs:

Preliminary data on changes in proteinuria, median UPCR, SLEDAI-2K, and key lupus serologic markers at W25 are presented here. Whole blood transcriptomic analysis was performed.

Results: Ninety-three percent of enrolled pts were female with mean age of 32.1 years, mean LN duration of 3.7 years, mean UPCR of 3.5 mg/mg, and a mean SLEDAI-2K score of 11.3. The most common TEAEs were injection site reaction (98% were Grades 1 or 2) and systemic injection reaction (97% were Grades 1 or 2), Table 1. Four fatalities (4.8%) and 16 total TESAEs (in 19% of pts) occurred. Evidence suggestive of co-morbidities immediately prior to study drug administration (e.g., possible systemic infection) and/or possible underlying disease characteristics (e.g., cardiovascular) were present in fatal events.

Among the 39 evaluable pts with Class III/IV ± V LN, 42% (5/12) of those treated with 60 mg zeto achieved a UPCR ≤0.5 at W25. The median percent change in UPCR from baseline was -67% at W13 and -79% at W25, suggesting a rapid improvement in proteinuria with 60 mg zeto administration, Table 2. Additionally, improvements in SLEDAI-2K, serologic markers of SLE including anti-dsDNA, C3 and C4 were observed in both zeto arms.

Conclusion: Safety analysis of enrolled pts indicated overall similar safety profiles between zeto dosed at 30 mg and 60 mg, and these findings are consistent with previous studies of zeto in LN. Preliminary efficacy data from a treatment evaluable population with Class III/IV ± V LN in the PALIZADE trial offer encouraging activity in pts receiving a 60 mg dose of zeto.

Table 1. Key features of the BLISS-LN study design. AZA, azathioprine; CYC, cyclophosphamide; eGFR, estimated glomerular filtration rate; GC, glucocorticoid; IV, intravenous; PERR, primary efficacy renal response.

Study design component	BLISS-LN (Belimumab – NCT01639339)
Key endpoints	Primary endpoint: PERR at Week 104 Key secondary endpoint: CRR at Week 104
PERR definition	uPCR ≤0.7; eGFR no worse than 20% below the pre-flare value or ≥60 ml/min/1.73 m², and prednisone dose ≤10 mg/day at Week 24; and no rescue therapy except for short-term rescue in Weeks 24–76 for reasons other than LN. No GC rescue treatments were allowed in Weeks 76–104
CRR definition	uPCR <0.5; eGFR no worse than 10% below the pre-flare value or ≥90 ml/min/1.73 m², and prednisone dose ≤10 mg/day at Week 24; and no rescue therapy except for short-term rescue in Weeks 24–76 for reasons other than LN. No GC rescue treatments were allowed in Weeks 76–104
Recruitment	N=448; Americas, Europe, China, South Korea, Thailand, Taiwan, Philippines
LN classes	Class III or IV (± concomitant class V), or pure class V LN
Study treatment procedure	Belimumab IV 10 mg/kg every 28 days to Week 100
Standard therapy (excluding GC)	Induction therapy with IV CYC (500 mg every 2 weeks) or MMF (target 3 g/day). Maintenance therapy of AZA (2 mg/kg per day) or MMF (1–2 g/day)
GC use at induction	Oral prednisone (≤60 mg/day) Optional 1–3 IV methylprednisolone pulses (500–1000 mg each) at induction
GC tapering schedule	Mandatory taper to ≤10 mg/day prednisone by Week 24, as part of PERR and CRR endpoints. Permitted short-term rescue treatment between Weeks 24 and 76 for non-LN reasons. Patients violating GC regimen rules considered as treatment failures
Prohibited medications	B-cell therapy and any non-belimumab biologics. CYC induction within 3 months before trial initiation
Premedication	None required

Table 2. BLISS-LN CRR responder data at Weeks 76 and 104 for a subgroup of patients receiving MMF with active class III or IV LN ± concomitant class V. *Data shown are for a post hoc subgroup of patients who received MMF standard therapy (No CYC); †CRR responder rates for the combined subgroups "class III or IV" and "class III or IV + V" were manually calculated using data on the number of responders in each subgroup; ‡OR adjusted for race, baseline uPCR and baseline eGFR. BEL, belimumab; CI, confidence interval; OR, odds ratio; PBO, placebo.

	CRR class III or IV pure proliferative (MMF subgroup)*		CRR class III or IV + V mixed proliferative/ membranous (MMF subgroup)*		CRR† class III or IV ± concomitant class V pure proliferative and mixed proliferative/ membranous (MMF subgroup)*	
	BEL (n=94)	PBO (n= 96)	BEL (n=41)	PBO (n=40)	BEL (n=135)	PBO (n=136)
Week 76						
CRR responders	37.2%	25.0%	29.3%	20.0%	34.8%	23.5%
Treatment difference vs PBO	12.2%		9.3%		11.3%	
Week 104						
CRR responders	35.1%	17.7%	26.8%	17.5%	32.6%	17.6%
Treatment difference vs PBO	17.4% OR: 2.34‡ (95% CI: 1.17–4.69)		9.3% OR: 1.86‡ (95% CI: 0.61–5.66)		14.9%	

Background/Purpose: Belimumab, a human IgG1λ monoclonal antibody that selectively binds B-lymphocyte stimulator, was first approved in 2011. It is the only biologic approved for LN and SLE. With greater than 10 years of real-world experience, EULAR acknowledged early use of belimumab in SLE, and ACR recommends its use in LN.

Reinforcing the central role of B-cells in LN immunopathogenesis, Phase 3 trials successfully investigated belimumab (BLISS-LN; NCT01639339[1]) and obinutuzumab (REGENCY; NCT04221477) in biopsy-proven active LN plus standard therapy (ST). Study differences (e.g. populations, concomitant medications, endpoint timings, and definitions) present challenges in comparing LN trial outcomes. In this regard, BLISS-LN's unique design allowed inclusion of pure ISN/RPS class V

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and cyclophosphamide ST. To better align with the design of the REGENCY and NOBILITY (NCT02550652) trials, we analyzed post hoc a BLISS-LN subgroup of patients with active class III or IV LN ± concomitant class V who received MMF ST (i.e. excluding pure class V and cyclophosphamide ST).

Methods: BLISS-LN was a 104-week global trial of 448 adult patients with active class III or IV (± concomitant class V) or pure class V LN.[1] Key features of the BLISS-LN study design (**Table 1**) included a stringent complete renal response (CRR) definition that differs from other trials (BLISS-LN-CRR defined as urinary protein-to-creatinine ratio [uPCR] < 0.5, eGFR ≤10% below the pre-flare value or ≥90 ml/minute/1.73 m^2, and no rescue therapy).[1] Additionally, BLISS-LN-CRR defined treatment failure as use of prohibited therapy and not achieving mandatory prednisone taper to ≤10 mg/day by Week 24.

Results: Of the overall 448 patients in BLISS-LN, 271 had active class III or IV LN ± concomitant class V and received MMF ST. CRR data for this subgroup (referred to as the "MMF subgroup") using prespecified definitions are shown in **Table 2**. At Week 76 in the MMF subgroup, BLISS-LN-CRR treatment difference between belimumab and placebo was 11.3% for class III or IV ± concomitant class V, and 12.2% for class III or IV only. At Week 104, BLISS-LN-CRR treatment difference was 14.9% for class III or IV ± concomitant class V, and 17.4% for class III or IV only.

Regarding safety, in the BLISS-LN MMF subgroup, serious adverse events up to Week 104 were lower with belimumab (24.4%, n=40/164) than placebo (32.1%, n=53/165).

Conclusion: Building on the extensively demonstrated safety[2] and efficacy profiles of belimumab across SLE and LN, this post hoc subgroup analysis of patients with active class III or IV LN ± concomitant class V receiving MMF in BLISS-LN demonstrated enhanced renal responses with belimumab versus placebo at Weeks 76 and 104. This improved outcome is also observed when compared to the overall BLISS-LN population.[1] Belimumab has additionally been shown to be safe and efficacious in patients with LN in the real world.[3] Benefit/risk profiles, real-world effectiveness and data from extra-renal SLE should be considered to inform LN treatment decisions.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Current goals of treatment for systemic lupus erythematosus (SLE) are to achieve low disease state/remission, prevent flares, minimize organ damage, and decrease long-term morbidity and mortality. Therapies providing durable clinical responses without requiring chronic administration are lacking. Rese-cel (formerly CABA-201) is a fully human, autologous 4-1BB CD19-CAR T cell therapy, designed to deeply and transiently deplete CD19 positive cells following a weight-based, single infusion. This approach may enable an "immune system reset" and durable meaningful clinical responses without chronic therapies. RESET-SLE^{TM} (NCT06121297) is an ongoing Phase 1/2 trial in 2 independent cohorts of non-renal SLE and lupus nephritis (LN).

Methods: Patients were 18 to 65 years with SLE, ANA+ or anti-dsDNA+, and Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI 2K) ≥8 despite standard of care (SOC) therapy (non-renal SLE cohort), or active, biopsy-confirmed class III or IV ± V LN despite SOC (LN cohort). A single infusion of 1x10^6 CAR T cells/kg was administered following preconditioning with fludarabine and cyclophosphamide. All non-glucocorticoid (GC) immunomodulatory (IM) agents were discontinued by Day -5. Adverse events, use of SLE medications, SLEDAI-2K changes, achievement of the definition of remission in SLE (DORIS), lupus low disease activity state (LLDAS), and renal responses were assessed. CAR T cells and B cells were profiled in peripheral blood samples pre- and post-infusion by digital PCR and flow cytometry, respectively. Serum cytokines were measured using the mesoscale discovery platform.

Results: As of 31 March 2025, 7 patients have been infused with rese-cel and have at least 4 weeks of follow-up (Table 1). One additional patient has been infused and is in early follow up.

Rese-cel was well-tolerated with Grade 1 cytokine release syndrome (CRS) reported in 2 patients (SLE-2 and LN-1). As previously reported, LN-1 experienced Grade 4 immune effector cell-associated neurotoxicity syndrome (ICANS), associated with a potential occult infection based on cytokine and TCR clonality profiling, which rapidly resolved following standard management.

Robust clinical improvement has been observed in all 7 patients (Table 2).

CAR T cells expanded rapidly and peaked between days 7 and 16 post-infusion, with LN-1 also having a second peak at day 28, followed by contraction. Serum IFNγ rapidly increased concurrently with or prior to rese-cel expansion. Peripheral

SLEDAI-2K score[‡] (baseline to latest follow-up)	26→5	10→0	8→2	8→2	22→4	14→6	16→12
UPCR[§] (baseline to latest follow-up)	1.08→0.5	N/A	N/A	N/A	7.22→0.47	4.85→2.62	2.04→0.97
CRR[¶] (at latest follow-up)	✓	N/A	N/A	N/A	✓	–	–
GC-free	✓	✓	✓	✓	✓	✓	✓
IM-free[†]	✓	✓	✓	✓	✓	✓	✓

*As of MAY 01, 2025.
[†]Enrollment in the LN cohort required class III/IV +/- V LN. SLE-1 had isolated class V LN and extra-renal SLE disease activity (but met inclusion criteria for the non-renal cohort.
[‡]SLEDAI-2K components at latest follow up: SLE-1, leukopenia-1, complement-2, dsDNA-2; SLE-2, dsDNA-2, SLE-4, dsDNA-2, LN-1, hematuria-4, proteinuria-4, pyuria-4.
[§]SLE-1 is undergoing cyclosporine therapy for a non-SLE-related, non-renal-cell related event at latest follow-up.
CRR, complete renal response; DORIS, definition of remission in SLE; eGFR, estimated glomerular filtration rate; GC, glucocorticoid; IM, immunomodulatory; LLDAS, lupus low disease activity state; LN, lupus nephritis; N/A, not applicable; rese-cel, resecabtagene autoleucel; RESET, Resetting SEB-Tolerance; SLE, systemic lupus erythematosus; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; UPCR, urine protein-creatinine ratio.
DORIS = Clinical SLEDAI-2K=0 (irrespective of serology); PGA ≤0.5; antimalarials, low-dose glucocorticoids (prednisone ≤5 mg/day), stable immunosuppressives including biologics. LLDAS = SLEDAI-2K score ≤4, with no activity in major organ systems (renal, central nervous, cardiopulmonary, vasculitis or fever); no new SLEDAI-2K-assessed disease activity compared with the previous visit; PGA score ≤1; prednisone or equivalent dosage ≤7.5 mg/day and no non-standard immunosuppressant dosing; antimalarials allowed. CRR = UPCR ≤0.5 mg/mg, ≥60 mL/min or no confirmed eGFR decrease of >20% from baseline, no receipt of rescue therapy.
Caballetta, Bin: Data on file.

B cells were rapidly reduced within the first 2 weeks and started reconstituting between 8 and 20 weeks in all patients to date. Reemergent B cells presented initially with a transitional naïve phenotype (CD19+CD20+CD38++CD24++).

Conclusion: Data from SLE and LN patients infused with rese-cel shows early clinical responses, including meeting the DORIS remission criteria and complete renal response, and an acceptable safety profile, in the setting of CAR T cell expansion and peripheral B-cell reduction. These initial data suggest the potential for rese-cel to reset the immune system in SLE and LN, allowing patients to achieve meaningful clinical responses off all IM agents.

Abstract Number: 2469

Development of Consensus Statements on Glucocorticoid Use in Systemic Lupus Erythematosus

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2437–2469) Systemic Lupus Erythematosus – Treatment Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic glucocorticoid (GC) therapy is indispensable for treating active systemic lupus erythematosus (SLE) and lupus nephritis (LN), while contributing significantly to comorbidities and irreversible damage. The judicious limitation of GC use while effectively managing disease activity represents a critical yet unresolved challenge. This study aimed to formulate pragmatic recommendations for GC utilization in SLE.

Methods: Adhering to established consensus guideline procedures, Taiwan College of Rheumatology (TCR) SLE Special Interest Group (SLE-SIG) formulated a set of recommendations utilizing a systematic literature review and a formalized Delphi process. The literature review group identified the topics of interest and the scope of review, and generated preliminary statements. The selected questions constitute (1) general GC usage, tapering, and targets, (2) GC dosing across organ systems, and (3) special considerations on SLE antiphospholipid syndrome, SLE pulmonary arterial hypertension, and pregnancy. Organ involvements and severities were evaluated based on BILAG-2004 and SLEDAI-2K. The GC doses were

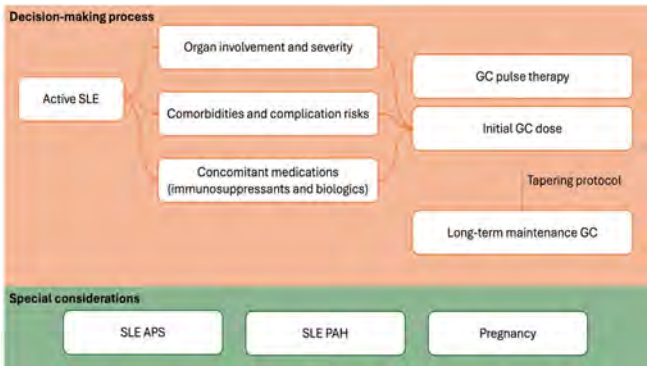

Figure Proposed decision-making process of glucocorticoid dosing in SLE

Table Summary of preliminary recommendations of initial glucocorticoid doses

Statements	Starting dose	MTP pulse
Mild disease and constitutional symptoms	as low as possible	reserved
Mucocutaneous and arthritis	0.3-0.5 mg/kg	reserved
Lupus nephritis: general	0.3-0.5 mg/kg	preferred
	0.5-1.0 mg/kg	optional
Lupus nephritis: high risk	0.5-1.0 mg/kg	preferred
Neuropsychiatric SLE: mild-to-moderate	0.3-0.5 mg/kg	preferred
Neuropsychiatric SLE: severe	0.5-1.0 mg/kg	
Life or organ-threatening, internal organ SLE	0.5-1.0 mg/kg	preferred
Non-life or organ-threatening, internal organ SLE	0.5 mg/kg	optional
SLE-APS and SLE-PAH	preferred over not using GC	
Pregnancy: maternal disease	0.3-0.5 mg/kg, non-fluorinated GC	
Pregnancy: fetal disease	fluorinated GC	

specified in weight-adjusted daily doses (prednisolone equivalent) and the GC pulses were described in daily doses (methylprednisolone equivalent.) A preliminary Delphi round by the expert panel was exercised to deduce the statements based on evidence review and group consensus, and the final statements were modified.

Results: A series of consensus statements encompassed three overarching principles regarding GC utilization in SLE, five general recommendations pertaining to GC initiation, tapering, and therapeutic goals, and eleven organ-specific recommendations. The preliminary evaluation of GC regimens for active SLE involved assessing organ involvement and severity, considering comorbidities and the potential risk of complications, and evaluating concomitant medication regimens, including immunosuppressants and biologics. The initial GC dose and GC pulse therapy were determined based on this evaluation, with the utilization of a tapering protocol to reach the target long-term GC dose at 5 mg/day by week 24 (Figure).

Organ-specific statements delineated the recommended initial GC dose and GC pulses. Organ involvement was categorized as mild disease and constitutional symptoms, mucocutaneous and arthritis, lupus nephritis (LN), neuropsychiatric SLE (NPSLE), and internal organ SLE. The latter three categories were further stratified according to severity for LN and NPSLE, and potential life- or organ-threatening disease for internal organ SLE, respectively. Statements regarding GC use in special considerations, including SLE with anti-phospholipid syndrome (SLE-APS), SLE with pulmonary arterial hypertension (SLE-PAH), and pregnancy, were also provided (Table).

This report presents preliminary consensus statements, subject to a formal Delphi process and subsequent voting by the expert panel to establish agreement levels. The final recommendations will be revised accordingly.

Conclusion: These preliminary statements provide evidence-driven, consensus-based guidance on GC dosing in SLE.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiovascular death ranks as the second leading cause of mortality related to systemic sclerosis (SSc), with coronary microvascular dysfunction (CMVD) likely contributing to this outcome. Positron emission tomography (PET) myocardial perfusion imaging (MPI) has emerged as the noninvasive gold standard for assessing myocardial blood flow (MBF) and myocardial flow reserve (MFR), offering unparalleled accuracy in detecting CMVD. We undertook the present study to explore the relationship between vasodilators, SSc disease-modifying antirheumatic drugs and CMVD in SSc patients.

Methods: We conducted a retrospective study involving patients diagnosed with SSc who underwent 82-rubidium PET MPI from July 2016 to April 2025 for clinical indications. These patients were compared to a control group without connective

Table 1. Baseline and imaging characteristics in systemic sclerosis (SSC) patients and matched controls.

Angiotensin receptor blocker (n=14)	1.24 (0.36-4.09)	0.727		
PAH therapy (n=16)	0.44 (0.11-1.46)	0.201		
Statin (n=26)	3.72 (1.34-10.86)	0.013	**7.14 (1.86-36.87)**	**0.008**
Aspirin (n=-16)	1.31 (0.41-4.10)	0.642		
Beta blocker (n=16)	2.57 (0.82-8.37)	0.106		
ACE inhibitors (n=7)	1.21 (0.22-5.95)	0.816		

tissue disease, matched 3:1 for age, sex, body mass index (BMI), cardiovascular comorbidities, and presenting symptoms. Differences between groups were analyzed using the Chi-Square test and the Wilcoxon rank-sum test. Univariable and multivariable logistic regression models were used to assess SSc-related predictors of clinically significant reduced MFR (< 2.0). Parameters with p< 0.05 in univariable analysis were included in multivariable model. Statistical analyses were performed with R version 4.4.2.

Results: The final cohort included 67 patients with SSc (87% female, mean age: 61 years, 14 with diffuse cutaneous SSc, disease duration: 12 ± 10 years) and 201 matched controls (Table 1). While stress MBF was not significantly different between SSc patients and controls (2.47 [IQR: 1.99-2.82] vs. 2.43 [IQR: 1.91-3.04] ml/g/min, p=0.85), rest MBF was significantly higher in SSc patients (1.14 [IQR: 0.92-1.37] vs. 1.00 [IQR: 0.78-1.24] ml/g/min, p=0.01) and MFR was significantly lower (2.17 [IQR: 1.84-2.57] vs. 2.44 [IQR: 1.96-2.96], p=0.01, Figure 1). Rates of abnormal perfusion, ischemic ECG changes, stress left ventricular ejection fraction, and visual coronary calcium scores were comparable between SSc patients and controls. In SSc patients, multivariable analysis identified mycophenolate mofetil (MMF) use as associated with significantly reduced odds for abnormal MFR (odds ratio [OR]: 0.09 [95% confidence interval[CI]: 0.01-0.56], p=0.017), whereas calcium channel blocker use (OR: 7.77 [95% CI: 1.93-42.53], p=0.008) and statin use (OR: 7.14 [95% CI: 1.86-36.87], p=0.008) were associated with higher odds of abnormal MFR (Table 2).

Conclusion: Patients with SSc exhibit significantly reduced PET-derived MFR compared to matched controls, indicating higher CMVD prevalence. Our finding of a significant association between calcium channel blocker or statin use and abnormal MFR may reflect more severe systemic microvascular disease. Conversely, the observed association between MMF use and lower incidence of reduced MFR suggests potential benefits through mechanisms such as cytokine suppression, antioxidant activity, or enhanced nitric oxide production. Further studies are warranted to validate these findings and to elucidate the effects of MMF on microvascular function in SSc.

Automated Feedback and Quality Control in Nailfold Capillaroscopy: A Tool for Clinical and Educational Use

Borja del Carmelo Gracia Tello[1], Gema María Lledó Ibáñez[2], Luis Sáez Comet[3], Eduardo Ramos ibáñez[4] and SEMI - GEAS, [1]Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain, [2]Hospital Clínic de Barcelona, Barcelona, Spain, [3]Hospital Universitario Miguel Servet, Zaragoza, Spain, [4]Capillary.io, Zaragoza, Aragon, Spain

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Nailfold capillaroscopy is a key tool in the early diagnosis of systemic sclerosis and related disorders. However, incorrect image acquisition can lead to misclassification of capillaroscopic patterns, potentially delaying diagnosis and affecting clinical decisions.

To support clinical reliability we developed a lightweight, real-time system for automatic quality assessment of nailfold capillaroscopy (NFC) images. The system supports exclusion of invalid images from analysis and reporting, provides immediate feedback during image acquisition, and aids clinician training by detecting typical image acquisition problems during a capillaroscopy examination.

Methods: A small and efficient deep learning model based on the ConvNeXt V2 architecture was trained to identify frequent NFC image issues: low magnification, blurring, reflections, incorrect placement, underexposure, and invalid content. For valid images (those without problems), the model also estimates diagnostic usability as low quality or acceptable quality.

Low quality images were defined as diagnostically acceptable but with imperfect focus or suboptimal capillary visibility, while acceptable quality images had clear visualization suitable for confident pattern recognition.

The model was trained on a dataset of 10,866 annotated images. An image may have multiple problem annotations, but quality grading (low or acceptable) was applied only to images without any problems. The number of annotations per annotation type are shown in Table 1.

To ensure clinical reliability, model evaluation metrics were computed at a confidence threshold of 0.85.

Results: The model achieved exceptional performance in detecting low magnification images, with an F1-score of 0.99, and invalid content, with an F1-score of 0.96, two of the most critical categories for ensuring diagnostic image quality. It also showed strong performance in identifying blurry images (F1 = 0.84) and those with excessive reflections (F1 = 0.83).

In terms of quality grading of valid images, the model effectively distinguished between low and acceptable quality among valid images, achieving an F1-score of 0.8316 for low-quality cases. The rest of performance metrics are shown in Table 2.

Conclusion: This real-time model based on ConvNeXt V2 helps ensure that nailfold capillaroscopy examinations are useful and valid. It automatically detects common problems in images and checks whether valid images have enough quality for diagnosis. Because it is fast and lightweight, it can be used during image capture to give immediate feedback, avoid invalid images, and improve the consistency of capillaroscopies. This makes the process more efficient and helps both clinicians and researchers achieve better, more reliable results as well as being a useful tool in the training of new physicians.

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Gastrointestinal (GI) involvement is among the most frequent organ manifestations in systemic sclerosis (SSc), yet the timing of presentation of GI manifestations remains incompletely understood. In this retrospective analysis, we aimed to describe the baseline prevalence and the incidence of new GI disease manifestations over time in a real-life, large SSc cohort.

Methods: We included patients from our center's cohort fulfilling the ACR/EULAR 2013 criteria for SSc or the VEDOSS criteria. Electronic medical records were searched for data regarding the presence and the time of

GAVE	9 (1.4%)	5 (1.2%)	2 (2.0%)	0 (0.0%)
Gastroparesis	4 (0.6%)	1 (0.2%)	3 (2.9%)	0 (0.0%)
SIBO	5 (0.8%)	3 (0.7%)	2 (2.0%)	0 (0.0%)
CIPO	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)
Chronic constipation	17 (2.6%)	5 (1.2%)	5 (4.9%)	3 (10.0%)
Chronic diarrhea	8 (1.2%)	2 (0.5%)	4 (3.9%)	1 (3.3%)
Anal incontinence/dyssinergy	15 (2.3%)	5 (1.2%)	4 (3.9%)	2 (6.7%)
GI Bleeding	12 (1.8%)	9 (2.1%)	2 (2.0%)	1 (3.3%)
UCLA SCTC GIT 2.0 total score	0.29 (±0.33)	0.14 (±0.14)	0.59 (±0.13)	1.30 (±0.29)

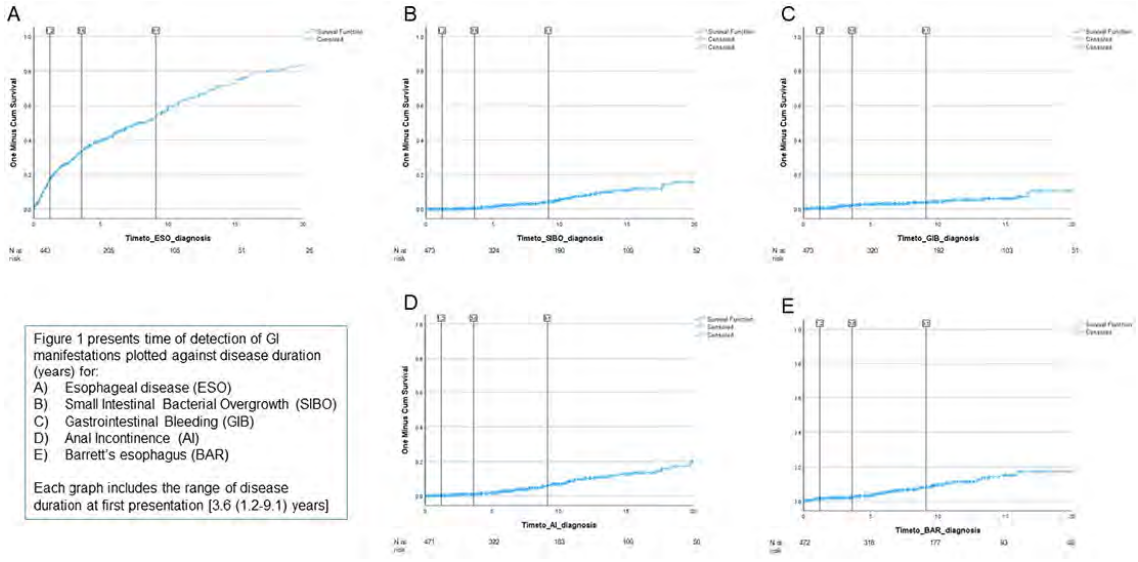

Figure 1 presents time of detection of GI manifestations plotted against disease duration (years) for:
A) Esophageal disease (ESO)
B) Small Intestinal Bacterial Overgrowth (SIBO)
C) Gastrointestinal Bleeding (GIB)
D) Anal Incontinence (AI)
E) Barrett's esophagus (BAR)

Each graph includes the range of disease duration at first presentation [3.6 (1.2-9.1) years]

Figure 1

detection of specific GI diagnoses. We focused on esophageal disease (defined as at least one of: reflux, dysphagia, or aperistalsis), gastroparesis, gastric antral vascular ectasia (GAVE), small intestinal bacterial overgrowth (SIBO), chronic intestinal pseudo-obstruction (CIPO), chronic constipation, and chronic diarrhea. In addition, data of the University of California at Los Angeles/Scleroderma Clinical Trials Consortium Gastro-Intestinal Tract instrument 2.0 (GIT 2.0) questionnaire were also collected at each annual visit, when available. Based on the GIT 2.0 score, GI disease burden was categorized at baseline into 3 groups: (1) none to mild, (2) moderate, and (3) severe-to-very severe symptoms (Khanna D. et al, Arthritis Rheum 2009). We assessed baseline prevalence of GI diagnoses and used survival curves to investigate the timing of GI diagnoses from disease onset, defined as time from the first non-Raynaud's sign or symptom.

Results: We included 658 patients: 83.6% females, mean age 55.4 (SD 15.0) years, 566 (86%) with available GIT 2.0; additional baseline clinical data are displayed in Table 1. At the first visit, 318 (48.3%) patients already presented with GI manifestations or diagnoses. Of these, the most common was esophageal disease (45.0%), while all other clinically relevant GI manifestations had an initial prevalence of < 4%. According to the GIT 2.0 categories, most patients had none to mild symptoms, while 102 (15.5%) had moderate and 30 (4.6%) had severe-to-very severe GI disease.

Over a mean follow-up time of 3.3 (SD 3.2) years, additional patients developed new GI complications, with the cumulative prevalence increasing to 65% at last follow-up. In particular, esophageal disease increased to 61.1%, Barrett's esophagus from 3.8% to 7.9%, GAVE from 1.4% to 4.3%, SIBO from 0.8% to 7.0%, anal incontinence from 2.3% to 7.6% and GI bleeding from 1.8% to 5.3%. Only 4 patients, already diagnosed with SIBO, developed CIPO during follow-up.

Focusing on patients with known disease duration from SSc onset [n=476 (72%), median 3.6 (IQR 1.2-9.1 years)], we observed that esophageal involvement tended to appear earlier (median time from disease onset: 7.5 years), while others like Barrett's esophagus or SIBO occurred later (Figure 1 A to E).

Conclusion: GI involvement in SSc is frequent and dynamic, with distinct time patterns for individual complications. Early manifestations such as esophageal disease precede more severe complications like GAVE and SIBO. Longitudinal tracking of GI disease in SSc provides important insights into its natural history and may inform anticipatory management strategies.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is associated with both micro- and macrovascular damage, increasing cardiovascular (CV) risk. The SCORE2 algorithm estimates CV event risk in the general population but may underestimate it in SSc. Nailfold capillaroscopy (NFC) detects microangiopathy typical of SSc, which may improve CV risk prediction in this population.

To evaluate the predictive value of NFC findings for CV events and assess whether incorporating these into the SCORE2/SCORE2-OP algorithms improves risk stratification.

Methods: We conducted a multicenter retrospective study of 276 SSc patients without prior CV events. SCORE2 was applied to patients aged 40–69, and SCORE2-OP to those ≥70. NFC was performed at diagnosis. A Cox regression identified NFC variables associated with incident MCE during follow-up. Based on these results, a modified SCORE2 was calculated by applying hazard ratios (HRs) of the baseline NFC findings, to the original SCORE2 score. ROC curves assessed the discrimination of original versus the modified model. Patients were categorized into standard risk levels (low, moderate, high, very high), and the Net Reclassification Index (NRI) was calculated.

Results: Over a median follow-up of 9.5 years, 45 patients (16.3%) experienced a CV event. Baseline characteristics are summarized in Table 1. Hemorrhages ($p = 0.002$) and avascular areas ($p < 0.001$) at diagnosis were significantly associated with subsequent CV events. In multivariate Cox analysis, hemorrhages showed an independent protective effect (HR = 0.333, $p = 0.01$), while avascular areas were independently associated with increased risk (HR = 2.238, $p = 0.034$) (Table 2).

The modified SCORE2 showed improved discrimination (AUC 0.767) compared to the original (AUC 0.680) (Figure 1). At the optimal threshold (1.83%), the modified SCORE2 yielded a sensitivity of 85.2% and specificity of 58.4%, versus 74.1% and 59.4% for the original model.

Table 1: Demographic, clinical and laboratory data from the cohort

	N = 276 (%)
Female / Male	248 (89.9) / 28 (10.1)
Age at time of diagnosis, mean (SD)	62.83 ±15.66
Body mass index, mean (SD)	25.28± 4.92
Cardiovascular risk factors	
Smoking history	44 (15.9)
Alcohol consumption	55 (19.9)
Arterial hypertension	90 (32.6)
Systolic arterial pressure, mmHg, mean (SD)	129.85 (20.46)
Diabetes mellitus	25 (9.1)
Dyslipidemia	106 (38.4)
Colesterol total, mg/dL, mean (SD))	196.04 (37.43)
HDL, mg/dL, mean (SD))	53.94 (15.2)
LDL, mg/dL, mean (SD)	122.27 (34.57)
Atheroma plaque	82 (29.7)
Disease duration, years, median, (IQR 25th - 75th)	9.5 (5-14)
SSc cutaneous involvement	
Diffuse	42 (15.2)
Limited	180 (65.2)
Sine esclerodermia	45 (16.3)
Telangiectasias	78 (28.3)
Digital ulcers	76 (27.5)
Calcinosis	46 (16.7)
Oesophageal involvement	110 (39.9)
interstitial lung disease	68 (24.6)
Pulmonary hypertension	34 (12.3)
Cardiac involvement	51 (18.5)
Renal involvement	11 (4)
Arthritis	63 (22.8)
ANA	218 (79)
ATA positive	42 (15.2)
ACA positive	102 (37)
RNA polimerase III positive	7 (2.5)
Cardiovascular event during follow-up	45 (16.3)
Type of event	
Myocardial infarction	21 (46.67)
Peripheral vascular disease (ischemia o thrombosis)	15 (33.33)
Ictus	9 (20)
Deaths	
Total	57 (20.7)
Attributable to cardiovascular events	13 (22.81)

Some patients suffered more than one cardiovascular event during follow-up

Results are presented as the number of cases with percentage, mean ± standard deviation (SD), or median with interquartile range (IQR) for the 25th–75th percentile.

Table 2. Multivariate Cox-regression analysis of predictors for cardiovascular events

Table 2. Multivariate Cox-regression analysis of predictors for cardiovascular events

	Hazard ratio	95% Confidence interval	p
Age	0.995	0.959 – 1.033	0.789
Arterial hypertension	1.219	0.262 – 2.469	0.759
Dyslipidemia	1.050	0.400 – 2.756	0.920
Digital ulcers	1.644	0.663 – 4.074	0.283
Interstitial lung disease	**3.815**	**1.560 – 9.330**	**0.003**
Pulmonary hypertension	1.848	0.689 – 4.956	0.222
Cardiac involvement	1.496	0.549 – 4.072	0.431
Haemorrhages in baseline NFC	**0.333**	**0.144 – 0.773**	**0.010**
Avascular areas in baseline NFC	**2.238**	**1.061 – 4.723**	**0.034**

ABBREVIATIONS: NFC = nailfold capillaroscopy

Among patients with CV events, 33% were correctly reclassified to higher risk and 7% incorrectly to lower risk. Among non-event patients, 3% were correctly reclassified to lower risk and 5% incorrectly to higher risk. The total NRI was +0.239, indicating improved net reclassification.

Conclusion: Adjusting the SCORE2 algorithm using NFC findings at the time of diagnosis improves cardiovascular risk prediction in patients with systemic sclerosis. Avascular areas confer increased risk, while hemorrhages appear protective. These microvascular markers may support more personalized cardiovascular prevention strategies in this high-risk population.

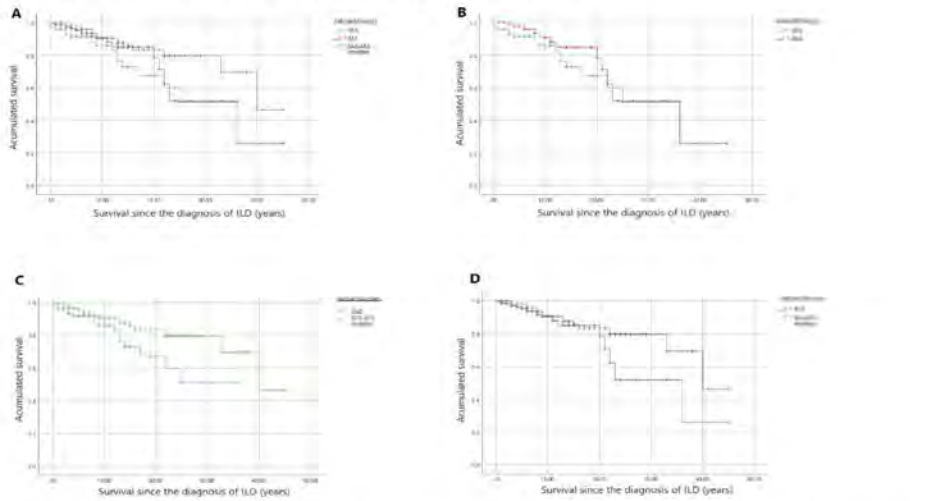
Figure 1. Kaplan–Meier survival curves in SSc-ILD patients according to autoantibody subsets.



A) Overall survival from ILD diagnosis stratified by serological subgroups: anticentromere antibody-positive (ACA), anti-topoisomerase I antibody-positive (ATA), and ACA/ATA-negative groups. No statistically significant difference was observed (log-rank p=0.164).
B) Pairwise comparison between ACA- and ATA-positive groups showed no significant survival difference (log-rank p=0.471).
C) ACA-positive patients showed significantly worse survival than ACA/ATA-negative patients (log-rank p=0.041).
D) Survival comparison between ATA- and ACA/ATA-negative groups was not statistically significant (log-rank p=0.305).

Note: Survival curves reflect follow-up from ILD diagnosis. Tick marks represent censored observations. Group comparisons were assessed using the log-rank test.

Background/Purpose: Anticentromere antibody (ACA)-positive interstitial lung disease (ILD) in systemic sclerosis (SSc) is traditionally considered less aggressive than anti-topoisomerase I (ATA)-positive ILD. However, its clinical profile and prognosis remain poorly defined. We aimed to characterise ACA-associated SSc-ILD and compare it with other serological subsets.

Methods: Multicentre cross-sectional observational study including 76 ACA-positive SSc-ILD patients, who were compared with ATA-positive (n=54) and ACA/ATA-negative (n=147) groups.

Results: ACA-positive SSc-ILD patients developed ILD earlier than ATA-positive and ACA/ATA-negative individuals (2.5 vs. 5.6 and 3.5 years), although this difference was not statistically significant (p=0.389). Compared with the other groups, ACA-positive patients had higher %pFVC (96.3% vs. 83.5% and 86.9%; p=0.013), lower FEV1/FVC ratio (91.6% vs. 99.2% and 98.8%; p=0.004), and better functional capacity at ILD diagnosis, with fewer patients classified as NYHA class III–IV (14.5% vs. 42.6% and 32%; p=0.017). They also showed lower %pKCO (p=0.008) and a higher FVC/DLCO ratio (p=0.016), reflecting indolent microvascular damage and increased pulmonary vascular resistance. The different characteristics of the three serological groups are presented in table 1.

Worsening of ILD according to ATS criteria was observed in 14.5% of ACA-positive patients. Although no significant differences were found in antifibrotic therapy indication or advanced interventions, 2.6% of ACA-positive patients underwent lung transplantation and 2.6% received autologous haematopoietic stem cell transplantation. The characteristics of ACA-positive SSc-ILD patients are presented in table 2.

Overall survival analysis revealed no significant differences across the three groups (p=0.164), although ACA/ATA-negative patients showed better survival than ACA-positive patients (p=0.041; HR 0.498, p=0.045). The survival analysis is presented in Figure 1.

Conclusion: ACA-positive SSc-ILD does not seem to have a more favourable long-term prognosis compared with other serological subsets.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Gastroesophageal reflux disease may contribute to the progression of interstitial lung disease in systemic sclerosis (SSc). However, it is unclear whether reflux severity or treatment with proton pump inhibitors (PPIs) impacts longitudinal pulmonary function. The purpose of this study was to examine whether either reflux severity as measured by a validated gastrointestinal symptom questionnaire (UCLA SCTC GIT 2.0) or PPI use is associated with longitudinal pulmonary function in SSc.

Methods: Patients were included if they were enrolled in the CONQUER registry, met 2013 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for SSc, completed at least one UCLA SCTC GIT 2.0, and were not pregnant at CONQUER enrollment or during follow-up. We included patients who completed at least 1 pulmonary function test (PFT) for the baseline analysis and at least 2 PFTs for the longitudinal analysis. Baseline missingness and univariate mixed-effect longitudinal regression were used for variable selection to create a mixed-effect longitudinal regression model predicting longitudinal ppFVC using reflux severity on UCLA GIT 2.0 (none or mild, moderate, severe or very severe), PPI use, the interaction between PPI use and GERD severity, as well as appropriate adjustment variables (age, sex, race, disease duration at baseline, follow-up time, baseline modified Rodnan skin score, smoking status, SSc subtype [limited or diffuse], modified Rodnan skin score, scleroderma autoantibodies [Scl70, centromere, RNA Polymerase III, two subserologies, ANA negative, ANA only], and the presence of traumatic ulcers).

Results: One-thousand thirty-nine patients were included, of whom 187 (18.0%) had severe or very severe reflux and 255 (24.5%) had moderate reflux (Table 1). Baseline ppFVC was lower in patients with severe or very severe reflux compared to those with mild or no reflux (81.6% vs. 88.4%). Severe or very severe reflux was significantly associated with longitudinal ppFVC decline in the univariate analysis (-6.1, 95% CI -9.5 to -2.8; p=-0.002; Table 2) but not in the multivariable-adjusted analysis. PPI use was greatest in those with severe-very severe reflux and was independently associated with longitudinal

ppFVC decline in both the univariate (-4.9, 95% CI -7.5 to -2.5, p< 0.001) and multivariable-adjusted models (-4.2, 95% CI -7.7 to -0.7; p=0.018). The interaction between PPI use and GERD severity was significant in the unadjusted model (-7.5, 95% CI -11.3, -3.8; p< 0.001) but not in the multivariable-adjusted model.

Conclusion: Severe or very severe reflux was associated with longitudinal ppFVC decline in univariate analysis, but the association was not statistically significant after adjustment for other variables. PPI use was an independent risk factor for ppFVC decline even after adjustment for GERD symptom severity. Use of PPI in patients with SSc may reflect greater esophageal dysmotility or aspiration risk, independent of GERD symptom severity. Alternatively, PPI use may directly contribute to ppFVC decline, possibly by reducing the concentrations and effectiveness of immunosuppressive medications or increasing pulmonary infection risk.

Background/Purpose: Systemic sclerosis is a severe, potentially fatal disease, characterized by progressive fibrosis of skin and internal organs. Blinatumomab is a bispecific CD3/CD19-T-cell engager (BiTe) approved for treatment of relapsing/refractory Philadelphia chromosome negative, CD19-positive B-precursor-acute lymphocytic leukemia.

Methods: After our first case of blinatumomab for acute progressive systemic sclerosis despite conventional therapy, we now report of our cohort of up to date four BiTe treated patients.

Results: All patients showed rapidly progressive skin fibrosis as well as internal organ involvement, namely myocardial fibrosis in our first patient and pulmonary fibrosis in the other three. We administered four cycles of blinatumomab in our first two patients and two cycles with higher daily dose in the other two patients due to good initial results and low grade toxicity. All patients reported of rapid improvement of skin symptoms with a decrease of the Rodnan Skin Score score from (range) 20 to 5 at our last follow-up. Furthermore we could demonstrate receding cardial as well as pulmonary fibrosis, as seen in imaging (cardiac MRI) and lung function tests (increase of DLCOs by up to 11 %). In all patients, peripheral B cell counts declined completely from the first day of treatment with recovery to normal levels within weeks after treatment. Peripheral T cells were significantly reduced on the first day of treatment, but quickly recovered to normal levels and remained stable during subsequent cycles. IgG and Scl 70 ab levels temporarily decreased after treatment. Remarkably, with the exception of a transient neutropenia in one of the four patients, there were no significant adverse events, in particular ICANs, CRS or infections.

Conclusion: Blinatumomab resulted in profound B-cell depletion and a significant decrease in serum IgG with no increased susceptibility to infections. Clinically, the therapy led to a rapid and sustained improvement in symptoms. Further studies are needed to determine the value of B-cell depleting therapy with blinatumomab in systemic sclerosis.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The therapeutic landscape for systemic sclerosis- interstitial lung disease (SSc-ILD) has rapidly evolved over the past decade, with increasing adoption of immunosuppressive (IST) and anti-fibrotic therapies. However, real-world data on current treatment strategies, including combination regimens, treatment switches, and clinical predictors for treatment decisions, remain limited. This study aims to characterize treatment patterns and their clinical drivers in the contemporary era using the EUSTAR database.

Methods: We analyzed SSc-ILD patients from the EUSTAR registry first assessed since ^{3} 2017. Treatment courses were defined as any use of IST and/or anti-fibrotic drugs ^{3}3 months. Treatment strategies were classified as: (1) switch: change from one therapy to another during follow-up; (2) discontinuation: stopping a primary therapy without initiating another; (3) unmodified: no changes during follow-up; (4) combination: concurrent use of ^{3} 2 drugs. Frequency and combinations of therapies were described. Logistic regression analyses were used to identify clinical factors associated with treatment strategies.

Results: Among 277 patients, 159 (57%) received IST and/or anti-fibrotic therapy since their first evaluation, Table 1. Multivariable analysis showed that shorter disease duration (OR 0.991, 95% CI 0.987–0.996, p< 0.001) and presence of myositis (OR 9.93, 95% CI 1.94–51.76, p=0.006) were associated with treatment initiation. The different treatment courses are summarized in Figure 1 and grouped according to the 4 most used IST: mycophenolate mofetil (total courses 377, panel A), methotrexate (total courses 187, panel B), rituximab (total courses 257, panel C) and tocilizumab (total courses 122, panel D). A total of 213 treatment switches occurred (see Figure 2). Higher mRSS (OR 1.031, 95% CI 1.002 – 1.062, p = 0.035) and arthritis (OR 3.034, 95% CI 1.551 – 5.936, p = 0.001) were associated with treatment switching in multivariable logistic regression. Younger age (OR 0.968, 95% CI 0.953 – 0.985, p < 0.001), higher dyspnea class (OR 1.557, 95% CI 1.189 – 2.039, p = 0.001), and inflammatory arthritis (OR 2.560, 95% CI 1.354 – 4.840, p = 0.004) were associated with combination therapy. No predictor was associated with treatment discontinuation.

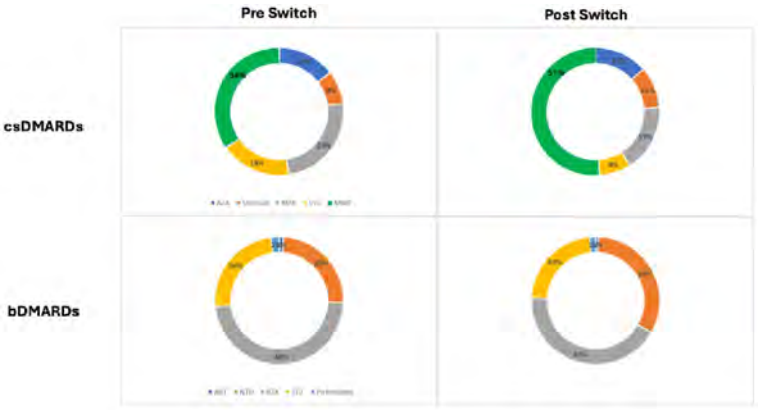

Figure 2. The use of csDMARD and bDMARDs in SSc-ILD patients switching therapies.

Conclusion: In current clinical practice, a considerable amount of SSc-ILD patients is treated. Treatment decisions are influenced not only by lung function but also by systemic features such as arthritis and myositis. Combination strategies and treatment modifications are frequently used in SSc-ILD, reflecting a more individualized approach. These findings have important implications for future trial design and highlight the urgent need for evidence-based guidance on combination and sequential therapies.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Vasculopathy is a central driving clinical, histopathologic and pathogenic feature of juvenile systemic scleroderma (jSSc), juvenile dermatomyositis (JDM) and juvenile scleroderma-overlap syndrome (jOverlap). While we recognize distinct clinical patterns of vasculopathy between diseases and disease states, we lack a complete understanding of underlying pathomechanisms driving vasculopathy. In this study, we evaluated endothelial cell (EC) dysregulation markers in a cohort of jSSc, JDM and Overlap patients to identify common and disease-specific biomarkers of vasculopathy that may reflect underlying pathophysiology and disease activity.

Methods: Sixteen biomarkers of EC dysregulation were assessed in plasma from patients with jSSc (n=39), JDM (n=50), jOverlap (n=22) and age-matched controls (n=41) using customized LegendPlex kits from Biolegend, and collected via flow cytometry using Sony ID7000 and Cytek Aurora instruments. The Ang 1/2 ratio was calculated as a surrogate marker of vascular health. Clinical data were obtained from the National Registry of Childhood Onset Scleroderma (NRCOS) and the University of Michigan JDM cohort, including disease activity outcomes in jSSc (clinical assessment and modified Rodnan skin score-mRSS), disease-associated antibody status, and disease type. Biomarker levels were normalized using Z-scores with group differences analyzed by ANOVA, Tukey's tests, and Kruskal-Wallis, and mRSS correlations assessed via Spearman's rho.

Results: Angiogenesis signaling markers Ang1 and Ang 1/2 ratio were significantly elevated in jSSc, while Ang2 and Tie2 were increased in JDM (Fig 1, Table 1). Inflammatory cytokine CXCL10 was significantly higher in JDM and jOverlap patients compared to jSSc and controls. Glycan-binding Gal-9 levels were highest in JDM, followed by jOverlap and then jSSc, while E-selectin showed a similar but less pronounced pattern. Cell adhesion molecules PECAM-1 and VCAM-1 were elevated in jSSc and jOverlap patients, as was ICAM-1, which was particularly elevated in active relative to inactive jSSc samples.

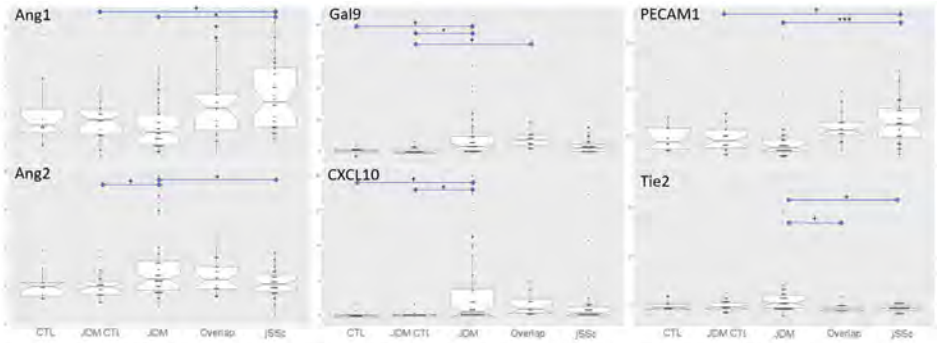

Figure 1. Angiogenesis-related markers show significant changes in the Ang1/2-Tie2 axis. Ang1 is significantly increased in jSSc vs JDM and control, while Ang2 shows a significant increase in JDM vs. jSSc. Gal9 shows significant increases in JDM and overlap patients. IFN-mediated CXCL10 shows significant increase in JDM with trended increases in overlap and jSSc. Cell-cell adhesion molecule PECAM1 was significantly increased in jSSc over JDM with overlap showing an intermediate expression. Tie2 (Ang2 receptor) shows a significant increase in JDM vs overlap and jSSc patients.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Angiogenesis biomarker expression by diagnosis and physician-assessed global and skin-scored disease activity. A. Juvenile systemic scleroderma (jSSc, n=42) and overlap syndrome (n=21) show significant differences from age-matched controls (n=15) for expression of ICAM1, VCAM-1, CXCL10, Gal-9, PECAM-1, and Ang1/2 ratio. PECAM-1 and Ang1/2 ratio show greater expression in jSSc than overlap, while the remaining markers show greater increase in overlap patients. B. Similar changes are observed in physician-assessed inactive vs active samples, particularly CXCL10 and Gal-9 that show greater increase in overlap patients than jSSc, while Ang1/2 ratio shows greater increase in both active and inactive jSSc patients. Ang-2 demonstrates greater increase in inactive jSSc and active overlap disease. C. Spearman's Correlation Coefficients were tested for mRSS (i.e. a disease activity measure) association with angiogenesis biomarkers showing association with Gal-9 in jSSc and pooled patients, Ang-2 in overlap patients, and Ang-1 in pooled patients. E-Selectin also showed significant association with pooled patients.

Ang1/2 ratio	Median	5.34	7.50	4.48	5.19	6.12	0.70787
	Q1	3.68	4.89	4.02	2.71	4.86	
	Q3	8.67	9.76	6.10	9.08	6.12	

Table 2. Myositis-associated Antibodies were associated with angiogenesis biomarker changes. VCAM-1, CXCL10, and Gal-9 were all significantly increased in PM/Scl+ patients and each except CXCL10 was also significantly increased in Scl-70+ patients.

Among antibody-defined subsets, PM-Scl+ and Scl-70+ patients showed notable increases in Gal-9 and VCAM-1, and PM-Scl+ patients also showed increased CXCL10 expression.

Conclusion: Distinct angiogenic patterns are observed in JDM and jSSc patients, with jOverlap having a unique profile between both conditions. The Ang1/2-Tie2 axis is inverse between JDM and jSSc, and differs from prior adult scleroderma data. This may suggest earlier disease or unique disease progression in pediatric patents. Increased Gal-9 and CXCL10 expression in JDM and overlap patients, versus prominent cell adhesion molecule expression in jSSc, may define differential biomarker signatures and offer new tools for assessing disease activity and therapeutic response.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SS) is a rare connective tissue disorder characterized by progressive fibrosis of the skin and internal organs, including lungs, heart and kidneys. Furthermore, SS may increase osteoporosis risk due to chronic inflammatory state, malabsorption/malnutrition, limited mobility and use of corticosteroids therapy. Currently, emerging evidences suggest that SS might represent an independent factor for low BMD, further compromising skeletal health. Additionally, SS patients generally present with overlapping comorbidities, such as rheumatoid arthritis, hypercholesterolemia, hypothyroidism, etc., which may further exacerbate fracture risk (FR) and overall health outcomes. Given the fragile health status of this population, early identification of skeletal fragility is essential for optimal patient management and improved quality life. For this, the present study aims to assess the impact of SS on imminent (within 5 y) FR using Radiofrequency Echographic Multi Spectrometry (REMS) technology, by comparing patients either with SS alone and with SS plus additional comorbidities. A secondary aim is to explore the contribution of comorbidities to increased FR.

Methods: The 5-y FR analysis was assessed by combining both quantitative (BMD, T- and Z-score) and qualitative (bone microarchitecture via Fragility Score, FS) data. REMS technology automatically provides a risk classification system consisting of 7 increasing risk levels, named from R1 to R7, each corresponding to a defined probability of imminent FR. To ascertain the impact of comorbidities on the likelihood of experiencing an incident fracture, a logistic regression was performed.

Results: A cohort of 91 Caucasian patients (both genders) either affected by SS (n = 64, median age: 64.3 yo, 42.2% women < 65 yo) or by SS + other comorbidities (n = 27, median age: 69 yo, and 33.3% women < 65 yo) underwent spinal REMS scan. The FR analysis at major osteoporotic fracture showed that SS patients were classified as follows: R1 (9.3%), R3 (42.2%), R4 (1.6%), R5 (20.3%), R6 (6.3%) and R7 (20.3%). Likewise, SS + comorbidities showed a similar distribution across the 7 classes: 3.7% (R1), 48.2% (R3), 7.4% (R4), 18.5% (R5), 3.7% (R6) and 18.5% (R7). Likewise, the T-score and FS analyses showed similar values between the SS (T-score: -2.2 ± 0.8 and FS: 41.4 ± 19.9; mean ± SD) and SS + comorbidities (T-score: -2.3 ± 0.7 and FS: 43.8 ± 20.4; mean ± SD). Logistic regression did not show any significant association between SS or SS + comorbidities and increased FR, thus indicating that the overlap of other pathological conditions does not exacerbate an already altered skeletal health status.

Conclusion: In conclusion, in our study SS alone appeared to be the primary factor contributing to compromised bone quality and quantity. These findings underscore the importance of early bone health assessment and monitoring in SS

patients through REMS technology, particularly given the potential for skeletal fragility even in the absence of additional comorbidities. Clinical studies focusing also on exploring the impact of a single comorbidity rather than grouped multiple factors are ongoing to assess how each comorbidity influences fracture skeletal risk in SS patients.

Respiratory Muscle Weakness in a Systemic Sclerosis Cohort

Fabian Mendoza[1], Wendy Perdomo[2], Timothy Wilson[1] and Sergio Jimenez[1], [1]Thomas Jefferson University, Philadelphia, PA, [2]Thomas Jefferson University Hospital, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune disorder marked by vascular damage, immune dysregulation, and fibrosis. Lung involvement, particularly interstitial lung disease (ILD), carries high morbidity and mortality. Respiratory muscle weakness (RMW), though underrecognized in SSc, may contribute to pulmonary function decline independent of parenchymal involvement. Standard pulmonary function tests (PFT) measurements, such as forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO), may decline in patients with RMW, complicating ILD assessment. Diagnostic tools, including maximal inspiratory pressure (MIPs) and diaphragmatic ultrasound, are used to diagnose RMW. This study aims to investigate the prevalence of RMW in a SSc US population, describe the phenotype of patients with RMW, and examine the association of the proposed measurement of RMW with lung volumes and DLCO consecutive patients with SSc. We also correlate RMW with other measurements of sarcopenia in a subpopulation.

Methods: We examined PFTs measurements of RMW in 100 consecutive patients at the Jefferson Scleroderma Center at Thomas Jefferson University. Clinical phenotype, SSc-specific antibodies, MIPs, MEPs, FVC, DLCO, and the presence of ILD at HRCT were studied. We defined RMW as a MIP of less than 50%. Measurements of sarcopenia, including hand dynamometer, fast walking test, and bioimpedance, were correlated in a subgroup of patients.

Chi-square was used to compare categorical variables. Spearman's rho correlation was used to test for significant associations amongst the parameters of interest. Statistical significance was assumed at an alpha value of 0.05.

Results: From 100 SSc patients, 86 had complete PFTs data and were included for analysis. Nine patients (10.47%) were identified to have RMW at the predetermined value. In these patients, 40% displayed limited phenotype, 40% diffuse, and 10%. Sine Scleroderma versus a 25.9% of diffuse phenotype in the patients without RMW (p=0.07). Creatine Kinase value was (120.4 ±89.8 U/L) [20-458] with no difference with SSc patients with no RMW. Only one patient in the RMW group had the diagnosis of myositis. SSA/RO-52 was the most prevalent autoantibody in patients with RMW (3/9). 33.3% of the RMW-SSc patients (3/9) did not have ILD, and 44.4% (4/9) presented less than 10% of parenchymal involvement at HRCT. MIP values directly correlate with MEP (rs = 0.31, p = 0.031), and FVC (rs = 0.29, p = 0.043). No conclusive correlation was found with measurements of generalized sarcopenia.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: RMW is prevalent in more than 10% of patients with SSc in this cohort. Diffuse phenotype and +Ro52 are more prevalent in SSc-RMW. The myositis phenotype was not commonly seen in these patients. A direct correlation between MIPs values and FVC was found. Raising awareness and identifying this phenotype opens the possibility for pharmacological and non-pharmacological therapeutic interventions. Correlation with FVC is of particular importance and requires further study since it is one of the most used values for disease progression in clinical practice and clinical research.

Prevalence and Trends of Suicidal Ideation Among Hospitalized Adults with Systemic Lupus Erythematosus (SLE): A National Inpatient Sample Analysis (2016–2020)

Fatima Khdeir and Aysheh Khdeir, ECU Health Medical Center, Greenville, NC

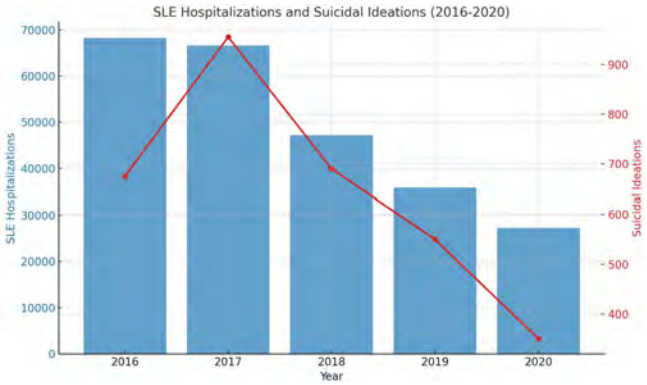
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease associated with psychiatric comorbidities, including depression and suicidal ideation. However, national trends over time have not been fully characterized.

Methods: We conducted a retrospective cross-sectional analysis using NIS data from 2016–2020. Adult patients (age ≥18) diagnosed with SLE were identified using ICD-10 codes. Suicidal ideation was detected using diagnosis code R45.851. Weighted survey procedures were applied for national estimates. Secondary outcomes included age, sex, race, and psychiatric comorbidities such as generalized anxiety disorder, depression, bipolar disorder, and psychotic disorders.

Results: The total weighted number of SLE hospitalizations from 2016 to 2020 was approximately 245,300 patients. Among these, 1.31% had documented suicidal ideation. Patients with suicidal ideation were notably younger, with a mean age of 42.1 years, compared to 47.3 years among those without ($p < 0.001$). No significant differences were observed between males and females. However, there were clear racial disparities, with White patients accounting for the highest



SLE hospitalizations (blue bars) Suicidal ideations (red line) From 2016 to 2020.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

proportion of suicidal ideation cases (53.6%). Psychiatric comorbidities—including anxiety disorders, bipolar disorder, psychotic disorders, and substance abuse—were all significantly associated with increased suicidal ideation ($p < 0.001$). Trend analysis revealed that suicidal ideation cases rose from 675 in 2016 to a peak of 955 in 2017, before steadily declining to 350 in 2020. During the same period, overall SLE hospitalizations also showed a decreasing trend.

Conclusion: Although the overall rate of suicidal ideation among hospitalized SLE patients remains low, psychiatric comorbidities significantly increase risk. After a peak in 2017, a decreasing trend was observed through 2020, likely due to improved psychiatric screening, advances in SLE treatment, multidisciplinary care approaches, and increased recognition of neuropsychiatric risk factors.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Gastrointestinal (GI) involvement affects over 80% of patients with systemic sclerosis (SSc), contributing significantly to morbidity and representing the third leading cause of disease-related mortality. Symptoms can affect any GI tract segment and often appear early in the disease course. To date, no disease-specific treatment exists, and management remains symptomatic. The underlying mechanisms are not fully understood, and the clinical course is highly variable.

This study aimed to identify SSc endotypes associated with GI involvement, determine clinical predictors of GI symptoms, and explore the relationship between disease duration and GI manifestations using data from the SSc Progression INvestiGation (SPRING) registry of the Italian Society of Rheumatology.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. DLCO, mean (SD)	72.64 (19.85)	66.23 (19.85)	64.44 (21.49)	618	**<0.001**

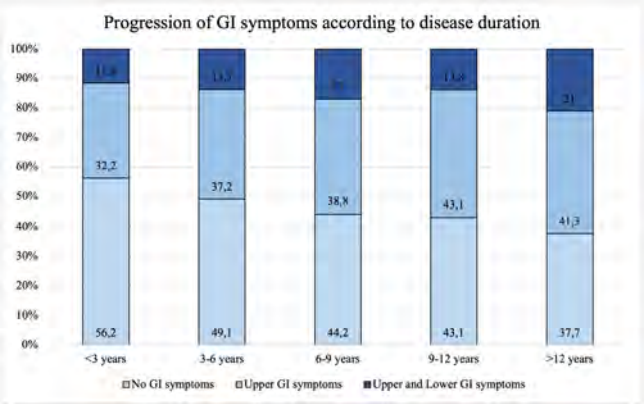

Figure 1. Stratification of GI extent according to disease duration.

Methods: Patients fulfilling the 2013 ACR/EULAR classification criteria and with available GI symptom data were included. GI involvement was defined by the presence of symptoms in at least one of the esophageal, gastric, or intestinal tracts. GI manifestations were classified as "upper GI involvement" (esophageal/gastric symptoms only) or "lower GI involvement" (intestinal symptoms regardless of upper GI symptoms). Chi-square and Student's t-test were used for descriptive comparisons. Logistic regression was used to identify predictors of GI involvement; ordinal regression assessed predictors of increasing GI disease extent.

Results: Among 2178 patients, 1917 met inclusion criteria. Of these, 1073 (56%) reported GI symptoms. Patients with GI involvement had longer disease duration ($p< 0.001$) and more severe disease features, including diffuse cutaneous SSc (dcSSc), interstitial lung disease (ILD), and digital ulcers (DU) (all $p< 0.001$). Autoantibody status, sex, and age were similar across groups. GI involvement increased with longer disease duration, peaking in those with >12 years of disease (62.3%, Figure 1). Logistic regression identified telangiectasias, tobacco exposure, dcSSc, ILD, DU, and longer disease duration as independent predictors of GI symptoms.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Patients with more extensive GI involvement (both upper and lower) had higher prevalence of severe disease markers, including dyspnea, lower DLCO, and telangiectasias (all p< 0.001, Table 1). Ordinal regression confirmed disease duration, female sex, ILD, DU, dcSSc, telangiectasias, and tobacco exposure as predictors of increasing GI extent. However, in a separate analysis focused on progression from upper to lower GI involvement, only DU, telangiectasias, and anti-centromere antibodies emerged as significant predictors, while disease duration was not.

Conclusion: A more severe SSc phenotype is associated with both the presence and the extent of GI involvement. Key independent risk factors include disease duration, dcSSc, ILD, DU, and tobacco exposure. While disease duration plays a central role in the onset of GI symptoms, it does not appear to drive progression from upper to lower tract involvement, suggesting different mechanisms for initiation versus extension of GI disease.

Abstract Number: 2483

Is There a Seasonal Variation in Raynaud's Phenomenon Severity in Patients with Systemic Sclerosis?

Gulsen Ozen[1], Lan Yu[2], Maureen Lauffoon[2], John Pauling[3] and Robyn Domsic[2], [1]University of Iowa Carver College of Medicine, Coralville, IA, [2]University of Pittsburgh, Pittsburgh, PA, [3]North Bristol NHS Trust, Bristol, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Raynaud's phenomenon (RP) is the most common manifestation of systemic sclerosis (SSc) leading to substantial pain and impaired hand function. Establishing treatment efficacy for SSc-RP in clinical trials has been challenging, not least because of the expected seasonal variation in RP severity experienced by patients. There is very limited data on seasonal variation of SSc-RP severity. We aimed to assess how the SSc-RP severity varies throughout the year using the Assessment of SSc–Associated RP (ASRAP) questionnaire, a novel validated patient-reported instrument capturing the severity and impact of SSc-RP.

Methods: SSc patients fulfilling the 2013 ACR/EULAR classification criteria from a single Scleroderma Center completed the ASRAP questionnaire during their regular follow-up visits between October 2022 and September 2024. Data on patients' disease characteristics, comorbidities and medications were collected. Monthly and seasonal changes in ASRAP scores (derived from calibrated items, range 20-80, cohort range 31-75), RP attack duration and frequency were assessed by disease features. Patients with ≥2 questionnaires in the follow-up were assessed for intra-individual seasonal variability of SSc-RP severity.

Figure. ASRAP score, RP attack daily frequency and duration by disease features throughout the year in patients with SSc

45.4 to 50.6 throughout the year (patient-acceptable symptom state threshold=45.3), lowest in July and highest in January (*Table 1, Figure*). Although the difference between July and January (delta 4.7) did not reach statistical significance, this level was consistent with previously noted preliminary "Minimally important clinical difference of 4.17" (*Table 2, Figure*). Patients with a history of DP/DU, pulmonary hypertension (PH) had more variation in RP severity by ASRAP (higher scores in cold months than warm months) throughout the year compared to those without these conditions (*Table 2, Figure*). Smokers had more RP severity, as did those prescribed vasodilators. Similarly, by seasons, patients with DP/DU had significantly higher scores in winter compared to summer (52.7 [9.3] vs. 46.6 [10.9], P=0.04) unlike those without DP/DU (46.1 [8.1] vs. 46.1 [10.8], P=0.997) (*Figure*). Although the average daily RP attacks were more frequent and RP attack duration were longer in cold months than warms months, neither reached statistical significance (*Figure*). At individual patient level among those with ≥2 ASRAP questionnaires (N=102), a similar pattern noted with more variation in those with DU/DP and vasodilator use.

Conclusion: SSc patients with evidence of more severe SSc vasculopathy (DP, DU or PH) exhibited more seasonal variation of SSc-RP severity, as did active smokers. ASRAP scores are highest (worse) in winter and lowest in summer. These findings may help SSc-RP clinical trial design informing physicians about recruitment timing, stratification by more severe vasculopathy and anticipated effect size between winter and summer.

Abbreviations. ACA = anticentromere antibodies; AIH = Autoimmune Hepatitis; GAVE = Gastric Antral vascular Ectasia; NFC = Nailfold Capillaroscopy; PBC = Primary Biliary Cholangitis; SD= standard deviation

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Background/Purpose: To analyze the clinical associations of anti-Nucleolar Organizer Region 90 antibodies (NOR90) antibodies in patients with systemic sclerosis (SSc)

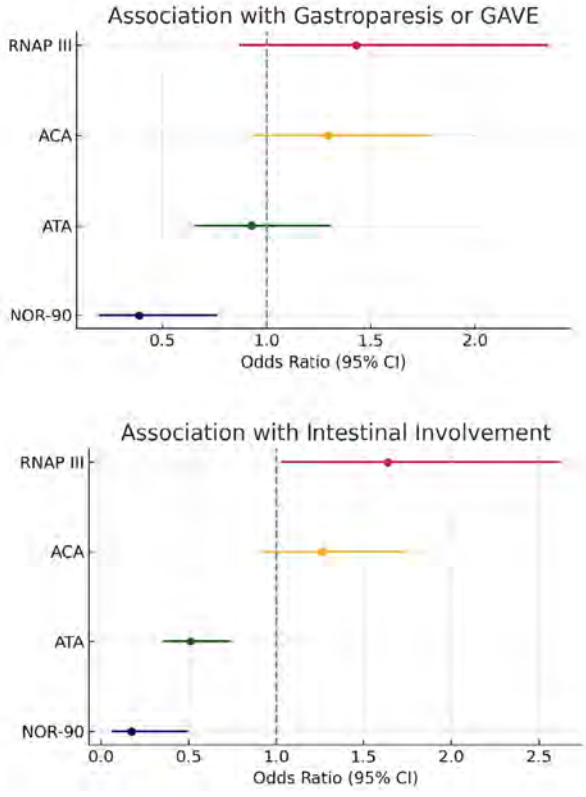
Methods: Cross-sectional study of NOR90-positive SSc patients from two tertiary hospitals. Anti–NOR90 antibodies were detected using the EUROLINE SSc profile (IgG) kit (Euroimmun, Germany). Only patients with repeated moderate or strong positivity were included.

Results: Among the 21 patients with anti–NOR-90 antibodies (95% women), the limited cutaneous subset of SSc was the most prevalent (67%), followed by early disease (5%). Their main characteristics are summarised in Table 1. Nailfold capillaroscopy most frequently revealed normal (28.5%) or non-specific (28.5%) patterns, with only 43% exhibiting one of the three Cutolo patterns.

All patients presented with Raynaud's phenomenon (100%), and the most frequent manifestations included telangiectasias (43%), upper and lower gastrointestinal (GI) symptoms (oesophageal: 81%; gastric: 14%, predominantly gastroparesis; intestinal: 24%), interstitial lung disease (ILD) (38%), and arthralgias (28.5%).

Among the 8 patients with ILD, 63.5% were asymptomatic at diagnosis. Pulmonary function tests at that time were preserved, with a mean (± SD) predicted %CVF of 107 ± 19 (interquartile range [IQR], 95.5–115) and a predicted %DLCO of 80 ± 18 (IQR, 72.5–91). No cases required rescue biologic or antifibrotic therapy, progressed to progressive pulmonary fibrosis, or underwent lung transplantation.

Figure 1. Association of NOR90 and SSc-criteria abs (ATA; ACA; RNAP III) with gastric and intestinal involvement



23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Fourteen patients (67%) were also positive for at least one SSc-criteria antibody: anti-centromere (62%), including CENP-A (57%) and CENP-B (62%), and RNA polymerase III (14%). None tested positive for ATA/Scl70 antibodies.

Compared with the 293 patients lacking these antibodies (see Table 1), individuals in the anti–NOR-90 group showed significantly less microvascular involvement, with lower frequencies of telangiectasias (43% vs 72%; p=0.005), absence of digital ulcers (0% vs 18%; p=0.032), and a reduced prevalence of calcinosis (0% vs 20%; p=0.018). They also had less frequent gastrointestinal involvement (gastric: 14% vs 30%; p=0.024; intestinal: 24% vs 48.5%; p=0.029) and a lower prevalence of pulmonary arterial hypertension (0% vs 10%; p=0.012). No significant differences were observed in other disease domains. This group also exhibited lower rates of RNAP III positivity.

The association of anti–NOR-90 antibodies with a lower prevalence of intestinal involvement remained significant in multivariable logistic regression adjusted for ATA/Scl70, ACA, and RNAP III, with an OR of 0.332 (95% CI: 0.119–0.931; p=0.036; see Figure 1). The OR for gastric involvement (gastroparesis or GAVE) was 0.395 (95% CI: 0.113–1.374; p=0.144).

Conclusion: Patients with anti–NOR90 antibodies exhibit a distinct systemic sclerosis phenotype, primarily characterized by limited cutaneous involvement, less frequent microvascular and gastrointestinal manifestations, non-severe ILD when present, and absence of pulmonary arterial hypertension. These findings suggest a potentially milder burden of visceral involvement compared to patients without anti–NOR90 antibodies.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: To estimate the prevalence of the progressive pulmonary fibrosis (PPF) phenotype among patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD) and identify risk factors that may predict its development.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 1. Results of the Ridge Logistic Regression Model

Predictor	Coefficient	Odds_Ratio	95% Confidence Interval (CI)
(Intercept)	-1.091	0.33	0.19 – 0.53
Age at diagnosis	-0.060	0.94	0.76 – 1.17
Presence of symptomatic ILD	0.029	1.02	0.80 – 1.30
%pFVC <70	0.375	1.45	1.16 – 1.84
%pDLCO <60	0.2271	1.25	1.02 – 1.56
Esophageal involvement	-0.104	0.90	0.70 – 1.15
Pulmonary hypertension	0.1781	1.19	0.94 – 1.49

Methods: A multicentric ambispective study was conducted in four tertiary Spanish hospitals. The diagnosis of PPF was based on the 2022 ATS/ERS/JRS/ALAT criteria for progressive pulmonary fibrosis, requiring at least two of the following three criteria: (1) increased fibrosis on HRCT; (2) worsening respiratory symptoms; and (3) an absolute decline in predicted FVC% by ≥5% or in DLCO% by ≥10% within one year of follow-up

Results: The series included 168 patients with SSc-ILD confirmed by thoracic HRCT. All patients fulfilled the 2013 ACR/EULAR classification criteria for SSc. Based on radiological findings, 70.8% (119) had an NSIP pattern, 11.3% (19) a UIP pattern, 3.6% (6) an OP pattern, 5.4% (9) mixed patterns, and 8.9% (15) an indeterminate pattern.

Of the 168 patients, 37 (22.0%) exhibited radiological worsening, 27 (16.1%) experienced clinical worsening, and 37 (22.0%) showed functional decline. Of these, 31 (18.5%) met the criteria for PPF.

In the comparative analysis, PPF patients were more often men (39% vs. 11.4%; p=0.001) and had a higher prevalence of oesophageal involvement (89.3% vs. 63.6%; p=0.010). Pulmonary arterial hypertension was also significantly more frequent (32.1% vs. 12.5%; p=0.023).

The median time from ILD diagnosis to the evaluation visit was similar between groups: 81.5±84 months (IQR 47–180) in patients with PPF and 71±73 months (IQR 25–131) in those without PPF (p=0.126). PPF patients had lower baseline %pFVC (69.1±18 vs. 88.5±24; p< 0.001) and %pDLCO (51.8±14 vs. 62.9±17; p=0.004), and a higher proportion of %pFVC < 70 (57.1% vs. 19.3%; p=0.001) and %pDLCO < 60 (64.3% vs. 19.3%; p=0.001). Their 6MWT distance was also shorter (356±97 m vs. 409±102 m; p=0.028). As expected, lung transplantation was exclusive to the PPF group (42.8%; p< 0.0001), and mortality was significantly higher (14.3% vs. 2.3%; p=0.014), despite the greater use of biologic agents as rescue therapy (37.3% vs. 0.7%; p=0.001).

A multivariable logistic regression analysis with Ridge penalisation was performed to assess predictors of PPF. The model included six variables: age at diagnosis, oesophageal involvement, PAH, symptomatic ILD, %pFVC < 70, and %pDLCO < 60 (see Table 2). Younger age at diagnosis (coefficient = –1.72), oesophageal involvement (+0.17), PAH (+0.10), and %pFVC < 70 (+0.17) were positively associated with PPF development, whereas symptomatic ILD (+0.08) and %pDLCO < 60 (–0.17) showed weaker associations (See Table 1).

Conclusion: In our series, the prevalence of PPF in SSc-ILD reaches 18.5%. Factors such as %pFVC < 70 at ILD diagnosis, esophageal involvement, and the development of PAH appear to increase the risk of PPF.

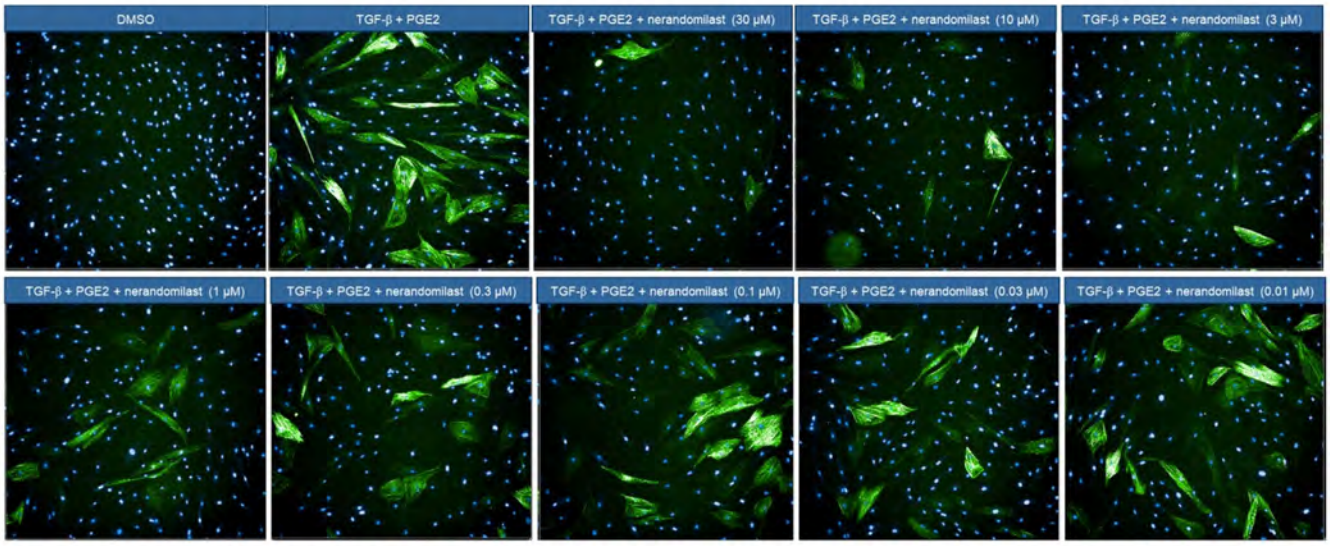
SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disorder marked by immune dysregulation, vasculopathy, and progressive fibrosis affecting the skin and multiple internal organs, including the gastrointestinal (GI) tract.[1] GI manifestation is the most prevalent complication of SSc, affecting up to 90% of patients.[2] The pathophysiology for SSc GI manifestations is not fully elucidated and may vary across patients; however, it involves myopathy, neuropathy and fibrosis.[1] Animal studies confirm that fibroblast dysfunction has a role in structural or motility abnormalities seen in SSc GI manifestations.[1] Small intestinal dysmotility occurs in 40–88% of patients with SSc, and approximately 20–50% of patients experience GI manifestations involving the colon or large intestine;[3-4] this high prevalence underscores the need for effective therapies.

Phosphodiesterase 4B (PDE4b) inhibition is associated with antifibrotic and immunomodulatory effects.[5-6] Nerandomilast, an oral preferential inhibitor of PDE4B, has shown antifibrotic effects *in vitro* by inhibiting extracellular matrix (ECM) production in both smooth muscle cells and intestinal fibroblasts, suggesting potential benefits in reducing tissue remodeling and intestinal fibrosis. This study investigated the effects of nerandomilast on primary intestinal smooth muscle cells and fibroblasts using *in vitro* models.



αSMA is shown in green and cell nuclei in blue. Abbreviations: αSMA, alpha-smooth muscle actin; DMSO, dimethyl sulfoxide; PGE2, prostaglandin E2; TGF-β, transforming growth factor-β.

Figure. Fluorescent microscope cell images showing the effect of nerandomilast inhibition on expression of αSMA (fibrotic marker) induced by TGF-β in muscle cells of human fibrostenotic Crohn's disease (n=4 donors)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: Normal primary human-derived intestinal fibroblasts and smooth muscle cells were treated with nerandomilast following cytokine stimulation. The effects of nerandomilast on smooth muscle cell proliferation, mediated by interleukin-1 beta and basic fibroblast growth factor, were measured using a 5-ethynyl-2'-deoxyuridine assay. Total nuclei number was calculated for transforming growth factor beta and prostaglandin E2-stimulated intestinal fibroblasts. Antifibrotic effects of nerandomilast were determined using an *in vitro* fibrosis model and by measuring the fibrosis markers alpha-smooth muscle actin (αSMA) and ECM protein collagen type I alpha 1 chain (Col1α1) in smooth muscle cells and fibroblasts, respectively.

Results: Nerandomilast reduced the proliferation of intestinal smooth muscle cells and fibroblasts. Additionally, nerandomilast significantly decreased the levels of αSMA in smooth muscle cells (Figure) and reduced Col1α1 expression in fibroblasts.

Conclusion: This study demonstrates the potential of nerandomilast as a therapeutic option for GI manifestations in SSc. *In vitro*, nerandomilast had significant antifibrotic effects on cell types relevant to intestinal remodeling and fibrosis present in SSc. These findings support further investigation of PDE4B inhibition as a targeted approach to managing intestinal fibrosis in SSc.

Cardiovascular and venous thromboembolic events in systemic sclerosis: Epidemiological analysis of the Clinical Practice Research Datalink

John Pauling[1], Rachel Charlton[2], Laura Ross[3], Neil McHugh[4] and Anita McGrogan[2], [1]North Bristol NHS Trust, Bristol, United Kingdom, [2]University of Bath, Bath, [3]St. Vincent's Hospital Melbourne, Fitzroy, Victoria, Australia, [4]University of Bath, Bath, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Cardiovascular disease is a leading cause of mortality in systemic sclerosis (SSc). We investigated the association between SSc and the occurrence of both cardiovascular and thromboembolic events using the Clinical Practice Research Datalink (CPRD).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: A validated case-ascertainment strategy identified SSc patients in the CPRD. A cohort study design examined rates of coronary arterial disease (CAD), cerebrovascular disease, peripheral artery disease (PAD) and venous thromboembolism (VTE) in SSc patients matched to non-SSc comparators by age, sex and location in a 1:6 ratio. Prevalent and incident cases of SSc were analysed separately. Cox regression analysis was used to determine hazard ratios for event occurrence, adjusted for traditional cardiovascular risk factors.

Results: We identified 877 eligible incident cases of SSc who were matched to 5262 patients without SSc (83.7% female), with a mean follow-up of 8 years. We identified a higher background prevalence of CAD, PAD and VTE at baseline (predating diagnosis) in the SSc cohort (Table 1). The incidence of CAD events in SSc males was 122.3 per 10,000 cases compared to 51.4 per 10,000 non-SSc males; whereas corresponding rates in females were lower for both groups at 43.7 and 28.8 per 10,000 in SSc and non-SSc females respectively (Table 2). Both the unadjusted and adjusted HRs for cardiovascular and VTE events are presented in Table 3. The overall adjusted HR for CAD events was 1.86 (95%CI 1.21-2.87), p=0.005. A similar but stronger association was present for PAD, with an overall adjusted HR of 2.37 (95%CI 1.42-3.95, p=0.001), which was again influenced by high incidence rates in SSc males (139.2 per 10,000 (95% CI 77.1-251.4)) compared with non-SSc male comparators (29.0 per 10,000 (95% CI 17.8-47.4)). In contrast to CAD and PAD, there was no

NA, event rates too low to run adjusted model for male patients.
* CAD, cerebrovascular disease and venous/pulmonary embolism/thrombosis were adjusted for BMI, smoking, prior history of treated hypertension, prior history of hypercholesterolaemia and/or statin prescribing, aspirin prescribing in the year before index date, NSAID prescribing in the year before index date. PAD was adjusted for BMI, smoking, prior history of treated hypertension, prior history of hypercholesterolaemia and/or statin prescribing.

apparent difference between the incidence of cerebrovascular disease events in SSc and non-SSc subjects, and no apparent sex-difference was observed (Tables 2 and 3). The incidence of peripheral venous thrombosis was higher than pulmonary embolism (33.4 vs. 28.1 per 10,000 SSc subjects). The risk of DVT was almost twice that found in non-SSc controls (adjusted HR: 1.84, 95%CI 1.05-3.23, p=0.033), with no sex difference in incidence rates noted. The increased risk of pulmonary thromboembolic disease was even higher with an adjusted HR of 3.01 (95%CI 1.49-6.07, p=0.002) and was increased for both sexes.

Conclusion: To our knowledge, this is the first study to demonstrate an excess risk of cardiovascular events prior to the diagnosis of SSc, in a cohort matched by age, sex and diabetes status. We have identified an increased risk of cardiovascular events and VTE, both prior to a diagnosis of SSc and within 8 years of SSc diagnosis. Work is needed to establish the mechanism of arterial/venous thrombotic events in SSc. Such insight will facilitate more targeted and effective preventative strategies and improve outcomes in SSc.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Rituximab (RTX) was approved in Japan as a new treatment strategy for systemic sclerosis (SSc). Intravenous rituximab (375mg/m^2) is administered once a week for 4 weeks, every 6 months. This RTX regimen is unique compared to those used in other countries. However, there are few studies on the long-term efficacy and safety of this RTX treatment strategy.

Table1. Patients' characteristics at baseline

	Total (n=25)
Age (years old)	59.28 ± 11.56
Male/female (n)	3/22
dcSSc/lcSSc (n)	10/15
Anti-topoisomerase I (n)	6
Anti-centromere (n)	6
Anti-RNA polymerase III (n)	3
Disease duration (years)	10.26 ± 9.63
mRSS	9.36 ± 9.41
Interstitial lung disease (n)	18
Gastrointestinal disease (n)	12
Pulmonary hypertension (n)	5
Active digital ulcers (n)	3
Concomitant glucocorticoid (n)	12
Concomitant immunosuppressant (n)	4

Values are presented as mean ± standard deviation or number(n).

Figure 1. mRSS after administered RTX

		Electrolyte imbalance	1

*Some cases have experienced multiple events

This study aimed to evaluate the real-world efficacy of RTX for skin involvement and its safety up to 2 years in SSc patients treated at our institution.

Methods: We retrospectively analyzed the efficacy of RTX treatment for skin involvement at 0, 6, 12 and 24 months in SSc patients at our hospital from August 2021 to April 2025. Efficacy for skin lesions was evaluated using the modified Rodnan's total skin thickness score (mRSS). Safety was evaluated based on adverse events after RTX administration, with particular attention to infections.

Results: Twenty-five SSc patients who could be evaluated at 6 months after administered RTX were included in our analysis. There were 10 cases with diffuse cutaneous systemic sclerosis and 15 cases with limited cutaneous systemic sclerosis (Table 1). The mean disease duration prior to the initiation of RTX was 10.26 ± 9.63 years. Figure 1 showed mRSS trend after RTX administration. The mean mRSS at the initiation of RTX was 9.36 ± 9.41, and at 6 months average score of 8.68 ± 11.01 was not significantly reduced (p=0.185). However, the average mRSS at 12 months was 7.65 ± 9.64, which was significantly lower compared to 0 and 6 months respectively (p=0.045 and 0.026)(n=20). On the other hand, the mean mRSS at 24 months were 6.17 ± 6.21, which was not significantly different from 0, 6, 12 months respectively (P=0.125, 0.375, and 0.750)(n=6).

Table 2 showed the adverse events after RTX therapy. Infections were the most common adverse events during the 24-month period. Notably, the frequency of infections tended to increase in the latter 12 months. The most frequently observed infections were COVID-19 in the first 12 months and bacterial pneumonia in the second 12 months.

Conclusion: RTX therapy for SSc improved skin stiffness up to 12 months after initiation of treatment. However, there was a trend toward increased adverse events such as infection after 12 months. Further study is needed to determine the long-term efficacy and safety of RTX therapy for SSc.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Mixed connective tissue disease (MCTD) is a rare systemic disorder that belongs to connective tissue diseases (CTD). Approximately 25% of MCTD patients will meet the classification criteria for at least one other CTD after a median follow-up of 8 years. MCTD has long been debated as an early nonspecific phase/symptom of differentiated connective tissue diseases (dCTD), similarly as others "pre-CTD" states described in literature such as interstitial pneumonia with autoimmune features (IPAF) or very early diagnosis of systemic sclerosis (SSc) (VEDOSS).

Methods: We aimed to evaluate the predictive value of dCTD classification, IPAF, and VEDOSS criteria in MCTD patients. We conducted an observational study within the French MCTD cohort. This cohort includes patients diagnosed with MCTD in 15 rare disease reference and competence centers, including two pediatric centers, across France, according to at least one of the four diagnostic criteria for MCTD and who, at disease onset, did not fulfill classification criteria for SSc, systemic lupus erythematosus, Sjögren's disease (SjD), idiopathic inflammatory myopathies, nor rheumatoid arthritis. IPAF, VEDOSS and current dCTD classification criteria were used to classify patients.

Results: Three hundred and twenty-four patients were included and followed for a median [IQR] duration of 101 [48-176] months. Two hundred and eighty-four (87.7%) patients were females, with a median age at diagnosis of 34 [24-45] years. Among them, 111 (34.3%) progressed into a dCTD, *i.e.* 50 (15.4%) SSc, 40 (12.3%) systemic lupus erythematosus (SLE),

ACR: American college of rheumatology, C3: complement component 3, C4: complement component 4, EULAR: European alliance of associations for rheumatology, MCTD: Mixed connective tissue disease, MCTD-SLE$^+$: patients with MCTD who progress to SLE, MCTD-SLE$^-$: patients with MCTD who did not progress to SLE, N: Number, SLE: Systemic lupus erythematosus

and 11 (3.4%) SjD. At MCTD diagnosis, 38 (11.7%) patients had ILD, and all of them fulfilled the IPAF criteria; among which 15 (39.5%) progressed into a dCTD (*vs*. 75 (26.2%) in patients who did not fulfill IPAF criteria; p=0.09) (**Table 1**). At diagnosis, 293 (90.4%) patients fulfilled VEDOSS criteria (MCTD-VEDOSS$^+$) (**Table 2**). All of them had Raynaud's phenomenon and antinuclear antibodies. After a median follow-up of 101 [48-176] months, 46 (15.7%) of the 293 MCTD-VEDOSS$^+$ patients progressed to SSc, compared to 4 (12.9%) of patients not fulfilling VEDOSS criteria (p=0.8). Among MCTD-VEDOSS$^+$ patients, an abnormal nailfold capillaroscopy at MCTD diagnosis was significantly associated with progression toward SSc (p=0.01). At baseline, SSc classification criteria did not predict evolution toward SSc, whereas antiphospholipid antibodies and low C3 and/or low C4 were predictive of an evolution toward SLE (p=0.01 and p=0.04, respectively) (**Table 3**).

Conclusion: At MCTD diagnosis, fulfillment of IPAF and/or VEDOSS classification criteria was not predictive of evolution toward SSc, whereas antiphospholipid antibodies and low C3 and/or low C4 were predictive of an evolution toward SLE. This suggests that MCTD patients should be excluded from IPAF and VEDOSS.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Stress-induced cardiomyopathy (SIC), also known as Takotsubo cardiomyopathy (TCM), is characterized by acute left ventricular dysfunction, often triggered by emotional or physical stress. In recent years, SIC has been increasingly recognized in patients with underlying systemic inflammatory disorders. Systemic sclerosis (SSc), a chronic autoimmune disease, is known to affect the heart through mechanisms such as myocardial fibrosis and arrhythmias. However, data on the intersection of SIC and SSc are limited, and the clinical outcomes of this rare overlap remain poorly defined.

Methods: We conducted a retrospective analysis of the National Inpatient Sample (2017–2022), identifying adult hospitalizations with a primary diagnosis of stress-induced cardiomyopathy. We initially evaluated several autoimmune diseases for their association with clinical outcomes; systemic sclerosis showed a potentially important association, justifying further evaluation. Patients were then stratified into two groups: those with and without coexisting systemic sclerosis. Outcomes included in-hospital mortality, length of stay, and total hospital charges. Survey-weighted logistic and linear regression models were used to assess associations, adjusting for demographics, comorbidities, and hospital characteristics. Firth logistic regression was employed to address rare-event bias in mortality analyses.

Results: Among 51,415 patients hospitalized with stress-induced cardiomyopathy, only ~70 (0.14%) had a comorbid diagnosis of systemic sclerosis, highlighting the rarity of this overlap. Patients with SSc were predominantly female (100% vs. 89.6%, $p = 0.20$), more likely to be Black (35.7% vs. 6.0%, $p < 0.001$), and had a higher comorbidity burden (Charlson category 3: 71.4% vs. 28.3%, $p = 0.004$). There was no significant difference in mean age (66.8 vs. 67.3 years, $p = 0.82$). In adjusted logistic regression, SSc was independently associated with increased odds of in-hospital mortality (OR 7.39, 95% CI: 1.54–35.56, $p = 0.013$). These findings were consistent in Firth logistic regression (OR 8.61, 95% CI: 1.92–38.58, $p = 0.005$), reinforcing the robustness of the association.

Patients with SSc also had a longer mean LOS (6.29 vs. 3.61 days; 95% CI: 2.18–10.39 vs. 3.52–3.69) and higher mean hospital charges ($77,652 vs. $58,425; 95% CI: $40,356–$114,948 vs. $56,444–$60,407). Although unadjusted comparisons showed higher LOS and charges in the SSc group, these differences were not statistically significant in adjusted models (LOS $\beta = 2.13$, $p = 0.322$).

Conclusion: Systemic sclerosis was associated with significantly higher in-hospital mortality among patients with stress-induced cardiomyopathy (Takotsubo cardiomyopathy), despite its rarity. Both survey-weighted and Firth logistic regression analyses consistently demonstrated this association, reinforcing the robustness of the findings and minimizing the influence

of confounding and small-sample bias. These results highlight a clinically vulnerable subgroup that warrants closer monitoring. This rare overlap warrants further prospective studies to elucidate underlying immunologic mechanisms and enhance risk stratification.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-Nucleolar Organizer Region 90 (anti-NOR90) antibodies target nucleolar proteins involved in ribosomal RNA transcription and processing, key steps in protein synthesis. These antibodies have been identified in a wide range of systemic autoimmune rheumatic diseases (SAD), particularly systemic sclerosis (SSc) and Sjögren's syndrome (SS), but also in systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA)(1). Some studies have suggested an increased incidence of malignancy in anti-NOR90–positive patients, although findings are inconsistent (2)(3). Our aim was to characterize the clinical profile and frequency of autoimmune diseases and cancer in patients with anti-NOR90.

Methods: We carried out a retrospective, observational and multicenter study including anti-NOR90–positive patients attended at two tertiary hospitals in Spain between January 2013 and April 2025. Antibody detection was performed using the EUROLINE SSc Profile IgG autoAb kit (Euroimmun, Germany). Demographic, clinical, and diagnostic data were collected through electronic medical record review. Descriptive analyses were conducted using measures of central tendency (mean or median) and dispersion (standard deviation-SD or interquartile range-IQR) for continuous variables, and frequencies and percentages for categorical variables.

Results: Seventy-nine anti-NOR90–positive patients were identified (Table 1), mostly females (82%), with a mean age of 63.2±15.6 years. Median follow-up time since anti-NOR90 detection was 38 [17–59.5] months. Over half of the patients were diagnosed with a SAD, most frequently SSc (48.8%), followed by SS (29.2%). Twenty of them (48.8%) showed visceral involvement, predominantly pulmonary in the form of interstitial lung disease (ILD).

dsSSc	1 (2.4)
Pre-scleroderma	3 (7.3)
SSc sine scleroderma	1 (2.4)
Scleromyositis	1 (2.4)
SS	**12 (29.2)**
Primary/ Secondary	6 (14.6)/ 6 (14.6)
RA	6 (14.6)
SLE	4 (9.8)
UCTD	3 (7.3)
Anti-synthetase syndrome	2 (4.9)
ANCA- associated vasculitis	1 (2.4)
*3 overlap with SS, 1 with RA	
Other diagnosis	
GVHD (%)	4 (5)
IPAF (%)	5 (6.3)
Visceral involvement in patients with SAD (n, %)	**20 (48.8)**
Pulmonary	16 (39)
ILD	15 (36.6)
Cardiac	3 (7.3)
Renal	3 (7.3)
Hepatic	3 (7.3)
PBC	2 (4.9)
AIH	1 (2.4)
Cancer (n, %)	16 (20)
Isolated NOR positivity in cancer patients (n, %)	4 (25)

The frequency of malignancy was 20%, distributed among hematologic malignancies (43.75%), non-melanoma skin cancers (18.75%), and solid tumors (37.5%). Within these cases, only one third (31.2%) had a concurrent SAD diagnosis: one limited SSc, one scleromyositis, one undifferentiated connective tissue disease and two overlap syndromes (one with SLE and one with SSc plus SS).

Additionally, other autoantibodies were detected in 75% of cancer cases, most commonly anti-CENP B (41.6%), anti-Ro52 (41.6%), and anti-Ku (33.3%). Overall mortality during the follow-up was 16.4%, with 46% of deaths occurring in patients with cancer.

Conclusion: In our patients, anti-NOR90 antibodies were frequently associated with SAD and showed a notable incidence of malignancies, particularly hematologic. The presence of these antibodies may warrant closer clinical monitoring in routine practice, and larger studies should be conducted to further investigate their potential role as biomarkers for cancer risk and their clinical implications in SAD.

Autoantibody Profiles and Disease Trajectories in Early Systemic Sclerosis: Insights from a Prospective Cohort

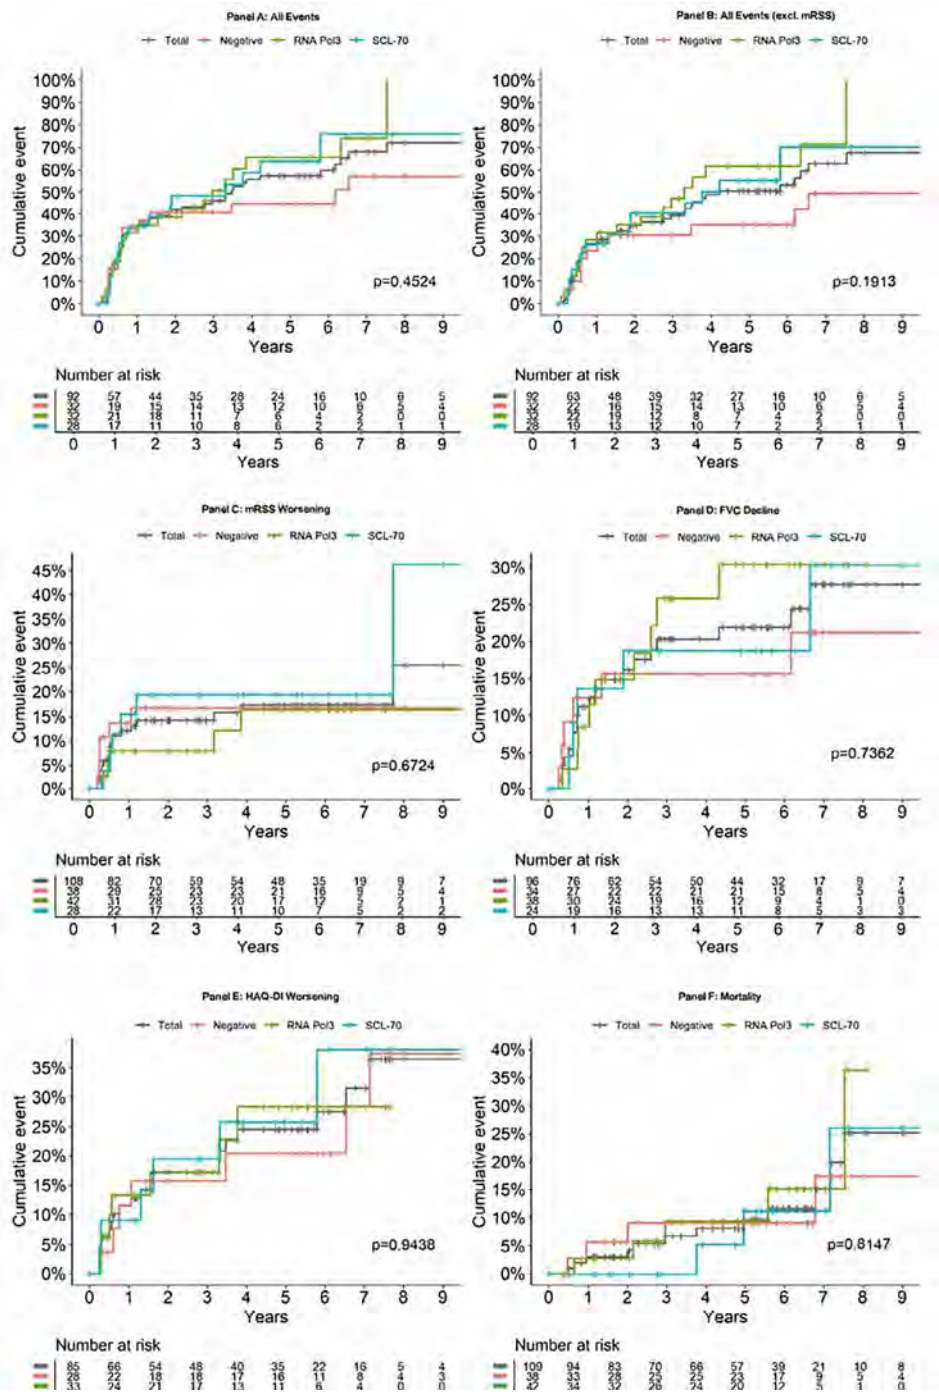
Marzieh Jamali[1], Amisha Kaur[1], Suiyuan Huang[1], James St. Clair[2], John Varga[1], Carleigh Zahn[2], Erica Mulcaire-Jones[1], Alain Lescoat[1] and Dinesh Khanna[1], [1]University of Michigan, Ann arbor, MI, [2]University of Michigan, Ann Arbor

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disease with high mortality. Early stratification by autoantibody (SSc-Ab) profile may inform prognosis and management, but data in early SSc remain limited. This study evaluated clinical features, treatment, and outcomes by SSc-Ab subtype in early SSc.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License



Cumulative incidence curves for the whole group and by SSc-Ab subtype. The data should be interpreted as time to the first clinical event. For Panel A, time to first event was assessed by meeting any of the following- mRSS worsening defined as as 5-unit absolute increase or 25% relative increase compared to baseline; FVC % absolute 10% decline compared to baseline; HAQ-DI as 0.5-unit absolute increase compared to baseline; Pulmonary hypertension as mean PAP ≥ 25 mmHg on right heart catheterization; Scleroderma renal crisis; Left heart failure defined as left ventricular ejection fraction ≤ 45%; and mortality. Panel A: Composite clinical events, including mRSS; Panel B: Composite events excluding mRSS; Panel C: Skin progression (mRSS worsening); Panel D: Lung function decline (FVC ≥10%); Panel E: Functional disability (HAQ-DI progression); Panel F: All-cause mortality.

Methods: We analyzed data from 116 patients (pts) enrolled in a prospective registry at a scleroderma center who had diffuse cutaneous SSc (dcSSc) or at-risk for progression based on serologic and clinical features. The at-risk group included those with swollen hands or sclerodactyly with anti-Scl-70 (Scl70) or anti-RNA polymerase 3 (RNAP3) Abs, and/or tendon friction rubs(1). Patients were classified into three groups: RNAP3, Scl70, or Triple Negative (negative for RNAP3, Scl70,

Table 2. Number of Events for the Whole Group and by SSc-Ab during Follow-Up Period

Variables	Total n=92	Negative n=32	RNA Pol3 n=32	SCL-70 n=28	P-value
Any events	51 (55.4%)	15 (46.9%)	20 (62.5%)	16 (57.1%)	0.4429
mRSS worsening[1]	12 (13.0%)	6 (18.8%)	3 (9.4%)	3 (10.7%)	0.5447
FVC-% worsening[2]	12 (13.0%)	4 (12.5%)	5 (15.6%)	3 (10.7%)	0.9270
HAQ-DI worsening[3]	15 (16.3%)	5 (15.6%)	5 (15.6%)	5 (17.9%)	0.9651
Scleroderma renal crisis	5 (5.4%)	0 (0.0%)	4 (12.5%)	1 (3.6%)	0.0778
Pulmonary hypertension on RHC[4]	5 (5.4%)	0 (0.0%)	2 (6.3%)	3 (10.7%)	0.1907
LVEF ≤ 45%[5]	1 (1.1%)	1 (3.1%)	0 (0.0%)	0 (0.0%)	1.0000
Mortality	4 (4.3%)	0 (0.0%)	3 (9.4%)	1 (3.6%)	0.2075

Multiple events might occur at the same time as the first event, so the sum of individual events may exceed the number of any events. Each organ row denotes the first event in the participating subject
[1]mRSS: Modified Rodnan Skin Score, defined as a 5-unit absolute increase or 25% relative increase in mRSS compared to baseline.
[2]FVC-%: Forced Vital Capacity percentage, defined as an absolute 10% decline in FVC-% compared to baseline.
[3]HAQ-DI: Health Assessment Questionnaire-Disability Index, defined as a 0.5-unit absolute increase in HAQ-DI compared to baseline.
[4]Pulmonary hypertension on Right Heart Catheterization, defined as mean PAP ≥ 25 mmHg.
[5]LVEF: Left Ventricular Ejection Fraction, with left heart failure defined as LVEF ≤ 45%.

and anti-centromere). We analyzed longitudinal data including change in modified Rodnan skin score (mRSS), forced vital capacity (FVC), HAQ-DI, organ complications, and mortality. Time-to-event analyses stratified by SSc-Ab group were conducted using cumulative incidence curves and the log-rank test.

Results: A total of 116 pts had a median follow-up of 5.3 years (IQR: 2.1, 6.7); 109 (93.9%) had SSc-Ab data available (Table 1). The mean age was 51.1 years and 65.1% were female. Median disease duration from non-Raynaud phenomenon was 1.0 year . Of the 109, 38.5% were RNAP3+, 26.6% were Scl70+,and 34.8% were Triple Negative. dcSSc was present in 85.3%; 14.7% had at-risk features. RNAP3+ were older (mean 56 years), had the highest mRSS (mean 24.9 units), and the highest predicted FVC (mean 86.2%). At baseline, 61.5% of patients were receiving DMARDs, most commonly mycophenolate mofetil (40.4%), followed by methotrexate (12.8%) and cyclophosphamide (4.6%), while prednisone was used in 22.9%. During follow-up, immunosuppressive therapy was initiated or continued in 92.7% of patients, with variation across Ab subtypes (100% in Triple Negative, 85.7% in RNAP3+, and 93.1% in Scl70+; p=0.03). Mycophenolate mofetil remained the most frequently used agent (78.9%), followed by methotrexate (19.3%).

Of 109 pts, 17 had an event before registry entry and were not included in the time to composite event analysis. Overall, 55.4% experienced ≥1 new clinical event (Table 2), with the majority having mRSS worsening (13%), FVC decline ≥10% (13%), and HAQ-DI worsening (16.3%) as the first event; mortality occurred in 4 (4.3%) pts.

Cumulative incidence curves (Figure Panels A and B) show a trend toward a lower incidence of first events over time in the Triple Negative. mRSS worsening happened predominantly in the first 2 years, whereas FVC decline, HAQ-DI disability, and mortality continued over several years. Panels C-D show a trend toward higher incidence for mRSS worsening in pts with SCL70 and FVC decline in both RNAP3 and SCL70. Panel E-F show the impact of different SSc-Ab on HAQ-DI worsening and mortality. None of these trends were statistically significant.

Conclusion: Distinct SSc-Ab in early SSc are linked to distinct organ involvement and clinical trajectories. Pts continue to have progressive organ involvement and high mortality despite current management strategies.

Abstract Number: 2493

Investigating scoring systems to measure clinically relevant changes in systemic sclerosis-related finger acro-osteolysis over time, as assessed in serial hand radiographs

Michael Hughes[1], Graham Dinsdale[2], Aayushi Agnihotri[3], Joanne Manning[2], Muditha Samaranayaka[4], Jonathan Harris[2] and Ariane Herrick[5], [1]The University of Manchester, Manchester, England, United Kingdom, [2]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom, [3]The University of Manchester, Manchester, United Kingdom, [4]Salford Royal Hospital, Salford, United Kingdom, [5]The University of Manchester, UK, Aberdeen, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Acro-osteolysis (A-O, terminal tuft digit resorption) is characteristic of systemic sclerosis (SSc), occurring in 20-25% of patients (1). Outcome measures are much needed. Following our previous work (2) that developed a scoring system for A-O, our objective was to examine different methods of scoring A-O over time, specifically comparing subjective clinician opinion to more formal digit-by-digit scoring, to investigate their potential as outcome measures.

Methods: Patients identified from a tertiary referral centre for SSc who had a first visit between 2006-2018, who had suitable radiographs (both hands, two time points). The final image set contained 180 image pairs from 90 patients.

Radiographs were presented to a single observer for assessment:

1. 180 single (blinded) images; 10 fingers/digits scored: 0 (normal) to 4 (complete terminal tuft resorption); total (sum of all digits), maximum, and Johnstone scores (2) calculated.

2. 90 image pairs presented (left vs right) in a randomised order. Images reviewed answering "is the acro-osteolysis status of the right-hand image more or less severe than the left-hand image?": 5-point ordinal scale: much less severe (-2) to much more severe (+2).

Images with fewer than 3 classifiable digits per hand were excluded. Missing values in included images were replaced with the average score (mean of all other digits).

For paired images the clinician change scores were used to dichotomise: ‘‘changers’’ (patients assessed as changing over time) who were scored ‘‘much more severe’’ (+2) or ‘‘more severe’’ (+1) and ‘‘no change’’ scoring ‘‘same’’ (0), ‘‘less severe’’ (-1), or much less severe (-2). We derived ‘‘change over time’’ data between pairs of images – with change calculated in (1) total score, (2) maximum score, and (3) Johnstone score.

We investigated differences in scoring between the ‘‘changers’’ vs. ‘‘no change’’ groups using T-tests (total) or Mann-Whitney tests (maximum, Johnstone).

Results: Patient demographics (n=90) are presented in Table 1. No score could be given in 102/1800 digits assessed due to amputation (n=17, 17%) or obscured digit (n=85, 83%). 10/180 images, and 9/90 pairs were excluded due to missing data. 81 image pairs were analysed after meeting our criteria, with 25 ultimately labelled as ‘‘changers’’, and 56 labelled as ‘‘no change’’. Figure 1: box plots comparing change-over-time data (total, max, or Johnstone) between the two groups from

Table 1. Patient demographics.

Median (IQR) age, years	53 (44-63)
Sex (female), n (%)	75 (83%)
Subtype limited cutaneous SSc, n (%)	66 (73%)
Smoking (never smokers), n (%)	67 (74%)
Median (IQR) disease duration (since 1st non-Raynaud's manifestation), years	3.7 (1.0-8.5)
History of digital ulceration, n (%)	59 (66%)
History of amputation, n (%)	6 (7%)
Presence of calcinosis (clinical), n (%)	43 (48%)
Presence of calcinosis (radiographic), n (%)	52 (58%)
Positive ANA, n (%)	73 (81%)
Positive anti-centromere, n (%)	32 (36%)
Positive anti-PMScl, n (%)	1 (1%)
Positive anti-RNA Polymerase III, n (%)	8 (9%)
Positive anti-RNP, n (%)	8 (9%)
Positive anti-Scl70, n (%)	18 (20%)

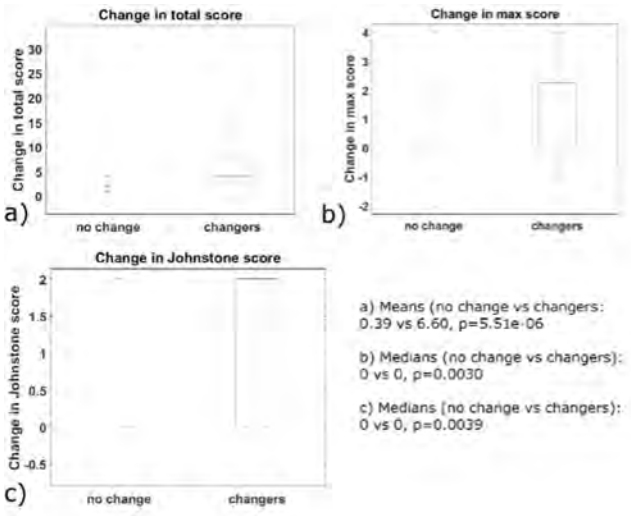

Figure 1. Boxplots comparing changers and no change groups as defined by clinician opinion (paired image assessment): a) Change in total score, b) change in maximum score, and c) change in Johnstone score. Comparisons of means/medians for a, b and c are shown bottom right, with p-values from T-test or Mann-Whitney tests as appropriate.

the dichotomised subjective clinician change score. A significant difference in change in total score of >6 points is identified between the two groups.

Conclusion: Total score appears to show promise for measuring clinically relevant change in A-O. Maximum and Johnstone scores are less sensitive with no obvious difference in group medians (despite statistical significance), likely due to the relatively large number of cases with zero change in both groups. We have explored pragmatic options for quantifying clinically relevant change in A-O with relevance to future longitudinal studies including impact of treatment.

Abatacept Reduces CD319+ (SLAM-F7) Cytotoxic T Cells and Cytokine Production in Systemic Sclerosis

Mikel Gurrea-Rubio[1], Kohei Maeda[2], Qi Wu[3], Phillip L Campbell[2], Camila I Amarista[2], Alexander Stinson[4], Ray Ohara[5], Laura Cooney[6], Michael Whitfield[7], Pei-Suen Tsou[8], Dinesh Khanna[8] and David Fox[9], [1]University of Michigan - Ann Arbor, Ann Arbor, MI, [2]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA, Ann Arbor, MI, [3]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA, Ann Arbor, [4]University of Michigan, Department of Internal Medicine, Division of Rheumatology, Ann Arbor, MI, [5]University of Michigan, Department of Internal Medicine, Division of Rheumatology, West Bloomfield, MI, [6]Immune Tolerance Network, Ann Arbor, MI, [7]Geisel School of Medicine, Lebanon, NH, [8]University of Michigan, Ann Arbor, MI, [9]University of Michigan, Dexter, MI

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: While the ASSET clinical trial (placebo-controlled blinded trial of abatacept) in patients with diffuse cutaneous systemic sclerosis (dcSSc) did not meet its primary endpoint of statistically significant improvement in the modified Rodnan skin score (mRSS), patients with early disease (≤ 5 years) and inflammatory subtype, showed meaningful clinical improvement compared with the placebo group[1-2]. We also found that SSc patients have increased percentages of CD4+ T cells and B cells, but a lower percentage of CD8+ T cells compared to healthy control subjects. Importantly, a robust expansion of CD319+ T cells was seen among the CD4+ cells, whereas they were barely detectable in healthy subjects[3]. We now know that these CD4+CD319+ (also known as SLAM-F7+) cells are highly cytotoxic and are

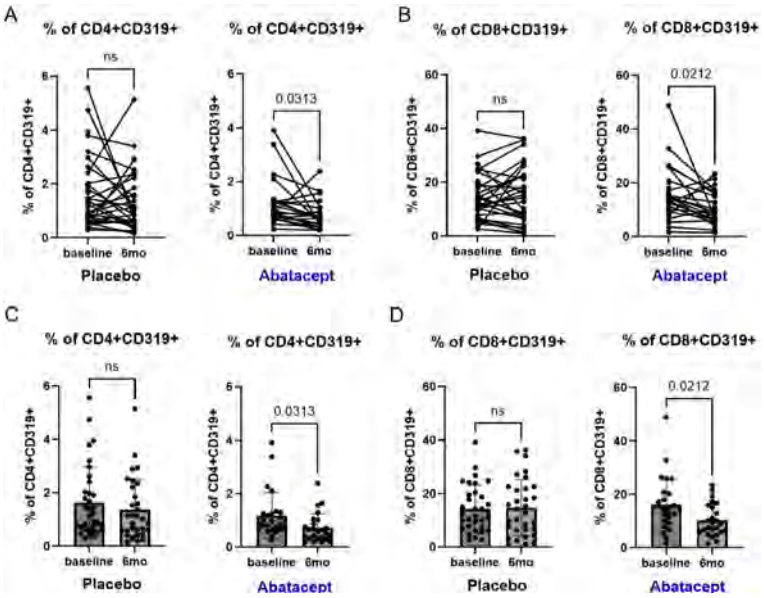

Figure 1. Abatacept reduces cytotoxic CD4+CD319+ and CD8+CD319+ cell populations in systemic sclerosis. (A): CD4+CD319+ and (B): CD8+-CD319+ cells were examined at baseline and 6 months after abatacept or placebo treatment. Patients treated with abatacept showed a significant decrease of CD319+ T cells within CD4+ cells and CD8+ (*p<0.05, paired t-test). (C) and (D): Data presented in boxplots.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

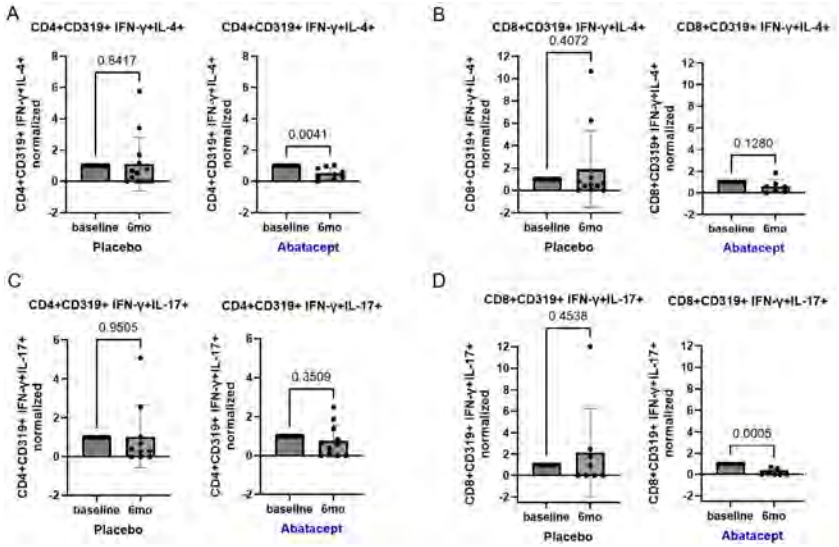

Figure 2. Abatacept reduces the percentage of IL-4/IFN-γ producing CD4+CD319+ and CD8+CD319+ cells in systemic sclerosis. Frequencies of IFN-γ, IL-4 and IL-17 cells within CD4+CD319+ and CD8+CD319+ cells were assessed 1, 3 and 6 months after treatment. Similarly, dual IFN-γ/IL-4, IFN-γ/IL-17 and IL-4/IL-17 production was also assessed at the same time-points. (A): Reduction of dual IL-4/IFN-γ producing CD4+ CD319+ cells was observed in abatacept treated patients at 6 months ($p<0.05$), but not in the placebo group (n.s.). (B): A decrease in IL-4/IFN-γ producing CD8+ CD319+ cells was seen in the abatacept group, although differences did not reach statistical significance ($p=0.0128$). Similarly, abatacept lowered IL-17/IFN-γ production in CD8+ CD319+ cells ($p=0.0005$), but not in CD4+ CD319+ cells at 6 months (C and D). Other analyses of single cytokine production and dual IL-4/IL-17 production did not reach statistical significance (data not shown). Data was normalized to baseline (*$p<0.05$, paired t-test).

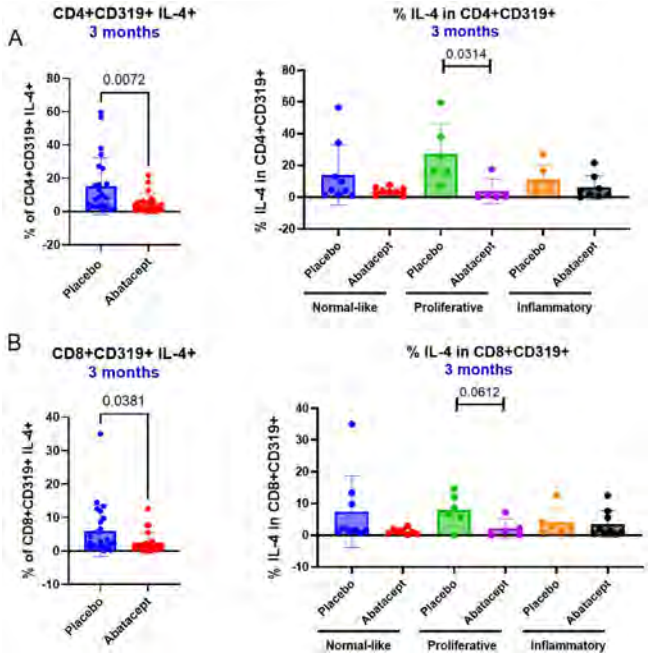

Figure 3. Abatacept decreases IL-4 producing CD4+CD319+ and CD8+CD319+ cells in proliferative subtype patients. (A): IL-4 producing CD4+-CD319+ and CD8+CD319+ cells were statistically decreased in the abatacept group at 3 months ($p=0.0072$). When comparing subtypes of SSc based on their gene signature, we observed a statistically significant reduction in IL-4-producing CD4+CD319+ cells after among the proliferative subtype ($p=0.0314$). (B): Abatacept decreases IL-4 producing CD8+CD319+ cells ($p=0.0381$). A reduction was also seen when comparing abatacept vs placebo in the proliferative subgroup at 3 months. Significant differences between abatacept vs placebo were assessed by a paired-t test. Differences between normal-like, proliferative and inflammatory subsets were assessed using one-way ANOVA with Tukey's multiple comparison test (*$p<0.05$).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

a dominant T cell population in perivascular lymphocytic infiltrates in SSc skin. In this new study, we analyzed the effects of abatacept on both CD4+CD319+ and CD8+CD319+ cells in peripheral blood of 67 dcSSc patients enrolled in the ASSET trial.

Methods: All SSc patients were participants in the ASSET study where longitudinal blood was available. Lymphocyte subsets were characterized by multi-parameter flow cytometry of peripheral blood mononuclear cells at times 0, 1, 3 and 6 months of the ASSET study. Patients were stratified according to their pattern of gene expression on baseline skin biopsies, into three predefined distinct subgroups: inflammatory, fibroproliferative and normal-like. Cytotoxic CD319+ T cells and production of the cytokines INF-γ, IL-4 and IL-17 were measured by intracellular flow cytometry, in both unstimulated cells and following T cell activation in overnight cultures.

Results: A profound decrease of CD319+ T cells was seen within CD4+ cells and CD8+ cells at 6 months (p=0.0313 and p=0.0212 respectively) in patients treated with abatacept compared with placebo **(Figure 1)**. Frequencies of IL-4+ cells within CD4+CD319+ and CD8+CD319+ cells were significantly reduced at 3 months (p=0.0072 and p=0.0381 respectively) but significance was not reached at 6 months. Reduction of dual IL-4/IFN-γ producing CD319+ cells was observed in abatacept treated patients at 6 months, but not in the placebo group **(Figure 2)**. Among normal-like, proliferative and inflammatory SSc subtypes, we found a statistically significant decrease in IL-4 producing CD4+CD319+ cells in the proliferative subtype at 3 months when compared to placebo **(Figure 3)**.

Conclusion: Abatacept has shown promise as a therapy in a subset of early dcSSc patients, emphasizing the need to explore its effects on abnormal and potentially pathogenic immune cell subsets. Here, we demonstrate that abatacept effectively reduces CD319+T cell numbers systemically and also decreases the proportion of CD4+CD319+ cells that are engaged in IL-4 and IL-4/IFN-γ production. Given the fact that CD319 is aberrantly expressed on both CD4+ and CD8+T cells in dcSSc patients, targeting these cells might hold great promise for therapeutic adjustment of lymphocyte balance and function in dcSSc.

Background/Purpose: Scleroderma (SSc) is an autoimmune disease characterized by dermal inflammation and fibrosis. Patients with SSc have high systemic levels of estradiol (E2), a form of estrogen, compared to age-matched controls, and worse mortality. E2 also contributes to dermal fibrosis in SSc, but we are unsure of its role in dermal inflammation. Using bulk RNA sequencing (RNA seq), we investigated inflammatory pathways in E2-treated dermal tissue.

Methods: We isolated total RNA from human skin tissue treated with ethanol (ETOH, vehicle) or E2 for 48 hours for bulk RNA seq. Using bioinformatics software, we identified statistically significant inflammatory genes and pathways. We confirmed transcript and protein levels using qPCR and ELISA, respectively. Primary human skin dermal fibroblasts from healthy donors treated with ETOH or E2, and dermal fibroblasts from patients with SSc were used for mechanistic studies. Statistical significance was defined as $p< 0.05$.

Results: We detected and confirmed that *CXCL2*, *CXCL3*, *CXCL5*, *CXCL8*, and *CCL20* chemokines are significantly increased in E2 treated skin tissue compared to ETOH. Additionally, these chemokines are induced by E2 in primary human dermal fibroblasts, with E2-induced CXCL5 and CCL20 transcript and secreted protein levels dependent on the MAPK pathway. We detected an association between E2-induced *IL-6* and *CXCL8* and *CCL20* ex vivo transcripts. Using inhibitors to prevent IL-6 and STAT3 signaling prior to E2 stimulation prevented E2-induced *CXCL2*, *CXCL3*, *CXCL8*, and *CCL20* transcripts ex vivo. While SSc dermal fibroblasts treated with anastrozole to prevent E2 generation produced significantly less *CXCL3*, *CXCL5* and *CXCL8*, but not *CXCL2* or *CCL20* transcripts, treatment with bazedoxifene, a selective estrogen receptor modulator and IL-6/STAT3 inhibitor, produced less CXCL5 and CXCL8 secreted protein.

Conclusion: E2 increases *CXCL2*, *CXCL3, CXCL5*, *CXCL8*, and *CCL20* chemokines in dermal tissue and fibroblasts. Although the MAPK pathway is important in their E2-induced expression, IL-6/STAT3 signaling is paramount to E2-induced chemokine expression. Our data suggests E2 production and estrogen receptor signaling through IL-6/STAT3 signaling is responsible, in part, for increased CXCL5 and CXCL8 in SSc. Therefore, E2 augments highly active inflammatory pathways in SSc.

Abstract Number: 2496

Comparing Long-term Outcome Across Systemic Sclerosis Subgroups Using a Multi-Organ Disease Progression Score

Philip Yee[1], medha kanitkar[2], stefano rodolfi[3], Voon H. Ong[2] and Christopher Denton[4], [1]Division of Medicine, Centre for Rheumatology, University College London, London, England, United Kingdom, [2]Division of Medicine, Centre for Rheumatology, University College London, London, United Kingdom, [3]University College London, London, United Kingdom, [4]University College London, UK, London, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Evaluating disease modification in systemic sclerosis (SSc) is challenging and requires long term studies. This is especially relevant to limited cutaneous (lc)SSc where severe organ involvement occurs later and less frequently than in diffuse cutaneous (dc)SSc. We have tested a novel composite "time to clinically meaningful progression"

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Baseline characteristics of the cohort divided according to cutaneous phenotype and ACA status

	DcSSc (n=920)	LcSSc (n=1937)	P value
Age of onset	45 (35-55)	47 (36-57)	0.0024
Female sex	692 (75.2%)	1691 (87.3%)	<0.0001
ILD	395 (42.9%)	514 (26.5%)	<0.0001
PAH	43 (4.7%)	161 (8.3%)	<0.0001
SRC	81 (8.8%)	16 (0.8%)	<0.0001
Severe gut	15 (1.6%)	74 (3.8%)	<0.0001
Severe heart	46 (5%)	39 (2%)	<0.0001
ACA+	28 (3%)	852 (44%)	<0.0001
Limited cutaneous subset			
	ACA+ (n=852)	**ACA- (n=926)**	
Age of onset	50 (39-59)	45 (33-55)	<0.0001
Female sex	787 (92.3%)	767 (82.8%)	<0.0001
ILD	62 (6.3%)	427 (46.1%)	<0.0001
PAH	88 (10.3%)	65 (7%)	0.008
SRC	1 (0.1%)	15 (1.6%)	<0.0001
Severe gut	56 (6.6%)	18 (1.9%)	<0.0001
Severe heart	10 (1.2%)	27 (2.9%)	0.007

endpoint (termed MINIMISE) in a large cohort of SSc to evaluate potential as a clinical trial endpoint for long term interventional or observational research across SSc subsets. We have also explored differences in long term outcome between ACA positive and ACA negative lcSSc, reasoning that ACA negative may show greater progression, and be especially informative in clinical trials.

Methods: Demographic, clinical, and serological data were explored in 2894 well characterized patients followed in our centre. We tested performance of the MINIMISE endpoint that assessed time to first development of new diagnosis of pulmonary arterial hypertension at right heart catheterization (according to current haemodynamic definition at time of diagnosis), new evidence of interstitial lung disease (ILD) with forced vital capacity (FVC) < 70% predicted or worsening of established ILD (reduction in FVC ≥10% in 12 months or between 5 and 9% with contemporary reduction in DLCO ≥15%), new onset severe cardiac involvement attributed to SSc (systolic ejection fraction drop to < 45% or pericardial effusion impairing cardiac function or arrhythmia requiring antiarrhythmic therapy or need for a cardiac device), new onset severe gastrointestinal (GI) involvement (enteral nutrition supplementation for ≥3 weeks or any parenteral feeding or hospital admission for intestinal pseudo-obstruction or obstruction), new onset scleroderma renal crisis, new onset severe digital vasculopathy requiring hospitalization, absolute increase of ≥5 modified Rodnan skin score units, or all-cause mortality.

We performed a time to event analysis for the MINIMISE composite outcome from disease onset, defined by first non-Raynaud SSc manifestation. Kaplan Meier survival failure estimates curves and Cox proportional hazards regression analysis compared disease and ACA subsets. P< 0.05 were considered statistically significant.

Results: Baseline characteristics of the cohort are summarised in **Table 1**. Around one third of cases had dcSSc and as expected this was associated with more frequent disease complications except for PAH and severe GI involvement that were most frequent in lcSSc. A total of 902 (31.6%) patients met the outcome in the first 10 years of the disease; 543 in the lcSSc group. Survival analysis revealed a significantly lower frequency of MINIMISE events in lcSSc vs DcSSc (**Figure 1**). Moreover, when considering only lcSSc, ACA negative patients had significantly more events over time (**Figure 2**).

Conclusion: In lcSSc, clinically meaningful progression, defined by the MINIMISE endpoint, is more frequent in ACA-negative patients. This subgroup may have greatest need and benefit from disease-modifying treatment, and this could be explored in a long-term event driven study although our data suggest that a large cohort and long term follow up will be essential to show benefit in lcSSc.

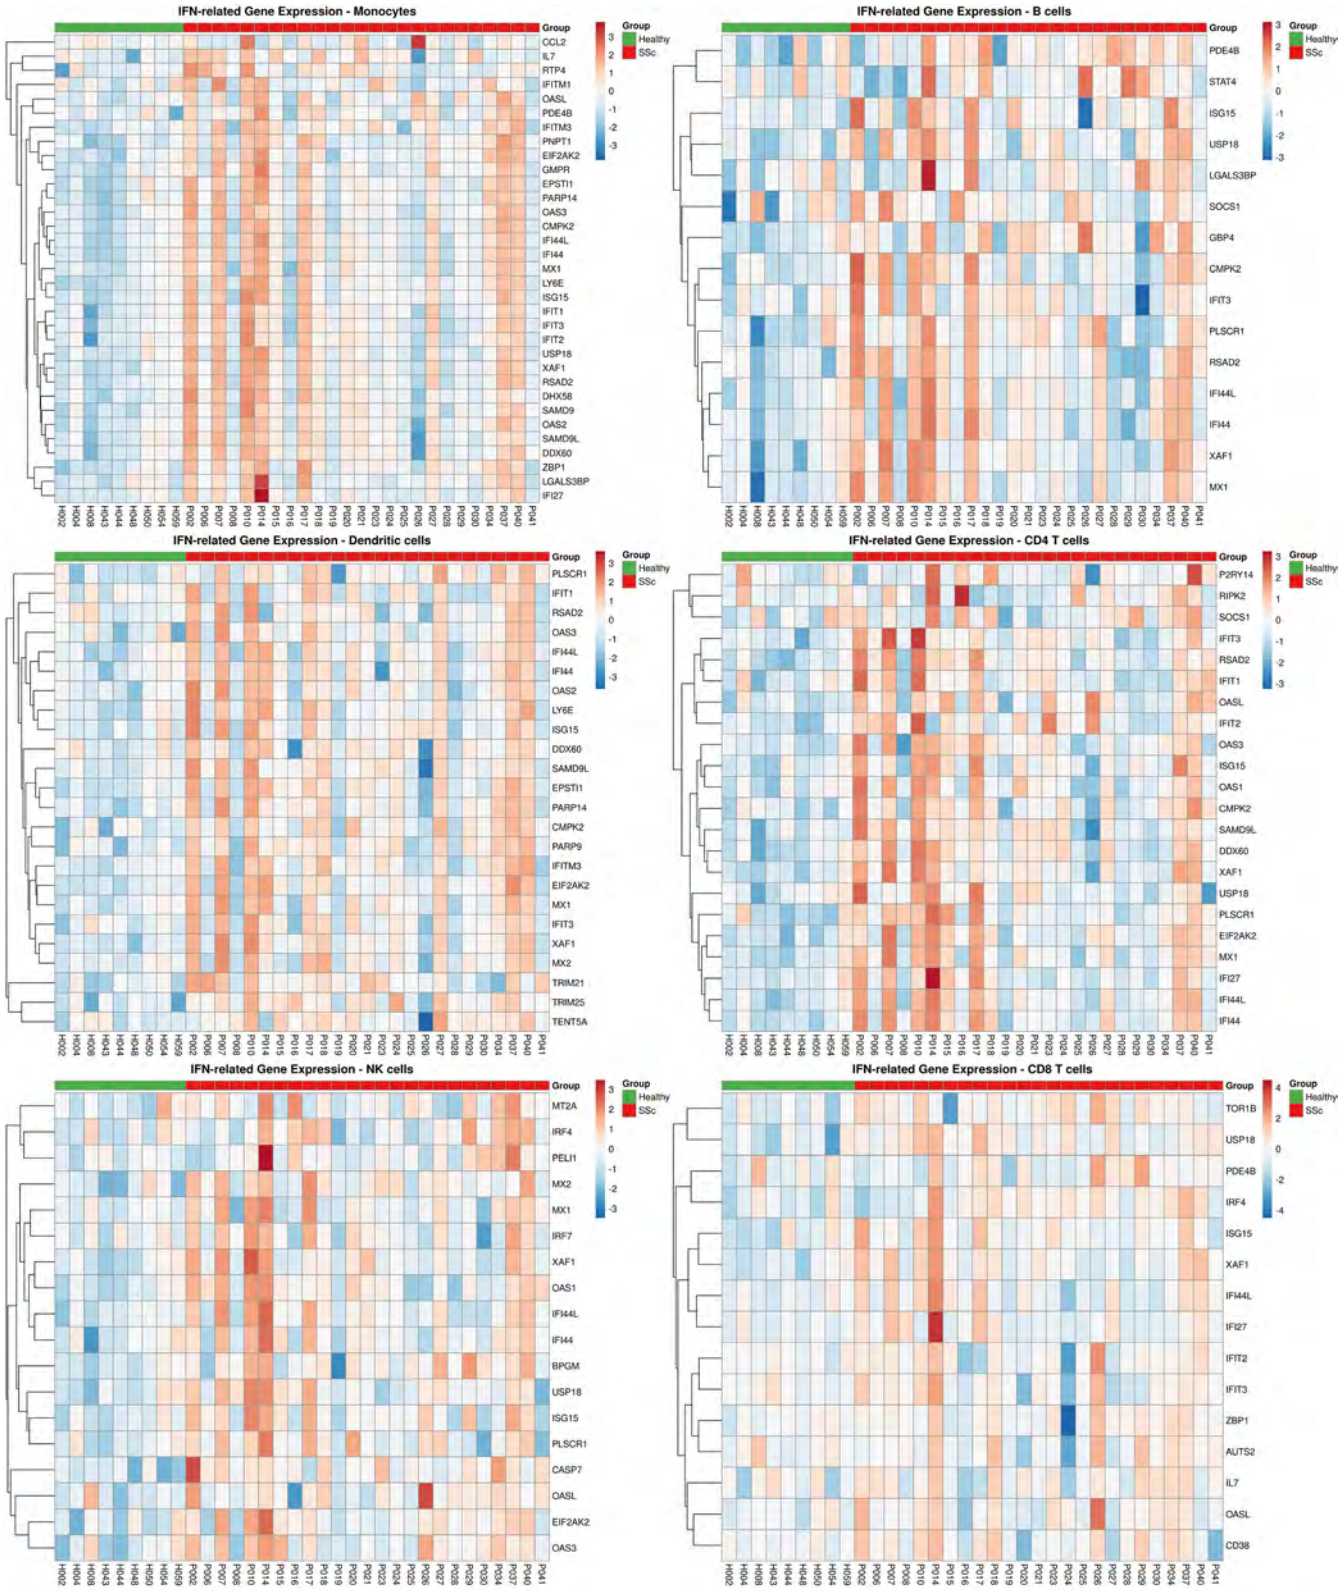

Figure 1. IFN-related DEGs across the different PBMCs subtypes. For each subtype (Monocytes, dendritic cells, NK cells, B cells, CD4 T cells and CD8 T cells), pathway analysis showed significant upregulation of the IFN type I and type II related pathways. Monocytes displayed the highest number of IFN-related DEGs (n = 33). Columns represent subjects (P = Patient, H = Healthy control), rows represent genes.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. IFN Z scores across different patients (P) (columns) and PBMC subtypes (rows). The heatmap evidences the strong heterogeneity of IFN Z scores both among different patients (columns) and within each patient among different celltypes(rows). For each cell type, the Z-score was calculated using only the IFN-related DEGs specific to that cell type (Figure 1). We assessed for association between categorical (a) and continuous (b) clinical variables. Anti-centromere antibodies (ACA), anti-RNA polymerase III antibodies (RNPIII), anti-topoisomerase I antibodies (Scl70), Revised EUSTAR Activity Index (r-EUSTAR AI), Scleroderma Clinical Trials Consortium Activity Index (SCTC-AI), modified Rodnan Skin Score (mRSS), Functional Vital Capcity (FVC), Diffusing Capacity of the Lung for Carbon Monoxide (DLCO), Carbon monoxide transfer coefficient (KCO).

Background/Purpose: Autoimmunity is a hallmark of SSc pathogenesis. Emerging evidence suggests that interferon (IFN) signaling plays a role in predicting SSc patients at risk of progression. Understanding the alterations in the transcriptome of SSc Peripheral Blood Mononuclear Cells (PBMCs) may provide key insights into the role of IFN signaling and improve patient stratification.

Methods: We performed single cell RNA sequencing of PBMCs from 25 early (≤ 5 years from diagnosis), active SSc (ACR/EULAR 2013) patients and 9 age-matched healthy controls using the Chromium Next GEM protocol. Active SSc was defined by progression of skin or lung fibrosis and/or arthritis. Cellranger was used for read alignment, Seurat v5 for analysis. PBMCs were annotated via Azimuth. Differentially expressed genes (DEGs) were identified using FindMarkers ($|\log2FC| \geq 0.5$, FDR ≤ 0.05). Pathway analysis (MSigDB Hallmark, Reactome) was performed on upregulated DEGs (adj p ≤ 0.05).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

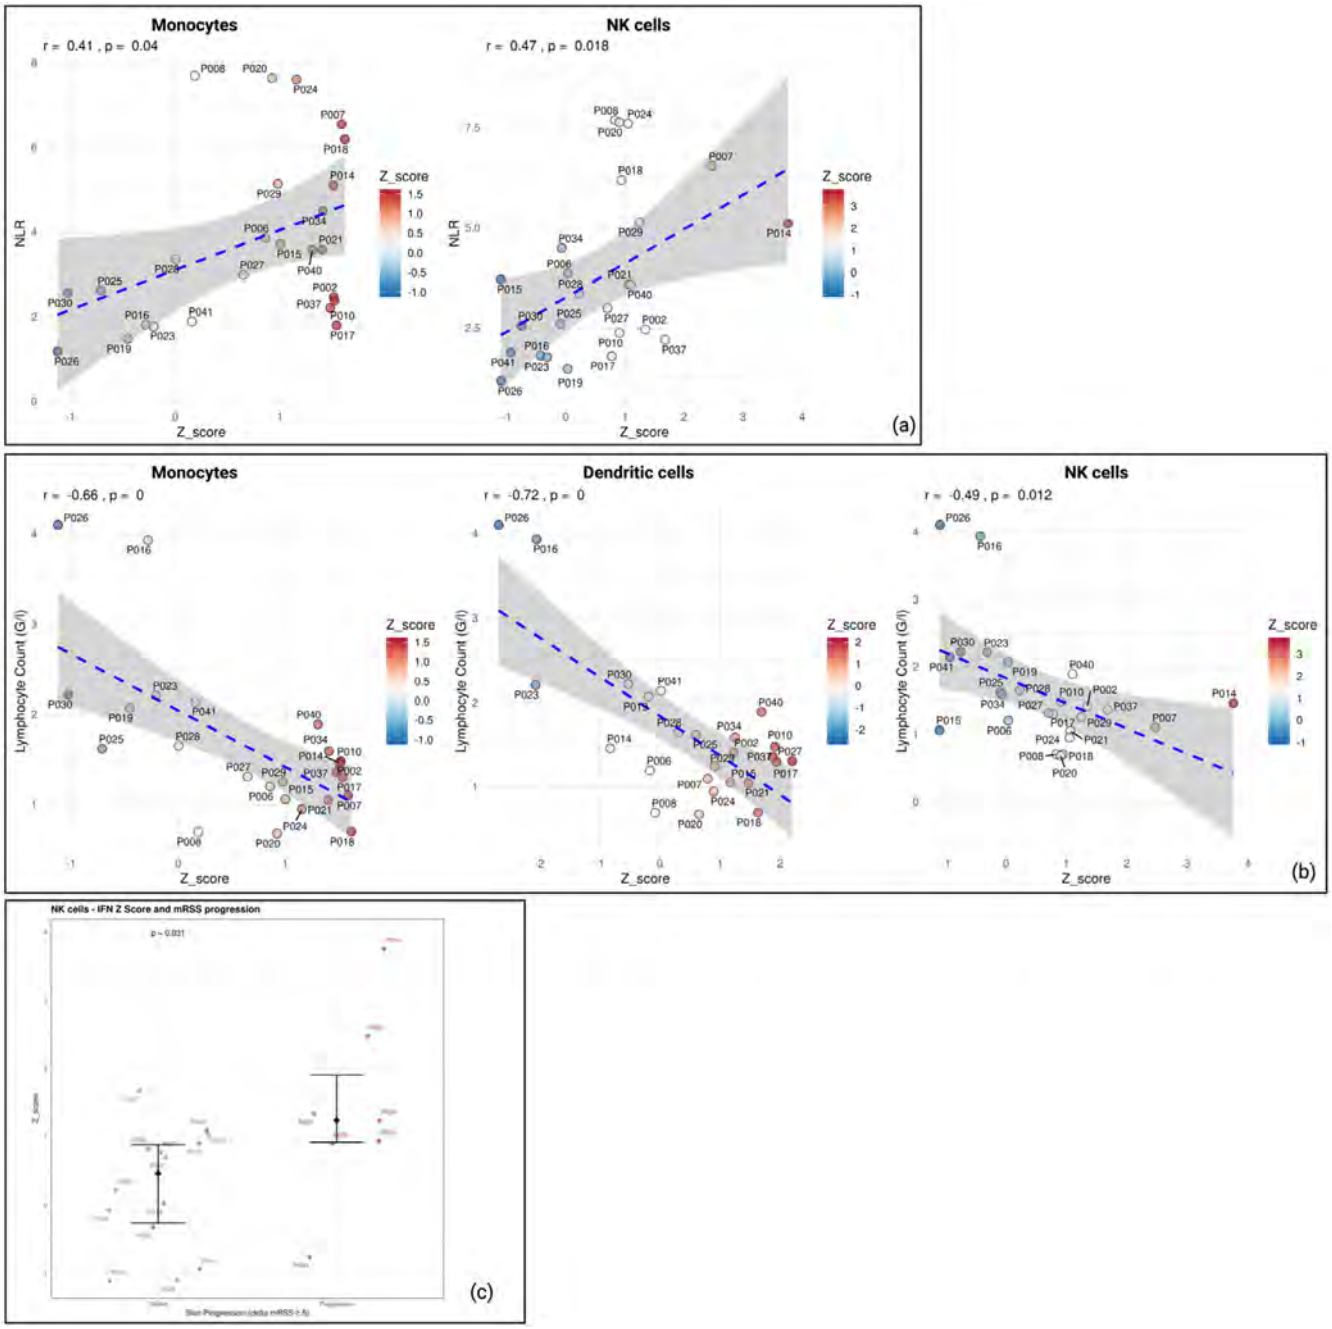

Figure 3. Significant linear regression analysis between celltypes IFN Z scores and NLR (a), lymphocyte count (b). NK cells IFN Z Score grouped by skin fibrosis (mRSS) progression at 1 year (c).

Z-scores for selected DEGs were calculated from count-per-million normalized pseudocounts. Clinical data included autoantibody status, dcSSc, Interstitial Lung Disease (ILD), disease activity indices, CRP, ESR, mRSS, lung function test, neutrophil (N)/lymphocyte (L) counts, and NL Ratio (NLR). Association between Z-scores and continuous clinical variables were assessed using linear regression. Differences in Z scores between patient groups were tested using Mann–Whitney U test.

Results: In the SSc cohort, 88% had ILD, 36% dcSSc, with a median disease duration of 12 [3-22] months. PBMCs (n = 108'138) were annotated as monocytes, dendritic, NK, B, CD4 T and CD8 T cells. Upregulated DEGs related to IFN-α and γ pathways were detected in all cell types (Figure 1) with overall significantly increased expression of *IFI44L, ISG15, EIF2AK2*, and *XAF1*. A prominent heterogeneity in the expression of IFN-related DEGs was observed between SSc samples

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

across all cell types (Figure 1). IFN Z scores further confirmed the substantial heterogeneity between different cell types and individual patients (Figure 2).

Linear regression analysis revealed no significant association between IFN Z-scores and disease activity (r-EUSTAR and SCTC activity indices). In contrast, the IFN Z-scores of monocytes (r = 0.41, p = 0.04) and NK cells (r = 0.47, p=0.018) showed a positive, significant association with NLR (Figure 3a). A significant negative association with L counts and the IFN Z scores was found in monocytes (r = -0.66, p = < 0.001), dendritic cells (r = -0.72, p = < 0.001), and NK cells (r = -0.49, p = 0.012) (Figure 3b). Baseline IFN Z-scores in NK cells were higher in skin progressors (n = 5) at one year (p = 0.031) (Figure 3c). No other clinical parameter was predicted by celltype IFN Z score (Figure 2a-b).

Conclusion: Our data highlight the heterogeneity of IFN response both among patients with active SSc and across different PBMC types within the same patient. IFN response associated with NLR — a predictor of organ involvement and poor prognosis — specifically in monocytes and NK cells.

Other clinical parameters, including disease activity, did not associate with the IFN response signatures in PBMCs.

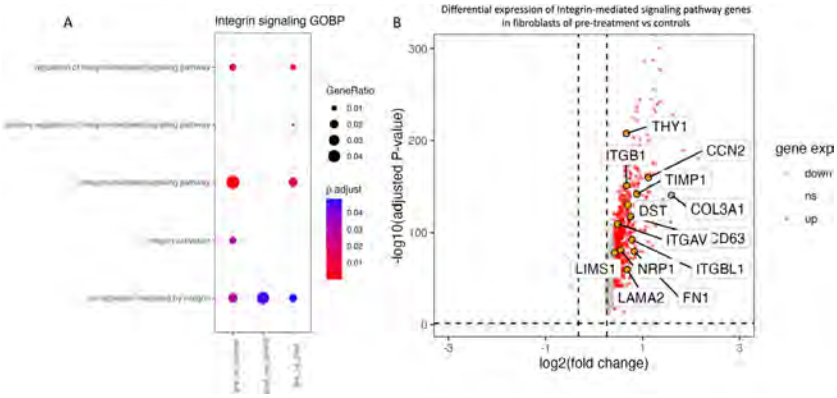

Figure 1: A. Integrin-mediated signaling pathway enriched in the fibroblasts of only pre-treatment skin (pre_vs_control), and not of the post-treatment skin biopsies (post_vs_control). B. Integrin-mediated signaling pathway genes up-regulated in fibroblasts of pre-treatment skin compared to the control skin

Background/Purpose: Systemic sclerosis (SSc) is characterized by skin fibrosis, dysregulated immune response, and vascular system dysfunction. Interstitial lung disease (ILD) is one of the leading causes of SSc-related deaths (Cottin 2019). SSc, associated with ILD, severely affects the immune system and contributes to skin and lung fibrosis. Hematopoietic stem cell transplantation (HSCT) works by resetting the immune system and is emerging as a potential therapeutic strategy for patients with severe SSc-ILD. However, in skin and in peripheral blood mononuclear cells (PBMC) of these patients, the molecular mechanisms and the cell populations that are impacted by the transplant are yet to be identified.

Methods: Single-cell RNA sequencing (scRNA-seq) and assay for transposase-accessible chromatin using sequencing (ATAC-seq) of skin biopsies and PBMCs were performed from four human healthy controls and three SSc-ILD patients before and one year after transplantation. The R packages Seurat (v4.3.0) and Signac (v1.11.0) were used to analyze the scRNA-seq and ATAC-seq data. Cell-cell communication analysis was performed using the R package CellChat (v2.1.2).

Results: Three patients (mean age 54 (range 37-63), 2 men and 1 woman) underwent myeloablative autologous stem cell transplant. The pre (mean 24, SD 5) and post one year (mean 6.33, SD 6.66) modified Rodnan skin score (mRSS) and pre (mean 70, SD 13.45) and post (mean 82, SD 12.12) forced vital capacity percent improved in all patients. A total of 41,181 skin cells were annotated into 10 major cell types and a total of 38,236 PBMCs were annotated into 5 major cell types from the sequencing data. 11,293 skin fibroblasts (FB) were sub-clustered into 7 FB subtypes, with COL11A1+, LTBP2+, and myofibroblasts (CILP_COL8A1+ FBs) showing diminished expression of the pro-fibrotic genes CTGF (CCN2), TAGLN, and VGLL3 post-transplantation at the levels comparable to healthy controls. Enriched cell-cell communication of the CD6/ALCAM pathway was noted only in pre-treatment skin biopsies but neither in post-treatment nor in controls. Additionally, integrin-mediated signaling pathway was found to be enriched in the fibroblasts of pre-treatment skin, and not in the post-treatment skin biopsies (Figure 1). In PBMCs, CD4 T cell proportion was similar in controls and pre-treatment samples but reduced in post-treatment biopsies. LCK pathway, involved in activation of T cell signaling, was found to be associated with cell-cell communication only in pre-treatment PBMC samples but absent in both post-treatment and healthy control.

Conclusion: Our data identify a reduction in expression of pro-fibrotic genes in FB subtypes and diminished signaling of pathways involved in mediating inflammation in SSc-ILD patients who underwent HSCT therapy.

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Sjogren's disease (SjD) is a common systemic autoimmune disorder characterized by progressive inflammation of the exocrine glands, resulting in dry eyes and dry mouth. Anti-Ro/SSA antibodies are the prototypical serologic marker of SjD, but they are also detected in other systemic autoimmune diseases, including systemic sclerosis (SSc). The prevalence and clinical implications of anti-Ro/SSA antibodies in SSc remain poorly understood. We hypothesized that

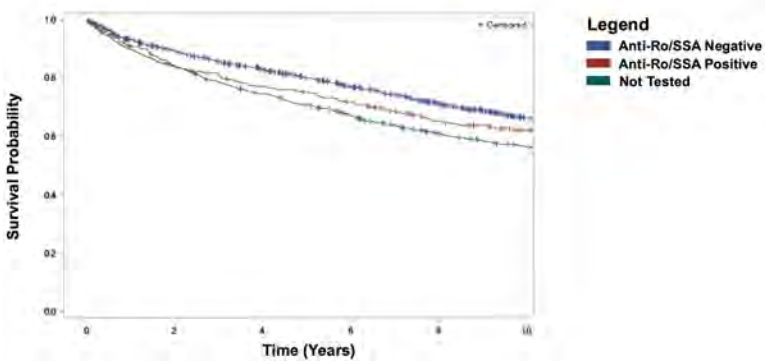
Figure 1: 10-Year Survival of SSc patients By Anti-Ro/SSA antibody status



anti-Ro/SSA antibodies confer distinct prognostic risk factors beyond sicca symptoms in patients with SSc. Our objective was threefold: 1) establish Ro/SSA seropositivity prevalence in SSc, 2) determine the frequency of sicca symptoms, and 3) assess if increased frequencies of specific organ complications were associated with Ro/SSA positivity.

Methods: We evaluated all new patients presenting with systemic sclerosis between 1980 and 2024 at a single university-dedicated scleroderma center. Participants underwent comprehensive serologic testing, including ANA, immunodiffusion, protein, and RNA immunoprecipitation (IP). Dedicated ELISA or IP screening for Ro/SSA antibodies was performed as clinically indicated. Demographics, clinical features, and survival were compared over long-term follow-up among patients who were anti-Ro/SSA positive, anti-Ro/SSA negative, or not tested.

Results: There were 3,116 patients seen for an initial visit during this time period. In the cohort, 1,985 underwent anti-Ro/SSA testing. Amongst those tested, 13.8% (273/1,985) were anti-Ro/SSA positive. Amongst the concomitant SSc antibodies, SSA/Ro positivity occurred significantly more frequently with anti-U1RNP positivity, and significantly less with anti-RNA polymerase III antibodies (Table 1), even after correcting for multiple comparisons amongst the antibodies.

Despite the presence of anti-Ro/SSA antibodies, only 47% of patients had objective dry eyes and 45% reported dry mouth, suggesting these antibodies may occur in the absence of a full SjD phenotype.

SSA positivity was not associated with a difference in cutaneous subtype. It was, however, associated with significantly higher rates of pulmonary fibrosis by imaging Table 1& 2). Not surprisingly, the lowest mean FVC was lower in Ro/SSA positive patients. Interestingly, there were higher rates of pHTN (Table 1 & 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Kaplan-Meier survival analyses showed reduced 5- and 10-year survival among anti-Ro/SSA positive and untested patients compared to anti-Ro/SSA negative individuals (Figure 1).

Conclusion: Here, we show that 14% of SSc tested patients had Ro/SSA antibodies. As expected, anti-Ro/SSA patients were more likely to have sicca symptoms. Notably, anti-Ro/SSA positive patients had significantly increased rates of pulmonary fibrosis and pHTN. Anti-Ro/SSA positive patients also demonstrated reduced survival at 5 and 10 years. Untested individuals showed a similar survival decrement. Taken together, these data show that anti-Ro/SSA positivity identifies a clinically meaningful SSc phenotype with increased pulmonary involvement and worse prognosis, highlighting its potential role in clinical care and future research.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: SSc is a rare autoimmune connective tissue disorder; up to 64% of patients with SSc develop interstitial lung disease (ILD), which can result in loss of lung function, diminished quality of life, and premature death. It also contributes a substantial economic burden through healthcare resource use (HCRU), medical expenses, and loss of productivity. This systematic literature review (SLR) evaluated the economic burden and HCRU associated with SSc in patients with ILD (SSc-ILD) and without ILD.

Methods: This SLR (GSK Study 222155) identified eligible studies (patients of any age with SSc, irrespective of severity and subtype) through database searches, with manual searches of recent peer-reviewed SLRs, meta-analyses, and health technology assessment reports. SLR conduct and reporting followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Only cost of illness and HCRU studies published as full text articles, conducted in key countries of interest (United States [US], Canada, United Kingdom, France, Germany, Spain, Japan, and China), with an observation period ending between 2013 and 2023 were selected for data extraction. Cost outcomes included total healthcare, direct, and indirect costs. HCRU outcomes included hospitalization data and length of inpatient (IP) stays. Treatments received for SSc (any use) were also assessed. The Newcastle-Ottawa Scale was used to assess the quality of studies.

Results: Out of 3042 records identified, 54 studies were considered eligible and a total of 17 studies (data reported from US, Canada, England, France, and Spain with sample sizes from 24 to 95,515) were extracted (**Figure**); all were determined to have an overall low risk of bias.

Marked variation in costs associated with SSc overall and SSc with or without ILD were observed across studies (**Table 1**). Total direct healthcare costs up to $47,095 per patient per year were reported for SSc overall in the US. Where reported, direct healthcare costs were notably higher for SSc-ILD versus SSc without ILD. Patients with SSc-ILD generally had longer IP stays than those without ILD, while data on hospitalization/emergency room visits were limited (**Table 2**).

Treatment rates varied across studies. Glucocorticoids were the most common treatment for SSc/SSc-ILD (global usage: 24.0–74.1%; US rates: 24.0–44.7%), followed by mycophenolate mofetil, while less than 4% of patients received biologics.

Conclusion: These data demonstrate the substantial economic burden and HCRU with SSc and suggest that SSc-ILD has a greater impact on these measures than SSc without ILD, likely due to greater disease severity and associated impairments. However, cost/HCRU estimates varied widely, which may be partially attributable to differences in population criteria and study methodologies. Findings were restricted to five countries reporting scarce indirect cost data. Therefore, there is a need for more comprehensive studies that evaluate a broader range of cost/HCRU outcomes across diverse settings for patients with SSc-ILD, which will help validate and expand upon existing evidence to better characterize the economic burden of SSc-ILD.

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disease characterized by endothelial dysfunction, self-reactive immune response and progressive systemic fibrosis[1]. It is well established that bone micro- and macroarchitectural damage is more prevalent in patients (pts) with SSc compared to healthy subjects(HS)[2]. Moreover, in SSc pts severe microvascular damage exhibit significant alterations in bone health, indicating a strong connection between microvascular

Table I. Statistically significant Spearman correlations between hand BMD and BMC and clinical features, antibody profiles, and NVC parameters in SSc patients. Abbreviations: BMD: bone mineral density; BMC: bone mineral content; SSc: systemic sclerosis; GI: gastrointestinal involvement; mRSS: modified Rodnan skin score; NVC: nailfold videocapillaroscopy; ACA: anticentromere antibodies; SCL70: anti-topoisomerase I antibodies.

dysfunction and muscle/bone impairment[3]. Consequently, the impaired peripheral microcirculation may contribute to the development of localized hand osteoporosis in SSc. The aim of this study was to assess the hand bone quality in SSc pts in correlation with peripheral microcirculatory status assessed with NVC analysis.

Methods: Hand (left and right) and total BMD and BMC were assessed by DXA and a dedicated software (GE Lunar, USA) in 32 SSc pts (age 61 ± 14 years, 94% women) affected by limited or diffuse cutaneous (dcSSc 47%) according to the 2013 EULAR/ACR criteria and 30 age-matched HS. Progressive peripheral microvascular damage, assessed by validates nailfold capillaroscopy (NVC)[4]. Statistical analysis was carried out by non-parametric tests and logistic regression analysis was performed to examine the influence of the capillary loss and hand bone status.

Results: Data revealed significantly lower hand BMD and BMC values (mean±SD) in SSc pts and age matched HS (BMD 0.31 ± 0.07vs 0.39 ± 0.06, $p < 0.01$; BMC 21.27±7.32 vs 30.09 ± 7.8, p< 0,01). The presence of SSc was associated with lower hand BMD compared with HS (adjusted for age, gender, BMI and history of osteoporosis; Beta= -0.2234, $p = 0.025$). In SSc pts a positive correlation was observed between hand and both spine vertebral bodies values ($r(30) = 0.4671$, $p = 0.007$) and femoral bone status (Neck $r(30) = 0.3866$, $p = 0.029$; total $r(30) = 0,354$, $p = 0,047$). Clinical, laboratory and NVC correlations have been performed (Table I). The regression analysis revealed that reduced capillary count significantly accounted for 38.26% of the variance in BMD values ($R^2 = 0.3826$, $F = 17.35$, $p < 0.001$).

Conclusion: In conclusion, hand bone status in SSc pts was found significantly lower compared to spine and femor bone and HC as well as associated with disease severity. The hand bone damage seems linked to the microvascular insufficiency. Therefore, care to the bone status should be taken as consequence of the progressive microvasculatory damage/ insufficiency in SSc.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a clinically and biologically heterogeneous autoimmune disease characterized by multiorgan involvement, substantial morbidity, and high mortality. Traditional classification systems (based on the extent of cutaneous involvement or autoantibody status) fail to fully capture the complexity of disease expression and progression. There is a growing need for more precise patient stratification strategies that reflect underlying pathophysiology and can guide therapeutic decisions. Molecular approaches such as proteomic profiling may enable a shift from descriptive to mechanism-based classification frameworks in SSc.

Our objective was to identify biologically and clinically distinct subgroups of SSc patients through unsupervised clustering of clinical and serological data, combined with high-throughput serum proteomic analysis.

Table 1. Comparison of clinical and serological characteristics between the two identified clusters of SSc patients (PRECISESADS cohort). ¶: variables included in the clustering algorithm. ILD: interstitial lung disease; PAH: pulmonary arterial hypertension; GERD: gastroesophageal reflux disease; bDMARD: biologic disease-modifying antirheumatic drug.

Variable	PRECISESADS cohort (n=402)	Cluster 1 (n=221)	Cluster 2 (n=181)	p-value
Age (years), mean (SD)¶	58.1 (12.9)	57.2 (13.2)	59.2 (12.4)	0.12
Disease duration (years), mean (SD)	10.8 (8.7)	10.2 (9.6)	11,6 (7.5)	0.10
Sex (female), n (%)¶	339 (84.3)	188 (85.1)	151 (83.4)	0.75
ILD, n (%)¶	140 (34.8)	32 (14.5)	108 (59.7)	**< 0.01**
Sclerodactyly, n (%)¶	288 (71.6)	118 (53.4)	170 (93.9)	**< 0.01**
PAH, n (%)¶	76 (18.9)	20 (9)	56 (30.9)	**< 0.01**
Limited cutaneous phenotype, n (%)	216 (53.7)	133 (60.2)	83 (45.9)	**< 0.01**
Raynaud phenomenon, n (%)¶	389 (96.8)	209 (94.6)	180 (99.4)	**0.01**
Ever smoking, n (%)¶	55 (13.7)	32 (14.5)	23 (1.7)	0.71
Hypertension, n (%)	129 (32.1)	72 (32.6)	57 (31.5)	0.90
Centromere positivity, n (%)	149 (37.1)	96 (43.4)	53 (29.3)	**< 0.01**
Scl-70 positivity, n (%)	114 (28.4)	44 (19.9)	70 (38.7)	**< 0.01**
Arthritis, n (%)¶	118 (29.4)	46 (20.8)	72 (39.8)	**< 0.01**
Calcinosis, n (%)¶	93 (23.1)	15 (6.8)	78 (43.1)	**< 0.01**
Digital ulcers, n (%)¶	39 (9.7)	11 (5)	28 (15.5)	**< 0.01**
Telangiectasias, n (%)¶	239 (59.5)	88 (39.8)	151 (83.4)	**< 0.01**
GERD, n (%)¶	267 (66.4)	117 (52.9)	150 (82.9)	**< 0.01**
Dyslipidemia, n (%)	98 (24.4)	57 (25.8)	41 (22.6)	0.54
Pitting scars, n (%)¶	198 (49.3)	65 (29.4)	133 (73.5)	**< 0.01**
Current bDMARD, n (%)	10 (2.5)	2 (0.9)	8 (4.4)	**0.04**
Current immunosuppressants, n (%)	106 (26.4)	32 (14.5)	74 (40.9)	**< 0.01**
Obesity, n (%)	39 (9.7)	23 (10.4)	16 (8.8)	0.72
Esophageal dysmotility, n (%)¶	200 (49.7)	77 (63.6)	123 (68)	**< 0.01**
Statins use, n (%)	84 (20.9)	42 (19)	42 (23.2)	0.36
Puffy fingers, n (%)	225 (56)	116 (52.5)	109 (60.2)	0.14
Muscle weakness, n (%)¶	72 (17.9)	21 (9.5)	51 (28.2)	**< 0.01**

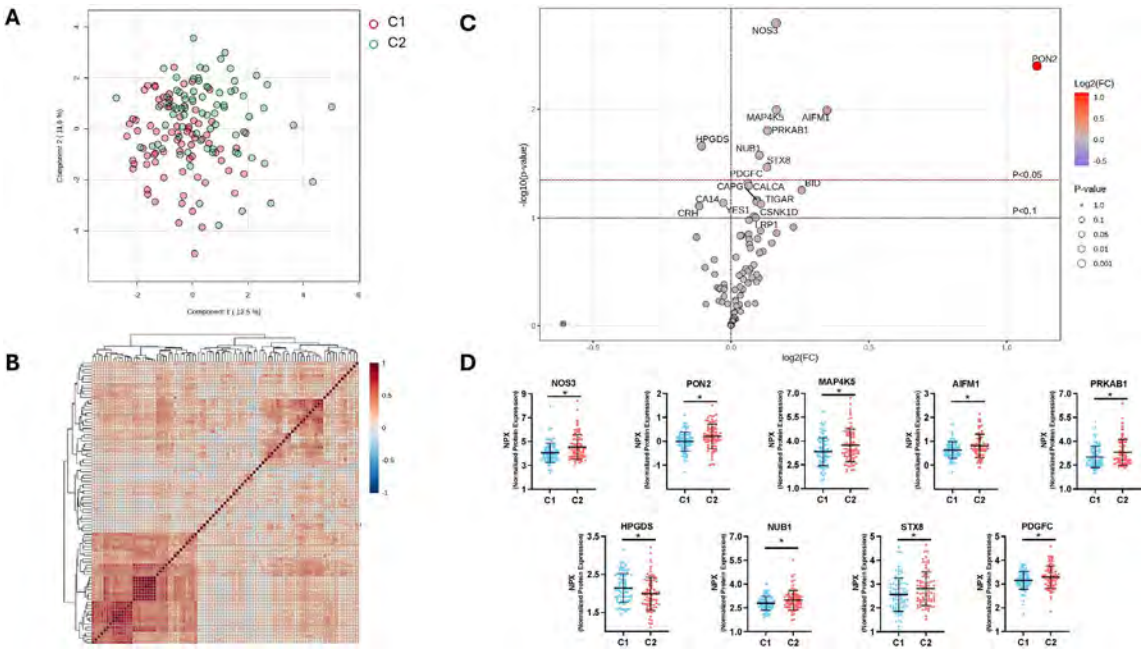

Figure 1. Proteomic analysis of organ damage markers in SSc. (A) Principal component analysis (PCA) of SSc patient clusters based on organ damage-related proteomic markers. (B) Heatmap showing correlations among protein levels across all patients. (C) Volcano plot of differentially expressed proteins between SSc clusters. (D) Circulating levels of statistically significant proteins differentiating cluster 1 and cluster 2.

Methods: Clinical and serological data from 402 patients in the multicenter PRECISESADS cohort were analyzed using k-means clustering to define SSc subtypes. Internal validity was assessed using statistical indices; external validation was performed in an independent Spanish cohort (n=213). Proteomic profiling was conducted on a representative subset of 154 patients using a targeted 92-protein OLINK® panel focused on organ damage. Functional validation was carried out

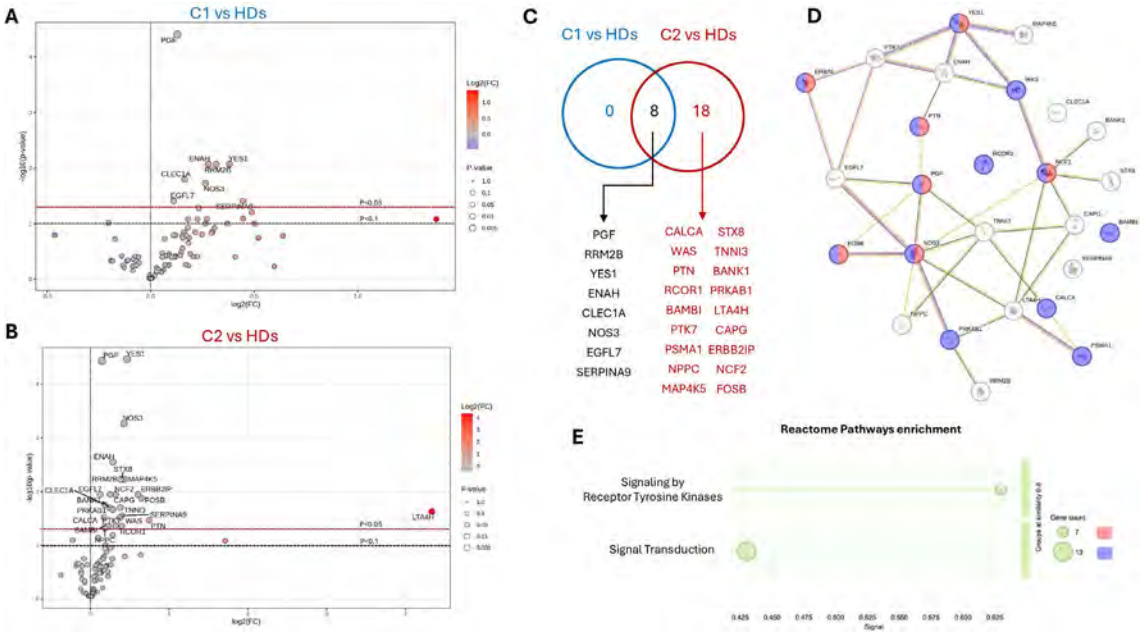

Figure 2. Comparative volcano plots and functional interaction network of differentially expressed proteins in SSc patient clusters vs healthy donors. (A) Volcano plot comparing protein expression between healthy controls and patients in Cluster 1. (B) Volcano plot showing the comparison between healthy controls and Cluster 2 patients, with a greater number of significantly upregulated proteins. (C) Venn diagram showing the overlap of differentially expressed proteins in clusters 1 and 2 compared to healthy donors. (D, E) Functional interaction network of the differentially expressed proteins compared to healthy controls, constructed using the STRING platform The analysis reveals a dysregulation of the Signaling by Receptor Tyrosine Kinases pathway (proteins in red) and signal transduction (proteins in purple).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. by treating immortalized fibroblasts with serum from patients in each cluster, followed by RT-qPCR analysis of fibrotic and inflammatory gene expression.

Results: Two robust and clinically distinct clusters were identified and independently validated. Cluster 2 was associated with a more severe phenotype, including a higher prevalence of interstitial lung disease (59.7% vs. 14.5%), pulmonary arterial hypertension (30.9% vs. 9%), and musculoskeletal involvement. A detailed comparison of demographic and clinical characteristics between clusters is provided in Table 1.

Proteomic analysis revealed 26 upregulated proteins in Cluster 2, including PDGFC, NOS3, and PRKAB1 (linked to fibrosis, endothelial injury, and metabolic stress (Figures 1A-D)). Compared to healthy donors, Cluster 2 showed greater proteomic dysregulation than Cluster 1 (Figures 2A-E), and pathway enrichment highlighted alterations in receptor tyrosine kinase signaling and immune activation. Functional assays confirmed that serum from Cluster 2 patients induced upregulation of profibrotic (PDGFRB, WNT3A) and proinflammatory (TNF, IL1B) genes in fibroblasts. Several proteins also correlated with clinical features such as pulmonary hypertension and esophageal dysmotility.

Conclusion: This integrative approach combining unsupervised clustering, proteomics, and functional validation identifies molecularly and clinically meaningful SSc subgroups. The findings support the use of circulating protein profiles to refine patient stratification and move toward personalized management in SSc.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2470–2503) Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Skin fibrosis is a cardinal manifestation of diffuse cutaneous systemic sclerosis (dcSSc) and is routinely measured via the modified Rodnan skin score (mRSS); however, mRSS is limited by its operator-dependence and may not reflect the complex disease biology at the cutaneous compartment. A recent high dimensional multi-omic analysis identified 3 serum proteins independently associated with mRSS: tenascin C (TNC), cartilage oligomeric matrix protein (COMP), and collagen type IV alpha 1 (COL4A1). Integrating their serum concentrations, a composite biomarker score to reflect skin involvement was derived and tested in 2 cohorts from a single centre. Whilst there was correlation of the composite marker

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

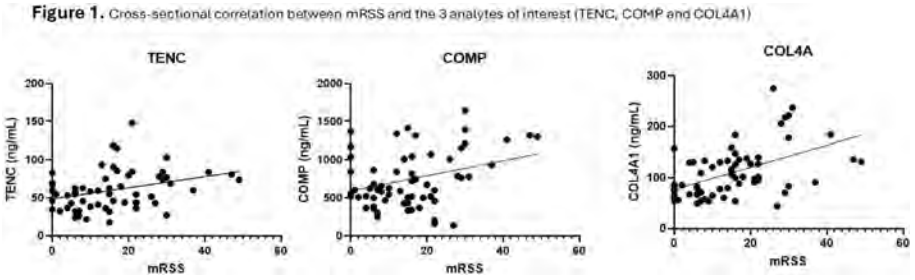

Figure 1. Cross-sectional correlation between mRSS and the 3 analytes of interest (TENC, COMP and COL4A1)

and its components with mRSS and some association with underlying treatment, the results of these studies were inconclusive, potentially due to the narrow range of mRSS and modest impact of standard immunosuppressive treatment in the SSc cohorts. The aim of the present study was to validate this composite biomarker score in a cohort with a greater dynamic range of mRSS and high percentage of patients receiving intensive immunosuppressive treatment.

Methods: We selected patients from 2 centres in the Netherlands who participated in the Autologous Stem Cell Transplantation International Scleroderma (ASTIS) trial. Serum concentrations of TNC, COMP and COL4A1 were measured via commercially available enzyme linked immunosorbent assay (ELISA) kits on samples at baseline, 12 months and 24 months. Serum levels of target analytes were correlated with mRSS data cross-sectionally and longitudinally. Spearman's test, Bland Altman test, univariable and multivariable linear regression were used to test for correlation. A p value < 0.05 was considered statistically significant.

Results: We included 21 patients: 11 treated with cyclophosphamide (CYC), and 10 subjected to autologous haematopoietic stem cell transplant (HSCT). Median mRSS was 21 at baseline, 12 at 12 months, and 6 at 24 months. The concentrations of all 3 analytes showed a significant correlation with mRSS when evaluated cross-sectionally at all the timepoints (**Figure 1**), with COL4A1 maintaining statistical significance at multivariable analysis (r=0.0952, p=0.001). From these data, we derived a refined composite serum biomarker score to predict actual mRSS (**Figure 2**). Next, we assessed the performance of the analytes as dynamic biomarkers of mRSS, however only changes in COMP were associated with mRSS variation (r= 0.013; p= 0.012). Finally, although both treatment arms had the same degree of mRSS variation from baseline to 24 months (i.e. 15 points), the change in COL4A1 concentration was significantly larger in the HSCT group than in the CYC group (**Figure 3**).

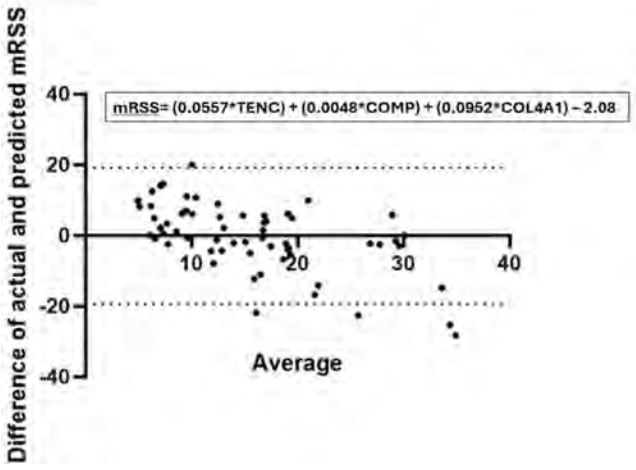

Figure 2. Bland-Altman plot of predicted and actual mRSS, including a refined formula to predict mRSS

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3. Change in COL4A1 concentrations from baseline to 24 months across the 2 treatment groups

Conclusion: Our refined composite biomarker score predicts mRSS score cross-sectionally, however the performance of these analytes as dynamic markers of cutaneous involvement is poor.

The differences for serum COL4A1 across treatment groups, with greater reduction in the HSCT group, was associated with a long-term survival advantage in the ASTIS trial which warrants further evaluation of the role of this protein as a predictive marker in dcSSc

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Eosinophilic Granulomatosis with Polyangiitis (EGPA) is a rare systemic vasculitis that can lead to significant morbidity and mortality. This study aims to evaluate the demographic, clinical, and hospital-related characteristics associated with in-hospital mortality among EGPA hospitalizations using a claims-based US national database.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Methods: A retrospective analysis of the National Inpatient Sample (NIS) database from 2017 - 2021 was conducted to identify adult hospitalizations with a primary or secondary diagnosis of EGPA (ICD 10: M30.1). Descriptive statistics were used to compare patients discharged alive and those who suffered in-hospital mortality. All variables with $p \leq 0.2$ in the univariable screen were included in a multivariable logistic regression model to assess independent predictors of in-hospital death. $p \leq 0.05$ was considered significant in multivariable analysis. Cells of data containing hospitalization records with a value of 1 to 10 were not reported to protect hospital privacy as per the Healthcare Cost and Utilization Project (HCUP) data service agreement.

Results: A total of 9,095 hospitalizations for EGPA were identified, with an in-hospital mortality rate of 2.9% (n = 265) (Table 1). Patients who died in-hospital were older (median age 69 vs. 63 years ; $p = 0.018$), had a higher median Charlson Comorbidity Index (CCI) (3 vs. 2; $p = 0.01$), higher acute kidney injury (AKI) (66.0% vs. 19.9%; $p < 0.001$), higher alveolar hemorrhage (5.7% vs. 0.8%; $p < 0.001$), higher concurrent infection (79.2% vs. 46.2%; $p < 0.001$), higher heart failure

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Infection	4.45	<0.001	2.27 - 8.69
Myocardial Infarction	1.98	0.202	0.69 - 5.63

Table 3: Multivariable Logistic Regression for In-hospital Death for EGPA from NIS 2017-2021. Abbreviations: AKI= Acute Kidney Injury; CCI= Charlson Comorbidity Index; EGPA= Eosinophilic Granulomatosis with Polyangiitis; HLH= Hemophagocytic Lymphohistiocytosis; HF= Heart Failure; NIS= National Inpatient Sample Database.

Variable	Odds Ratio	P value	95% C.I.
Age	1.03	0.071	1.00 - 1.05
Male	1.58	0.131	0.87 - 2.87
Medicare	1.77	0.617	0.19 - 16.44
Medicaid	6.17	0.117	0.63 - 60.07
Private Insurance	0.76	0.814	0.07 - 7.70
CCI	1.16	0.137	0.95 - 1.40
AKI	4.81	<0.001	2.50 - 9.25
Alveolar Hemorrhage	6.92	0.014	1.47 - 32.46
HF (Systolic or Diastolic)	1.03	0.935	0.48 - 2.22
HLH	6.10	0.062	0.91 - 40.73
Infection	3.56	<0.001	1.81 - 7.01
Myocardial Infarction	1.24	0.745	0.34 - 4.42

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(37.7% vs. 22.9%; $p = 0.012$), longer median hospital length of stay (10 vs. 4 days; $p < 0.001$), and higher median total hospital charges ($154,087 vs. $43,916; $p < 0.001$). The variables from the univariable screen showing an association with in-hospital mortality were age, male sex, Medicare insurance, Medicaid insurance, private insurance, CCI, AKI, alveolar hemorrhage, heart failure, hemophagocytic lymphohistiocytosis, infection, and myocardial infarction (Table 2).

In multivariable regression analysis, independent predictors of in-hospital mortality included AKI (OR 4.81; 95% CI 2.50 - 9.25), alveolar hemorrhage (OR 6.92; 95% CI 1.47 - 32.46), and infection (OR 3.56; 95% CI 1.81 - 7.01) (Table 3). Age, sex, insurance type, and comorbidity burden were not independent predictors of in-hospital death in EGPA.

Conclusion: In this large, nationally representative cohort, EGPA hospitalizations had a 2.9% in-hospital mortality rate. AKI, alveolar hemorrhage, and infection were strong independent predictors of mortality. These findings highlight the need for early recognition and management of these complications to improve outcomes in hospitalized EGPA patients.

Abstract Number: 2505

Avacopan is Not Associated With An Increased Risk of Infection Compared to Glucocorticoids in Patients with ANCA-Associated Vasculitis

BEATRIZ MARIA FRANCO HONDERMANN, LOYOLA UNIVERSITY MEDICAL CENTER, OAK PARK

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Avacopan is a novel C5a receptor inhibitor recently approved for treatment of ANCA-associated vasculitis as an alternative to glucocorticoids, It has demonstrated superior efficacy in achieving remission and improving renal outcomes. However, limited studies have compared the safety profiles, particularly the risk of severe infections, between avacopan and glucocorticoids in AAV patients. This meta-analysis aims to evaluate the combined risk of severe infections in patients treated with avacopan compared to those treated with glucocorticoids.

Methods: A comprehensive literature search was performed on Pubmed, Cochrane and Embase databases for randomized controlled trials (RTCs) comparing risk of infection in patients with ANCA-related vasculitis treated with Avacopan versus Glucocorticoids. Severe infection were defined as pneumonia, UTI, neutropenic sepsis, sepsis, fungal infection, reactivation of HSV, meningitis or others as specified by each study. Statistical analysis was performed using Review Manager 5.17. Heterogeneity was assessed by I^2 statistics.

Results: A total of 681 patients from 5 RCTs were included, with 351 (51.5%) receiving avacopan. The mean age was 60.5 years (±14.5), and 46% were female. The follow-up duration ranged from 12 to 52 weeks. Pneumonia was the most commonly reported severe infection. Eight deaths due to severe infections were reported across the studies. The pooled relative risk (RR) for severe infections was 0.84 (RR 0.84; 95% CI: 0.62–1.15; p=0.9; I^2=0%), indicating no statistically significant difference between the avacopan and glucocorticoid groups (Forest Plot 1). Similarly, the RR for death due to infection was 0.37 (RR 0.37; 95% CI: 0.09–1.61; p=0.64; I^2=0%), showing no significant difference between the two treatment groups (Forest Plot 2).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Forest Plot 1

Forest Plot 2

Conclusion: In conclusion, treatment with Avacopan does not increase the risk of severe infection compared to glucocorticoid treatment in patients with ANCA-associated vasculitis. These results support current literature suggesting better overall outcomes of patients with ANCA-vasculitis treated Avacopan without an increased risk of infection.

Abstract Number: 2506

Timing, Management, and Outcomes of Venous Thromboembolic Events in ANCA-Associated Vasculitis: A Retrospective Cohort Study

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA-associated vasculitis (AAV) has been associated with an increased risk of venous thromboembolic events (VTE). However, limited data are available regarding the precise timing, nature, severity, management, and recurrence of VTE in this population. This study aimed to characterize the clinical features of VTE in AAV patients and assess the impact of immunosuppressive and antithrombotic therapy on outcomes.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We conducted a retrospective monocentric cohort study including patients diagnosed with AAV according to the 2022 ACR/EULAR classification criteria who experienced at least one VTE. VTE types, timing in relation to AAV diagnosis and disease activity, therapeutic strategies (including anticoagulation duration and immunosuppression), and VTE-related outcomes were recorded. Recurrence rates and their association with vasculitis flares were also analyzed.

Results: Among 34 patients with AAV and VTE, 28 (82%) had granulomatosis with polyangiitis, 2 (6%) microscopic polyangiitis, and 4 (12%) eosinophilic granulomatosis with polyangiitis. The most common VTEs were pulmonary embolism (n=21, 62%), deep vein thrombosis (n=20, 59%), with 9 patients (26%) experiencing both, and deep vein thrombosis of atypical sites (n=2, 6%).

VTE occurred within the first 6 months of AAV diagnosis in 16 cases (47%), or following a vasculitis flare in 9 patients (26%). In these patients, the median time from diagnosis of vasculitis to VTE was 30 days (IQR 11–96). In the remaining 9 patients, VTE occurred at a median of 69 days (IQR 50–82) after AAV flare. Median Birmingham Vasculitis Activity Score (BVAS) at VTE onset was 5.5 [IQR 0–15].

At the time of VTE, 88% of patients (n=30) were under immunosuppressive treatment and 29 were receiving systemic glucocorticoids with a median prednisone dose of 32.5 mg/day (IQR 9–60). Anticoagulation therapy was administered for a median duration of 6 months [IQR 3–8.25]; 43% received < 6 months, 43% between 6–12 months, and 14% >12 months.

Recurrent VTE occurred in 6 patients (19%) after anticoagulant discontinuation, of whom 3 experienced recurrence concomitant with vasculitis relapse. Two patients (6%) died as a direct consequence of thromboembolic complications.

Conclusion: VTEs in AAV patients frequently occur during periods of active disease and predominantly manifest as pulmonary embolism or deep vein thrombosis. Despite immunosuppressive treatment, thrombotic events still occur. Recurrence was observed in 20% of patients, particularly during relapse. These findings underscore the importance of considering VTE when clinically suspected, especially during AAV onset or relapse.

Background/Purpose: Avacopan, an oral C5aR antagonist, is approved for the treatment of ANCA-associated vasculitis (AAV) as a steroid-sparing alternative. While clinical trials demonstrated a positive benefit/risk ratio, post-marketing surveillance remains essential to assess its real-world safety. Based on its pharmacological activity and on case reports from the literature, we sought to evaluate infectious and hepatic adverse events (AEs) associated with avacopan.

Table 2. Details of infectious and hepatic adverse events reported with avacopan in the WHO global safety database.

Reporting characteristics	Avacopan n=2,775
Infection adverse event	438 (15.8%)
Respiratory tract infection[a]	206 (47.0%)
Pneumonia[a]	118 (26.9%)
COVID-19 infection[a]	96 (21.9%)
Urinary tract infection[a]	45 (10.3%)

Table 3. Reporting odds ratio of infection with avacopan as compared with immunosuppressants.

Adverse event	Drugs	Cases	Non-Cases	ROR [95% CI]
SOC « infection and infestation »	Avacopan	438	2,337	**2.50 [2.25-2.76]**
	All drugs	2,247,893	30,042,962	Ref.
	Avacopan	438	2,337	**0.78 [0.70-0.86]**
	Immnosuppressant	921,686	3,839,956	Ref.
SMQ « sepsis »	Avacopan	35	2,740	**2.37 [1.69-3.30]**
	All drugs	173,068	32,117,787	Ref.
	Avacopan	35	2,740	1.02 [0.73-1.42]
	Immnosuppressant	58,696	4,702,946	Ref.

Footnote: "Cases" were safety reports including an infectious adverse reaction identified using the System Organ Class (SOC) "Infections and infestations", and Standardised MedDRA Queries (SMQ) "Sepsis" (MedDRA, https://www.meddra.org/). Comparators were all drugs and immunosuppressants drugs (ATC code L04). ROR (95% CI) were calculated as adbc (adbc. e ±1.961a+1b+1c+1d), where a is the number of cases reported with avacopan, b is the number of non-cases (i.e., all other adverse drug reactions reports) reported with avacopan, c is the number of cases reported with all other drugs and d is the number of non-cases reported with all other drugs. Threshold for signal detection is defined as a ROR lower boundary 95% confidence interval ≥1 and a number of cases ≥3. Significant associations (adverse event-drug combination) are presented in bold. Abbreviations: Ref., reference; ROR, reporting odds ratio; SMQ, Standardised MedDRA Queries; SOC, System Organ Class,

Methods: We used VigiBase, the WHO global pharmacovigilance database, up to April 30, 2025. We analyzed and described individual case safety reports related to infectious and hepatic AEs. Disproportionality analyses were performed using reporting odds ratios (RORs) and 95% confidence intervals (CI). A signal was considered significant if the lower CI limit exceeded 1.

Results: Of 32.3 million individual case safety reports, 2,775 involved avacopan (median age 62 years, 40.4% female), with 88.3% from North America (**Tables 1 and 2**). Infectious AEs occurred in 438 cases (15.8%). The median time to onset of infection was 28 days (IQR 7-78). Most cases were considered serious (262, 59.8%), including 130 (29.7%) with hospitalization or prolonged hospitalization, and 41 (9.4%) were fatal. Most frequent reported infections were respiratory tract infections (47%), with COVID-19 (21.9%) and pneumonia (26.9%), urinary tract infections (10.3%) and ENT infections (9.8%). Invasive fungal, CMV and *Pneumocystis jiroveci* infections were reported in 1.1%, 0.9% and 0.5%, respectively. Hepatic events occurred in 77 cases (2.8%), mainly cytolytic hepatitis (24.1%), with a median time to onset of 47 days (IQR 40-63), and 3 were fatal. No vanishing bile duct syndrome was reported. Disproportionality analysis revealed a significant overreporting of infections (ROR 2.50 [2.25-2.76]) or sepsis (ROR 2.37 [1.69-3.30]) compared to all treatments in VigiBase, but not compared to immunosuppressants (ROR 0.78 [0.70-0.86] and ROR 1,02 [0,73-1,42], respectively), with even a significant underreporting of infections with avacopan (**Table 3**).

Conclusion: This study based on VigiBase characterizes the profile of infectious AEs reported with avacopan, which does not appear to differ from the known profile of infections in AAV patients. Avacopan was not associated with an increased risk of reporting of infections compared to immunosuppressants. These data, while reassuring, are preliminary and highlight the need for continued post-marketing surveillance to confirm the long-term safety profile of avacopan.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA-associated vasculitis (AAV) imposes a high morbidity burden, both from the disease itself and from treatment-related side effects, often compromising patients' quality of life (QoL). Despite this, patient-reported outcomes (PRO) remain insufficiently studied compared to physician-reported measures. We present initial PRO data from a prospective, longitudinal cohort of individuals with AAV.

Methods: The Mass General Brigham AAV Prospective Registry (AAVPR) enrolls patients with GPA, MPA and EGPA at any stage of disease and regardless of disease activity status. Participants complete surveys every 6 months capturing treatments, comorbidities, and PROs, including the SF-12 and the AAV-PRO, among other variables. The SF-12 gathers physical and mental healthdata in 8 domains and provides physical and mental component summaries (PCS, MCS; 0-100 with lower scores indicating worse QoL). The AAV-PRO collects information in 6 domains (0-100 with higher scores indicating worse QoL and disease burden), including organ-specific symptoms (OSS), systemic-symptoms (SS), treatment side-effects (TSE), social and emotional impact (SEI), concerns about the future (CAF) and physical function (PF). We performed multivariable-adjusted regression to identify factors associated with PROs at baseline and multivariable-adjusted difference-in-difference (DID) regression to identify factors associated with change in PROs from baseline to 6 months. Covariates considered included age, sex, disease duration, glucocorticoid (GC) and immunosuppression use within 6 months prior to baseline, ANCA type and multimorbidity.

Table 1: Patient Characteristics at the Time of Enrollment in the AAV Prospective Registry

	Individuals with AAV (N=92)
Age	59.9 (14.5)
Sex, female	64 (69.8)
Race, White	87 (94.6)
ANCA type	
PR3	39 (42.4)
MPO	35 (38.0)
Dual positive	2 (2.2)
Negative	16 (17.4)
Disease duration, months, median (IQR)	38 (4; 79.5)
AAV treatment within 6 months	
Glucocorticoids	40 (43.5)
Immunosuppression	
Rituximab	50 (54.4)
Cyclophosphamide	7 (7.6)
Azathioprine	3 (3.3)
Methotrexate	10 (10.9)
Mycophenolate mofetil	3 (3.3)
Avacopan	16 (17.4)
Comorbidities	
Pulmonary*	44 (47.8)
Cardiovascular#	52 (56.5)
Diabetes	9 (9.8)
End-stage renal disease	3 (3.3)
Malignancy‡	20 (21.7)
Multimorbidity^	52 (56.5)

Values are n (%) for categorical variables and mean (SD) for continuous variables unless otherwise specified. *Including chronic obstructive pulmonary disease, sleep apnea, bronchiectasis, interstitial lung disease and/or asthma. #Including hypertension, myocardial infarction, coronary artery disease undergoing revascularization, carotid artery stenosis, peripheral artery disease, atrial fibrillation, heart failure and/or stroke. Including gastrointestinal, lung, breast, urogenital, hematologic, bone and soft tissue, brain, skin, and/or thyroid malignancy. ^≥1 Comorbidity. AAV, ANCA-associated vasculitis.

Table 2. AAV-PRO and SF-12 at Baseline and 6 Months

	Individuals with AAV (N=92)			
	Baseline	6 months	Difference	P values
AAV-PRO domain				
Organ-specific symptoms	24.4 (22.3)	22.3 (19.7)	-2.1 (14.9)	0.178
Systemic symptoms	28.3 (22.9)	27.5 (21.8)	-0.8 (16.5)	0.637
Treatment side-effects	24.6 (18.1)	23.1 (16.3)	-1.5 (14.9)	0.275
Social and emotional impact	29.1 (23.4)	23.8 (20.9)	-5.3 (16.0)	0.002
Concerns about the future	32.7 (25.8)	29.2 (23.4)	-3.5 (18.1)	0.069
Physical function	16.9 (21.1)	14.6 (20.0)	-2.3 (14.9)	0.139
12-Item Short Form Inventory Survey				
Physical component summary	44.6 (10.7)	43.9 (10.1)	-0.7 (8.3)	0.423
Mental component summary	49.9 (10.1)	51.2 (8.9)	-1.3 (9.2)	0.185

Values are mean (SD). The AAV-PRO ranges 0-100 with higher scores indicating worse quality of life and disease burden. The SF-12 ranges 0-100 with lower scores indicating worse quality of life. AAV, ANCA-associated vasculitis; PRO, patient-reported outcome

Results: Among 92 participants with ≥6 months of follow-up, the mean (SD) age was 59.9 (14.5) years, and the median (IQR) duration of disease at baseline was 38 (4-79.5) months. The cohort was predominantly female (69.6%) and White (94.6%), with 38% MPO-ANCA positive patients. Most common AAV treatments within 6 months prior to baseline included GCs (43.5%) and rituximab (54.4%). Additional baseline features are in **Table 1**. Over 6 months, the SF-12 PCS and MCS, and most AAV-PRO domains remained relatively stable, except for SEI scores, which significantly improved (**Table 2**). At baseline (**Table 3**), females reported worse AAV-PRO OSS and TSE scores compared to males. Patients with disease duration ≥6 months had better baseline AAV-PRO OSS, TSE, and PF scores than those with shorter disease duration. Over a 6-month period (**Table 3**), PR3-positive patients showed improvement in AAV-PRO SS, whereas MPO-positive patients worsened (baseline to 6 months mean difference -5.8 for PR3 vs 5.9 for MPO). Additionally, patients with disease duration ≥6 months experienced less improvement in AAV-PRO SEI (baseline to 6 months mean difference -2.8 for ≥6 months vs -11.7 for < 6 months) and a decline in SF-12 MCS (baseline to 6 months mean difference -0.3 for ≥6 months vs 5.3 for < 6 months) compared to those with shorter disease duration. No other statistically significant associations were found.

Abstract Number: 2509

Predicting future relapse with proteomics in ANCA-Associated Vasculitis

Evan Barnes[1], Nora Shepherd[2], Colebrooke Johnson[1], David O'Dea[1], Bohang Jiang[3], Emily Hyle[2], Zachary Williams[4], Zachary Wallace[5] and Gary Reynolds[6], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]MGH, Boston, MA, [4]Massachusetts General Hospital, Nancy, KY, [5]Massachusetts General Hospital, Newton, MA, [6]Massachusetts General Hospital, Newcastle upon Tyne, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Outcomes for ANCA associated vasculitis (AAV) have been transformed in recent years with many patients achieving prolonged periods of remission. Guidelines advise continuing maintenance therapy following initial treatment for at least 24-48 months but beyond this there is debate in balancing the risks of disease relapse against those of prolonged immunosuppression. These decisions could be guided by biomarkers to identify patients who are likely to remain in remission or could predict incipient flare at an early stage. In this study we explored the utility of serum proteomics measured from patients in clinical remission to predict their risk of future relapse.

Methods: Serum samples and matched clinical data from participants with MPO- or PR3-ANCA+ AAV were retrieved from an ongoing prospective cohort study at Mass General Brigham. The levels of 92 circulating proteins were measured using the Olink inflammation proteomic assay. Relapse was defined as a change in clinical symptoms prompting new or modified treatment after achieving initial remission, and for those patients, additional information was collected including creatinine, presence of sinopulmonary symptoms, and treatment provided during relapse. Proteomic data from the population who experienced relapse was compared to control populations those who did not experience relapse to identify significant changes in protein expression as compared via unpaired t-tests. Adjustment for multiple comparisons was based on the 10% false discovery rate (FDR) procedure.

Results: We identified 44 patients who were in remission when serum was sampled for proteomic analysis. This cohort was balanced for sex (55% female) and ANCA specificity (50% MPO-ANCA) (**Table 1**). Over the follow-up period 29.5% of patients (n=13) experienced at least one flare. The commonest manifestation of flare was sinopulmonary involvement (77%) (**Table 2**). The only baseline clinical predictor of future flare was male sex (p=0.04), whereas neither age (p=0.12) nor ANCA subtype (p=0.90) was predictive. There were higher rates of relapse in those who received cyclophosphamide (46% vs 29%) and lower levels in those who received Rituximab (55% vs 15%), but neither was statistically significant (**Table 2**). Proteomic analysis revealed that elevated levels of the IL6-family cytokine Oncostatin M (OSM) during remission was significantly associated with future risk of flare (adjusted p value < 0.001) (**Figure 1**).

CCL23	0.4425	0.02249	0.4812
MCP-1	0.3767	0.02615	0.4812

Conclusion: For many patients with AAV the most pressing clinical dilemma is identifying when treatment can safely be withdrawn. In deriving a biomarker serum proteomics are an attractive modality because sampling is minimally invasive, assays are robust and can be captured longitudinally. In this preliminary study we identify the IL-6 family cytokine OSM as being predictive of future flare. This is consistent with our previous analysis that has found that OSM is significantly raised in active AAV. While the number of patients in our cohort who flared was low, this study supports the potential of this approach. Our future work will expand this cohort and explore the effect of treatment and whether longitudinal changes can enhance its predictive power.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: ANCA specificity has shown an association with patients' genetic profile, cytokine profile, certain clinical presentations, serologic response to treatment, and risk of recurrence.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Severe infections occur in approximately 35% of patients with ANCA-associated vasculitis, with a 4.4-fold increased risk compared to the general population. This risk is highest during the first year of the disease, during which infections represent the leading cause of death

The aim of this study is to investigate the relationship between ANCA specificity and the risk of severe infection occurrence during the course of AAV.

Methods: This retrospective, observational study included patients diagnosed with AAV meeting the Chapel Hill Consensus Conference classification criteria who were treated at two hospital centers in southern France between January 1st 2010 and March 30th 2024.•The population was divided in two groups based on the presence or absence of anti-PR3 and anti-MPO ANCA. Patients without ANCA or with non-specific ANCA were excluded. The occurrence of severe infections—defined as those requiring hospitalization, surgical intervention, intravenous antibiotic therapy, or resulting in death—was assessed within three years following inclusion in patients enrolled during either a first onset or a relapse of vasculitis. We compared severe infection occurrence between the groups and conducted a proportional hazards Cox regression model adjusted for sex, age >65 years, FFS ≥1, respiratory involvement, relapse versus first onset status, and for induction therapy (with or without cyclophosphamide).

Results: Of the 529 screened patients, 270 were included in the analysis: 117 with PR3-ANCA vasculitis and 153 with MPO-ANCA vasculitis, of which 142 were GPA, 95 MPA, and 23 EGPA cases. The median age was 65.5 years [IQR: 57-75], and 48% were female. During follow-up, 89 patients (32.9%) developed a severe infection—57 (64.1%) in the MPO group and 32 (35.9%) in the PR3 group—corresponding to cumulative incidences of 7.34 and 4.12 cases per 100 person-years, respectively. Most infections occurred within the first year of follow-up, coinciding with the period of highest immunosuppressive burden. The median time to onset of severe infection was 8 months [range 1–19]; it was shorter in the MPO-ANCA group (4 months [range 1–18]) compared to the PR3-ANCA group (11 months [range 1.5–24]) (p=0.048). Bacterial pneumonia was the most frequently observed infection.

The adjusted proportional hazards Cox regression model found an trend between the presence of anti-MPO ANCA and the risk of severe infection with a HR of 1.55 (95% CI: 0.97 – 2.48; p=0.06).

Conclusion: Our findings showed that MPO-ANCA specificity is associated with an increased risk of severe infections in patients with ANCA-associated vasculitis. Consistent with prior observations, most infections occurred within the first year of follow-up, with no significant difference in infection risk between cyclophosphamide and rituximab treatment arms. These results underscore the prognostic relevance of ANCA specificity in AAV.

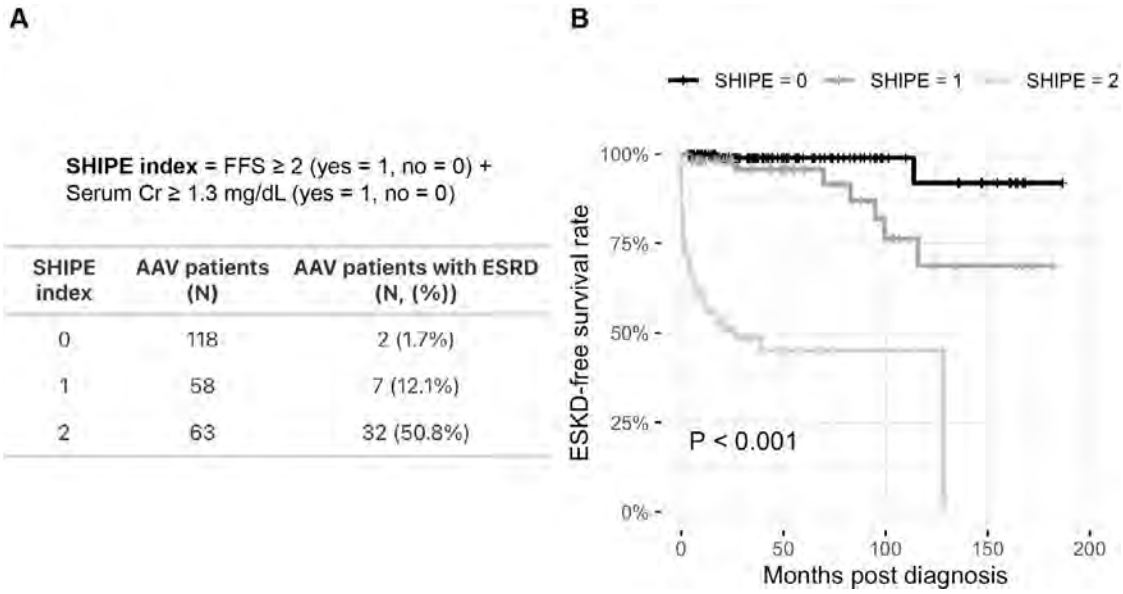

Figure 1. The SHIPE index for AAV patients

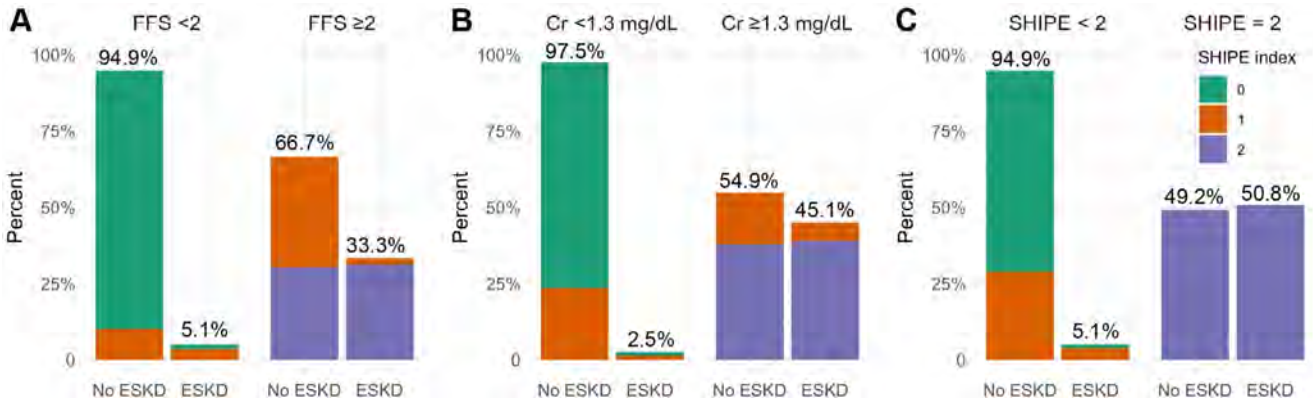

Figure 2. Comparison of three predictors — FFS, serum creatinine, and SHIPE index — for ESKD

Background/Purpose: This study aimed to develop a simple, robust, and ethnoregion-specific index for predicting progression to end-stage kidney disease (ESKD) in Korean patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV).

Methods: Baseline data from 239 Korean patients with AAV enrolled in a tertiary hospital cohort were analyzed to identify independent predictors of ESKD using univariable and multivariable Cox proportional hazards models. The SHIPE index was constructed by summing the highest tertiles of the identified predictors: Five-Factor Score (FFS ≥2) and serum creatinine (≥1.3 mg/dL), with 1 point assigned to each criterion met. Cumulative ESKD-free survival rates across SHIPE index scores were compared using Kaplan-Meier analysis.

Results: A SHIPE index score of 2 was significantly associated with lower cumulative ESKD-free survival rate compared to scores of 0 or 1 ($P < 0.001$). By integrating two independent predictors, the SHIPE index provides a simple yet effective tool for risk stratification, demonstrating greater robustness against variability in single predictors such as serum creatinine. This index demonstrated clinical utility, providing a straightforward method for identifying high-risk patients in real-world settings.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The SHIPE index is a novel, robust, and convenient tool for predicting ESKD progression in Korean patients with AAV. This study introduces a practical framework for developing tailored prediction indices that can be adapted for diverse ethnic and regional populations. Its simplicity and practical applicability make it well-suited for routine clinical use. Future prospective studies are needed to validate the SHIPE index in larger, multi-ethnic cohorts and ensure its broader applicability.

Abstract Number: 2512

Contribution of the CALLY index at diagnosis to early prediction of all-cause mortality in patients with ANCA-associated vasculitis

Jang Woo Ha[1] and Sang-Won Lee[2], [1]Division of Rheumatology, Department of Internal Medicine, Yongin Severance Hospital, Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea, [2]Yonsei university college of medicine, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: This study retrospectively investigated whether the initial C-reactive protein (CRP)-albumin-lymphocyte (CALLY) index at diagnosis can contribute to early prediction of all-cause mortality during follow-up in patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV).

Methods: This study included 323 patients with AAV. Clinical data at AAV diagnosis and those during follow-up were collected. The CALLY index was calculated using the following equation: serum albumin (g/L) × lymphocyte count (/mm3) / CRP (mg/L) /10,000. The parameter of serum albumin (g/L) of an equation of the CALLY index was corrected by multiplying the measured serum albumin (g/dL) by 10.

Results: The median age was 61.0 years (36.2% male and 63.8% female). The median CALLY index was calculated as 0.48. Of the 323 patients, 45 (13.9%) died during the follow-up period of 53.7 months. In ROC curve analysis, the optimal cut-off of the CALLY index for all-cause mortality was determined as 0.55 (area 0.715). Patients with the CALLY index ≤0.55 at AAV diagnosis had a significantly higher risk for death (relative risk 7.294), and exhibited a significantly lower cumulative patients' survival rate than those with the CALLY index >0.55. In multivariable Cox proportional hazard analysis, the CALLY index ≤0.55 (hazard ratio [HR] 3.913), age (HR 1.037) and male sex (HR 2.326) were independently associated with all-cause mortality during follow-up in patients with AAV.

Conclusion: This is the first study to demonstrate that the initial CALLY index at diagnosis could be useful in predicting all-cause mortality during follow-up in patients with AAV.

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by systemic necrotizing vasculitis affecting small and medium-sized vessels, and defined by the presence of eosinophilia, extravascular granulomas, and eosinophil tissue infiltration.

Mepolizumab (MPZ), the first anti-interleukin-5 monoclonal antibody proven effective and safe in the MIRRA clinical trial, has been widely used to treat patients with EGPA.

Therefore, it is pertinent to analyze all published data from real world studies to better understand the effectiveness and safety of MPZ in clinical practice setting.

We aimed to conduct a systematic review of all published clinical research on the real world effectiveness and safety of 300 mg MPZ treatment in patients with EGPA

Methods: A systematic literature review was conducted to identify studies reporting data on the effectiveness and safety of MPZ in patients with EGPA in a real world setting, included in OVID, Medline, and EMBASE databases, covering articles published by November 2024.

This review encompassed studies that reported data on MPZ at the Food and Drug Administration and European medicines Agency approved dose of 300 mg.

Results: Involving a total of 2,639 patients, 14 studies provided specific data on those receiving 300 mg of MPZ, including prospective, ambispective, or retrospective designs, with follow-up periods from 3 to 48 months. Remission rates ranged from 37.9% to 82.0% at 12 months, from 58,3% to 72.7% at 24 months, and stabilized 64% at 48 months.

Treatment with 300 mg MPZ led to a significant reduction in disease activity, as assessed by BVAS, which decreased from 17 to 0 at both 3 and 6 months in one study, and from 4 to 0 at 6, 12, and 24 months in another study. The annualized rate of EGPA-related hospitalizations decreased from 0.54 to 0.02 events/person-year at 48 months. The proportion of patients without immunosuppressive therapy rose to 79% during the 48 months follow up period. No significant differences in Vascular Damage Index score at 12 months were observed, suggesting that MPZ therapy was effective in controlling organ damage progression. Additionally, there was a reduction in glucocorticoid (GC) use, with GC discontinuation rates of up to 41.7% at 24 months and a reduction in GC doses to ≤ 4 mg/day in up to 68% in all the identified articles. The blood eosinophil counts decreased significantly, reaching counts ranging 55-100 cell/μl. A significant reduction in the proportion of ANCA-positive patients was also observed after treatment with MPZ 300 mg.

In terms of safety, MPZ was well-tolerated with adverse events reported primarily as mild to moderate upper respiratory tract infections. The overall rate of MPZ retention was 100% at 6 months and ranged from 90% to 100% at 12 months.

Conclusion: This systematic review of the published evidence on MPZ 300 mg in real-world clinical practice confirms significant clinical benefits from patients with EGPA by improving remission rates, reducing GC dependence, and decreasing disease activity, maintaining a favorable safety profile. These results complement data from clinical trials

Abstract Number: 2514

Comparison of Demographics and Outcomes of Inpatient Hospitalization of Severe Asthma Patients with Eosinophilic Granulomatosis with Polyangitis. A Study on the National Inpatient Sample Database

Prakriti Subedi[1], Anil Regmi[2], Karun Shrestha[3], Manoj Ghimire[4], Sajana Poudel[5], Kalpana Ghimire[1], Oshna Pandey[1] and Clement Tagoe[6], [1]St. Barnabas Hospital, Bronx, NY, [2]Parkview Health, Fort Wayne, IN, [3]St. Barnabas Hospital Internal Medicine Residency, Bronx, NY, [4]St Barnabas Hospital, BRONX, NY, [5]Cook County Health, CHICAGO, NY, [6]Albert Einstein College of Medicine, FRESH MEADOWS, NY

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare vasculitis marked by asthma and eosinophilia, often leading to severe, persistent respiratory symptoms. Unlike severe asthma without EGPA, patients with EGPA typically have longstanding asthma prior to vasculitis onset and show widespread eosinophilic inflammation. These differences necessitate distinct treatment approaches. This study compares the demographic and clinical characteristics of patients with severe asthma with and without EGPA using data from the National Inpatient Sample Database.

Table 1: Patient Demographics

Patient characteristics	Severe asthma with EGPA (n=775)	Severe asthma without EGPA (n=201,765)	p-value

Arrythmia	75(9.68)	17157(13.46)	0.19
Mechanical ventilation	55(7.1)	16585(8.22)	0.61
severe sepsis/septic shock	25(3.23)	6090(3.02)	0.87
Acute respiratory failure	335(43.23)	92428(45.81)	0.54

Methods: A retrospective cross-sectional study was conducted using data from NIS (2016 to 2021). Primary and secondary diagnoses were identified using International Classification of Diseases (ICD-10) codes. All patients aged >18 years with severe asthma were included in the study. Patients were divided into two groups: those with severe asthma and EGPA (n=775) and those with severe asthma without EGPA (n=201,765). Demographics, hospital region, comorbidities, complications, and outcomes, including mortality, length of stay, and hospitalization charges, were compared between the 2 groups. Statistical analysis was done using STATA v.17.

Results: The mean age of patients with severe asthma and EGPA was 52.06 years compared to 51.75 years in those without EGPA (p=0.82). A significantly lower proportion of females was observed in the EGPA group (60.64%) compared to the non-EGPA group (71.43%) (p=0.004). In the EGPA group, there was a higher percentage of White patients (68.87% vs. 50.47%) and a lower percentage of African American patients (17.72% vs. 29.98%). A higher proportion of EGPA patients were treated in urban teaching hospitals (84.52% vs. 75.74%, p=0.06). Comorbidities such as diabetes (8.39% vs. 19.24%, p=0.0006) and chronic obstructive pulmonary disease (5.81% vs. 12.18%, p=0.01) were less common in the EGPA group. However, the incidence of acute myocardial infarction (10.97% vs. 5.5%, p=0.002) was higher in the EGPA group. Notably, there was no significant difference in terms of complications like pneumothorax, acute respiratory failure and mechanical ventilation. There were no statistically significant differences in the outcomes, including mortality, hospital stay, and total costs, between the 2 groups.

Table 3: Primary Outcomes

Outcomes	Severe asthma with EGPA (n=775)	Severe asthma without EGPA (n=201,765)	p-value
Mortality, n(%)	10(1.29)	3070(1.52)	0.81
Length of Stay (LOS) in days, mean (95% CI)	5.6(4.61-6.69)	4.84(4.78-4.9)	0.12
Total charges,$,mean (95% CI)	67676(49920-85433)	54533(53361-55745)	0.14

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: This study demonstrates that patients hospitalized with severe asthma and concomitant eosinophilic granulomatosis with polyangiitis (EGPA) exhibit distinct demographic and clinical profiles compared to those without EGPA. Importantly, the presence of EGPA does not appear to increase the risk of acute respiratory complications such as pneumothorax, acute respiratory failure, or the need for mechanical ventilation. Moreover, no significant differences were observed in key hospital outcomes—including mortality, length of stay, or total hospitalization costs. These findings suggest that although EGPA defines a unique subset within the severe asthma population, it does not independently contribute to worse short-term inpatient outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Neurologic involvement (NI) is common in ANCA-associated vasculitis (AAV) and often irreversible. It is unknown whether patients with AAV and NI accumulate more damage than those without NI. The objective of this study was to evaluate the association between NI and cumulative damage in patients with AAV.

Methods: Data from adults with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic GPA (EGPA) participating from 2006 to 2021 in a multicenter longitudinal observational study were analyzed. Cohorts were divided by the presence of NI at any point in their disease course. Neurologic damage items (NDI) were classified as disease-specific (cranial nerve lesion, chronic pachymeningitis, neuropathy, and neuropathic pain) and non-disease specific (strokes, seizures, transverse myelitis, and neurologic mass). Group differences were tested using Kruskal-Wallis test for continuous variables and Fisher's exact test for categorical. General and robust linear regression models were generated to estimate the differences in Vasculitis Damage Index (VDI), ANCA Vasculitis Index of Damage (AVID), AAV-Disease-Specific Damage (AAV-DSD), and AAV-Non-DSD scores. We also estimated the differences in AAV-DSD and Non-DSD scores with NDI removed. These models were adjusted for sex, age at diagnosis, and time from diagnosis to last damage assessment.

Table 1. Characteristics of patients with ANCA-associated vasculitis stratified by neurologic involvement

Characteristics	All (N=1322)	Without NI (N=796)	With NI (N=526)	*p*-Value
Age at diagnosis (years) (Mean (SD))	48.7 (16.4)	46.8 (16.9)	51.4 (15.4)	< 0.001
Sex (female)	731 (55.3%)	450 (56.5%)	281 (53.4%)	0.283
Self-reported ancestry				0.430
Asian	59 (4.5%)	32 (4.0%)	27 (5.1%)	
Black/African American	25 (1.9%)	17 (2.1%)	8 (1.5%)	
White	1192 (90.2%)	722 (90.7%)	470 (89.4%)	
Other	16 (1.3%)	7 (0.8%)	9 (1.7%)	
Missing	30 (2.3%)	18 (2.3%)	12 (2.3%)	
Ethnicity				0.288
Hispanic	32 (2.4%)	15 (1.9%)	17 (3.2%)	
Non-Hispanic	1194 (90.3%)	723 (90.8%)	471 (89.5%)	
Missing	96 (7.3%)	58 (7.3%)	38 (7.2%)	
Follow-up time (years) (Median (Q1, Q3))	6.9 (3.3, 12.0)	7.0 (3.5, 12.2)	6.7 (3.2, 11.9)	0.307
Disease category				< 0.001
GPA	871 (65.9%)	580 (72.9%)	291 (55.3%)	
MPA	168 (12.7%)	127 (16.0%)	41 (7.8%)	
EGPA	283 (21.4%)	89 (11.2%)	194 (36.9%)	
ANCA type (ELISA)				< 0.001
MPO-ANCA	336 (25.4%)	199 (25.0%)	137 (26.0%)	
PR3-ANCA	648 (49.0%)	425 (53.4%)	223 (42.4%)	
Both	11 (0.8%)	7 (0.9%)	4 (0.8%)	
ANCA negative	327 (24.7%)	165 (20.7%)	162 (30.8%)	

Abbreviations: AVID, ANCA-Associated Vasculitis Index of Damage; EGPA, eosinophilic granulomatosis with polyangiitis; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; NI, neurologic involvement; SD, standard deviation; VDI, Vasculitis Damage Index.

Results: Data from 1322 patients [65.9% GPA, 12.7% MPA, 21.4% EGPA] were analyzed: 526 (39.8%) had NI and 796 (60.2%) did not. Of those with ANCA results, 995 (75.3%) were ANCA positive (49.0% PR3-ANCA, 25.4% MPO-ANCA, 0.8% both). Older patients had more NI. Two-thirds of adults with EGPA had NI (**Table 1**). Among all AAV, patients with NI were estimated to have higher VDI (0.6 points; 95% CI: [0.35, 0.86], $p < 0.0001$), AVID (1.1 points; 95% CI: [0.66, 1.54], $p < 0.0001$), and AAV-DSD (0.91 points; 95% CI: [0.71, 1.12], $p < 0.0001$) scores than those without NI. The AAV-DSD score remained higher in those with NI even when NDI were removed. The AAV Non-DSD score was not different between NI groups. Among patients with GPA, those with NI had higher damage scores than those without, even with NDI removed. For MPA, those with NI only had higher AAV-DSD scores than those without. For EGPA, those with and without NI had no difference in scores. For both types of ANCA damage scores were higher among patients positive ANCA vs. those negative, even with NDI removed. Among patients negative for ANCA, those with NI only had higher AAV-DSD scores than those without (**Table 2**). Among patients with NI, those with GPA had more damage than those with MPA or EGPA. There were no differences in damage scores between PR3-ANCA, MPO-ANCA, and ANCA-negative groups (**Table 3**). Damage scores among patients with NI did not differ based on presence or absence of central vs. peripheral nervous system disease manifestations.

Conclusion: Patients with AAV and NI experience greater neurologic and non-neurologic cumulative damage than those without NI. The differences are driven by disease-specific items of damage. Of patients with NI, those with GPA, PR3-ANCA, or MPO-ANCA accumulate the most damage. These results highlight the importance and burden of NI in AAV.

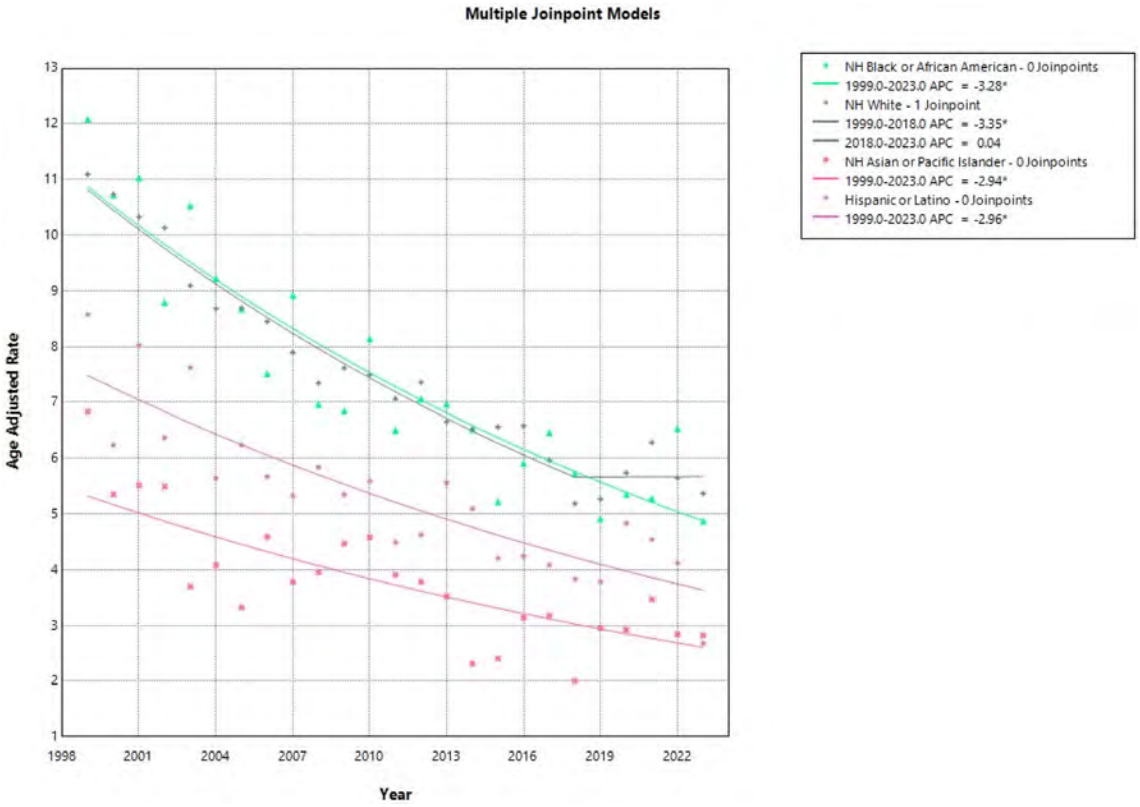
Background/Purpose: Primary systemic vasculitides comprise a group of immunological disorders that inflame blood vessel walls and are categorized by the size of the blood vessels involved (small, medium, and large vessel vasculitis). This group of disorders has an elevated mortality rate among rheumatologic diseases, as prior studies have suggested. While earlier analyses have studied mortality trends related to this group of disorders, newer, more updated research is limited, especially concerning trends beyond 2019.

Methods: Datasets from the CDC WONDER Multiple Cause-of-Death public use records from 1999 to 2023 were used to analyze deaths in adults ≥25 years old, assigning ICD-10 codes (M30 and M31 series) to primary systemic vasculitis by year and place of death, as well as by demographic (sex, age group, race) and regional (state, census region, rural-urban) stratifications. Age-adjusted mortality rates (AAMR) were calculated per 1,000,000 with 95% confidence intervals by standardizing crude mortality rates (CMR). Annual percent change (APC) and average annual percent change (AAPC) were evaluated using Joinpoint regression software.

Results: A total of 39,093 deaths occurred from 1999 to 2023, mostly in medical facilities (61.8%). The AAMR declined from 11.2 in 1999 to 4.9 in 2023 (AAPC: -3.3; 95% CI: -3.6 to -2.9). Women had a higher average AAMR compared to men, along with a higher rate of decrease (AAPC women: -3.4; 95% CI: -3.8 to -3.0; men: -2.9; 95% CI: -3.3 to -2.4). Adults aged ≥65 years had the highest average AAMR, along with the highest rate of decrease among the age groups (AAPC ≥65 years: -3.4; 95% CI: -3.7 to -3.0; 45–65 years: -2.9; 95% CI: -3.5 to -2.4; 25–44 years: -2.2; 95% CI: -3.2 to -1.3).

Racially, non-Hispanic (NH) White populations had the highest average AAMR, along with the highest rate of decrease (AAPC NH White: -2.7; 95% CI: -3.3 to -2.2; NH Asian/Pacific Islander: -2.9; 95% CI: -3.8 to -2.0; Hispanic/Latino: -3.0; 95% CI: -3.7 to -2.1; NH Black/African American: -3.3; 95% CI: -4.0 to -2.6).



Trends in Vasculitis-Related Mortality by Race, United States (1999–2023)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Primary Systemic Vasculitis Mortality by Sex (1999–2023)

Primary Systemic Vasculitis Mortality by Census Region (1999–2023)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Regionally, the Midwest had the highest average AAMR, though the South had the highest rate of decrease (AAPC South: -3.4; 95% CI: -3.8 to -3.0; West: -2.8; 95% CI: -3.6 to -2.1; Midwest: -3.1; 95% CI: -3.6 to -2.6; Northeast: -3.2; 95% CI: -3.7 to -2.7).

From 1999 to 2020, state-wise AAMRs ranged from 5.1 in Hawaii to 12.6 in Vermont. From 2021 to 2023, AAMRs ranged from 3.7 in Louisiana to 11.8 in Minnesota. From 1999 to 2020, rural areas had a higher average AAMR, though urban areas had a higher rate of decrease (AAPC urban: -3.8; 95% CI: -4.1 to -3.4; rural: -2.5; 95% CI: -3.0 to -2.0).

Conclusion: Though primary systemic vasculitis-related mortality rates in adults declined from 1999 to 2023, disparities across demographic and regional groups remain, highlighting the need for targeted prevention and support systems to improve outcomes in at-risk communities.

Abstract Number: 2517

Predictors for Mortality in Patients Who Received Plasmapheresis for Diffuse Alveolar Hemorrhage in ANCA-Associated Vasculitis

Sai Shanmukha Sreeram Pannala[1], Medha Rajamanuri[2], Srikar Sama[3], Fares Saliba[4], Omar Mourad[5], Koushik Varma Sangaraju[6], Veena Katikineni[7] and Anastasia Slobodnick[8], [1]Zucker School of Medicine at Hofstra/Northwell at Staten Island University Hospital, staten island, new york city, NY, [2]Southern Illinois University School of Medicine, Springfield, IL, [3]University of California San Francisco Fresno, Fresno, CA, [4]Staten Island University Hospital, Staten Island, NY, [5]Zucker School of Medicine at Hofstra/Northwell at Staten Island University Hospital, Staten Island, NY, [6]St. Luke's University Health Network, Bethlehem, PA, [7]Desert Orthopaedic and Rheumatologic Institute, Apple Valley, CA, [8]Northwell, Staten Island, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Plasmapheresis (PLEX) has a compelling rationale in its ability to remove pathogenic ANCAs, in the management of ANCA-associated vasculitis (AAV), particularly in patients with severe manifestations such as diffuse alveolar hemorrhage (DAH). Despite its theoretical benefits, the role of PLEX in AAV + DAH remains debated, and inconsistent evidence regarding its long-term effects on mortality and organ function raises important questions. Our study aims to compare the risk of in-hospital mortality in patients with AAV + DAH who received PLEX to those who did not, seeking to clarify the role of PLEX in improving clinical outcomes and addressing current uncertainties regarding its efficacy in this context.

Methods: Using the National Inpatient Sample database from January 2020 to December 2022, we extracted data on AAV + DAH (AAVDAH), categorizing patients into two groups: those who received plasmapheresis (AAVDAHpl) and those who did not (AAVDAH). We analyzed key demographic, clinical, and hospital-related factors, including gender, age, race, Charlson Comorbidity Index (CCI), income, payer, region, and bed size. The primary outcome was in-hospital mortality, with secondary outcomes including LOS, total charges, sepsis, mechanical ventilation, and pressor requirements. Adjusted odds ratios for mortality and complications were calculated using logistic regression.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: Odds ratios (ORs) with 95% confidence intervals (CIs) for outcomes comparing AAVDAH with plasmapheresis (AAVDAHpl) and AAVDAH without plasmapheresis.

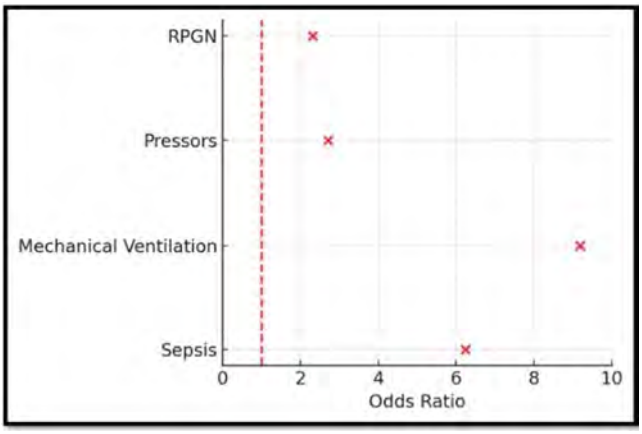

Figure 2: Adjusted odds ratios (aORs) with 95% confidence intervals (CIs) for mortality, adjusting for complications, in patients with AAVDAH who received plasmapheresis (AAVDAHpl).

Table 1: Baseline Characteristics Comparison Between AAVDAH and AAVDAH with Plasmapheresis (AAVDAHpl).

Characteristic	AAVDAH (No Plasmapheresis)	AAVDAH (Plasmapheresis)
Females	44.29%	49.33%
Mean Age	54.45 years	56.65 years
Race Distribution (White)	63.40%	58.33%
Race Distribution (Black)	11.39%	15.28%
Race Distribution (Hispanic)	17.08%	20.83%
Charlson Comorbidity Index (Category 0)	22.45%	16.00%
Charlson Comorbidity Index (Category 1)	12.93%	14.67%
Charlson Comorbidity Index (Category 2)	25.85%	24.00%
Charlson Comorbidity Index (Category 3)	38.78%	45.33%
Household Income (Quartile 1)	27.99%	30.67%
Household Income (Quartile 2)	26.28%	20.00%
Household Income (Quartile 3)	25.26%	30.67%
Household Income (Quartile 4)	20.48%	18.67%
Primary Payer (Medicare)	41.50%	45.33%
Primary Payer (Private Insurance)	18.37%	13.33%
Hospital Region (Northeast)	19.05%	32.00%
Hospital Region (South)	27.55%	29.33%
Hospital Region (Midwest)	29.59%	20.00%
Hospital Region (West)	23.81%	18.67%
Hospital Bed Size (Small)	11.90%	9.33%
Hospital Bed Size (Medium)	27.21%	29.33%
Hospital Bed Size (Large)	60.88%	61.33%

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: A total of 1,470 AAVDAH patients were identified, with 375 receiving PLEX (AAVDAHpl). The mean age was 54.45 years in the AAVDAH group and 56.65 years in the AAVDAHpl group. Regarding comorbidity burden (CCI), 25.85% of AAVDAH patients had moderate, compared to 24.00% in AAVDAHpl, and 38.78% had severe burden, compared to 45.33% in AAVDAHpl. AAVDAHpl patients were more likely to be admitted to hospitals in the Northeast (32.00% vs. 19.05%) (Table 1).

The mean LOS was significantly longer in the AAVDAHpl group (23.59 days) vs. 13.79 days ($p < 0.001$), and total charges were higher ($424,256.7 vs. $220,514.1, $p < 0.001$).

The odds of death in the AAVDAHpl group was 1.99 (95% CI: 1.03 - 3.85) ($p = 0.0415$). Significant associations were found between PLEX and various complications, including sepsis (OR = 2.08, $p = 0.041$), mechanical ventilation (OR = 4.82, $p < 0.001$), and pressor requirement (OR = 5.04, $p < 0.001$). RPGN was significantly associated with PLEX (OR = 4.06, $p = 0.0044$) (Fig 1).

Adjusted analyses revealed that mechanical ventilation, sepsis, and pressor requirement were strongly associated with increased mortality in the AAVDAHpl group ($p < 0.001$ for all), while RPGN was not statistically significant ($p = 0.120$) (Fig 2).

Conclusion: This study indicates that PLEX treatment in AAV + DAH may be linked to higher mortality and more severe complications, highlighting the need for a cautious and individualized approach to its use. However, our results are limited by the lack of data on other treatments received by patients for their AAV. The increased risk of complications associated with PLEX further complicates its role in management. Therefore, further research is essential to identify when PLEX is most beneficial, especially in patients with DAH, and to clarify its optimal application in clinical practice.

Abstract Number: 2518

Impact of psychiatric comorbidity on disease outcomes in ANCA-associated vasculitis: A multi-center retrospective cohort study

Saloni Patel[1], Brendan Denvir[2], Maria Kaltchenko[1], Aaron Bao[3], Varsha Simha[1], Michael Cammarata[4] and Jun Kang[5], [1]Johns Hopkins University School of Medicine, Baltimore, [2]Johns Hopkins, Baltimore, MD, [3]Johns Hopkins School of Medicine, Baltimore, MD, [4]Johns Hopkins, Phoenix, MD, [5]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a systemic small vessel vasculitis associated with significant morbidity and complex care needs across a broad demographic spectrum. While prior studies have demonstrated an increased prevalence of mental health disorders among patients with AAV, the impact of pre-existing psychiatric conditions on disease outcomes remains insufficiently characterized. Given the potential interplay between psychiatric comorbidities and systemic inflammation, further investigation is warranted. This study aims to evaluate the influence of pre-existing psychiatric disorders on clinical outcomes and treatment patterns in adult patients diagnosed with AAV.

Table 1. ICD10 and RxNorm codes of outcomes of interest in TriNetX

Outcome	ICD10 Code
Renal	
Acute kidney failure	N17
Chronic kidney disease	N18
End-stage renal disease	N18.6
Pulmonary	
Hemorrhage from respiratory passages	R04
Interstitial lung diseases	J84
Pulmonary embolism	I26
Respiratory failure	J96
Dependence on supplemental oxygen	Z99.81
Dependence on a respirator	Z99.1
Infection	
Pneumonia	J12-J18
Urinary tract infections	N39.0
Skin and soft tissue infections	L00-L08
Sepsis	A41
Bacterial infections	A30-A49
Viral infections	B00-B09, B15-B20, B25-B34
Complications of glucocorticoid use	
Essential hypertension	I10
Diabetes mellitus	E08-E13
Osteoporosis	M80, M81
Cataracts	H25, H26
Glaucoma	H40-H42
Venous thromboembolism	I82
Prescription of glucocorticoids	**RxNorm code**
Prednisone	8640
Methylprednisolone	6902
Prescription of steroid-sparing immunosuppressants	
Cyclophosphamide	3002
Rituximab	121191
Azathioprine	1256
Methotrexate	6851
Mycophenolate mofetil	68149

Methods: We conducted a retrospective cohort study using the TriNetX network, comparing adult AAV patients with and without pre-existing psychiatric diagnoses (schizophrenia, schizoaffective disorder, bipolar disorder, major depressive disorder, or persistent mood disorder). Propensity score matching was performed for age, sex, race, and smoking status. Five-year incident risk of chronic renal disease, pulmonary disease, infections, venous thromboembolism, glucocorticoid use, and glucocorticoid-associated toxicities were compared using relative risk (RR) with 95% confidence intervals (CI). The ICD-10 and RxNorm codes corresponding to these outcomes, as defined within the TriNetX database, are presented in Table 1.

Results: A total of 1,121 AAV patients with preexisting psychiatric disorders and 17,465 without were included, with 1,116 patients in each cohort after matching (Table 2). Before matching, psychiatric comorbidity was associated with higher risks of acute kidney failure (RR 1.31, 95% CI 1.04–1.64), respiratory failure (1.59, 1.29–1.95), venous thromboembolism (1.37, 1.02–1.86), and infections. After matching, psychiatric comorbidity remained associated with increased risks of pneumonia (1.45, 1.09–1.94), skin infections (1.93, 1.40–2.67), sepsis (1.41, 1.01–1.96), and viral infections (1.55, 1.13–2.13). In unmatched analyses, patients with psychiatric disorders were more likely to be prescribed glucocorticoids (1.13, 1.09–1.18) and less likely to receive glucocorticoid-sparing immunosuppressants (0.81, 0.71–0.92); the latter association persisted after matching (Figure 1).

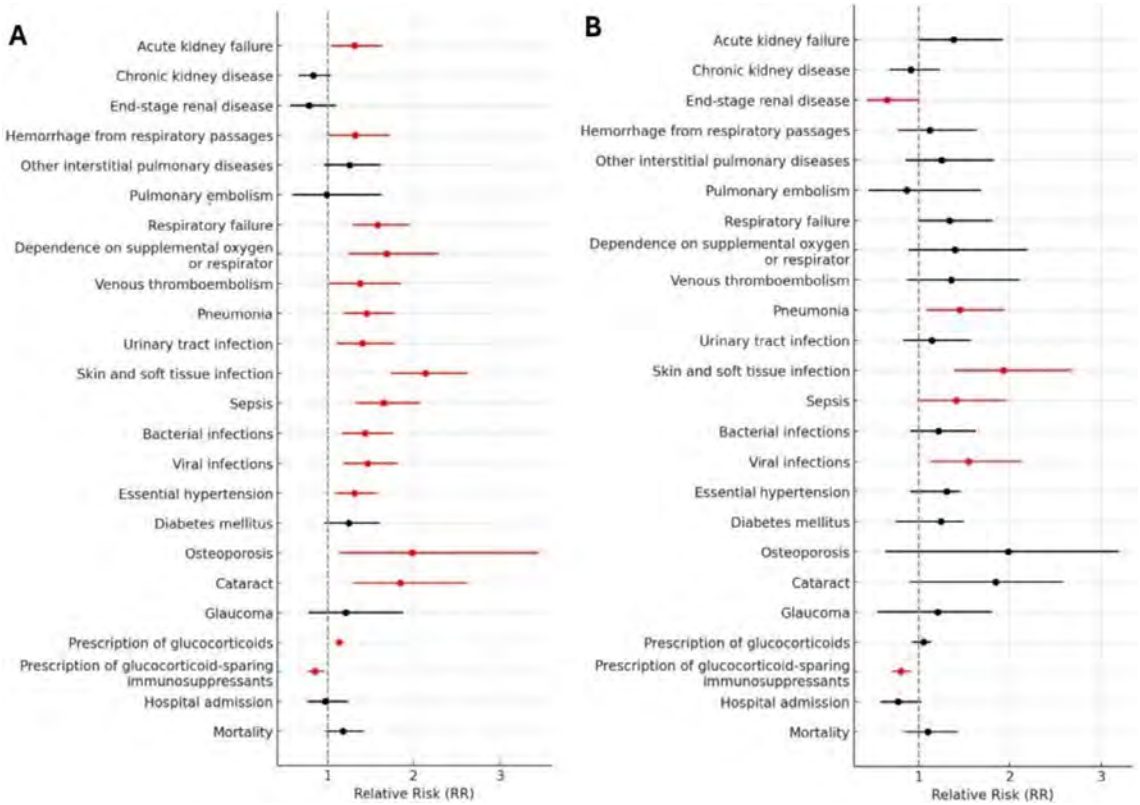
Abbreviations: AAV=ANCA-associated vasculitis, GPA=Granulomatosis with polyangiitis, MPA=Microscopic polyangiitis, EGPA=Eosinophilic granulomatosis with polyangiitis. *Covariates included in the propensity-score matched analysis



Relative risk of 5-year incident outcomes in adult ANCA-associated vasculitis (AAV) patients with a pre-existing psychiatric comorbidity. The reference group for both plots is the cohort of adult patients with AAV and no documented psychiatric disorder (schizophrenia, schizoaffective disorder, bipolar disorder, major depressive disorder, or persistent mood disorder) at any time point. Plot A shows the unadjusted analyses and plot B displays the adjusted analyses after propensity-score matching for age at AAV diagnosis, sex, race, and nicotine dependence in a 1:1 ratio between the cohort of interest and the reference cohort. The dashed gray vertical line in both plots represents no difference in relative risk between the cohorts. Plots highlighted in red indicate a statistically significant difference between cohorts.

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: In AAV, pre-existing psychiatric disorders are associated with increased infectious complications and decreased prescription of glucocorticoid-sparing therapies. Future research should investigate potential co-inflammatory interactions between psychiatric disorders and AAV, and socioenvironmental factors influencing medication adherence and access to care.

Drug-Induced Liver Injury	52	17.59	13.37 – 23.14	17.35

Background/Purpose: Avacopan, a C5a receptor inhibitor, is used as an adjunctive treatment for ANCA-associated vasculitis. Previous studies have highlighted its efficacy in reducing glucocorticoid use and improving renal outcomes. However, concerns regarding its safety profile, particularly hepatotoxicity and serious infections, remain significant. This study aims to investigate the incidence and characteristics of adverse events associated with Avacopan using the FDA Adverse Event Reporting System (FAERS) database. By analyzing real-world pharmacovigilance data, this study seeks to provide a comprehensive assessment of the risks posed by Avacopan, thereby informing clinical practice and enhancing patient safety.

Methods: The FAERS database was searched for adverse events related to avacopan. Data were reported as frequencies, proportional reporting ratio (PRR), and as reporting odds ratios (ROR) with a 95% confidence interval (95% CI).

Results: We analyzed 30,179,725 adverse event reports from the FAERS database. A total of 3,658 reports were associated with the use of avacopan. 39.15% of patients were females, whereas 32.34% had an unspecified sex. The most common group of adverse reactions was generalized side effects (1,103), followed by infections (675) and gastrointestinal disorders (635) (Figure 1). Patients on avacopan had a higher ROR of getting fatigue compared to all other drug users (ROR=2.422; 95% CI: 2.101-2.791). In addition, gastrointestinal disorders, including diarrhea and nausea, were higher

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

among avacopan users compared to other drug users (ROR= 2.611 and 2.028, respectively). Drug-induced liver injury was reported in 52 patients on avacopan, and patients who were taking the medications were significantly more likely to get this complication (ROR=17.59; 95% CI: 13.37-23.14) (Table 1).

Conclusion: In this large pharmacovigilance analysis, avacopan use was associated with a distinct adverse event profile, most notably fatigue, gastrointestinal symptoms, and a markedly increased reporting odds of drug-induced liver injury. While these findings underscore known risks observed in clinical trials, the elevated RORs for hepatic events warrant continued surveillance and caution in clinical use. Real-world safety data such as these are critical for guiding risk mitigation strategies and optimizing patient outcomes in ANCA-associated vasculitis.

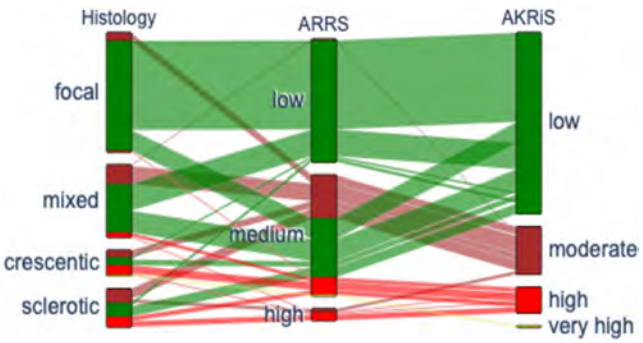
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Glomerulonephritis is a common and threatening manifestation in ANCA-associated vasculitis (AAV). To assess the risk of end-stage kidney disease (ESKD), various scores have been developed, with the ANCA renal risk score (ARRS) and the improved ANCA kidney risk score (AKRiS) [1] being introduced most recently. We aim to investigate its performance in granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) separately in comparison to histological finding.



Distribution of histological classification and their transformation into risk classes, color is taken from final AKRiS class to illustrate their origin and flow.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Changes ARRS -> AKRiS	up, n (%)				17 (7.7)
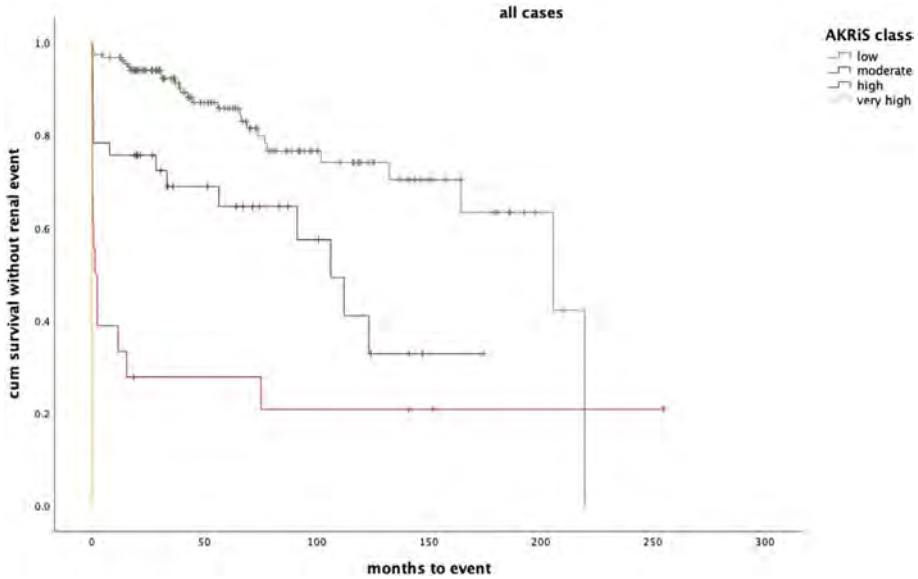
	down, n (%)				54 (24.5)
	same, n (%)				149 (67.7)

Histopathological findings and risk scores at diagnosis and outcomes of 220 patients having AAV with renal involvement.

Methods: We retrospectively analyzed 220 AAV cases between 1998 and 2021 who underwent renal biopsies and could be classified according to the 2020 ACR/EULAR criteria as either GPA or MPA. Follow-up visits were recorded every 6 months. The entire follow-up period was screened for the composite renal endpoint, which included death, dialysis, renal transplantation or the development or ESKD persistence with an eGFR < 15 ml/min/1.73 m^2 at or after six months of follow-up. The cases were analyzed according to histology and different risk scores. Comparison was done by Kaplan-Meier Curves, log-rank test and Herrell's C.

Results: Histological analysis revealed that renal biopsies from MPA patients showed significantly more sclerosis, interstitial fibrosis and tubular atrophy. In terms of histological classification, most cases fell into focal and mixed classes, which mainly transitioned into low- and medium-risk AKRiS categories. Higher risk classifications predominantly derived from crescentic and sclerotic classes (Fig. 1). The substantial group categorized as medium risk most frequently transitioned to lower risk scores within AKRiS. Kaplan-Meier-plots document a clear stratification for the chosen renal end-point. The comparison of ARRS and AKRiS by ROC and the AUC analyzes revealed slightly higher values of the new AKRiS score with an AUC of 0.76 as opposed to ARRS with an AUC of 0.70 (Tabl. 1). The AUC was consistently slightly higher for MPA than for GPA in both risk scores and generally higher for AKRiS than for ARRS. AKRiS stratification proved effective for predicting the composite renal endpoint (area under the curve ≥0.7, C-Index 0.899). ARRS and AKRiS classified 67.7% of cases into the same risk category, while AKRiS assigned a lower risk category in 24.5% of cases and upgraded to a higher risk category in only 7.7% of cases.



Kaplan-Meier-plot of the composite renal endpoint for each risk group .

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The new AKRiS score was found to be effective not only in predicting ESKD but also in assessing a strong composite renal endpoint in a large European AAV cohort, despite slight differences in histological and event patterns between GPA and MPA under comparable treatment regimen.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The DANGER score can predict mortality in patients with ANCA-associated vasculitis (AAV) with glomerulonephritis (GN). However, this score has not been widely validated and, moreover, there is no evidence of its use in AAV patients without GN. The aim of this study was to evaluate the performance of this score in AAV patients with or without GN from a Latin American cohort.

Methods: This was a medical records review study which included patients from the Almenara Vasculitis Cohort who had at least one visit between January 1990 and December 2024. Diagnosis of either microscopic polyangiitis (MPA) or granulomatosis with polyangiitis were included. Mortality was determined as the vital status according to the official information from the

Table 1. Unadjusted and adjusted analyses.

Levels of risk according to the DANGER score	Unadjusted HR (95% CI)	*p* value	Adjusted* HR (95% CI)	*p* value
Low	Ref.		Ref.	
Intermediate	2.71 (1.79 – 4.12)	**<0.001**	3.25 (1.87 – 5.65)	**<0.001**
High	5.04 (1.77 – 14.38)	**0.002**	8.91 (2.43 – 32.75)	**<0.001**

*Adjusted for age at diagnosis, sex and type of diagnosis.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Line 1 (blue): Low risk. Line 2 (red): Intermediate risk. Line 3 (green): High risk.

Figure 1. Kaplan-Meier plot of survival according to categories by the DANGER score.

Peruvian Department of Health. Sociodemographic and clinical features were obtained. The DANGER score includes four variables: age at diagnosis, history of hypertension or cardiac disease, and creatinine and hemoglobin levels at diagnosis. This score stratifies the risk of mortality in low, intermediate and high. Unadjusted and adjusted Cox regression models were done to assess the impact of the DANGER score. The model was adjusted for age at diagnosis, gender and type of diagnosis.

Results: Two hundred twenty-five patients were enrolled; most of them were female [154 (68.4%)]. Mean of age and time of follow-up were 59.4 (12.6) and 7.7 (7.1) years, respectively. MPA was the most frequent diagnosis [177 (78.7%)]. During the follow-up, 110 (48.9%) patients died. As to the DANGER score, 105 (46.7%), 113 (50.2%) and 7 (3.1%) patients had low, intermediate and high risk of mortality, respectively. Furthermore, each risk category was predictive of mortality in the unadjusted and adjusted analyses (Table 1). Overall survival according to the stratification is depicted in Figure 1.

Conclusion: The DANGER score had good performance in AAV patients with or without GN in a Latin American cohort. More studies in other populations are necessary to validate these findings.

Figure. Kaplan–Meier survival curves. A: Comparison of overall survival between patients with and without cardiac involvement showed no significant difference. B: No significant difference in survival was observed between patients with and without cerebrovascular involvement. C: Patients receiving maintenance prednisolone doses ≥7.5 mg/day demonstrated significantly reduced survival compared to those receiving <7.5 mg/day. D: Patients with disease onset at age ≥61 years had significantly lower survival rates than those with onset at ≤60 years.

these, cardiac involvement is most closely linked to poor outcomes. Although CNS involvement is rare and not included in the score, it may still affect prognosis. Major causes of death in EGPA include cardiac and CNS complications, gastrointestinal perforation, respiratory failure, and infections. Treatment typically includes glucocorticoids and cyclophosphamide, with newer agents like anti–IL-5/IL-5R monoclonal antibodies and rituximab for refractory cases. This study evaluated treatment and outcomes in patients with organ involvement affecting survival.

Methods: We retrospectively analyzed 51 patients with EGPA treated at our hospital from 2000 to 2024. The mean age at onset was 60.1±12.1 years. We focused on cardiac and cerebrovascular involvement. CNS lesions were included only if they occurred during the active disease phase. We also assessed the presence of lifestyle-related diseases (e.g., smoking, hypertension, dyslipidemia, diabetes) and ANCA status. Treatments used for remission induction and maintenance were reviewed. Prognosis was analyzed according to presence of cardiac and CNS involvement. In fatal cases, we examined causes of death, treatment regimens, and glucocorticoid dosages. Relative risk with 95% confidence intervals was used for analysis.

Results: All patients received glucocorticoids. Cyclophosphamide was used in 9 cases, rituximab in 2, IVIG in 17, mepolizumab in 35, azathioprine in 24, mycophenolate mofetil in 7, and methotrexate in 7. Mepolizumab was effective in reducing prednisolone doses.

Cardiac involvement was observed in 8 patients, all presenting during the initial phase. None relapsed after treatment. Cardiac function was evaluated over time using echocardiography, focusing on wall motion abnormalities and pericardial effusion. Two patients showed marked improvement with immunosuppressive therapy. One had pre-existing arteriosclerosis and responded poorly. However, all 8 survived beyond 12 months with no cardiac deterioration.

Cerebrovascular events occurred in 11 cases—9 cases at initial presentation, 2 cases at 3- and 11-years post-onset. Lifestyle diseases were not significant risk factors for cardiac or CNS lesions.

Four patients died (mean age 78±4 years). One died of liver cancer; three had refractory disease with persistent glucocorticoid dependency. Of these, two died from pneumonia and one from CNS involvement. Cardiac and CNS involvement were not significant prognostic factors. However, age ≥61 at onset and maintenance prednisolone doses ≥7.5 mg/day were significant risk factors.

Conclusion: Cardiac and cerebrovascular involvement in EGPA may be controlled long-term with appropriate early treatment. In contrast, older-onset patients with glucocorticoid-dependent disease require careful management to prevent fatal infections and poor outcomes.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2504–2523) Vasculitis – ANCA-Associated Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Glucocorticoids (GCs) are a cornerstone of remission induction therapy in microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA), but long-term GC use is associated with serious adverse effects. Therefore, minimizing GC exposure while maintaining disease control is a major therapeutic goal. However, the frequency and predictors of glucocorticoid-free clinical remission (GFCR) within the first year after treatment initiation remains unclear in patients with newly diagnosed MPA/GPA. This study aimed to investigate the rate and predictors of GFCR at week 48 in patients with newly diagnosed MPA or GPA, and to examine long-term outcomes up to week 96.

Methods: We conducted a retrospective cohort study using a multicenter, nationwide registry in Japan (J-CANVAS). Patients with newly diagnosed MPA or GPA and at least 48 weeks of follow-up were included. GFCR was defined as Birmingham Vasculitis Activity Score (BVAS) of 0 with complete GC withdrawal at week 48. Univariable and multivariable logistic regression analyses were used to identify factors associated with GFCR. Given the limited prior evidence regarding predictors of GFCR, variables for multivariable models were selected based on clinical relevance and statistical trends in univariable analysis (Model 1: $p < 0.05$, Model 2: $p < 0.20$).

Results: Among 728 patients with newly diagnosed MPA/GPA enrolled in the registry, 544 were included in the analysis. At week 48, 29 patients (5.3%) achieved GFCR. Baseline characteristics are shown in Figure 1, and treatment details and outcomes up to week 48 are summarized in Figure 2. In multivariable analysis, the use of rituximab (RTX) and avacopan within

‡ P-values are from a multivariable logistic regression model including factors with p-values < 0.20 in univariable analysis.
MPA, microscopic polyangiitis; MPO, anti-myeloperoxidase; ANCA, anti-neutrophil cytoplasmic antibody; BVAS, Birmingham Vasculitis Activity Score; eGFR, estimated glomerular filtration rate; CRP, C-reactive protein; RTX, rituximab; IVCYC, intravenous cyclophosphamide; AZA, azathioprine.
For statistical analyses, *p < 0.05, **p < 0.01.

Figure 3. Univariable and multivariable logistic regression analyses for predictors of GFCR at week 48

GFCR at week 48 were more likely to maintain GFCR at week 96 (58.6% vs. 4.5%, p < 0.001). Between weeks 48 and 96, the rates of death, relapse, and serious infection were similar regardless of GFCR status at week 48.

Conclusion: In this real-world cohort, the use of RTX and avacopan was independently associated with achieving GFCR at week 48, supporting their role in GC-sparing therapeutic strategies for AAV. Prospective studies are needed to validate these findings and guide individualized treatment approaches.

Abstract Number: 2524

Rituximab in the Treatment of Susac Syndrome: Single Center Descriptive Study with a Large Susac Cohort

Adam Brown[1], Leonard Calabrese[2] and Rula Hajj-Ali[3], [1]Cleveland Clinic, Shaker Heights, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic, Cleveland

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Susac Syndrome is a rare autoimmune condition causing microvascular occlusions in the brain, retina and inner ear leading to the characteristic triad of encephalopathy, branch retinal artery occlusion (BRAO), and sensorineural hearing loss, potentially leading to permanent disability and death if untreated. Approximately 400 cases of Susac Syndrome have been reported since its initial description in the 1970s. Only a handful of cases of Rituximab use in Susac Syndrome have been reported in the literature. The goal of this descriptive study is to highlight our experience with Rituximab from one of the largest cohorts of Susac Syndrome in the world.

Methods: A retrospective chart review of sixty-eight patient meeting the European Susac Consortium criteria was performed identifying all patients treated with Rituximab. The following were recorded: patient demographics, presenting signs/symptoms, whether the full triad of encephalopathy, vision and hearing loss were present, as well as immunosuppressive medications initiated, length of follow up and whether a patient had a flare while on immunosuppression. Rituximab initiation was divided into induction and rescue therapy. Rituximab was considered an induction therapy if it was given when Susac Syndrome was first diagnosed and rescue therapy if it was used after a patient flared while on another immunosuppressive agent. Flares were defined by objective changes in brain MRI, fluorescein angiography or audiometry in addition to clinical symptoms. Flares were considered to have occurred during maintenance therapy if the flare occurred after three months from the first infusion of Rituximab.

Results: Rituximab was used as either induction or rescue therapy in forty patients (58%) within the Susac Syndrome cohort. Twenty-nine patients (72%) receiving Rituximab had the full triad of Susac present at the time of diagnosis. Twenty-eight patients (70%) on Rituximab were followed at least twelve months. Rituximab was utilized either as monotherapy or in combination with other therapeutics such as IVIG or Mycophenolate Mofetil (MMF). Rituximab was used for induction therapy in nineteen patients and rescue therapy in twenty patients. Three patients out of forty flared (7%) while on Rituximab, all were on maintenance therapy at the time of the flare (3/29 flared when isolating to only those patients followed for at least a year (11%)). Flares were a mix of ocular (2) and brain (1). One patient flared while on Rituximab as monotherapy, another was on a combination with MMF 1,000 mg and another on IVIG. The average length of follow up was 3.5 years.

Conclusion: This is the largest cohort of patients with Susac Syndrome treated with Rituximab. The majority of patients did well with only three (7%) flaring while on Rituximab. In the literature, the triad of Susac Syndrome is present in less than twenty percent of patients. In our cohort of patients on Rituximab, the triad was present in seventy-two percent of patients at diagnosis indicating more serious disease. Rituximab has been utilized for multiple decades and considered a well-tolerated therapy, it's use in the treatment for Susac Syndrome should be further explored.

Background/Purpose: Small vessel vasculitis (SVV) presenting in the skin may be skin-limited or a manifestation of systemic vasculitis or an underlying autoimmune disease. However, no evidence-based protocols exist to identify patients at risk for systemic involvement. This study aimed to identify clinical features present at the time of initial evaluation that predict systemic disease in patients with SVV of the skin, to support early risk stratification and management.

Methods: This multi-center case-control study included 430 adults with biopsy-confirmed SVV of the skin, identified from pathology databases at Massachusetts General Hospital, Brigham and Women's Hospital, and the Hospital of the University of Pennsylvania. In accordance with Chapel Hill consensus criteria, cases were considered to have systemic disease if the SVV was associated with systemic vasculitis or connective tissue disease, or if the SVV caused objective organ dysfunction. Demographic, clinical, and laboratory features at initial presentation were assessed.[1] Univariate and multivariate logistic regression analyses were performed to estimate odds ratios (ORs) and 95% confidence intervals (CIs), with variable selection guided by elastic net regression and 10-fold cross-validation. Significance was set at $P < 0.05$.

Results: Among 430 patients (mean [SD] age, 55 [17.7] years; 55.5% male), 87 had systemic disease and 343 had skin-limited SVV. Multivariate analysis identified nausea/vomiting (OR 3.92; 95% CI 1.58–9.77), ulcerating or necrotic skin lesions (OR 3.26; 95% CI 1.24–8.59), abdominal pain/cramping (OR 2.71; 95% CI 1.19–6.18), and fatigue/malaise/lethargy (OR 2.61; 95% CI 1.28–5.32) as significantly associated with systemic disease. In a subset with urinalysis data (n=388), dipstick hematuria (3+) was associated (OR 2.40; 95% CI 1.23–4.68) and recent antibiotic use was inversely associated (OR 0.54; 95% CI 0.29–0.98) with systemic disease. Joint pain (OR 2.54; 95% CI 1.49–4.34) and younger age (OR 0.74 per SD increase; 95% CI 0.58–0.93) were associated in univariate but not multivariate analysis.

Conclusion: In this multi-institutional study of biopsy-proven SVV, we identified constitutional and gastrointestinal symptoms, necrotic or ulcerating lesions, and dipstick hematuria (3+) as predictors of systemic involvement. These point-of-care features may aid in identifying high-risk patients requiring further evaluation and closer monitoring.

Infection Risk Associated with Steroid-Sparing Therapies in GCA, PMR, and ANCA-Associated Vasculitis: A Systematic Review

Divya Sudireddy[1], Brent Leung[2], Jean Liew[3], Tuhina Neogi[4], David Felson[3], Michael LaValley[5] and David Flynn[2], [1]Boston Medical Center, Westborough, MA, [2]Boston University, Boston, [3]Boston University, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]Boston University School of Public Health, Arlington, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA), polymyalgia rheumatica (PMR), and ANCA-associated vasculitis (AAV) often require long-term glucocorticoid (GC) therapy, increasing the risk of infections, particularly in older adults with GCA and PMR. Biologics and small molecule therapies are increasingly used to reduce GC exposure but may also increase infection risk through immunosuppression. This systematic review aimed to evaluate the infection risk associated with these therapies along with concomitant GC treatment, as compared to GC treatment alone, in vasculitis clinical trials.

Methods: A comprehensive search of PubMed, Embase, and Cochrane, supplemented by ClinicalTrials.gov was conducted using terms related to GCA, PMR, AAV, biologic therapies (tocilizumab, sarilumab), small molecule therapies (upadacitinib, avacopan), glucocorticoids, and infections. We included randomized controlled trials (RCTs) published in English comparing biologics or small molecules with concomitant GC dosing (active intervention) compared to GC monotherapy (comparator), and reporting infection outcomes. Two independent reviewers screened titles and abstracts, conducted full-text reviews, and extracted data, including study characteristics, details about the intervention and comparator, mean cumulative glucocorticoid use, and overall infection outcomes. We calculated the difference in GC dose between the comparator and active intervention groups and relative risk of infection (active intervention versus comparator group).

Results: The initial search yielded 1,154 studies (Figure 1). We included 10 eligible phase II or III RCTs (1,487 patients total; Table 1). 4 trials evaluated tocilizumab, 2 sarilumab, 1 upadacitinib, and 3 avacopan among patients with GCA, PMR and AAV. All studies reported infection outcomes and included populations with mean age ≥50 years. Follow-up durations ranged from 6 to 18 months. Despite steroid-sparing protocols, cumulative GC use was greater than anticipated in both intervention and comparator groups. In most trials, the intervention group had lower cumulative GC exposure than the comparator group. The frequency of infection varied. When the comparators had much higher GC dosing than the active intervention, the RR for infection was either close to 1 or < 1 (Figure 2). When the active intervention GC dose was comparable to the comparator dose, the RR for infection was >1.

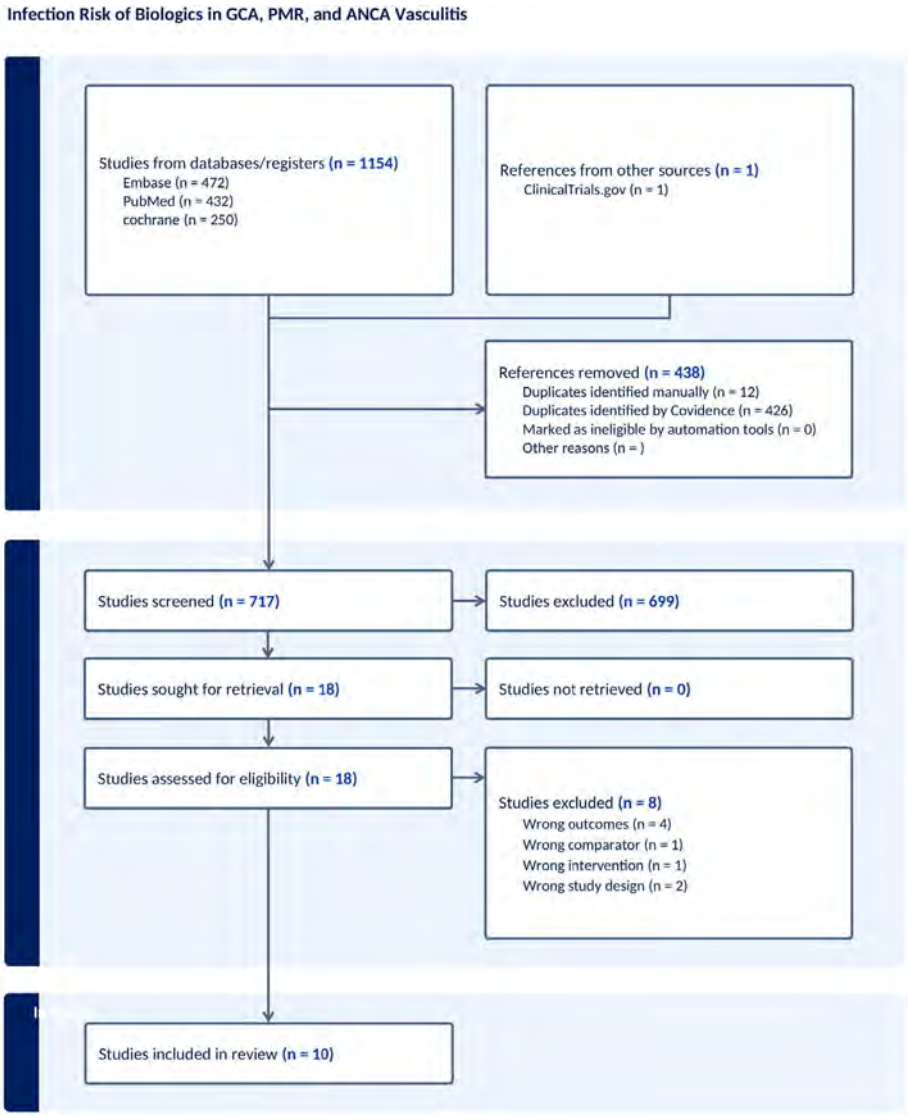

Figure 1. PRISMA flow diagram of study inclusion and exclusion

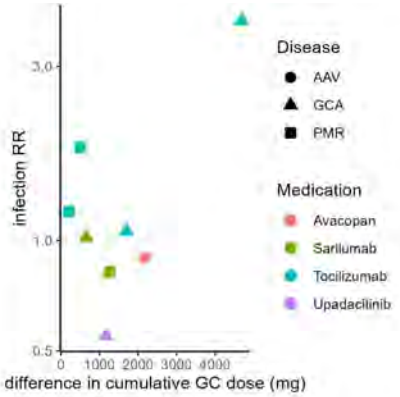
** These studies only reported serious infections
* These studies reported number of events

Q = every
BID = twice daily
NR = Data not reported



Abbreviations: AAV, ANCA associated vasculitis; GCA, giant cell arteritis; PMR, polymyalgia rheumatic; RR, risk ratio; GC, glucocorticoid

Infection RR is the risk of infection for the active intervention versus the comparator

The difference in cumulative GC dosing is the difference for the comparator group minus the active intervention group

Figure 2: Infection risk ratios versus difference in mean cumulative glucocorticoid dosing between active intervention and comparator

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Although biologics and small molecules had lower overall cumulative GC exposure, they did not consistently lead to a lower infection risk. When GC exposure was notably higher in the comparator group, infection risk was lower in the intervention group suggesting a possible protective effect of reducing GC. However, when GC doses were more comparable between groups, infection risk was higher in the active intervention arm, likely due to the immunosuppressive effects of combining biologic and small molecules with GC. These findings emphasize the importance of carefully considering infection risk in the management of patients, particularly in older adult populations.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Although rare, new-onset Behçet's syndrome (BS) and disease flares have been reported following vaccination. In this context, the recommendation of the Recombinant Herpes Zoster Vaccine (RVZ) for immunosuppressed patients raises important questions regarding its safety and immunogenicity in BS under immunosuppressive (IS) therapy.

Methods: This prospective, randomized, placebo-controlled, single-center trial included 46 BS patients under IS, randomized 1:1 into: P1 (RZV) and P2 (placebo) groups. A healthy control group (CG) of 138 subjects was included at a 3:1 ratio and age-paired to BS patients (±3 years for patients ≥50 years; 50–55 years for BS patients < 50 years). P1 and CG received two intramuscular RZV doses on D0 and D42, while P2 received placebo. At D84, blinding was opened and P2 received RZV following the same schedule. Blood samples were collected at baseline and 6-weeks after the second dose. Humoral immunogenicity was assessed by ELISA for anti-gE antibodies, with a positive response defined as a ≥4-fold increase above the baseline level. Geometric mean titers (GMTs) and factor increase (FI) were calculated. Local and systemic side-effects were recorded in a diary after RZV for both groups. BS patients recorded new oral/genital ulcers and disease activity was assessed at each visit with the Behçet's Disease Current Activity Form (BDCAF).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: BS patients were younger than controls [41(18–62) *vs*. 52(50–63)years, p=0.001], with 82.6% aged< 50 years *vs*. 100% of controls aged≥50 years (p=0.001).Percentage of female gender was lower in BS (39.1% *vs*. 65%;p=0.002).BS patients were using: azathioprine (54%), prednisone (37%), tumor necrosis factor inhibitors (30%), mycophenolate mofetil (22%), colchicine (13%), methotrexate (11%), tocilizumab (4%), cyclosporine (4%). Seroconversion was achieved by all BS patients (100%) and 99.3% of CG (p >0.999). A significant increase of GMT from baseline was observed in BS [0.12 (0.08-0.18) *vs*. 7.96(5.76-11.0), p< 0.001) and in CG [0.25(0.20-0.30) *vs*. 13.32(11.98-14.82), p< 0.001]. The increase in GMT of BS was lower than CG (7.96 *vs*. 13.32, p=0.02). FI in GMT was similar in BS and CG [66.3(41.0-107.2) *vs*. 53.8 (43.3-66.8), p=0.316]. Demographics and current therapy (including biologics and IS) did not influence antibody titers (p >0.05). Higher local (92% *vs*. 80.4%, p=0.028) and systemic (78% *vs*. 60.8%, p=0.0147) reactions were observed in CG compared to BS. Regarding disease safety, no significant differences in the percentage of new oral (p=0.622) and genital (p=0.608) ulcers, or in BDCAF scores (p=0.787) were observed.

Conclusion: Our study is the first to demonstrate that RVZ appears safe in immunosuppressed BS patients, without evidence of flares using standardized measures. Despite the universal vaccine response in younger BS, antibody titers were lower than in older healthy controls, who would normally predict a weaker response. Further studies are necessary to determine whether the lower antibody levels will compromise long-term protection. (ClinicalTrials NCT05879419).

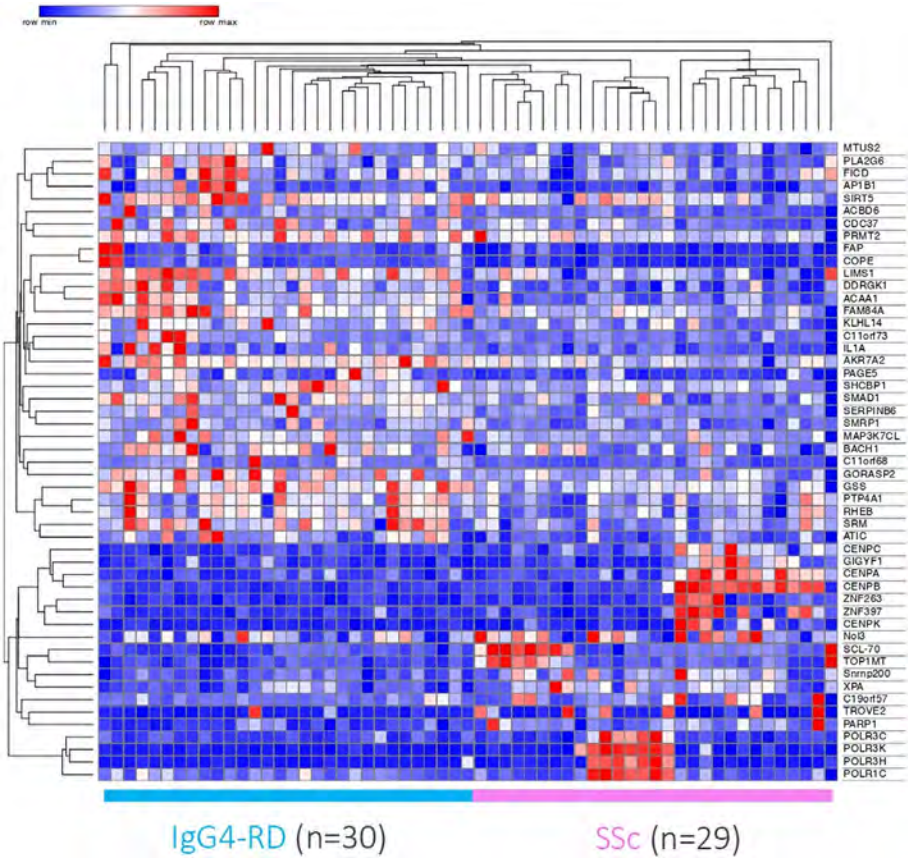

Figure 1. 51 differentially bound self antigens separate IgG4-RD from SSc patients by unsupervised hierarchical clustering. Heatmap with hierarchical clustering of differentially bound autoantigens between IgG4-RD (n=30) and SSc (n=29, 1 SSc patient was excluded.)

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic immune-mediated disease typified by mass-forming lesions. Self-antigens driving the oligoclonal expansion of plasmablasts have previously been reported. However, broad screening of the IgG repertoire from IgG4-RD patients for reactivity across the human proteome has yet to be done. The goal of this study was to identify novel, potentially causal, disease-specific autoantigens by broadly screening the human proteome.

Methods: The HuProt microarray, displaying 21,216 proteins in total, including 15,889 unique human proteins, was used to screen plasma samples from IgG4-RD patients and controls across discovery and validation batches. The discovery batch included IgG4-RD (N=30) and systemic sclerosis (SSc, N=30). The validation batch included IgG4-RD (N=42, 28 of which were not included in the initial batch), idiopathic pulmonary fibrosis (N=20), sarcoidosis (N=20), and healthy donors (N=20). Microarray data was normalized and analyzed for autoantigens selectively bound by IgG4-RD samples after adjusting for false discovery rate. Autoantibodies with frequencies >15% among IgG4-RD were selected for unsupervised hierarchical clustering. A separate analysis focused on the highest titer autoantibodies across cohorts was also conducted. Selected autoantigens were validated using a luciferase immunoprecipitation system (LIPS) assay.

Results: FAM84A and LIMS1 were the two autoantigens that most accurately distinguished IgG4-RD from SSc in the discovery batch, while expected autoantigens distinguished SSc including those against centromeric proteins, RNA polymerase III subunits, and topoisomerase **(Figure 1)**. Anti-FAM84A was present in 9/30 (30%) and anti-LIMS1 in 6/30 (20%) of the IgG4-RD cohort versus 0% in SSc and 1/30 (3%), respectively. The validation batch confirmed the presence of FAM84A and LIMS1 autoantibodies and identified four additional proteins to form a cassette of 6 autoantigens distinguishing IgG4-RD from HD. The additional four autoantigens included CCDC97, MAGEE1, ISM2 and SCG2. The nine anti-FAM84A samples from the discovery batch were reproducibly reactive to FAM84A in the validation batch. After excluding all

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

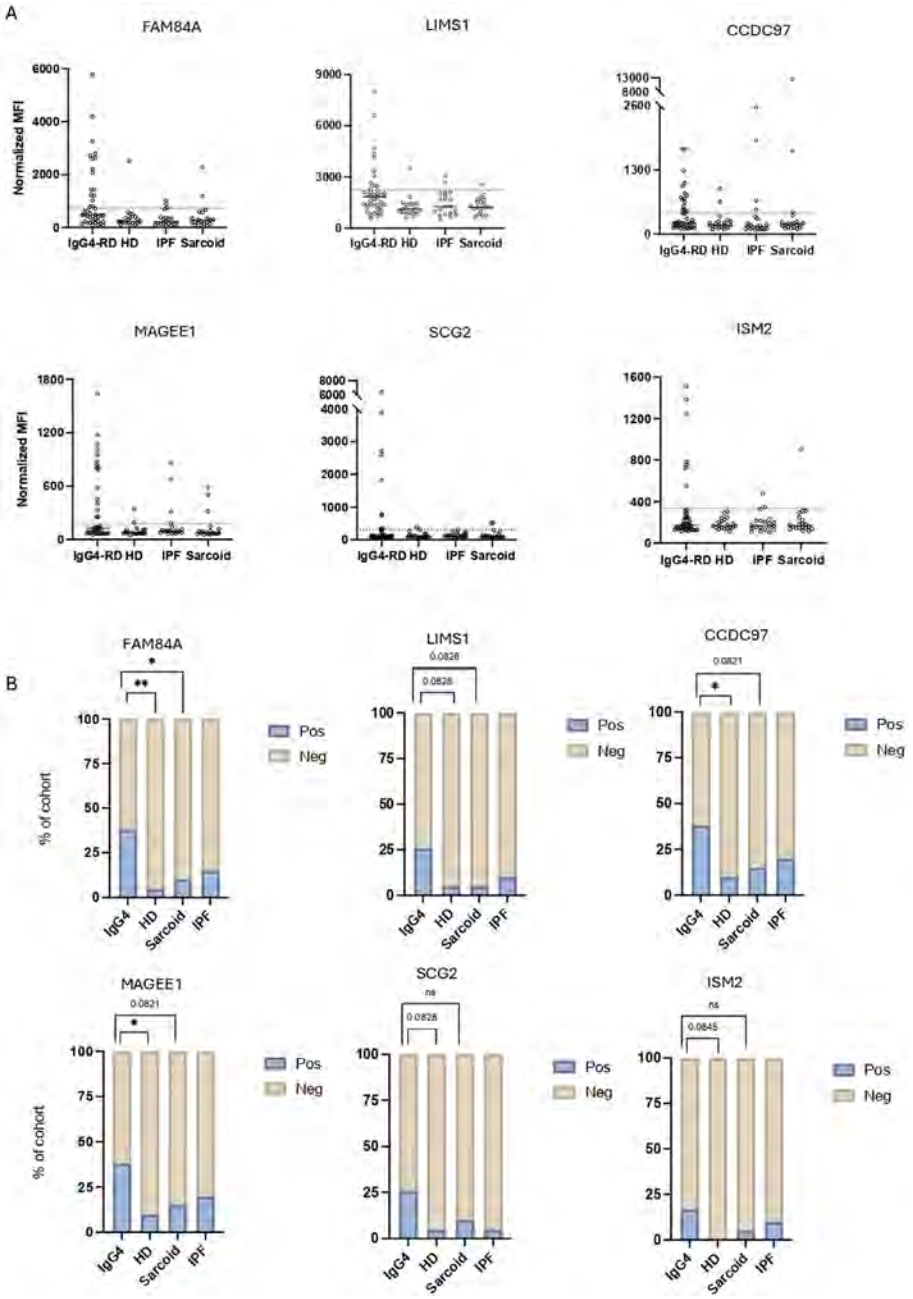

Figure 2 Granularly selected cassette of 6 autoantigens distinguish IgG4-RD patients (n=42) from healthy donors (n=20), IPF (n=20) and Sarcoidosis (n=20). (A) Dot plots showing normalized mean flourescent intensity (MFI) values for each selected autoantibody, dotted red line represents cutoff value computed based on healthy donor cohort by the 1.5*interquartaile range (IQR) rule. (B) Bar charts representing % of subjects in each cohort with MFI values for each selected autoantigen that is above the cutoff described in Figure 1A. P value comparing frequencies between IgG4-RD with healthy donors and sarcoidosis patients was computed by Fisher's exact test. Symbols: ns p value >0.05, *p ≤0.05, ** p≤ 0.01, *** p≤0.001, **** p≤0.0001.

overlapping samples between batches, frequencies of these autoantibodies were 7/28 (25%), 7/28 (25%), 14/28 (50%), 12/28 (43%), 7/28 (25%) and 5/28 (18%), respectively **(Figure 2)**. Reactivity to at least one of these 6 autoantigens was observed in 35 of the 42 (83%) IgG4-RD patients and the IgG4-RD cohort additionally clustered into three distinct groups based on antigen specificity **(Figure 3)**. Analysis focused on the highest titer autoantibodies identified ANXA11, as has been previously reported, and FAM84A. ANXA11 and FAM84A were validated by LIPS, with anti-FAM84A responses observed in 12% (23 of 192) of IgG4-RD patients and anti-ANXA11 in 12.5% (24 of 192). Anti-FAM84A patients showed enrichment for Mikulicz phenotype while anti-ANXA11 was linked to pancreatobiliary involvement.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3. The casette of 6 novel autoantigens segregates the IgG4-RD cohort into 3 clusters and enrich for specific organd manifestations. (A) Heatmap with hierarchical clustering depicting the 6 selected autoantigens in the validation batch . Three main clusters are identified by the unsupervised clustering. (B) Dot plot showing relative light unit (RLU) values from LIPS assay validating FAM84A in a larger cohort IgG4-RD (n=192) compared to healthy donors (n=121) and SSc (n=56). Dashed line represents the cutoff based on mean + 3*standard deviations of the healthy donor cohort. P values were computed with Mann-Whitney U test. Among FAM84A positive IgG4-RD patients, 52% showed lacrimal gland involvement and 39% showed parotid gland involvement. Among ANXA11 positive IgG4-RD patients 70% showed pancreatic involvement.

Conclusion: The novel cassette of 6 autoantigens including FAM84A, LIMS1, CCDC97, MAGEE1, ISM2, and SCG2 distinguished IgG4-RD from controls. Further efforts to validate these findings are needed.

Abstract Number: 2529

IgG4-Related Disease Paravertebral and Ureteropelvic Mass Presentations are Linked to Specific Disease Features

Federica Bonaso[1], Grace McMahon[2], Isha Jha[2], Guy Katz[2], Zachary Wallace[3], John Stone[4] and Cory Perugino[5], [1]University of Brescia, ASST Spedali Civili of Brescia, Massachusetts General Hospital, Monza, Italy, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital, Newton, MA, [4]Massachusetts General Hospital , Harvard Medical School, Concord, MA, [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic immune-mediated disease characterized by mass-forming fibrotic lesions. The aim of this work was to characterize the overall clinical and serological findings of paravertebral (PV) and ureteropelvic junction (UPJ) involvement as two uncommon manifestations that are nevertheless regarded as strongly suggestive of IgG4-RD.

Table 1. Demographics and Laboratory Values for patients with paravertebral (PV) mass, ureteropelvic junction (UPJ) involvement, and remainder of the IgG4-RD cohort. P-values were calculated by comparing the UPJ and PV groups with the remainder of the cohort by applying Mann-Whitney U test for continuous variables, and Fisher's exact test for categorical variables. Statistically significant p-values ($p < 0.05$) are shown in bold.

	Comparison Group: Fulfill ACR/EULAR Classification Criteria but do not have UPJ or PV masses	PV Mass	*P value PV vs. Comparison Group*	UPJ Mass	*P value UPJ vs. Comparison Group*

Methods: Patients with IgG4-RD were recruited from the Massachusetts General Hospital (MGH) Rheumatology Unit from 2008 to 2025. All patients included fulfilled the 2019 ACR/EULAR Classification Criteria for IgG4-RD. The presence of a PV or UPJ mass was determined by chart and imaging review. Demographics, age at diagnosis, organ involvement, and laboratory values were extracted from the medical record. Patients with PV or UPJ masses were compared to all other IgG4-RD patients in the registry.

Results: Among the 400 patients who fulfilled classification criteria in the MGH IgG4-RD registry, 7 (2%) had a PV mass and 11 (3%) had a UPJ mass. No patient had masses in both the PV and UPJ regions. PV masses were typically located anterolateral to the thoracic spine, abutting the vertebral bodies, and forming a band-like structure **(Figure 1A)**. UPJ masses were typically extrinsic to the kidney and abutting the renal vasculature and ureter but generally not causing hydronephrosis (82%, only two patients presented with hydronephrosis one of whom with concomitant retroperitoneal fibrosis) **(Figure 1B)**. All 7 patients with PV masses and 10 of 11 with UPJ masses were male. In contrast, the percentage of patients in the remainder of the cohort who were male was 68% (261 of 382). The median age of diagnosis for patients with PV masses, UPJ masses, and the IgG4-RD comparison group were 65.1, 65.4 and 61.8 years, respectively. Compared to all other IgG4-RD patients, those with PV masses had significantly higher median serum IgG4 values (891 vs 159 mg/dL, p=0.011) and median absolute and relative eosinophil counts (530 vs 180 cells/uL, p=0.015; 5.7 vs 2.7, p=0.015) **(Table 1)**. IgG4-RD patients with PV masses were more likely to have lacrimal gland (71% vs 31%, p=0.036), submandibular gland (86% vs 41%, p=0.023), retroperitoneal (57% vs 17%, p=0.020), and lung involvement (57% vs 21%, p=0.042). In contrast, patients with UPJ masses were more likely to have prostate (40% vs 11%, p=0.02) and pericardial (18% vs 2%, p=0.028) involvement **(Table 2)**.

Conclusion: Although masses in the PV and UPJ regions are considered highly suggestive of IgG4-RD, they occur in only a small minority of cases. Patients with either PV or UPJ masses tend overwhelmingly to be male, and those with PV masses have more exuberant immunologic disease activity (higher serum IgG4, more frequent peripheral eosinophilia) and more extensive organ involvement (higher frequency of lacrimal gland, submandibular gland, retroperitoneal, and lung involvement) compared to all other patients with IgG4-RD. In contrast, IgG4-RD patients presenting with UPJ masses are more likely to have prostate and pericardial involvement. Further studies incorporating imaging, histopathology, and treatment response among larger cohorts of IgG4-RD are needed to characterize these specific disease features further.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic immune-mediated disease characterized by mass-forming lesions and organ dysfunction. The smoldering tempo and often asymptomatic nature of IgG4-RD pose challenges in the monitoring of disease activity. At least fourteen protein biomarkers have been reported, including serum IgG4.

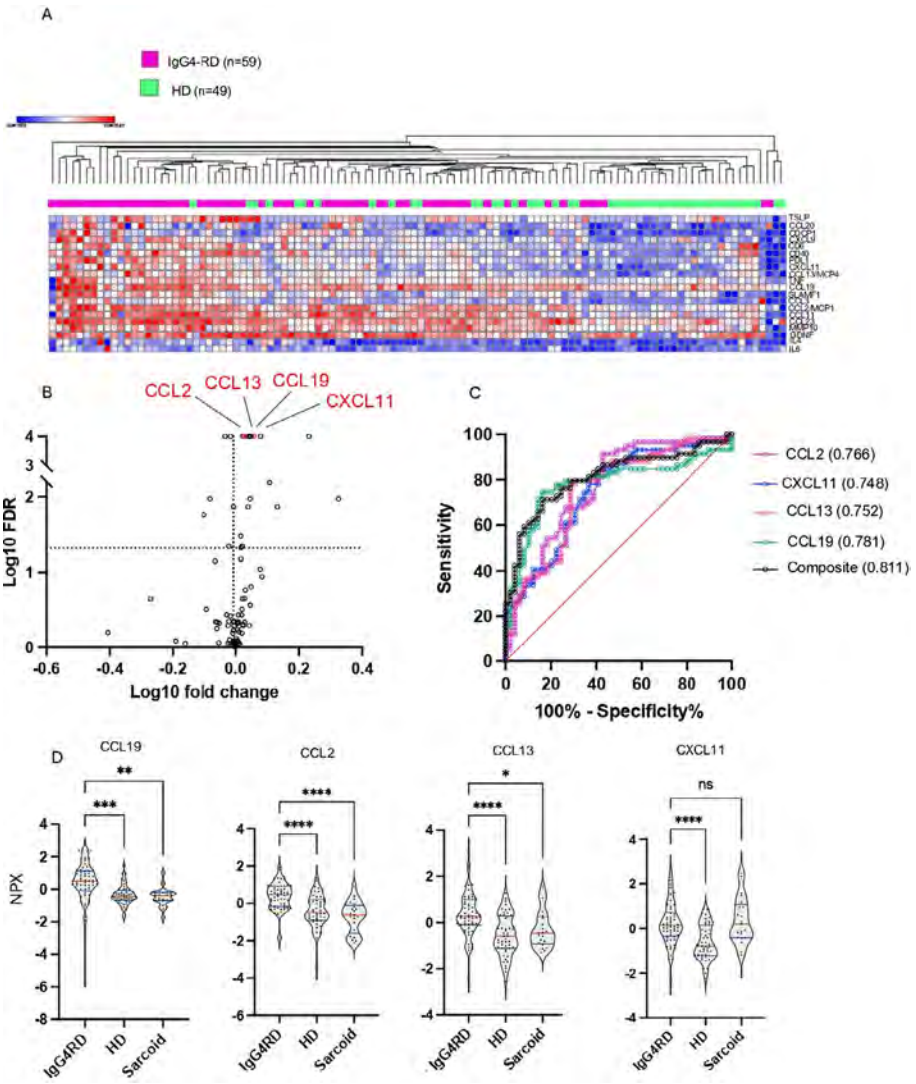

Figure 1. Screening of 92 inflammation associated proteins identifies a cassette of 20 proteins that distinguishes IgG4-RD. (A) Heatmap with hierarchical clustering of differentially abundant plasma proteins between IgG4-RD and healthy donors. (B) Volcano plot displaying log10 false discovery rate (FDR) values on the y-axis and log10 fold change values on the x-axis for all proteins included in the O-link 96 inflammation panel comparing untreated IgG4-RD (N=59) to age- and sex-matched healthy donors without immune mediated disease (N=49). Dashed line represents FDR adjusted p-value cut-off of 0.05 for significantly enriched proteins after controlling for multiple comparisons, age, and sex across cohorts. Red dots represent the four selected proteins positively enriched in IgG4-RD with FDR adjusted p-values <0.05. The 20 dots in the right upper quadrant represent proteins enriched in IgG4-RD patients. (C) Receiver operating characteristic (ROC) curve displays the ability of selected proteins to distinguish IgG4-RD from healthy donors. Areas under the curve are displayed parenthetically after each protein name in the legend. (D) Dot and violin plots displaying individual normalized protein expression (NPX) values for the CCL19, CCL2, CCL13 and CXCL11 in IgG4-RD, HD and sarcoidosis; blue lines represent interquartile range and red line represents median; p value was calculated by ordinary ANOVA. Symbols: ns p value >0.05, *p ≤0.05, ** p≤ 0.01, *** p≤0.001, **** p≤0.0001.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

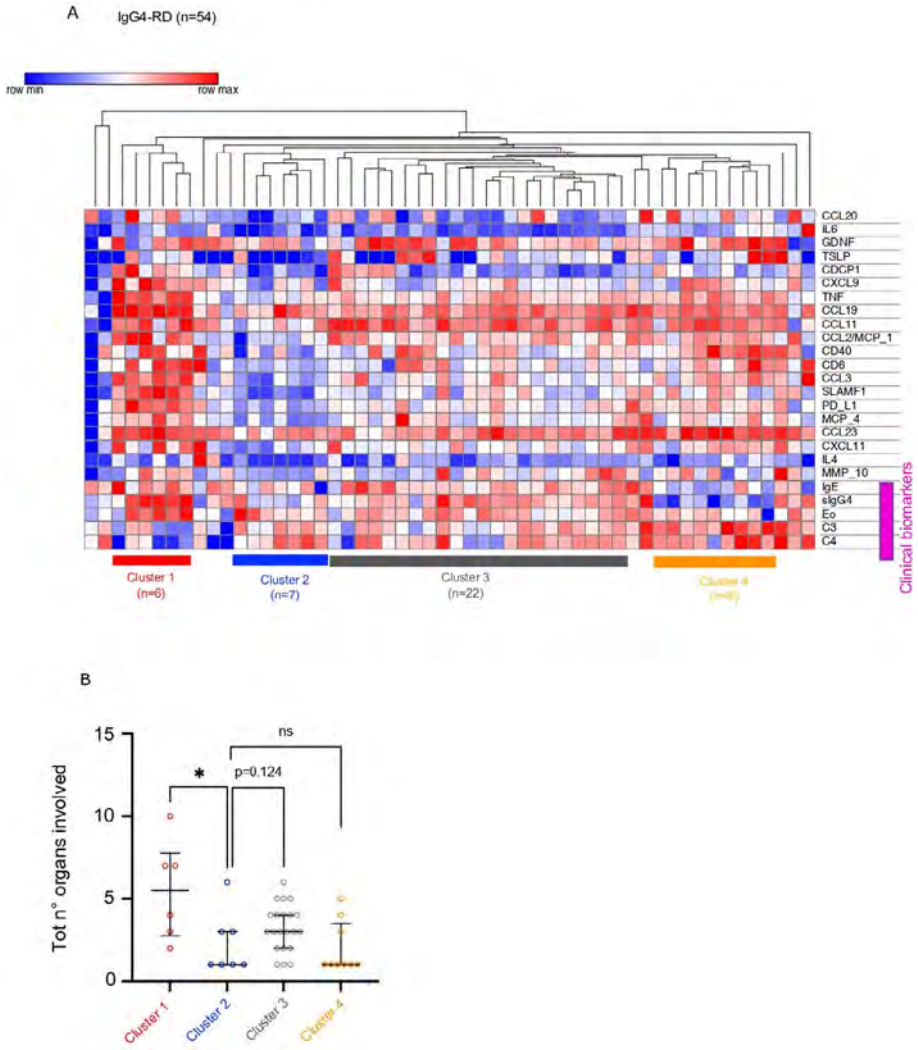

Figure 2. Novel biomarkers, including CCL19 and CCL2, correlate with extensive organ involvement and clinical biomarkers of severe disease. (A) Heatmap with hierarchical clustering of 20 IgG4-RD defining plasma proteins plotted with clinical biomarkers of severe disease including serum IgG4, IgE, absolute eosinophil count, C3, and C4 values. Only 54 patients had all clinical biomarkers available at time of blood draw. For hierarchical clustering the metric used was Euclidian distance and the linkage method was the average. (B) Dot plots showing total number of organs involved in each of the four clusters identified by hierarchical clustering, each dot corresponds to a patient belonging to one of the clusters. Bars represent median and interquartile range. P value the was calculated with Mann-Whitney U test. Symbols: ns p value >0.05, *p ≤0.05, ** p≤ 0.01, *** p≤0.001, **** p≤0.0001.

However, all reported biomarkers have been studied in relative isolation without direct comparison, and none have been demonstrated to correlate with relapsing disease. The goal of this study was to comprehensively screen inflammation associated proteins to identify novel biomarkers of disease activity in IgG4-RD that correlate with relapsing disease.

Methods: Ninety-two inflammation related proteins were measured across 59 patients with IgG4-RD, 49 healthy donors (HD), and 21 patients with sarcoidosis. Six IgG4-RD patients had pre- and post-prednisone samples available that were also studied. Statistical analyses were adjusted for age, sex, and multiple comparisons. Biomarkers that distinguished IgG4-RD were studied by receiver operating characteristic curves, hierarchical clustering, and linear regression. Flow cytometry was performed in a subset of patients to quantify activated $CD4^+$ T cells, activated B cell subsets, and plasmablasts.

Results: A cassette of 20 inflammation-associated proteins was identified that distinguished IgG4-RD from healthy donors **(Figures 1A-B)**. Among these, CCL19, CCL2, CCL13, and CXCL11 were the most accurate and non-redundant in defining IgG4-RD showing a composite area under the curve of 0.811**(Figure 1C)**. CCL19, CCL2 and CCL13 increased

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

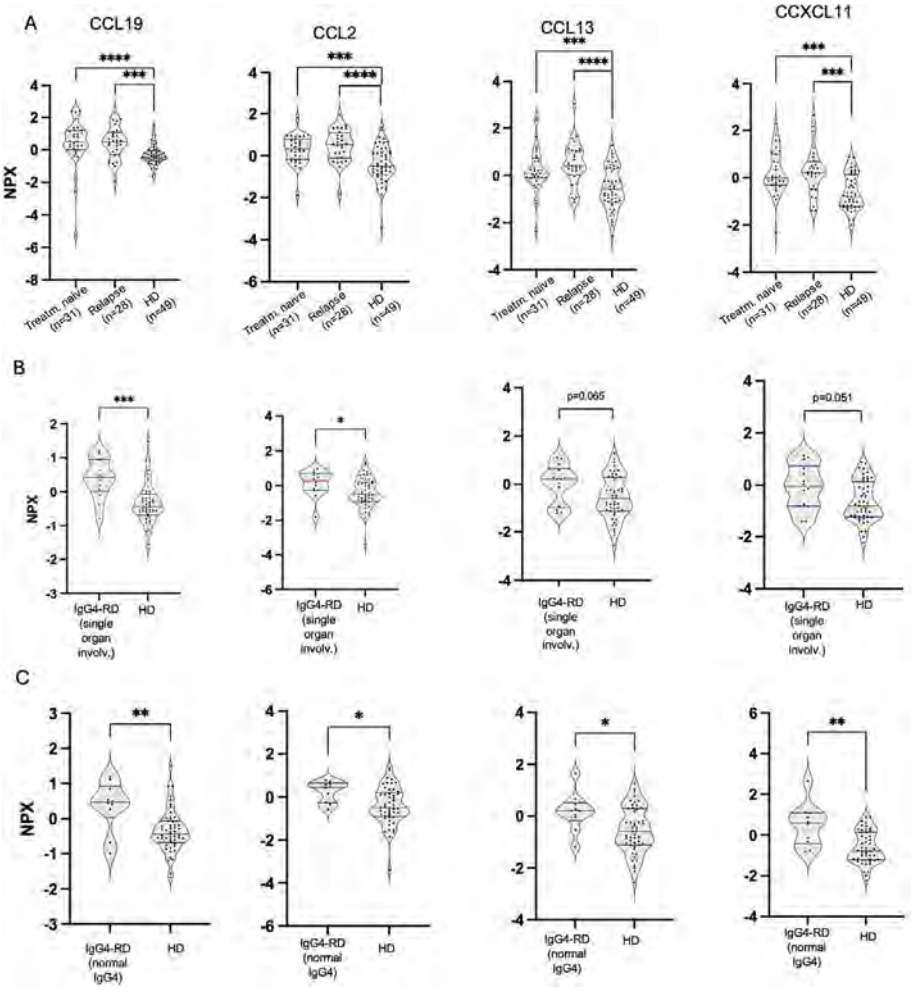

Figure 3. CCL19, CCL2, CCL13, CXCL11 may provide utility in difficult to monitor cases. (A) Dot and violin plots displaying individual normalized protein expression (NPX) values for the CCL19, CCL2, CCL13, and CXCL11 comparing treatment naïve and relapsing cohorts with healthy donors (HD). (B) Dot and violin plots displaying individual NPX values for the CCL19, CCL2, CCL13, and CXCL11 comparing IgG4-RD patients with single organ involvement (n=14) vs. HD. (C) Dot and violin plots displaying individual NPX values for the CCL19, CCL2, CCL13, and CXCL11 comparing IgG4-RD patients with normal serum IgG4 values (4-86mg/dl) (n=10) vs. healthy donors (HD). Blue lines represent interquartile range and red line represents median; p values computed by Mann-Whitney U test. Symbols: * p ≤0.05, ** p≤ 0.01, *** p≤0.001, **** p≤0.0001.

distinguished IgG4-RD from sarcoidosis whereas CXCL11 did not **(Figure 1D)**. These four biomarkers correlated with disease severity based on number of organs involved and clinical laboratory parameters of disease activity, including serum IgG4, IgE, absolute eosinophil count, and complement proteins C3 and C4 **(Figure 2)**. Furthermore, these four biomarkers showed the capacity to predict underlying states of $CD4^+$ T cell and B cell activation based on correlations with flow cytometry data. CCL19, CCL2, and CCL13 showed trends of decline following treatment with prednisone suggesting dynamic changes in response to immunosuppressive therapy and values declining in conjunction with remission. CCL19 and CCL2 were able to distinguish IgG4-RD patients with relapsing disease, single organ involvement, and normal baseline serum IgG4 levels from healthy donors **(Figure 3)**, suggesting promise in the clinical utility of these biomarkers.

Conclusion: CCL19, CCL2, CCL13, and CXCL11 are markedly upregulated in IgG4-RD. CCL19 and CCL2 may be particularly impactful in the longitudinal monitoring of disease activity while CCL19, CCL2, and CCL13 may also distinguish IgG4-RD from the mimicking condition sarcoidosis. Additional studies comparing other IgG4-RD mimickers and paired longitudinal samples are needed.

Abstract Number: 2531

Coronary periarteritis in IgG4-Related Disease

Georges El Hasbani[1], Daniel Larson[2], Matthew Koster[1] and Kenneth Warrington[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is characterized by chronic inflammation and fibrosis, which can affect multiple organs, especially the pancreas, salivary glands, and retroperitoneum (1). It may lead to periaortitis, affecting up to 20% of patients, and in rare cases, coronary periarteritis, which can cause severe complications like myocardial infarction (2). This case series aims to explore the clinical and radiological features of coronary periarteritis in IgG4-RD and discuss complications and treatment options.

1. Stone JH, Zen Y, Deshpande V. IgG4-related disease. N Engl J Med. 2012;366(6):539-51.

2. Katz G, Hedgire SH, Stone JR, Perez-Espina S, Fernandes A, Perugino CA, et al. IgG4-related disease as a variable-vessel vasculitis: A case series of 13 patients with medium-sized coronary artery involvement. Semin Arthritis Rheum. 2023;60:152184.

Methods: A review of the electronic health records was conducted using keywords related to IgG4-RD and coronary involvement. Out of 146 patients reviewed, 9 patients had confirmed IgG4-RD with coronary involvement. Data extracted included diagnosis date, serum IgG4 and C-reactive protein levels, imaging findings, cardiac complications, and treatment details.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. CT cardiac demonstrating thickening of the wall of the right coronary artery. H&E, pelvic lymph node biopsy with plasmacytosis. IgG shows most plasma cells express IgG. IgG4 shows 30-40% of plasma cells are IgG4-postive, with over 100/hpf.

Results: All 9 patients were male, with a mean age of 55.5 ± 5.7 years at diagnosis. The mean serum IgG-4 level was 738 ± 1280 mg/dL, while the mean C-reactive protein value was 39.9 ± 54.8 mg/L. The average time between diagnosis of IgG4-RD and coronary involvement was 2 years and 6 months. A tissue biopsy showed IgG4-positive plasma cells in all cases. Coronary artery involvement was primarily detected through CT angiography, showing thickening of vessel walls (Table) . The right coronary artery (RCA) was affected in 5 patients, the left anterior descending artery (LAD) in 4, and the left main coronary artery in 1. In 5 patients, the periarteritis involved the entire length of the coronary artery, and 1 patient had an aneurysm of the LAD. Regarding treatment, all patients received glucocorticoids, and 7 patients were additionally treated with rituximab (RTX). Two patients received RTX for induction only, while 4 patients had induction and maintenance RTX infusions. One patient developed ischemic heart disease, and one progressed to heart failure. Follow-up imaging showed partial or complete resolution of vessel thickening in 7 patients.

Conclusion: Coronary artery involvement in IgG4-RD is rare but significant, leading to periarteritis, and subsequently coronary aneurysm formation. The RCA and LAD appear to be most affected in this condition, with imaging techniques such as cardiac CT being effectively used as diagnostic tool. Rituximab has shown promising data in managing coronary involvement, though its use in this context remains limited, ultimately necessitating larger studies.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Temporal arteritis (TA) classically presents as a large-vessel vasculitis in older adults with cranial ischemic symptoms. However, in younger patients or in the presence of eosinophilia, alternative etiologies must be considered.

Methods: We conducted a retrospective, multicenter, descriptive study that included patients with 1) confirmed temporal arteritis, either by histologic confirmation or by the presence of typical clinical symptoms combined with imaging abnormalities, and 2) pretreatment blood eosinophilia >1000/mm^3. We also performed a literature review to identify additional cases of eosinophilia-associated temporal arteritis (EoTA). Finally, unsupervised hierarchical clustering was used to classify patients into subgroups to capture the full spectrum of EoTA.

Results: A total of 78 patients were included, i.e. 40 original cases and 38 from the literature review. The median age was 59 years [IQR 41.2-69.8] and 73% were male. The diagnosis of TA was based on histology in 85% of patients, while 33% also had imaging abnormalities.

Constitutional symptoms were reported in 63%, headache in 42%, TA induration in 29%, jaw claudication in 26%, and ocular ischemic events in 10%. Other manifestations included pulmonary (47%) and sinonasal (32%) involvement, and peripheral neuropathy (28%). Median eosinophil count was 3500/mm^3 [IQR 1800–7370], CRP was 28.8 mg/L [5.0–94.8], and 33% were ANCA positive, predominantly MPO-ANCA. Temporal artery biopsies showed eosinophilic and mononuclear cell infiltration in 69% and 53%, respectively, giant cells in 25%, and internal elastic lamina fragmentation in 40%.

Overall, 71% of patients met EGPA criteria, 53% met GCA criteria and 32% met both criteria according to the 2022 ACR/EULAR classification. In addition, 29% of patients were classified as hypereosinophilic syndrome (SHE).

First-line therapy consisted of glucocorticoids (GC) in 87%, in combination with immunosuppressive agent in 32% (conventional synthetic DMARDs in 18, biologic DMARDs in 5, eosinophil-targeting biologics in 4). At 6 months, 16 (27%) were in remission, 36 (61%) were GC-dependent, 2 (3%) were refractory, 5 (8.5%) had relapsed, while 19 (24%) did not reach the 6-month follow-up.

Cluster analysis identified four distinct groups. Cluster 1 (23%) included young men with isolated TA, low acute phase reactants, consistent with juvenile TA and Kimura disease, and had the highest remission rate (58%). Cluster 2 (32%) included middle-aged patients with systemic involvement, mainly cardiovascular, moderate CRP levels, consistent with HES, and showed frequent GC dependence (82%) and relapses (9%). Cluster 3 (15%) was characterized by older patients with typical features of GCA, with frequent GC dependence (78%). Cluster 4 (29%) included patients with sinonasal involvement, asthma and mononeuritis multiplex, high eosinophil counts and positive MPO-ANCA, consistent with EGPA and showed frequent GC dependence (82%).

Conclusion: Eosinophilia-related TA is a heterogeneous entity at the intersection of GCA, EGPA, HES, and localized TA. While systemic forms resemble EGPA or SHE, others, especially in younger patients, represent benign forms.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The systemic vasculitides are a family of rare diseases defined by immune-mediated inflammation and destruction of vasculature. Causal etiologies of most forms of vasculitis are unknown. Classification schemes to distinguish between forms of vasculitis typically rely on the clinical pattern of disease and do not incorporate biologic data about immune dysregulation. This study aimed to determine the relationship between tissue transcriptomics and clinical diagnoses by profiling skin lesions from patients with different types of vasculitis.

Methods: Patients with skin lesions attributed to one of nine pre-specified vasculitides were recruited into a multi-center prospective observational cohort. Bulk RNA was extracted from 4-6 mm punch biopsies of affected skin using a TRIzol-cholorform method (New England Biolabs Next Ultra II RNA library kit) and sequenced on a Nextseq 2000/NovaseqXPlus (Illumina).

Results: 70 patients underwent punch biopsies of vasculitic skin lesions. The cohort included patients with isolated cutaneous small-vessel vasculitis (CSVV) (n=18), IgA vasculitis (IgAV) (n=15), VEXAS (Vacuoles, E1-enzyme, X-linked, Autoinflammatory, Somatic) syndrome (n=10), granulomatosis with polyangiitis (GPA) (n=7), eosinophilic granulomatosis with polyangiitis (EGPA) (n=6), polyarteritis nodosa (PAN) (n=6), microscopic polyangiitis (MPA) (n=3), urticarial vasculitis (UV) (n=4), or cryoglobulinemic vasculitis (CryoV) (n=1) . The skin lesion morphology included purpuric macules (PM, n = 20), purpuric papules (PP, n=20), urticarial lesions (U, n=10), nodules (N, n=9), plaques (P, n=5), retiform purpura (RP, n=5), and one patient with unknown morphology. Plotting of principal component analysis eigen scores revealed that VEXAS

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

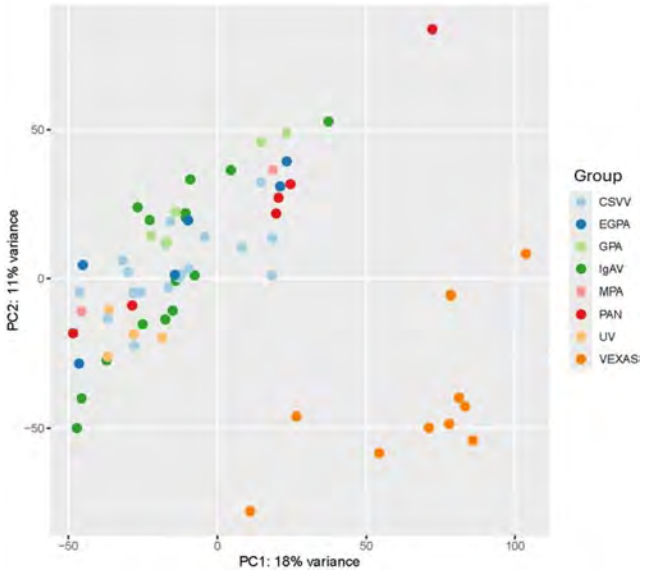

Figure 1: Principal component analysis grouping by type of vasculitis. Patients with cryoglobulinemic vasculitis and outliers were excluded from this analysis. PC: Principal component. CSVV: isolated cutaneous small-vessel vasculitis (n=18), EGPA: eosinophilic granulomatosis with polyangiitis (n=6), GPA: granulomatosis with polyangiitis (n=7), IgAV: IgA vasculitis (n=15), MPA: microscopic polyangiitis (n=3), PAN: polyarteritis nodosa (n=6), UV: urticarial vasculitis (n=4), and VEXAS: Vacuoles, E1-enzyme, X-linked, Autoinflammatory, Somatic syndrome (n=10).

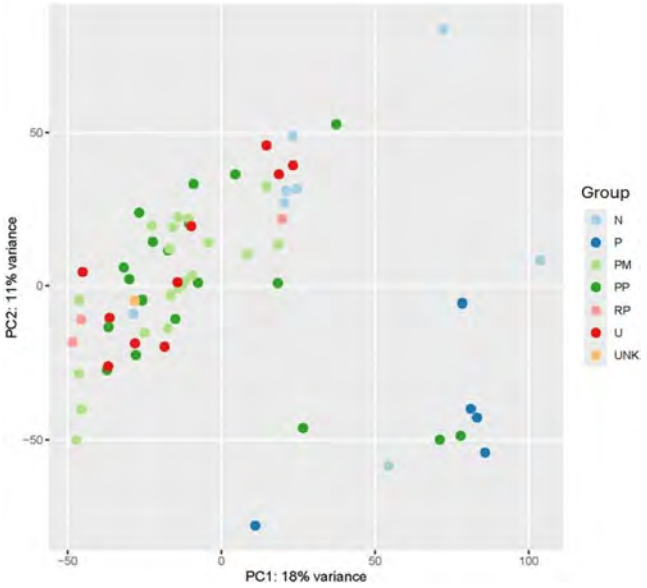

Figure 2: Principal component analysis grouping by skin lesion morphology among patients with skin manifestations of vasculitis. Patients with cryoglobulinemic vasculitis and outliers were excluded from this analysis. PC: Principal component. N: nodules (n=9), P: plaques (n=5), PM: purpuric macules (n = 20), PP: purpuric papules (n=20), RP: retiform purpura (n=5), U: urticarial lesions (n=10), and UNK: unknown (n=1).

samples clustered independently from the other forms of vasculitis in this cohort (**Figure 1**). There was no clear clustering based on skin morphology (**Figure 2**). Differential gene expression analysis revealed a substantial number of significantly differentially expressed genes (DEGs) between VEXAS and the other forms of vasculitis. Gene Ontology enrichment analysis identified a relative upregulation of interferon response genes in VEXAS. The top DEGs that defined this upregulation of the interferon pathway in VEXAS relative to the other forms of vasculitis were *XAF1* (log2 fold change = 4.132), *ISG15* (log2 fold change = 3.494), and *IFIT3* (log2 fold change = 3.453).

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: Direct profiling of affected tissue across different forms of vasculitis reveals shared and divergent pathophysiology. For example, tissue transcriptomics confirm that VEXAS has a strong interferon signature relative to other types of vasculitis. Clinical assessment of morphology without incorporation of biological data about immune dysregulation misses critical information. Our data supports that future classification schema for systemic vasculitides would benefit from the incorporation of biologic data with clinical features for the characterization of disease. This has the potential to lead to novel and personalized approaches to treatment.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: The associations of HLA-B51 and HLA-A26 with the onset of Behçet's disease (BD) are well established. Although BD manifests with a variety of clinical lesions, the relationships between specific HLA types and individual disease manifestations—especially HLA types beyond B51 and A26—remain unclear.

This study aimed to investigate the associations between HLA-A and HLA-B alleles and clinical lesions in Japanese patients with BD.

Table 1. HLA-A type of study participants.

HLA-A type	BD N=36	HC N=5308	*p*-value
A1	2.8%	1.0%	0.3071
A2	38.9%	43.4%	0.6173
A11	16.7%	16.8%	1.0000
A24	58.3%	61.1%	0.7345
A25	2.8%	NA	NA
A26	44.4%	20.7%	0.0014*
A31	11.1%	17.6%	0.3844
A33	11.1%	14.5%	0.8114

P values were determined by Fisher's exact test.
*Data were considered significant at $p < 0.05$.
HLA: Human Leukocyte Antigen; BD: Behcet's disease; HC: healty control; NA: not available.

Table 2. HLA-B type of study participants.

HLA-B type	BD N=36	HC N=5308	*p*-value
B7	8.3%	10.6%	1.0000
B27	2.8%	0.8%	0.2531
B35	13.9%	15.5%	1.0000
B39	2.8%	7.0%	0.5134
B44	11.1%	13.3%	1.0000
B46	8.3%	9.6%	1.0000
B48	8.3%	5.6%	0.4531
B51	36.1%	17.6%	0.0074*
B52	16.7%	21.8%	0.5477
B54	16.7%	14.0%	0.6289
B56	5.6%	1.8%	0.1406
B60	5.6%	10.8%	0.4244
B61	36.1%	25.5%	0.1777
B62	8.3%	16.3%	0.2584
B70/71/72	5.6%	3.1%	0.3109
B75	5.6%	2.0%	0.1641

P values were determined by Fisher's exact test.
*Data were considered significant at $p < 0.05$.
HLA: Human Leukocyte Antigen; BD: Behcet's disease; HC: healty control; NA: not available.

Methods: This retrospective study included patients with BD who visited Kagawa University Hospital in 2024 and whose HLA-A and HLA-B types had been analyzed. All patients were ≥18 years and met the International Criteria for Behçet's Disease. The frequency of HLA-A and HLA-B alleles in BD patients was compared with that in healthy Japanese individuals.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Table 3. Comparison of demographic and disease characteristics between HLA-B61-positive and HLA-B61-negative patients with Behcet's disease.

	Total	HLA-B61 positive	HLA-B61 negative	*p*-value
N	36	13	23	NA
Age, year	44.3 ± 12.2	41.0 ± 9.7	46.1 ± 13.2	0.3226
Female, n(%)	27 (75.0)	8 (61.5)	19 (82.6)	0.2347
Disease duration, year	8.6 ± 7.7	9.9 ± 6.3	7.8 ± 8.4	0.1143
HLA-B51 positive, n(%)	13 (36.1)	3 (23.1)	10 (43.5)	0.2920
HLA-A26 positive, n(%)	16 (44.4)	6 (46.2)	10 (43.5)	1.0000
Major lesions ever observed				
Oral ulcer, n(%)	36 (100)	13 (100)	23 (100)	NA
Genital ulcer, n(%)	32 (88.9)	12 (92.3)	20 (87.0)	1.0000
Skin lesion, n(%)	30 (83.3)	13 (100)	17 (73.9)	0.0679
Erythema nodosum, n(%)	11 (30.6)	6 (46.2)	5 (21.7)	0.1525
Thrombophlebitis, n(%)	2 (5.6)	0 (0)	2 (8.7)	0.5254
Papulopustular skin lesions, n(%)	29 (80.6)	13 (100)	16 (69.6)	0.0343*
Arthritis, n(%)	27 (75.0)	9 (69.2)	18 (78.3)	0.6933
Ocular involvement, n(%)	13 (36.1)	8 (61.5)	5 (21.7)	0.0298*
Epididymitis, n(%)	2 (5.6)	1 (7.7)	1 (4.4)	1.0000
Gastrointestinal involvement, n(%)	5 (13.9)	4 (30.8)	1 (4.4)	0.0470*
Nervous system involvement, n(%)	6 (16.7)	2 (15.4)	4 (17.4)	1.0000
Vascular involvement, n(%)	1 (2.8)	0 (0)	1 (4.4)	1.0000

P values were determined by Mann–Whitney U test and Fisher's exact test.
*Data were considered significant at $p < 0.05$.
HLA: Human Leukocyte Antigen; NA: not applicable.

Additionally, the prevalence of specific BD manifestations was analyzed according to HLA alleles. Statistical analyses were performed using the Mann–Whitney U test and Fisher's exact test.

Results: A total of 36 patients were included (mean age 44.3 years; 75.0% female; mean disease duration 8.6 years). As previously reported, HLA-B51 and HLA-A26 were significantly more prevalent in BD patients than in healthy controls (36.1% vs. 17.6%, p = 0.0074; 44.4% vs. 20.7%, p = 0.0014, respectively). No significant differences were found for other HLA alleles.

Among BD patients, those with HLA-B61 had significantly higher frequencies of ocular and gastrointestinal involvement compared to those without HLA-B61 (61.5% vs. 21.7%, p = 0.0298; 30.8% vs. 4.4%, p = 0.0470, respectively). No significant differences in age, sex, or disease duration were observed between HLA-B61–positive and –negative groups. Additionally, patients with HLA-A2 were significantly less likely to present with arthritis (p = 0.0144).

Conclusion: While HLA-B61 has been previously linked to ankylosing spondylitis and Crohn's disease, this study suggests a novel association between HLA-B61 and ocular and gastrointestinal manifestations in Japanese patients with Behçet's disease. Further studies with larger cohorts are warranted to confirm these findings.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's syndrome (BS) is a chronic inflammatory disorder characterized by a heterogeneous clinical presentation, occurring primarily in young adults and very rarely in children and adolescents. In addition, there are few studies that compared childhood-onset BS (cBS) and adult-onset BS (aBS), especially in non-endemic regions. Therefore, the objectives of the present study were to evaluate demographic, clinical and therapeutic data in cBS and aBS.

Methods: Medical records of 344 patients [99 cBS (≤ 18 years-old) and 245 aBS] from three tertiary Brazilian Rheumatology centers were reviewed in order to compare clinical and therapeutic features. cBS and aBS were classified according to International Study Group and/or the International Criteria for Behçet's Disease.

Results: The median age at diagnosis was 11(0.5-17) years in cBS and 30(18-76) years in aBS. The median follow-up time was significantly reduced in cBS compared to aBD [7(0-23) vs. 10(0-27) years, p=0.014], with similar female sex in both groups (56% vs. 62%, p=0.14). Classification criteria were fulfilled in 82% of cBS and 100% of aBS patients. Fever (30% vs. 15%, p=0.002), gastrointestinal involvement (55% vs. 14%, p=0.003), and a family history of autoimmune diseases (22% vs. 16%, p=0.001) were significantly higher in cBS compared to aBS. In contrast, genital ulcers (67% vs. 81%, p=0.01), cutaneous lesions (47% vs. 68%, p=0.001), including pseudofolliculitis (34% vs. 53%, p=0.001) and erythema nodosum (24% vs. 36%, p=0.03), uveitis (32% vs. 44%, p=0.03), corticosteroids (68% vs. 88%, p< 0.001), azathioprine (56% vs. 70%, p=0.01), cyclosporine (9% vs. 22%, p=0.004), cyclophosphamide (19% vs. 34%, p=0.001), and intravenous immunoglobulin use (9% vs. 18%, p=0.03) were significantly lower in the former group. Frequencies of oral and cutaneous ulcers, articular or central nervous system involvement, retinal vasculitis, colchicine, mycophenolate mofetil, and methotrexate use were similar in both groups (p >0.05).

Conclusion: cBS was rarely observed in our non-endemic region, potentially due to under recognition, as it often presented with nonspecific symptoms such as fever and gastrointestinal involvement. The broader spectrum of symptoms in aBS patients might account for the more extensive use of immunosuppressive agents.

High Levels of Fatigue and Poor Sleep Quality in Behçet Disease: a Cross-sectional Study from a Non-endemic Area

Mateus Augusto Rangel Nunes, Carlos Teixeira, Laurie Kumano, Gabriela Gutierrez, Vitor Grotti, Ana Paula Toledo Del Rio, Ibsen Coimbra, Alisson Pugliesi and Zoraida Sachetto, UNICAMP, Campinas, Brazil

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet's disease (BD) is a chronic systemic inflammatory disease classified as a variable vessel vasculitis of unknown etiology. It is marked by recurrent oral and genital aphthous lesions, skin lesions, and potential involvement of ocular, articular, intestinal, neurological, and vascular systems. In endemic areas, fatigue is a common symptom in BD patients, often associated with sleep disorders and reduced quality of life. This study aimed to assess fatigue and sleep disorders in patients with BD from a non-endemic area and correlate these symptoms with sociodemographic features.

Methods: This cross-sectional study involved patients with BD from a tertiary university hospital, all patients met the International Study Group (ISG) and International Criteria for Behçet's Disease (ICBD). Patients consented to participate in the study and provided data on age, sex, and socio-demographic characteristics. Also, patients were categorized based on the presence of fatigue. Fatigue was assessed with FACIT-Fatigue score (FFS). Sleep quality was evaluated using the Pittsburgh Sleep Quality Index (PSQI). Statistical analyses included Fisher's exact test for categorical variables and Student's t-test for continuous variables, with significance set at $p < 0.05$.

Results: The study included 42 patients, 22 of whom were female (52.3%), with a mean age of 47.6±14.1 years, and a low predominance of the white race (52.4%). Mean FFS was 32.4±10.8 and PSQI 9.09±4.79. A significant inverse relationship was found between FFS and PSQI (Pearson $r = -0.470$; $p < 0.01$). Patients with higher body mass index presented more fatigue (p=0.005). There were no significant differences regarding sex, ethnicity, smoking history, alcohol use, physical activity or marital status. A high frequency of poor sleep quality was present in patients with fatigue (51.6%; p=0.016). Additionally, patients with fatigue presented higher scores in PSQI global score (p=0.001) and its subdomains such as sleep onset latency (p=0.026) and sleep duration (p=0.040).

Conclusion: This study shows a high frequency of fatigue and poor sleep quality in BD patients from a non-endemic region. Our findings underscore the importance of recognizing these factors, suggesting the need for a multidisciplinary therapeutic approach to enhance the overall well-being of BD patients.

Abstract Number: 2537

Variation in Treatment Approaches in IgA-Vasculitis Among Pediatricians and Pediatric rheumatologists: A Cross-Sectional International Survey

Merav Heshin Bekenstein[1], Tali Elbaz[2], Yael Illous[2] and Barak Kandell[3], [1]Tel Aviv Medical Center Israel, Binyamina, Tel Aviv, Israel, [2]School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv, Israel, [3]The Academic College of Tel Aviv-Yafo, Tel Aviv, Israel

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

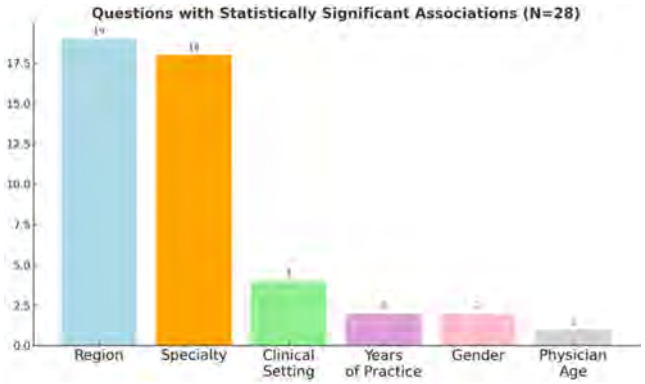
Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: IgA Vasculitis (IgAV) is the most common small-vessel vasculitis in children. Although there is no evidence-based recommendations for treating IgAV, the European SHARE recommendations published in 2019 provided international expert consensus for its treatment1. This study aims to explore the treatment and disease follow-up approaches in IgA Vasculitis among pediatricians and pediatric rheumatologists throughout the world, based on the disease presentation, including organ involvement and severity.

Methods: A 24-question electronic, cross sectional international survey was sent to pediatricians and pediatric rheumatologists through electronic platforms. Responses were anonymous and voluntary. Responses were analyzed for variability by geographic location, gender, experience, subspecialty and practice setting (hospital vs. clinic). 196 pediatricians were included in the analysis, of which 123 were pediatric rheumatologists.

Results: Geographic variability, gender, subspecialty, practice setting and clinical experience were all found to significantly affect the choice of treatment for HSP (Figure 1). Geographic location showed the greatest variability (Figure 2), followed by subspecialty (Figure 3). For example, in cases of severe gastrointestinal (GI) symptoms, the administration of high-dose Methylprednisolone IV at 30 mg/kg/day for three days, followed by tapering was more common in North America compared to Asia and Europe (p=0.043). For mild GI symptoms, pediatric rheumatologists were less likely to choose NSAIDs compared to general pediatricians (p=0.024) and preferred hydration and rest (p=0.024). Practice setting influenced treatment choices, with hospital-based physicians favoring IV steroids for severe GI and renal involvement more than clinic-based physicians (p=0.032). Gender was shown to have a limited impact, with minor differences noted in specific GI treatments. Clinical experience primarily affected steroid tapering duration, with more experienced physicians favoring shorter tapering periods (p=0.03).



The Statistically significant associations identified for each physician characteristic (out of 28 analyses). Geographic region (19/28) and medical specialization (18/28) showed the strongest effect on the treatment choices, while gender, experience, practice setting, and age had minimal impact.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Selected treatment questions demonstrating significant differences between geographic regions of the replying physicians. In cases of renal involvement, European physicians showed higher preference for ACE inhibitors/ARBs, while North American physicians preferred MMF and longer steroid tapering.

Selected treatment questions demonstrating significant differences between rheumatologists and general pediatricians. Rheumatologists reported higher use of ACE inhibitors/ARBs and MMF, along with a tendency toward longer steroid tapering.

Conclusion: To the best of our knowledge, this is the first international study to assess real-world treatment approaches to IgA vasculitis in children. The study reveals significant variability in the treatment preferences for IgAV, affected primarily by geographic location and subspecialty, with lesser contribution of clinical setting, years of practice and gender. These findings highlight the need to develop standardized, evidence-based clinical guidelines to the treatment approach for IgAV, in order to reduce variability and improve the care of children with IgA-Vasculitis.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet´s Disease (BD) was traditionally classified according to the International Study Group (ISG) in which oral ulcers were mandatory. International Team for the Revision of the International Criteria for BD (ITR-ICBD)are based on a scoring system. Our aim was to assess **a)** the sensitivity and **b)** the concordance between ISG and the ICDB criteria in global and severe ocular, vascular and neurological) BD.

Methods: Patients diagnosed with BD by expert rheumatologists in a well-defined population in Northern Spain between January 1980-November 2023 were studied. Both ISG and ICBD criteria were compared. Sensitivity and concordance were evaluated using two statistical methods: the Prevalence-Adjusted and Bias-Adjusted Kappa (PABAK), which accounts for the effects of prevalence and bias, and the unadjusted Cohen's Kappa coefficient.

Results: We studied 142 patients diagnosed with BD by expert rheumatologists (73 men, mean age: 36.4±13.9 years). Among them, 84 fulfilled the ISG criteria and 116 met the ICBD criteria, **figure 1** shows the overlap between expert diagnosis and the two classification systems. **a)** The sensitivity of the ISG and ICBD criteria in the overall cohort was 59.1% and 81.6%, respectively. Among patients with severe manifestations (ocular, vascular, or neurological), sensitivity increased to 71.2% for ISG and 92.5% for ICBD as shown in **figure 2**. **b)** The overall concordance between the two criteria was moderate, with a Kappa of 0.490 (95% CI: 0.356–0.623), and 70.4% of patients classified identically. When adjusting for prevalence and bias, concordance improved slightly (PABAK = 0.549). The highest agreement between classification criteria was observed when ocular involvement was deliberately added to all patients in the cohort (PABAK = 0.788; Kappa = 0.405), whereas the lowest agreement occurred when vascular involvement was added (PABAK = 0.338; Kappa = 0.216) (**figure 3**).

Conclusion: Sensitivity of the ICBD criteria was higher than the traditional ISG criteria in classifying BD, particularly in severe cases. Greater differences in concordance between both diagnostic criteria for BD were found when modifying the ocular involvement variable.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Worse health-related quality of life has been reported in individuals with polymyalgia rheumatica (PMR), yet the factors contributing to this burden – including the impact of glucocorticoids (GC) and GC-sparing agents – remain poorly understood. Longitudinal cohort studies incorporating patient-reported outcomes (PROs) can provide valuable insights to guide more patient-centered treatment. The objective of this study was to describe the baseline characteristics and PROs of patients in the ENRICH-PMR cohort, an ongoing longitudinal cohort of patients with PMR under rheumatology care.

Methods: A prospective cohort of patients with PMR was created within the Excellence Network in Rheumatology to Innovate Care and High-impact research (ENRICH), the largest US community-based, embedded, practice-based research network. Patients with a diagnosis of PMR routinely cared for in offices with access to a customizable in-office tablet app (I-PRO) deployed at routinely scheduled visits were invited to participate. The baseline I-PRO survey included information on date of diagnosis and current dose of GC use. Demographics, body mass index, and GC-sparing agent use was collected from electronic medical records. Comorbidities were identified using the RxRisk index, a validated medication-based measure of comorbidity.

PROs collected quarterly included 3 PROMIS measures: physical function, pain interference, and fatigue; PROMIS sleep and depression were collected annually. RAPID-3 was used to assess disease activity, and data on Patient Acceptable Symptom State (PASS) was collected to assess patients' perception of their health state. For this analysis, the most recent PROs available (i.e., closest to the time of enrollment) were included. Descriptive statistics were used to summarize the cohort and compare PROs by sex, using standardized mean differences (SMD) >0.10 to identify those that are likely clinically relevant.

Results: Between April and October 2024, 1,182 PMR patients completed the baseline survey. Most were female (64.8%), white (82.05), with mean (SD) age of 73.7 (9.1); nearly half were age ≥75. Over one-quarter (28.8%) were within two years of PMR diagnosis. The mean (SD) number of comorbidities was 7.8 (3.7). More than half (56.6%) were receiving GCs, and a majority (xx%) were on a GC-sparing agent, most commonly methotrexate.

Table 2. Current treatment in patients with PMR at time of inclusion in cohort (n=1182)	
Medication	N (%)
Glucocorticoids, any use	669 (56.6%)
Current glucocorticoid dose (mg/day) [among users]	
<2.5	174 (26.0%)
2.5 - <5	187 (28.0%)
5 - <7.5	151 (22.6%)
7.5 - <10	56 (8.4%)
10 - <15	63 (9.4%)
15 - <20	21 (3.1%)
≥20	17 (2.5%)
Conventional immunosuppressive medication	
Methotrexate	297 (24.2%)
Hydroxychloroquine	201 (16.4%)
Leflunomide	67 (5.5%)
Sulfasalazine	30 (2.4%)
Azathioprine	16 (1.3%)
Biologics	
Sarilumab	79 (6.4%)
Tocilizumab	58 (4.7%)
Rituximab	6 (0.5%)
Janus Kinase Inhibitors*	19 (1.6)
*Included tofacitinib and upadacitinib.	

Compared to males, female patients had a worse RAPID-3. Similarly, female patients reported lower physical function (41.3 (9.2) vs 44.9 (9.3), respectively) and greater pain interference (56.4 (9.2) vs 53.3 (8.3), respectively) as measured by PROMIS scores. This difference was clinically relevant based on SMDs >0.10. Overall, 37.0% of the cohort reported their current health state, as affected by PMR, to not be acceptable.

Conclusion: This baseline data from a large, prospective cohort of patients with PMR under rheumatology care shows that PMR patients experience a substantial impact of their disease across multiple PRO domains, and more than one-third express dissatisfaction with their current symptom state. Ongoing analyses will examine factors associated with worse PROs to inform more personalized PMR management strategies.

Table 3. Patient-reported outcomes by sex				
PRO (n)	All PMR patients, mean (SD)	Female, mean (SD)	Male, mean (SD)	SMD (95% CI)*
RAPID-3 (n = 1,182)	10.2 (6.3)	11.1 (6.2)	8.4 (6.1)	0.45 (0.33, 0.58)
Patient Global Scale (n = 1,182)	4.1 (2.6)	4.5 (2.6)	3.5 (2.6)	0.38 (0.26, 0.50)
PASS* (n = 1,182)	745 (63.0%)	467 (61.0%)	278 (66.8%)	-0.12 (-0.24, 0.00)
PROMIS domains**				
Physical function (n = 1,020)	42.6 (9.4)	41.3 (9.2)	44.9 (9.3)	-0.39 (-0.52, -0.26)
Pain interference (n = 508)	55.4 (9.0)	56.4 (9.2)	53.3 (8.3)	0.36 (0.17, 0.54)
Fatigue (n = 256)	50.5 (10.4)	52.0 (10.6)	47.7 (9.4)	0.43 (0.17, 0.69)
Depression (n = 1,117)	47.6 (9.5)	48.7 (9.8)	45.7 (8.5)	0.33 (0.20, 0.45)
Sleep Disturbance (n = 880)	50.2 (8.4)	50.9 (8.8)	49.0 (7.5)	0.23 (0.09, 0.37)

PASS = Patient acceptable symptom state; PROMIS = Patient-Reported Outcomes Measurement Information System; SMD = Standardized Mean Difference; CI = confidence interval
*SMDs > 0.10 indicate differences that are likely clinically relevant
** PROMIS domains are scored on a 1-100 scale and have mean of 50 and SD of 10. Scores within 5 units (i.e. ≥45 for PROMIS Physical function) and ≤55 for all other PROMIS domains, are considered normal.

Abstract Number: 2540

Monocyte-to-High-Density Lipoprotein Cholesterol Ratio as a Clinical Marker of Gastrointestinal Involvement in Behçet Syndrome

Hansun Song, **Seong-Ryul Kwon** and Mie Jin Lim, College of Medicine, Inha University, Incheon, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Behçet syndrome (BS) is a chronic multisystem vasculitis marked by recurrent mucocutaneous and ocular inflammation, and in a subset of patients, gastrointestinal (GI) involvement. Gastrointestinal BS (GIBS) is a clinically important phenotype due to its potential for severe morbidity and its diagnostic overlap with other inflammatory bowel disorders. Timely identification of GIBS remains a clinical challenge, often requiring invasive procedures such as colonoscopy. Thus, there is growing interest in identifying noninvasive biomarkers that can aid in risk stratification and guide diagnostic decision-making. The monocyte-to-high-density lipoprotein cholesterol ratio (MHR), reflecting both systemic inflammation and lipid-related oxidative stress, has emerged as a potential biomarker in several immune-mediated diseases. However, its utility in Behçet syndrome, particularly in detecting GI involvement, has not been established. This study aimed to evaluate the clinical significance of MHR in identifying gastrointestinal involvement in BS patients.

Table 1. Comparison of Inflammatory Parameters Between Behçet Syndrome Patients With and Without Gastrointestinal Involvement This table summarizes the results of independent t-tests comparing inflammatory markers between patients with gastrointestinal involvement (GI BS) and those without. Monocyte count and monocyte-to-high-density lipoprotein cholesterol ratio (MHR) were significantly higher in GI BS patients. HDL levels and monocyte percentage showed trends toward significance. Statistical significance was set at $p<0.05$. CI: confidence interval; HDL: high-density lipoprotein; MHR: monocyte-to-HDL ratio; WBC: white blood cell count.t-test results comparing GI BS and non-GI BS patients

GI BS	P-value	95% C.I	
WBC	0.113	-235.3	2154.83
Monocyte ratio in %	0.062	-0.045	1.81
Monocyte count	**0.011**	**25.06**	**180.73**
HDL	0.073	-14.4	0.66
MHR	**0.002**	**1.56**	**6.44**

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Methods: We retrospectively analyzed 2,074 patients with BS registered in the Clinical Data Warehouse of Inha University Hospital from January 1997 to December 2024. Diagnosis was based on the ISG (1990) and ICBD (2013) criteria. Patients were included if they underwent colonoscopy at or after diagnosis and had HDL cholesterol measured at a time point close to the colonoscopy. Exclusion criteria were infectious colitis, malignancies, or MHR data obtained outside the clinically relevant time window. MHR was calculated by dividing absolute monocyte count (/mm^3) by HDL cholesterol (mg/dL). Statistical analysis was performed using independent t-tests, with $p< 0.05$ considered significant.

Results: Among 86 eligible patients, 34 (39.5%) exhibited GI involvement. MHR was significantly higher in GIBS patients than in those without GI involvement (p=0.002, 95% CI: 1.56–6.44, Table1). Monocyte counts were also elevated in the GIBS group (p=0.011), particularly among males (p=0.021), while no significant difference was observed in females (p=0.081). HDL levels alone were not significantly different. These findings suggest that MHR, rather than its individual components, more accurately reflects the inflammatory burden associated with GI manifestations in BS.

Conclusion: MHR was associated with gastrointestinal involvement in Behcet syndrome patients. It can be utilized as a marker for identifying high-risk patient group in Behcet syndrome patients.

Elevated MHR is significantly associated with gastrointestinal involvement in Behçet syndrome and may serve as a clinically relevant, noninvasive marker for identifying high-risk patients. Given its accessibility, cost-effectiveness, and correlation with inflammatory burden, MHR may aid in early detection and risk-based decision-making in the management of GIBS. Validation in prospective studies could support its integration into clinical practice as a screening and monitoring tool.

Development of Severity Classification Criteria for Introduction of Infliximab for Chronic Pogressive Neuro-Behçet's Disease

Shunsei Hirohata[1], Hirotoshi Kikuchi[2], Tetsuji Sawada[3], Toshihiro Tono[4], Mitsuhiro Takeno[5] and Izumi Kawachi[6], [1]Nobuhara Clinic, Tokyo, Japan, [2]Teikyo University School of Medicine, 3-12-1 1308, Japan, [3]Tokyo Medical University, Tokyo, Japan, [4]Kitasato University School of Medicine, Kanagawa, Japan, [5]Nippon Medical School Musashi Kosugi Hospital, Kawasaki, Japan, [6]Niigata University Graduate School of Medicine and Dental Sciences and Niigata University Brain Institute, Niigata, Japan

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Chronic progressive neuro-Behçet's disease (CPNB) is characterized by progressive deterioration leading to disability and death. It has been appreciated that methotrexate (MTX) has beneficial effects for CPNB. Moreover, recent studies have demonstrated that infliximab (IFX) is effective for patients who had inadequate responses to MTX. However, it is unclear which patients should be treated and how, especially on the initiation of treatment. Thus, clinical markers of the severity would be helpful for decisions on treatment strategies. We therefore tried to determine severity classification criteria for introduction of IFX in patients with CPNB.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

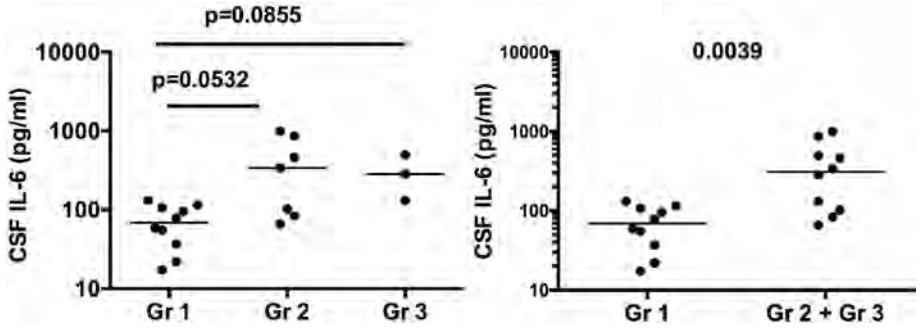

Figure 1 CSF IL-6 in 3 provisional severity groups.

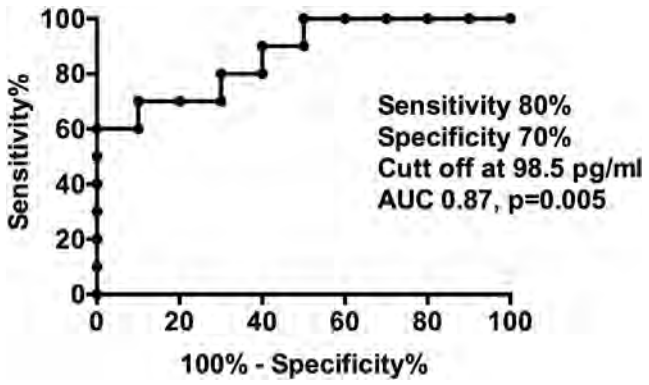

Figure 2 ROC analysis for CSF IL-6 between Gr 1 and combined Gr 2 + Gr 3.

Methods: Twenty-six patients with CPNB (19 males, 7 females, ages 47.7±15.6 years [mean±SD]), who had been collected in a multicenter study by the Japanese Research Committee from 2011 to 2013, were followed up for 6-216 months (median 93.0 months). The provisional severity levels were retrospectively determined according to treatment regimens and responses of the patients, such as - Group (Gr)1: no progression with MTX alone, Gr 2: no progression with combined MTX and IFX, Gr 3: progression even with combination of MTX and IFX. Cerebrospinal fluid (CSF) IL-6 levels and brain MRI findings before starting treatment, and progressions of neurobehavior manifestations after treatment were evaluated. The relationship between these parameters and provisional severity levels was examined retrospectively. Based on the results, new severity criteria were established.

Results: CSF IL-6 was significantly lower in Gr 1 than in combined Gr 2+ Gr 3 (p=0.0039), despite no significant difference among the 3 groups (**Figure 1**). ROC analysis disclosed that a cut-off of 98.5 pg/ml of CSF IL-6 discriminated between Gr 1 and combined Gr 2+ Gr 3 with 80% sensitivity and 70% specificity (AUC 0.87, p=0.005) (**Figure 2**). On the other hand, 3 patients among the 26 patients lacked brainstem atrophy on MRI, in whom no progression of symptoms was observed. Thus, the severity of CPNBD (stage 1-3) was formulated according to the presence of brainstem atrophy and the elevation CSF IL-6 over 99.0 pg/ml (**Table**). The higher stage tended to be associated with the progression in the 26 patients (p=0.0925).

Table Suggested severity criteria for CPNBD

Stage 1: brainstem atrophy (-)
Stage 2: brainstem atrophy (+) and CSF IL-6 below 99.0 pg/ml
Stage 3: brainstem atrophy (+) and CSF IL-6 over 99.0 pg/ml

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The severity classification criteria for CPNB, developed based on the presence of brainstem atrophy and the elevation of CSF IL-6 (over 99.0 pg/ml), were considered useful in determining treatment strategy. Thus, MTX alone would be recommended in stage 1, whereas combination of MTX and IFX should be considered in Stage 3. As for patients in stage 2, IFX should be considered for patients with persistent CSF IL-6 over 99.0 pg/ml despite increased doses of MTX.

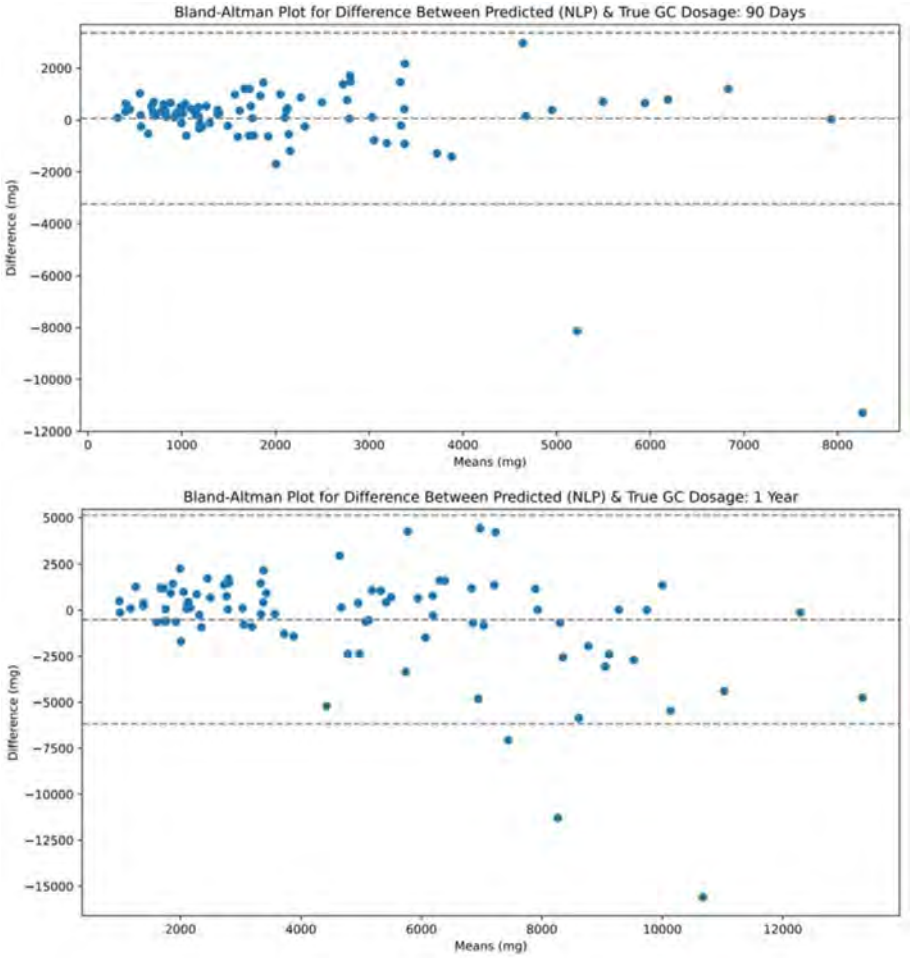

Figure 2 - Bland Altman Plot of NLP model vs physician-extracted data at 3 months and 1 year

Figure 2 - Bland Altman Plot of NLP model vs physician-extracted data at 3 months and 1 year

Background/Purpose: Glucocorticoids (GCs) are essential for managing giant cell arteritis (GCA) and polymyalgia rheumatica (PMR), but prolonged use poses risk due to cumulative dosing and side effects. (1) Accurate tracking of GC exposure is vital, yet electronic medical record (EMR) documentation is often inconsistent. (2) A meta-analysis of 25 studies found that the mean cumulative GC dose over one year was up to 5600 mg for PMR and 8200 mg for GCA patients. (3) We propose a natural language processing (NLP) tool to standardize GC data extraction from EMRs, an advancement over prior tools to improve care and research. (4)

Methods: Patients > 50 years of age with an ICD code for GCA or PMR were identified. Individuals without prescription GC coverage for > 75% of the first year, defined as 365 days following the initial ICD code entry, were excluded. A rule-based NLP model was created using EMR data to calculate systemic prednisone and methylprednisolone doses over time. Methylprednisolone doses were transitioned into prednisone equivalent doses at a 4:5 ratio. A validation cohort of 89 patients was created where a clinician performed chart review and documented dosage changes over time. Cumulative GC dose was estimated at 3 months and 12 months and model error recorded. The model was then applied to the entire cohort to record the average 90 day and 1-year cumulative GC dose.

Results: 956 patients met inclusion criteria. Of these, 714 had isolated PMR and 242 had GCA. 89 patients (45 GCA and 44 isolated PMR) were included for comparison of the model to physician-extracted data. The NLP-driven model compared to EMR data extracted by a physician revealed a mean relative error rate of 0.25% and 3.93% at 3 and 12 months for isolated PMR, respectively, with rates of 11.89% and 18.55% for GCA (**Figure 1)**. Bland-Altman plots in **Figure 2** showed

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 3 - Cumulative dose of entire GCA and PMR cohorts at 3 and 12 months.

low systemic bias (90 day mean difference 61.0, 95% CI -295.4 to 417.47; 1 year mean difference -512.1, 95% -1119.1 to 94.8). The mean cumulative full cohort dose is described in **Figure 3**.

Conclusion: The mean 1-year cumulative GC doses observed in our cohort for GCA and PMR are consistent with previous studies. An NLP-based model is a valid approach for estimating GC exposure over time. This can have relevance in large datasets and EMR's where GC doses have been difficult to calculate.

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: There is consensus that the visual prognosis in Behçet syndrome (BS) uveitis has considerably improved in time (1-3). We wanted to better quantitate this impression. To tabulate the prognosis of Behçet syndrome uveitis in the previous four decades in a dedicated BS outpatient clinic by utilizing a severe and irreversible visual acuity impairment definition as the main outcome measure.

Methods: Medical records of 9289 BS patients registered between the years 1976 and 2019 were screened for the presence of uveitis and severe visual impairment (SVI). SVI was defined as an irreversible visual acuity of ≤20/200 for at least 3 months. A standard form was used for retrieving data on demographics, clinical features, visual acuity, and treatments. Records with no or inadequate data (n=527) were excluded. The remaining 8762 patients were analyzed in 4 different time

Table 1. Visual outcome in male patients with Behçet uveitis

	GROUP 1 (1972-1989)	GROUP 2 (1990- 1999)	GROUP 3 (2000-2009)	GROUP 4 (2010-2019)
Number of BS patients	778	1518	1830	1152
Patients with uveitis, n/N (%)	524/778 (67.4)	819/1518 (54)	970/1830 (53)	630/1152 (54.7)
Number of patients without uveitis at registration	3/524	3/819	1/970	0/630
Patients with bilateral SVI at registration n/N (%)	50/524 (9.5)	59/819 (7.2)	43/970 (4.4)	24/630 (3.8)
Patients with initial unilateral SVI who developed bilateral SVI during follow up, n/N (%)	30/474 (6.3)	34/760 (4.5)	14/927 (1.5)	5/606 (0.8)

Patients without SVI in either eye who developed bilateral SVI during follow-up, n/N (%)	2/229 (0.9)	2/316 (0.6)	1/527 (0.2)	1/362 (0.3)
*at first year, n/N (%)**	*1*	*0*	*0*	*0*
*at third year, n/N (%)***	*1*	*0*	*0*	*0*

All percentages were calculated among the patients without initial bilateral SVI
* Patients who were followed for less than a year were excluded from the analysis ** Patients who were followed for less than 3 years were excluded from the analysis

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

periods according to the first registration year (G1:< 1990, G2: 1990- 1999, G3:2000-2009, G4:2010-2019). Men and women were analyzed separately.

Results: A total of 4409/8762 (50.3%) BS patients had uveitis during their disease course, and 776 /4409 (17.6%) of whom had SVI in either or both eyes. Among the patients who had SVI, 767 had uveitis at the time of the registration, as shown in Tables 1 and 2. They show that males had more frequent and severe uveitis in all time periods. Since there were a relatively small number of female patients with SVI, the results were formally analyzed only for males. The frequency of SVI decreased in time. This was true both among the patients with no SVI in either eye at the time of registration or the development of the presence of SVI only in one eye at the time of registration. Of particular note is that this decrease was considerably more pronounced among the male BS uveitis patients initially with no SVI, as seen in Table 1. In men, the proportion of patients progressing from unilateral to bilateral SVI was higher in the before-2000 group (64/199, 32%) compared to the after-2000 group (19/118, 16%) [$\chi^2 = 9.8$, $p = 0.002$]. Azathioprine was the most frequently used immunosuppressive, with 46% in G1 and 80-89% among the G2-4 patients. Similarly, no patients had used a-TNF agents in G1, 3 patients in G2, 12% of the patients in G3, and 38% in G4.

Conclusion: These data further emphasize the strikingly different disease course of BS uveitis between males and females. They also confirm the contention that we can currently much more effectively manage BS uveitis. We propose that the SVI definition we use strongly reflects better medical management rather than a milder natural disease course at recent times. This is supported by the more pronounced decrease in the frequency of bilateral SVI over time among BS uveitis patients who initially had no SVI, compared to those with unilateral SVI at the time of their registration in our clinic. Finally, our observations also emphasize that formal drug trials in BS uveitis should either be conducted separately in either sex or include enough patients of either sex to allow a meaningful analysis of the trial outcomes.

Abstract Number: 2544

Diagnostic value of vein wall thickness measurement for patients with suspected Behçet syndrome

ruken Alcin Bayraktar[1], Yasemin Kayadibi[2], Aysenur Kahveci[2], **Sinem Nihal Esatoglu**[3], Ibrahim Adaletli[2], Yesim Ozguler[3], Melike Melikoglu[3] and Gulen Hatemi[3], [1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey, [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Radiology, Istanbul, Turkey, [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Several studies have demonstrated increased venous wall thickness (VWT) in patients with Behçet's syndrome (BS) compared to healthy and diseased control groups. Ultrasonographic measurement of VWT has been proposed as a potential diagnostic tool to differentiate BS from other diseases. However, the diagnostic utility of this method remains controversial. An optimal approach to evaluate the diagnostic value of VWT measurement would be to perform

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Median (Q1-Q3) right CFVWT, mm	0.59 (0.53-0.69)	0.57 (0.50-0.66)	0.76 (0.63-0.87)	0.49 (0.47-0.53)
Median (Q1-Q3) left CFVWT, mm	0.60 (0.50-0.68)	0.57(0.49-0.67)	0.71 (0.62 -0.86)	0.48 (0.43 -0.50)

BS: Behçet's syndrome; BMI: Body mass index; CFVWT: Common femoral vein wall thickness; DVT: Deep vein thrombosis; PPL: Papulopustular lesions; Q1-Q3: First-third quartile, SD: Standard deviation

Doppler ultrasonography in patients referred for screening with a suspicion of BS, and determining the sensitivity and specificity based on the measurements of those who are and who are not diagnosed with BS after a multidisciplinary diagnostic work-up.

Methods: All individuals who presented to our clinic for BS screening between May 2023 and December 2023 were included. Additionally, 30 patients with vascular BS and deep vein thrombosis (DVT) and 36 healthy individuals were also enrolled. Two radiologists, blinded to the clinical diagnoses, independently measured the wall thickness of the common femoral vein (CFV), great saphenous vein (GSV), and small saphenous vein (SSV). Results were presented as medians and interquartile ranges, and intergroup comparisons were conducted using the Kruskal–Wallis test.

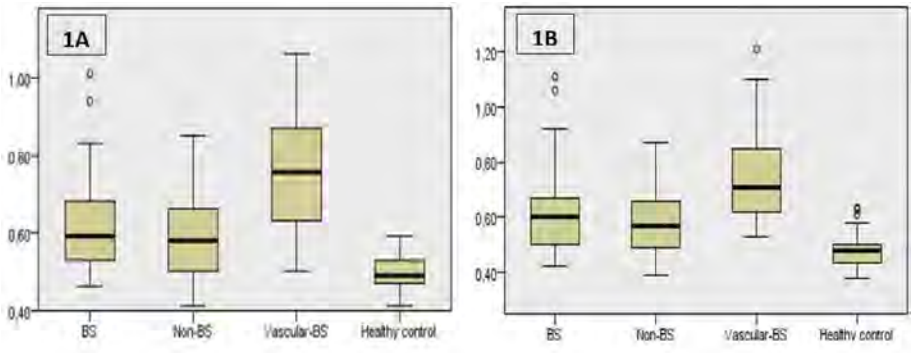

Figure 1. Right and left common femoral vein wall thickness across diagnostic groups

Right (1A) and left (1B) common femoral vein wall thickness in patients diagnosed with Behçet's syndrome after screening, patients diagnosed with non-BS inflammatory conditions, patients with vascular BS under follow-up, and healthy controls.

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: Among 84 screened individuals, BS was diagnosed in 45 patients, while 39 were found to have non-BS conditions. Lower extremity DVT was present in 5 of the BS patients and in 2 of the non-BS patients. The non-BS group were diagnosed with other conditions including spondyloarthritis, uveitis, inflammatory bowel disease, recurrent aphthous stomatitis, connective tissue diseases, systemic autoinflammatory disorders, and chronic thromboembolic pulmonary hypertension. Compared to other groups, healthy controls were younger, had lower body mass index (BMI), and were less frequently smokers. The highest median CFV thickness was observed in vascular BS patients [right: 0.76 mm (0.63–0.87), left: 0.71 mm (0.62–0.86)], followed by patients diagnosed with BS after screening [right: 0.59 mm (0.53–0.69), left: 0.60 mm (0.50–0.68)], non-BS patients diagnosed after screening [right: 0.58 mm (0.50–0.66), left: 0.57 mm (0.49–0.67)], and healthy controls [right: 0.49 mm (0.47–0.53), left: 0.48 mm (0.43–0.50)]. CFV thickness was significantly higher in vascular BS patients and significantly lower in healthy controls ($p < 0.001$ for all comparisons). However, there was no significant difference between BS and non-BS patients, and this pattern was consistent across other examined veins. This pattern remained unchanged after excluding the 7 patients with a history of lower extremity DVT. Inter-observer reliability between the radiologists was excellent (ICC for right CFV: 0.97; left CFV: 0.96).

Conclusion: Venous wall thickness was higher in both BS and non-BS patients compared to healthy individuals. However, VWT measurement did not aid in differentiating BS from other inflammatory diseases in patients referred for BS evaluation. The significantly increased VWT in vascular BS raises the question of whether this finding reflects vascular inflammation or vascular remodeling.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

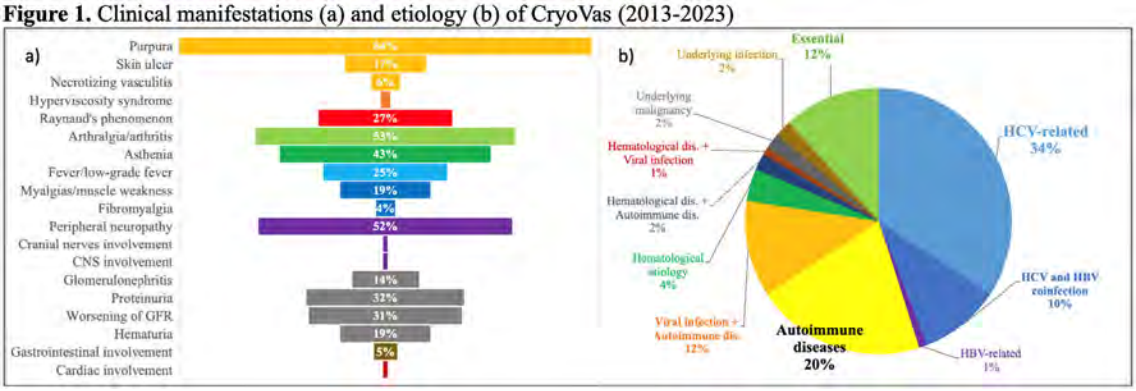
Session Time: 10:30AM–12:30PM

Background/Purpose: Cryoglobulinemic vasculitis (CryoVas) is a rare immune-complex-mediated disorder, often associated with hepatitis C virus (HCV) infection, autoimmune diseases (ADs), or other etiologies. Despite its clinical relevance, data on the prevalence and diagnostic yield of cryoglobulin testing remain scarce.

This study aims to evaluate the prevalence, clinical manifestations, outcomes, and underlying etiologies of CryoVas among patients with positive cryoglobulin tests over a 10-year period in a specialized laboratory.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Figure 1. Clinical manifestations (a) and etiology (b) of CryoVas (2013-2023)



Methods: We conducted a retrospective monocentric study analyzing all cryoglobulin tests performed in a specialized laboratory from 2013 to 2023. A total of 13,607 tests were performed, of which 1,593 (11.7%) yielded positive results, corresponding to 596 individual patients. Medical records were reviewed to confirm CryoVas diagnoses per classification criteria.

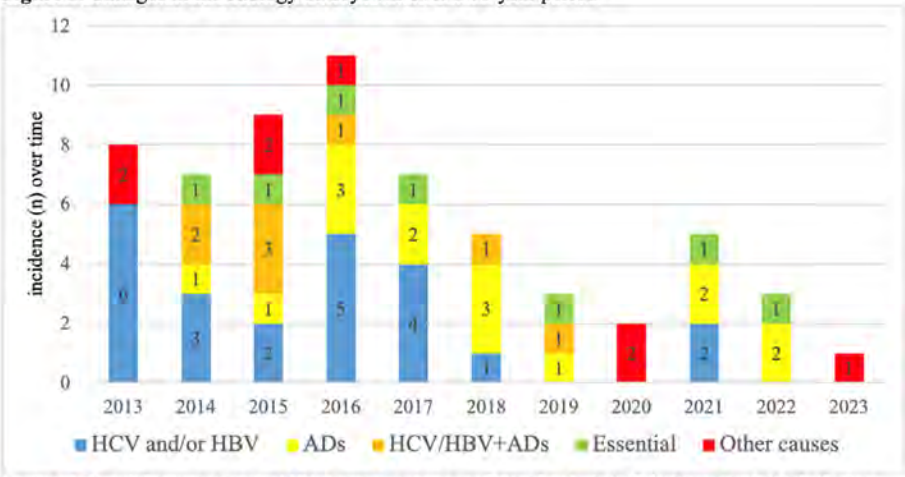
Results: Among 596 patients, 102 (17%) were diagnosed with CryoVas. Median age at onset was 65 years (IQR 56–73), with females comprising 65%. HCV-related CryoVas accounted for 34%, AD-related for 20% (mainly Sjögren's disease, 67%), and essential CryoVas for 12%.

CryoVas was diagnosed before 2013 in 40% of cases, 66% of whom had HCV/HBV. After 2017, with pan-genotypic HCV treatments, CryoVas incidence declined significantly (from 8.4 ± 1.7 to 3 ± 1.6 cases/year; ***p*=0.001**).

At onset of CryoVas, median BVASv3 was 6 (IQR 2–9). Type I CryoVas more often presented with ulcers, necrotizing vasculitis (***p*=0.001**), and hyperviscosity. Raynaud's was more frequent in AD-related CryoVas (***p*=0.025**). Glomerulonephritis and GI involvement were more common in essential CryoVas (***p*=0.011** and *p*=0.380, respectively). RF levels were higher in essential CryoVas (median 473 IU/L; ***p*=0.010**).

Two-thirds of AD-related CryoVas patients received Rituximab (RTX), while Belimumab (BEL) was used exclusively in AD-related and essential CryoVas.

Figure 2. Changes in the etiology of CryoVas over a 10-year period



Legend: ADs, autoimmune diseases; "Other causes" include malignancies, bacterial infections, hematologic diseases

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Over a median 7-year follow-up (IQR 3–11), relapse occurred in 71% of AD-related CryoVas vs. 42% of others (***p*=0.097**). Nearly one-quarter of AD-related patients were still on RTX at last follow-up. Although 94% achieved clinical remission, cryoglobulin clearance occurred in only 60%.

Conclusion: CryoVas remains a significant clinical condition, with its etiology progressively evolving in recent years.

Treatment approaches varied by etiology, with RTX serving as a cornerstone for CryoVas associated with ADs, while BEL demonstrated potential in select cases.

Despite advancements in treatment and high rate of complete clinical response, relapse rates remain high, particularly in autoimmune-related CryoVas. Additionally, cryoglobulin clearance was achieved in approximately 60% of patients during follow-up, reflecting a partial immunological response.

Session Title: (2524–2546) Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: IgG4-related disease (IgG4-RD) is a chronic immune-mediated fibroinflammatory condition characterized by fibrosis and organ damage. Although IgG4-RD is increasingly recognized, real-world clinical burden remains poorly understood. This study aims to characterize the US IgG4-RD population, their diagnostic journey, clinical characteristics, treatment patterns, and burden of illness.

Methods: Data were derived from the Adelphi IgG4-RD Disease Specific Programme (DSP)™, a cross-sectional survey of patients with IgG4-RD and their providers in the United States, collected from 2023 to 2024. Physicians provided data on patient demographics, symptomology, treatment and clinical outcomes. Patient reported outcomes (PROs) including, Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue, EuroQol 5-dimension 5-level (EQ-5D-5L), and Work Productivity and Activity Impairment (WPAI) were collected from patients.

Results: In total, 41 physicians returned data on 161 patients, and 27 patients completed surveys. Mean patient age was 55.4 ± 13.0 years, 62.1% were male and 71.4% were White (**Table 1)**.

Table 1 – Patient demographics

Patient age, years	n=161
Mean ± SD	55.4 ± 13.0
Patient sex, n (%)	n=161
Male	100 (62.1)
Ethnicity, n (%)	n=161
White	115 (71.4)
Other	46 (28.6)
Employment status, n (%)	n=156
Working full time	86 (55.1)
Not working due to retirement	28 (17.9)
Working part time	21 (13.5)
Other	21 (13.5)
Not working full-time due to IgG4-RD, n (%)	n=50
Yes	9 (18.0)

Mean age at symptom onset was 50.1 ± 13.2 years and time to diagnosis was 11.5 ± 21.8 months. Fatigue (41.6%), joint pain (23.0%), and weight loss (22.4%) were the most commonly reported symptoms at first consultation. The pancreas (31.7%), parotid glands (22.4%) and retroperitoneal fibrosis (19.3%) were the most commonly reported organ manifestations (**Table 2)**.

Primary care physicians (47.4%), gastroenterologists (20.4%) and rheumatologists (11.2%) were most commonly consulted about initial symptoms. Patients required a mean of 3.3 ± 2.0 consultations and providers, on average, used 13.4 ± 7.8 assessments to aid diagnosis. A different diagnosis than IgG4-RD was initially suspected for 90.2% of patients, most commonly conditions such as pancreatitis (15.4%), chronic fatigue syndrome (14.7%) and vasculitis (14.0%).

Treatment initiation was, on average, 8.9 ± 13.3 months following diagnosis. Rheumatologists (70.2%), gastroenterologists (41.0%) and primary care physicians (29.2%) primarily managed patients' treatment regimens. Prednisone was the most common first line therapy (66.3%), followed by rituximab (16.9%) and azathioprine (10.6%).

Table 2 – Patient diagnostic journey

Symptoms at first consultation, n (%)	n=161
Fatigue	67 (41.6)
Joint pain	37 (23.0)
Weight loss	36 (22.4)
Organ site manifestations at first consultation, n (%)	n=162
Pancreas	51 (31.7)
Parotid Glands	36 (22.4)
Retroperitoneal Fibrosis	31 (19.3)
Physician for first consultation	n=152
Primary care physician	72 (47.4)
Gastroenterologist	31 (20.4)
Rheumatologist	17 (11.2)
Physician making IgG4-RD diagnosis, n (%)	n=156
Rheumatologist	67 (42.9)
Gastroenterologist	55 (35.3)
Primary care physician	10 (6.4)
Ear, nose and throat specialist	7 (4.5)
Assessments conducted as part of IgG4-RD diagnosis, n (%)	n=161
Tissue Biopsy	142 (88.2)
Serum IgG4 levels	128 (79.5)
Physical examination	125 (77.6)
Computed tomography	119 (73.9)
C-reactive protein	111 (68.9)
Erythrocyte sedimentation rate	95 (59.0)
Serum IgG levels	88 (54.7)
Complete blood count	85 (52.8)

23265205, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 3- Patient-reported outcomes

FACIT Fatigue score (normal range ~40-45)	n=27
Mean ± SD	34.0 ± 13.7
EQ-5D-5L Score	n=27
Mean ± SD	0.8 ± 0.2
WPAI: Percent overall work impairment due to problem	n=14
Mean ± SD	20.1 ± 22.7
WPAI: Percent work time missed due to problem	n=15
Mean ± SD	10.9 ± 26.9
WPAI: Percent impairment while working due to problem	n=14
Mean ± SD	17.9 ± 18.9
WPAI: Percent activity impairment due to problem	n=27
Mean ± SD	34.1 ± 27.9

Hospitalizations due to IgG4-RD were reported for 14.3% of patients in the 12 months prior to the survey. Among those hospitalized, 68.4% were admitted via the emergency room. Patients reported impact to quality of life as characterized by PROs presented in **Table 3**.

Conclusion: Patients face delays in receiving a correct IgG4-RD diagnosis, with the diagnostic journey often involving multiple consultations and tests. IgG4-RD presents heterogeneously, and the majority of patients reported substantial burden of illness and impact to daily lives. Earlier clinical diagnosis and effective management may improve health outcomes and quality of life among patients with IgG4-RD.

Management of Uncontrolled Gout Among Rheumatologists: Findings from a Medical Chart Audit

Hyon K. Choi[1], Nana Kragh[2], Amod Athavale[3], **Bhavisha Desai**[4], Amal Gulaid[3], Abiola Oladapo[5], Brittany Smith[3] and Kenneth Saag[6], [1]MASSACHUSETTS GENERAL HOSPITAL, Lexington, MA, [2]Sobi, Kongens Lyngby, Denmark, [3]Trinity Life Sciences, Waltham, MA, [4]Sobi, Glastonbury, CT, [5]Sobi INC, Waltham, MA, [6]The University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Uncontrolled gout (UG) is defined by persistently high sUA levels, despite the use of oral urate lowering treatments (ULT), resulting in gout-related manifestations. Current ACR guidelines recommend a treat-to-target approach with routine sUA monitoring and a sUA goal of < 6mg/dL with the use of ULTs. The aim of this study was to assess current UG management, treatment practices and perceptions among rheumatologists.

Number of Years from Gout Diagnosis to Most Recent Visit	
Mean (SD)	6.3 years (5.9)
Number of Years on Most Recent ULT	
Mean (SD)	4.2 years (4.2)
sUA Level (Mean (SD))	
At initial gout diagnosis	9.2 mg/dL (1.3)
At initiation of most recent ULT	8.8 mg/dL (1.2)
Most Common Symptoms at Initial Gout Diagnosis (% of patients)	
Swollen joints	78%
Gout flares	76%
Visible tophi	75%
Joint pain	72%
Joint discomfort	69%
Most Common Symptoms at Initiation of Most Recent ULT (% of patients)	
Visible tophi	76%
Swollen joint	73%
Gout flares	67%
Joint pain	67%
Joint discomfort	61%

* UG is defined as the following: a) Inadequate control of symptoms and failure to normalize sUA with xanthine oxidase inhibitors, or where these drugs are contraindicated for the patient b) Serum uric acid (sUA) > 6 mg/dL c) A history of symptomatic gout (> 2 gout flares within 12 months, and/or presence of > 1 gout tophus, and/or current diagnosis of gouty arthritis)

Methods: A retrospective medical chart audit was conducted in the US from March to June 2024, via a web-enabled case report form, among board-certified rheumatologists with ≥3 years of clinical practice experience recruited via a panel. Respondents were required to have treated ≥25 patients with gout and ≥10 patients with UG in the last year. Data were abstracted from medical records of patients who met the following criteria: Diagnosed with UG, experienced gout related symptoms in the last year and have a sUA >6 mg/dL. Key variables included patient demographics, treatment history, adherence and healthcare resource utilization. Rheumatologists also completed an online survey related to their perceptions of UG management using a 1-7 Likert scale. Scores ≥6 indicates higher/strong level of satisfaction or agreement, while scores < 6 indicates the contrary.

Results: A total of 175 rheumatologists abstracted 409 records of patients with UG (**Table 1**). In the past year, on average (SD), physicians managed 149 (98) patients with gout, with 68 (39) classified as having UG. Most commonly reported comorbidities were renal impairment (71%), hypertension (47%) and obesity (36%). At most recent visit, most patients had visible tophi (90%; 39% considered very severe), gout flares (58%; 61% very severe), swollen joints (47%; 54% very severe), joint pain (47%; 48% very severe) and joint discomfort (47%; 49% very severe). Rheumatologists reported measuring sUA at every visit in a majority (90%) of their patients, with patients having on average (SD), 3.9 (2.6) routine visits in the past year. As

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Rationale for Treatment Selection

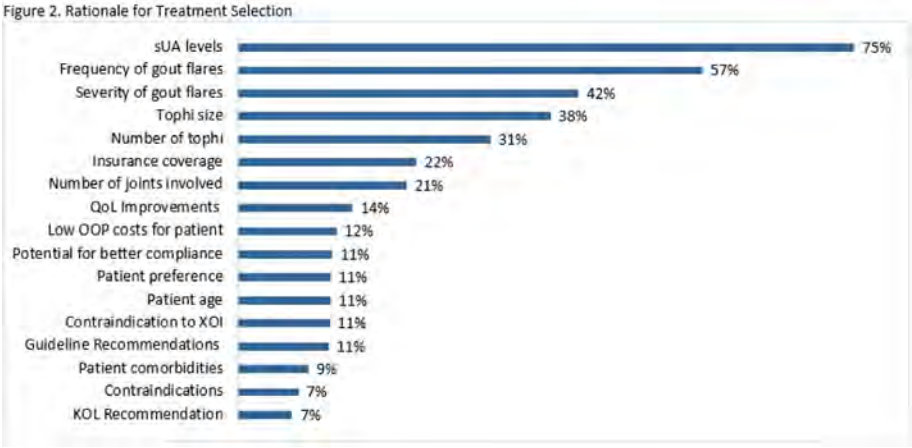

Figure 3. Rheumatologist Perceptions on Gout Treatment and Management
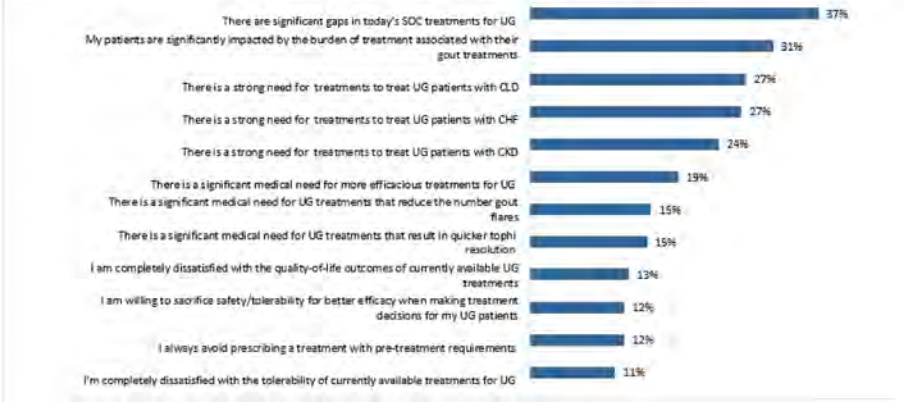
(% of HCPs that rated their level of agreement to the following statements as rated 6-7 on a scale from 1-7)



of the most recent visit, mean (SD) sUA level was 8.2 mg/dL (1.3). Clinical manifestations and sUA drive treatment choice, with treatments chosen due to sUA levels (75%), frequency of gout flares (57%) and severity of gout flares (42%) (**Figure 2**).

Patients with UG most recently received allopurinol (72%), with a median (IQR) dose of 300 mg/day (300-400) and 32% prescribed >300 mg/day. Other patients most recently received febuxostat (24%), colchicine (18%) and pegloticase (4%). Only 25% of patients were considered adherent (i.e., taking medication >75% of the time) with lack of compliance, most commonly attributed to forgetfulness (68%), lack of health literacy around medication (46%) or gout (35%). Rheumatologists were extremely satisfied with allopurinol in 60% of their patients, febuxostat in 50%, pegloticase in 22%. About 37% of rheumatologists indicated that unmet needs exist in current management of UG and 31% believed their patients are impacted by the burden of current gout treatments (**Figure 3**).

Conclusion: This study highlights the challenges rheumatologists face in managing UG and unmet needs in gout treatments as evidenced by high sUA levels, frequent flares and tophi presence and low adherence rates to current ULTs.

Abstract Number: 2550

Development of a 'Training Toolkit' to Support Advanced Practice Providers (APPs) Entry into a Rheumatology Musculoskeletal Ultrasound Subspecialty Clinic

Christopher Estes[1], Janeth Yinh[1], Mark Matza[2], Marcy Bolster[3] and Minna Kohler[4], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Newton, MA, [3]Massachusetts General Hospital, Concord, MA, [4]Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: The integration of advanced practice providers (APPs) into rheumatology practice may help address increasing demand and long wait times.[1] However, outcome data on APP involvement, particularly in procedural roles, remain limited. We report how ultrasound (US)-guided procedures performed by a newly hired APP in a high-volume, procedure-focused rheumatology musculoskeletal (MSKUS) clinic can enhance patient access to diagnostic and therapeutic interventions.

Methods: CPT codes for US-guided procedures performed by a newly hired APP were tracked over a 7-month period (8/2023–3/2024). Prior to this period, the APP had 1 year of experience performing palpation-guided injections and completed a rheumatologic MSKUS training program emphasizing procedural guidance. The APP performed over 100 US-guided procedures under direct supervision before transitioning to independent practice. Procedures included US-guided aspiration and/or corticosteroid injection. CPT codes were used to classify procedures sites with US-guidance: large joint/bursa (20611), intermediate joint/bursa (20606), small joint (20604), tendon sheath (20550), and carpal tunnel (20526). Data were analyzed by frequency and percentage of total procedures performed. Associated clinical diagnoses were also collected.

Results: Over the 7-month period, the APP performed a total of 284 US guided procedures during independently scheduled procedure clinics. Of these, 59% (n=167) were large joints/bursae, 11% (n=32) involved intermediate joints/bursae, 25% (n=70) were small joint injections, 2% (n=7) involved tendon sheaths, and 3% (n=8) were carpal tunnel injections (Fig. 1). Indications for procedures included joint effusion, synovitis, bursitis, tendinitis and carpal tunnel syndrome.

4. Hochberg M, Gravallese E, Smolen J, van der Heijde D, Weinblatt M, Weisman M. *Rheumatology*. 8th ed. Elsevier, Inc; 2023.

Underlying diagnoses among patients included inflammatory arthritis (rheumatoid arthritis, psoriatic arthritis, spondylarthritis), crystalline arthritis (gout, calcium pyrophosphate deposition disease), osteoarthritis, and mechanical overuse syndromes. Patient access improved to less than 2 weeks.

Conclusion: In an early implementation phase, the majority of US-guided procedures performed by a novice APP involved large joints (e.g. shoulders, hips, and knees) and small joints (e.g. MCP, MTP, PIP), with large joints comprising over half of all procedures. These findings guide referral planning and scope expectations for APPs new to a rheumatology MSKUS procedure clinic. Ongoing assessments will evaluate the evolution of procedure types and volumes over time as the APP gains experience, providing further insight into the scope and capacity of APPs in performing US-guided procedures within rheumatology practice demonstrating impact on rheumatology workforce expansion and patient access.

Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Point-Of-Care Ultrasound (POCUS) use among Advanced Practice Providers (APPs) is expanding across health care, yet formal rheumatology-specific POCUS training remains limited. Existing POCUS curricula for APPs in emergency medicine and critical care are not tailored to rheumatology needs[1,2]. The American College of Rheumatology Musculoskeletal Ultrasound Certification (RhMSUS)[3] is a recognized marker of competence, attainable by APPs, though

only two currently hold this designation4. We developed a rheumatologic POCUS curriculum to support APP integration into an outpatient rheumatology musculoskeletal ultrasound (MSKUS) clinic and patient care access expansion.

Methods: We developed a training program for a newly hired APP within a rheumatology MSKUS clinic at an academic center. In this model, the APP was precepted by 3 RhMSUS-certified rheumatologists, starting with clinical observation, progressing to supervised image acquisition, and MSKUS-guided procedures. Procedural competence progressed from large joints to small joints, then peri-articular structures. Protected time for the APP for both in-person and online POCUS education was included, supported by a Rheumatology Research Foundation workforce expansion grant, institutional funds, and APP personal funds. Competency was assessed through objective structured clinical examinations by supervisors and attainment of RhMSUS certification. APP clinics were limited to procedural applications and were conducted adjacent to supervising physicians' clinics for direct feedback.

Results: Together with general rheumatology training, MSKUS training was completed over eight months prior to launching independent APP clinics. The APP completed two 14-hour hands-on CME courses in rheum POCUS, attended MSKUS didactics and workshops alongside rheumatology fellows, accessed online, self-paced modules through the Ultrasound School of North American Rheumatologists (USSONAR), and reviewed MSKUS textbooks (Table 1). During this time, the APP had direct supervision of MSKUS-guided procedures in clinic. The APP achieved RhMSUS certification 10 months after starting independent practice, and 16 months after hire. Urgent patient access to the rheumatology MSKUS clinic improved to less than 2 weeks.

Conclusion: Integrating an APP into a rheumatology MSKUS practice can improve patient access and is supported by structured supervision, multimodal education, and educational funding. This framework offers a model for developing novice APPs into autonomous RhMSUS-certified rheumatology POCUS providers with procedural expertise.

Abstract Number: 2552

Effects of 360° Virtual Reality Embodiment Videos on Pain in Hand Osteoarthritis: A Within-Subject Pre-Post Study

David Vo[1], Robert Edwards[2] and Nancy Baker[3], [1]Tufts University, Huntington Beach, CA, [2]Brigham and Womens Hospital, Chestnut Hill, MA, [3]Tufts University, Medford, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is associated with chronic pain in the joints, which affects many individuals' daily function and quality of life. The sense of embodiment (SoE) is an illusory perception that an artificial body belongs to the real one and has been suggested to have analgesic effects for chronic pain (Baker et al, 2022). SoE can be facilitated through virtual reality (VR) and spherical video-based virtual reality (SVVR) (Serino et al., 2023). These studies suggest pre-recorded SVVR can be used as a non-pharmacological approach for pain modulation. This study evaluates the analgesic effects of

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Table 1. Participant changes in pain pre and post 5-minute SVVR intervention

		Mean(SD)	*p*	*r*
Pre-SVVR	NRS (Pre-SVVR)	1.9(1.5)		
Post-SVVR	NRS (During-SVVR)	1.0(1.2)	0.02	0.74
	NRS (Post-SVVR)	0.9(1.1)	0.01	0.80
	NRS (End-of-visit)	1.2(1.1)	0.16	0.44
	EQ	3.9(1.1)		
	IPQ	4.3(0.8)		

NRS= numeric rating scale for pain; EQ= embodiment questionnaire; IPQ= igroup presence questionnaire

embodiment-inducing SVVR in people with hand OA. We hypothesized that people with pain due to hand OA would have significantly reduced pain after SVVR.

Methods: We recruited 10 individuals with hand OA who completed the study in a single visit. We used a within-subjects pre-post design to evaluate the analgesics effects of a 5-minute SVVR intervention delivered through the Meta Quest 2 VR headset. Participants' subjective pain intensity ratings were recorded using a standard (0-10) numeric rating scale (NRS) before, during, and after the intervention. We measured the level of embodiment and presence the participants experienced from the SVVR using the Embodiment Questionnaire (EQ) and the Igroup Presence Questionnaire (IPQ).

Data analysis: We used a Wilcoxon Signed-Rank test to determine the significance of change scores. We calculated the effect size *r* with the following criteria: small 0.10-0.29; moderate 0.30-0.49; large ≥ 0.50.

Results: The SVVR significantly reduced pain intensity in people with hand OA during (p= .02; r= .82) and immediately following (p= .01; r= .90) the intervention with large effect sizes. Pain intensity was no longer significantly reduced (from baseline) at the end of the study visit (p= .16; r= 50). The SVVR was moderately effective in facilitating a sense of embodiment and presence in the participants (EQ= 3.9, IPQ= 4.3; out of a seven-point Likert scale). (See Table)

Conclusion: The SVVR intervention significantly reduced pain intensity in people with Hand OA during a single brief treatment. However, the acute analgesic effects were not sustained throughout of the full study visit, suggesting that additional (or longer) treatments might be required in order to maintain the reductions in pain. EQ and IPQ levels show moderate embodiment-inducing effects, suggesting that mechanisms such as distraction may be contributing to the intervention's pain-relieving effects.

Abstract Number: 2554

Real-World Observations on Symptom Response and Tolerability of Intravenous Immunoglobulin in Patients with Inflammatory Myopathies through a Nurse-Led Outcomes Monitoring Program in a Home Infusion Setting

Didem Saygin[1], **Elizabeth Neal**[2], Edward O'Bryan[3], Alisha Smith, PharmD[3], Leslie Myers[3] and Timothy Walton[3], [1]Rush University Medical Center, Chicago, IL, [2]CSI Pharmacy, Nash, TX, [3]CSI Pharmacy, Nash

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: (2547–2566) ARP Posters II

Session Type: Poster Session C

Session Time: 10:30AM–12:30PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are autoimmune diseases typically characterized by muscle weakness. Intravenous Immunoglobulin (IVIg) is an effective immunomodulatory therapy in patients with refractory IIM. However, data is limited regarding trajectory of patient reported symptom response and tolerability of IVIg among patients

Table 1. Baseline characteristics of the patients with IIM who receive IVIg through home infusion.

Variable	Patients with IIM (n =14)
Sex	
Female	8 (57%)
Male	6 (43%)

*5 out of 14 patients reported a side effect during their infusion

with IIM. This study aims to report the symptom change and treatment tolerance of IVIg naïve adults with IIM through implementation of a structured outcomes monitoring program within a home infusion and specialty pharmacy model.

Methods: As part of a proprietary clinical outcomes program, an IIM clinical care and patient-reported outcomes monitoring program was developed by a multidisciplinary team within a home infusion and specialty pharmacy organization. The patients with confirmed IIM diagnosis who were IVIg treatment naïve and had ≥2 IVIg infusions, were recruited between 5/2024 – 3/2025. The program integrated clinical safety assessments and structured collection of patient symptoms via Health Assessment Questionnaire (HAQ), Patient Global Disease Activity (PTGD), and Patient-Reported Outcomes Measurement Information System (PROMIS®) Physical Function (v2, 8b), Fatigue (v1, 7a), and Pain Interference (v1.1; 6a) and Brief Pain Inventory (BPI). Patients also responded to anchor questions regarding their symptoms. All data was collected

Figure 1. Change in patient reported outcome measures of patients with IIM at each IVIg infusion.

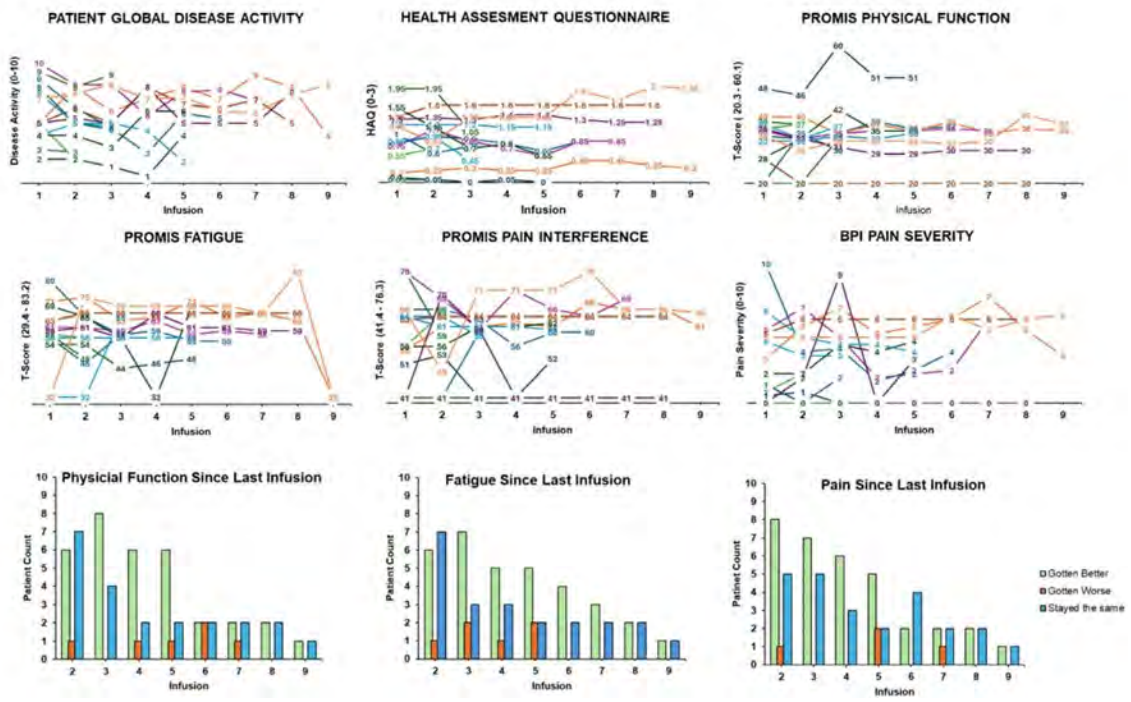

Figure 1. Change in patient reported outcome measures of patients with IIM at each IVIg infusion.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

by specialty pharmacy nurses prior to each IVIg infusion. Adverse drug reactions (ADRs) were identified through pharmacist-led patient interviews and review of nursing infusion documentation. Descriptive statistical analyses were conducted to summarize key findings.

Results: A total of 21 patients with IIM were enrolled in the program, of whom 14 (7 DM, 2 IMNM, and 5 PM; median age of 63 [47-49]) met the inclusion criteria and received their monthly IVIg infusions through a national home infusion service (**-Table 1**). Seventy-five infusion-related assessments were collected, with a mean 5 monthly IVIg infusions per patient (range 2-9). Baseline organ involvement of patients included muscle in 100% (n=14), joint in 57% (n=8), skin in 57% (n=8), and lung in 43% (n=6). One month after the 1st infusion, 6 patients (42.9%) reported improvement in their physical function and fatigue, 7 (50%) reported staying the same, and 1 reported worsening (7%) **(Figure 1)**. Most patients continued to report improvement at each infusion after 2nd, 3rd, and 4th infusions. Similar trends were observed for PTGD, pain intensity and interference. No severe ADRs were reported during the first 9 infusions. The most common side effect was headache (28.6%) and other mild side effects were within reported incidence rates **(Table 2)**.

Conclusion: This study demonstrated that IVIg-naïve IIM patients can be effectively monitored through a nurse-led, structured outcomes program which could represent a scalable approach for managing complex immunotherapy in decentralized environments. Approximately half of the patients reported improvement after one IVIg infusion. Symptomatic improvement and lack of serious adverse events suggest that the IVIg is well tolerated and may offer meaningful benefits to patients with IIM.

Abstract Number: 2558

Impact of Social Determinants of Health on Patient Perceptions of Home Infusion Therapy in the Treatment of Rheumatologic Conditions

Leslie Myers[1], Elizabeth Neal[2], Edward O'Bryan[1], Michele Way[3] and Timothy Walton[1], [1]CSI Pharmacy, Nash, [2]CSI Pharmacy, Nash, TX, [3]CSI Pharmacy, Olathe, KS

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Home infusion therapy is an established alternative site of care for patients requiring administration of infusion medications through a needle or catheter. Supported by clinically trained pharmacists and nurses, this model allows patients to receive therapy in their homes and has been associated with improved quality of life, reduced disruption to daily activities, and comparable clinical outcomes to traditional care settings. This study assessed patient perceptions of home infusion therapy, across diverse rheumatologic demographics, clinical status, race, level of education, and geographical location. The survey evaluated clinical experiences and Social Determinants of Health (SDoH) domains (e.g., financial impact, access to care, cultural sensitivity, emotional well-being, and safety).

Methods: A cross-sectional survey was conducted in a random 10% sample (N=300) of a national home infusion provider's patient population. From that sample, 24 rheumatologic patients completed the nurse-administered survey between April and July 2024. Inclusion criteria required active infusion under company-employed nurses. Patient conditions included

Myositis (N= 19), Myopathy (N =1), Lupus (N=1), Rheumatoid Arthritis (N=2), Sjögren's Syndrome (N=1). Survey responses were captured using Likert-scale and binary ("Yes/No") formats, with Likert-scale results summarized using median, interquartile range (IQR), and % of top anchor. The survey assessed accessibility, awareness, safety, financial impact, cultural awareness, mood improvement, and overall impression of home infusion therapy.

Results: The cohort included 83% females and 17% males, with a mean age of 54 (18-83). Immunoglobulin therapy represented 96% of patients and biologic therapies 4% (**Table 1**). Patients overwhelmingly perceived home infusion as cost- and timesaving (median = 10, IQR (1,3): 10,10), with 88% citing strong financial benefits. Accessibility barriers, such as transportation or caregiver availability, were noted by a minority. Patients reported high confidence in the safety of home infusions (median = 10, IQR (1,3): 10,10), and 83% found the therapy easy to access. Mood improvement was substantial when home infusion was compared to traveling to a hospital/infusion center for treatment (median = 10, IQR (1,3): 10,10), and 92% "very much so" felt home infusion positively impacted their emotional well-being. Cultural understanding by healthcare staff was rated variably; while 71% felt culturally understood, 29% did not. While 75% reported that home infusion "very much so" helped with the understanding of one's culture.

Table 2. Median Values and % of Top Anchor Reponses

Accessibility and Awareness	Median (IQR 1,3)	% of Top Response Anchor
Patient Difficulty to Afford Transportation to Infusion Therapy Outside of The Home 1 = Not Hard At All 10 = Very Hard	6 (2,10)	29
Patients Sureness Their Home Provided a Safe and Clean Environment for Infusion Therapy 1 = Not Sure 10 = Very Sure	10 (10,10)	92
Patients Sureness the Hospital/Infusion Center Was a Safe and Clean Place to Get Their Infusion Therapy 1 = Not Sure 10 = Very Sure	4 (1,6)	21
Patients Found it Easy to Receive Home Infusion Therapy When Needed 1 = Very Hard 10 = Very Easy	10 (10,10)	83
Financial and Time Impact	**Median (IQR 1,3)**	**% of Top Response Anchor**
Patients Felt the Option of Home Infusion Therapy Provided a Time and Cost Savings 1 = Not At All 10 = Yes A Lot	10 (10,10)	88
Patients Felt the Option of Home Infusion Therapy Helped Balance Their Work Schedule 1 = Not At All 10 = Yes A Lot	10 (10,10)	83
Patients Felt T heir Job, or Lack of One, Made it Difficult for Home Infusion Therapy 1 = Not At All 10 = Yes A Lot	3 (1,7)	21
Mood	**Median (IQR 1,3)**	**% of Top Response Anchor**
Patients Who Received Home Infusion Therapy Improved Their Mood When Compared to Traveling to a Hospital/Infusion Center for Treatment 1 = Not Really 10 = Very Much So	10(10,10)	92
Cultural Understanding	**Median (IQR 1,3)**	**% of Top Response Anchor**
Patients Felt Home Infusion Helped with the Understanding of a Their Culture 1 = Not Really 10 = Very Much So	10 (10,10)	75
Overall Perception Change of Home Infusion Therapy	**Median (IQR 1,3)**	**% of Top Response Anchor**
^ If Positive Perception Noted, Ranking of Perception Change 1 = Slightly Changed 10 = Greatly Changed	9 (8,10)	33

Median Values and % of Top Anchor Reponses

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Patients reported a strong preference for home infusion due to convenience and reduced exposure risk compared to infusion centers (**Figure 1 and Table 2**).

Conclusion: Home infusion therapy is highly valued by rheumatology patients, for its financial, work-life balance, mental health, and safety-related advantages. These findings support the need for broader adoption and education about home infusion as a patient-centered care model aligned with holistic health outcomes in rheumatologic patients.

Abstract Number: 2559

Increasing Clinical Trial Awareness in Sample of Underrepresented Systemic Lupus Erythematosus Patients

Leslie Ranken[1], Kyle Osborne[2], Robert Fairman[3], Gregory Russell[4], Sara Ohl[2] and Jessica Kearney-Bryan[5], [1]Atrium Health Carolinas Medical Center Wake Forest School of Medicine Charlotte, Charlotte, NC, [2]Atrium Health, Charlotte, NC, [3]Wellstar Health, Marietta, GA, [4]Wake Forest School of Medicine, Winston-Salem, NC, [5]Atrium Health Carolinas Medical Center, Charlotte, NC

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Underrepresented Systemic Lupus Erythematosus (SLE) patients are greatly underrepresented in SLE clinical trials. We aimed to increase clinical trial awareness with various interventions in our community practice with a small sample of patients.

Methods: The primary investigator's underrepresented SLE patients meeting ACR classification for the disease aged 18 and over were offered an electronic survey to assess their knowledge of clinical trials. They were given material about clinical trials and information from the Lupus Foundation and encouraged to contact them for support groups, etc. At year two, surveys were given to the same patients to see if they have increased knowledge of clinical trials in SLE, or to see if any of them have joined a clinical trial in the study period.

Results: At the end of year one, 86 patients filled out the demographics portion of the survey. Of these, 81% (n=70) % were Black, 14 % (n=12) were Hispanic/Latinx, 2% (n=2) were White, with 1% (n=1) Asian and 1% (n=1) not choose not to report race. Two (2%) of those 86 did not answer the questions regarding resources and could not be included; of those

Question	Baseline, N=58	Follow-up, N=58	*p* value*
1. Do you know that there are clinical trials for lupus patients?	27 (47%)	38 (66%)	**0.016**
If yes, do you know how to find them?	8/25 (32%)	18/36 (50%)	0.16
2. Have you ever been in a clinical trial for lupus?	2 (3%)	7 (12%)	0.096
3. If you qualified for a clinical trial for lupus, would you enroll?	30 (52%)	37 (64%)	0.090
4. Have you utilized the Lupus Foundation?	2 (3%)	5 (9%)	0.26

Survey Response Data

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

84, 58 (69%) completed a follow-up questionnaire. One had follow-up data but no baseline data. The 58 who provided data at both visits comprise the sample for analysis, as the goal was to compare baseline and follow-up responses to the same questions. Significant change was observed in the rate of awareness from baseline visit to the follow-up visit. Sixteen additional participants reported being aware of clinical trials at follow-up compared to baseline (while 5 changed from being aware at baseline to not at follow-up). This change is significant, p=0.016. As noted in the table, other areas (such as willingness to participate in a clinical trial if qualified to do so) also observed improved rates at follow-up, but no other changes were significant at the pre-established value of $p< 0.05$.

Conclusion: SLE is a serious chronic illness and clinical trials are necessary to get more drugs approved for treatment. Underrepresented populations are most severely affected, and yet there are barriers to clinical trial interest and entry. Our data showed that our intervention did increase clinical trial awareness in our small sample of patients. There was a trend for patients to say they would be willing to participate in a clinical trial if qualified to do so, but it did not become clinically significant. This could have been due to a small sample size. We do believe education is key to increasing underrepresented patients in SLE clinical trials.

Abstract Number: 2563

Factors Associated With Medication Use in the Preconception and Perinatal Period Among Women With Autoimmune Disorders: A Systematic Review

Olivia Novosel[1], Sabrina Chiodo[1], Yanara Marks[1], Lux Li[1], Renee Gabrielle Fajardo[1], Lauren Tailor[1], Lucy Zhao[1], Jessie Cunningham[2], Cristina Longo[3] and Sonia Grandi[1], [1]Child Health Evaluative Sciences, The Hospital for Sick Children, Toronto, ON, Canada, Toronto, ON, Canada, [2]Health Sciences Library, The Hospital for Sick Children, Toronto, ON, Canada, Toronto, ON, Canada, [3]Faculty of Pharmacy, University of Montreal, Montréal, QC, Canada, Montreal, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Autoimmune disorders (AD) disproportionately affect women of reproductive age, presenting challenges for disease management during the preconception and perinatal periods. Treatment decisions are complicated by the need to balance disease activity with potential risks to maternal and fetal health. Concerns about medication safety, teratogenicity, and disease severity often influence whether treatments are continued, discontinued, or switched. The objective of this review is to identify factors influencing medication use among women with AD who are attempting to conceive or are pregnant.

Methods: We conducted a systematic search in Ovid MEDLINE, Embase, CINAHL, and Cochrane Central for studies published from database inception until July 2024. Studies were included if they examined women with AD (e.g., inflammatory bowel disease (IBD), rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), multiple sclerosis (MS), vasculitis) in the preconception or perinatal periods, reported on medication use or decision-making, and were published in English. Both qualitative and quantitative studies were eligible for inclusion. Data on medication use were extracted and categorized using

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Factors and beliefs influencing medication use in the preconception and perinatal period among women with autoimmune disorders

the WHO Multidimensional Adherence Model. Themes were synthesized using a narrative approach. Study quality was assessed using JBI (formerly Joanna Briggs Institute) critical appraisal tools.

Results: Our search identified 6415 articles, of which 20 studies met the inclusion criteria. Factors influencing medication use included patient- and pregnancy-specific beliefs (e.g., safety concerns, perceived necessity, and disease knowledge), medication-related (type and preference), condition-related (disease severity and activity), healthcare provider influence and trust, and psychosocial factors such as social support and involvement in online communities. Factors contributing to the continuation of medications included trust in healthcare providers and knowledge surrounding disease management, while discontinuation was found to be influenced by concerns about fetal harm and distrust in medical advice. Notably, inconsistent messaging from providers emerged as a recurrent barrier to medication use.

Conclusion: Decisions surrounding medication use in women with AD during the preconception and perinatal periods are shaped by complex, multifactorial influences. Addressing gaps in provider consensus, improving patient education, and increasing patient supports could improve informed decision-making and management of disease. Future research should focus on including underrepresented AD subtypes beyond IBD and RA to better understand the experiences of women with these conditions.

Abstract Number: 2564

An Illustration-based Patient-reported Outcome Measure Reveals Concealed Symptoms in Patients with Rheumatoid Arthritis and the Factor Contributing to the Discrepancy Between Patient and Evaluator Global Assessments

Mie Fusama[1], Hideko Nakahara[2], Megumi Okada[3], Kayoko Sakagami[4], Ikuyo Noguchi[5], Harumi Matsumura[6], Hiroaki Ito[4], Kosaku Oda[5], Yoshitaka Shinto[3], Kenshi Higami[6], Satomi Higami[6] and **Tetsuya Tomita**[7], [1]Kansai University of International Studies, Miki, Japan, [2]Osaka Yukioka College of Health Science, Ibaraki, Osaka, Japan, [3]Shinto Orthopaedics and Rheumatology Clinic, Osaka, Japan, [4]Infusion Clinic, Osaka, Japan, [5]Oda Orthopedic Surgery Rheumatology Clinic, Nishinomiya, Japan, [6]Higami Clinic of Rheumatology and Diabetology, Kashihara, Japan, [7]Morinomiya University of Medical Sciences, Osaka, Japan

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: RA patients frequently encounter challenges in effectively communicating their symptoms to medical professionals. Recently, the "Okomarigoto Sheet" (OS), an illustration-based patient-reported outcome measure for RA patients, was developed and has been widely used in Japan. However, the OS's correlation with the conventional patient-reported outcome (PRO) has not been sufficiently evaluated. This study aims to investigate whether items on the OS are related to conventional measures of disease activity and PRO, and assess its effectiveness in facilitating patients' expression of their symptoms.

Methods: Participants were recruited from four clinics. The OS consists of three symptom scales - morning stiffness duration, the Visual Analogue Scale (VAS) for joint pain and fatigue (0 = none, 100 mm = very severe). Illustrations depicting symptoms in five different situations were also provided for each symptom. Each illustration is scored as follows: no symptoms = 0, mild-moderate symptoms = 1, severe symptoms = 2. The total score of 5 illustrations for each symptom ranges from 0-10, with the total score of whole illustrations ranges from 0 to 30; indicating symptom severity. The correlations between the total illustration score and disease activity and QOL (SF-12) were evaluated. The correlations between patient global assessment (PGA), evaluator global assessment (EGA), and swollen joint count (SJC) and the total score of 5 illustrations for each symptom were also analyzed. Statistical analysis was conducted using Spearman's rank correlation coefficient.

Results: 80 patients (mean age: 61 years old) responded to the questionnaire. The total score of whole illustrations was positively correlated with DAS28 (rs= 0.538) and CDAI (0.648), and negatively correlated with Physical Component Summary (-0.534) and Mental Component Summary (-0.417) of SF-12. Stiffness duration, pain and fatigue VAS were positively correlated with total score of 5 illustrations for each symptom. Of the patients who scored 0 on stiffness duration, pain and fatigue VAS, 9 patients had symptoms in the illustrations (5 for stiffness; 1 for pain; 4 for fatigue). In addition, PGA was significantly correlated with all of total score of 5 illustrations for each symptom (stiffness: rs=0.551, pain: rs=0.651, fatigue: rs= 0.353, respectively). However, EGA was significantly associated with the total scores of 5 illustrations for stiffness (rs=0.476) and pain (rs=0.449), but not fatigue (rs= 0.164). SJC was also associated with the total scores of 5 illustrations for stiffness (rs=0.263) and pain (rs=0.379), but not fatigue (rs= 0.083).

Conclusion: The illustration-based OS reflected the findings obtained using standard measures of disease activity and QOL. It has also the potential to clarify symptoms that are not adequately captured by VAS. Furthermore, total score of 5 illustrations for fatigue was associated with PGA but not with EGA and SJC. It was reported that EGA is most closely

Using Abdominal CT-Derived Bone Mineral Density and Psoas Volume for Opportunistic Osteoporosis Screening and Fracture Risk Assessment

Ye Liu[1], Hongke Wu[1], Amy Mudano[2], Omar Safarini[1], John Eddins[1], Carlos Cardenas[1], Lesley Jackson[1], Jeffrey Curtis[3] and Steven Rothenberg[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Foundation for Advancing Science, Technology, Education and Research (FASTER), Hoover, AL, [3]Foundation for Advancing Science, Technology, Education and Research, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: (2547–2566) ARP Posters II
Session Type: Poster Session C
Session Time: 10:30AM–12:30PM

Background/Purpose: Osteoporosis (OP) is assessed by dual-energy X-ray absorptiometry (DXA) for bone mineral density (BMD). Computed tomography (CT) offers an alternative for "opportunistic" screening. This study evaluated the performance of CT-derived BMD alone and combined with psoas muscle mass to classify OP based on DXA and predict major osteoporotic fracture (MOF) risk based on FRAX.

Methods: Consecutive abdominal CT scans (2015–2018) of women with DXA available within 1 year of the CT exam were processed to quantify L1 vertebral attenuation and psoas muscle volume. T-scores and EHR data were extracted for age, race, and BMI. We obtained the lowest T score among lumbar spine, femoral neck, or total hip. OP was defined as the lowest T-score ≤ -2.5. CT BMD was defined as L1 attenuation in Hounsfield units. We fit 4 probit models to evaluate the discrimination ability of identifying OP: CT BMD alone (Model 1), CT BMD + psoas volume (Model 2), CT BMD + age + race + BMI (Model 3), and CT BMD + psoas volume + age + race + BMI (Model 4). AUROCs were used to compare discrimination.

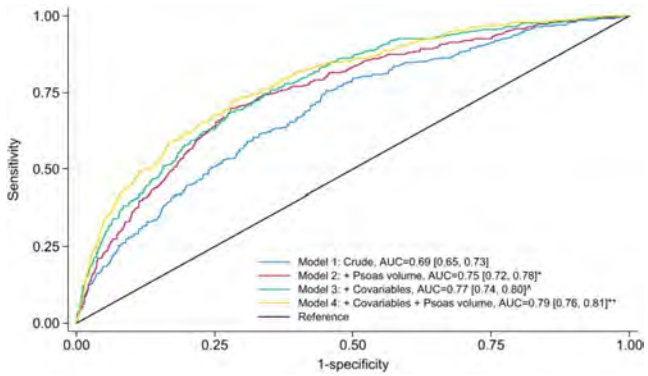

Figure 1. Abdominal CT-derived BMD and psoas volume in osteoporosis assessment: ROC curve comparison between models for osteoporosis classification (lowest T-score <=-2.5 vs. > -2.5) ROC curve comparison between models for osteoporosis classification (*: p<0.001 vs. Model 1. ^: p=0.18 vs. Model 2. **: p=0.039 vs. Model 3. N=1,442 women)

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 2. Regression-based nomogram for linear model predicting lowest T-score among lumbar spine, femoral neck, or total hip based on CT L1 BMD, psoas volume, and clinical variables (age, BMI, race)

Clustered bootstrap was used to calculate 95% CI and compare AUROC, accounting for repeated scans. We then built a linear model to predict the lowest T-score from CT BMD, psoas volume, age, race, and BMI by 5-fold cross-validation, with results visualized in a nomogram. A subgroup analysis of women with full FRAX risk factor data available was performed, modeling MOF risk ≥20% as the outcome, using similar analytical approaches.

Results: A total of 1,761 CT scans linked with DXA were analyzed(mean age: 67.5 ± 9.7). ROC curves and AUROCs are shown in Figure 1. Discrimination was modest (AUROC 0.69) using the CT L1 BMD alone and appreciably improved after adding psoas volume (AUROC 0.75). The AUROC for CT L1 BMD, independent of age, BMI, and race, was 0.67 [0.63–0.71], and for psoas volume was 0.62 [0.59–0.66] (p = 0.11). The linear model predicting lowest T-score showed good discrimination (g-index=0.84) and calibration (slope=0.996; see nomogram in Figure 2). However, neither CT BMD alone (AUROC = 0.66 [0.55–0.76]) nor combined with psoas volume (AUROC = 0.66 [0.56–0.76], p = 0.69) effectively identified high MOF risk.

Conclusion: Adding psoas muscle volume to L1 CT BMD from abdominal CT performed for other purposes significantly improved OP classification compared to CT L1 attenuation alone. Combining muscle volume and BMD measures may improve incidental OP diagnosis accuracy for targeted interventions.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Epidemiology & Public Health II (2567–2572)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Multimorbidity, the presence of multiple chronic conditions, is over-represented in RA. A cardiometabolic multimorbidity (CMM) phenotype has emerged in the general population, but is not well studied in RA despite cardiovascular disease (CVD) being the leading cause of death in RA. We evaluated the risk of CMM in RA and whether CMM risk has improved with advances in RA management.

Methods: Using national Veterans Affairs (VA) data, we identified incident RA patients (≥2 RA ICD codes, rheumatologist diagnosis, positive autoantibody or DMARD fill, plus ≥365 days in VA care before a DMARD fill or RA ICD code) matched up to 10 non-RA controls on age, sex, and VA enrollment year. Cohort entry was the date the RA algorithm was fulfilled. A traditional CMM outcome included coronary artery disease (CAD), stroke, and diabetes (DM). Given the growing recognition of Cardiovascular-Kidney-Metabolic (CKM) syndrome and its impact on both atherosclerotic CVD and heart failure (HF), an expanded CMM outcome was defined, informed by CKM syndrome components (CAD, stroke, HF, DM, hypertension [HTN], hyperlipidemia [HPL], chronic kidney disease [CKD], and obesity). Individual conditions were identified by ≥2 ICD codes ≥30 days apart. CMM onset was the date ≥2 conditions developed. We additionally defined more severe CMM phenotypes, requiring ≥3 and ≥5 (expanded CMM only) conditions. Patients meeting CMM outcomes prior to cohort entry were excluded. We examined the RA-related risk of CMM using Cox regression, stratified on matched sets and adjusting for age, sex, race, ethnicity, smoking status, BMI, rurality, and healthcare utilization. Censoring occurred at death or end of study period (1/2023). Temporal trends in CMM risk were evaluated in models stratified on RA diagnosis year (2000-2005, 2006-2011, 2012-2017), testing the linear interaction of RA status and time-period. Secondary analyses evaluated CMM risk stratified by seropositivity (RF and/or anti-CCP) and elevated inflammation (ESR and/or CRP) at baseline.

Results: We matched 28,537 RA patients (mean age 63, 85% male) to 252,602 non-RA controls. Over 2,522,982 person-years, 25,474 patients developed the traditional CMM outcome. The incidence of all CMM outcomes was higher in patients with RA (range aHR 1.14-1.31) in fully adjusted models (**Table 1**). The RA-related risk of CMM was higher in more recent time periods (p-for-trend < 0.001 for all CMM outcomes; **Figure 1**). The expanded CMM outcome severe phenotype (≥5 conditions) in the most recent time-period (RA diagnosis year 2012-17) was the most over-represented outcome in RA (aHR 1.42 [1.34-1.51]; **Figure 1**). CMM risk compared to controls was similar regardless of serostatus, while risk was typically accentuated in those with elevated inflammation (range aHR 1.13-1.48) at baseline compared to those with normal inflammatory measures (range aHR 1.12-1.18) (**Table 2**).

Table 1. Risk of cardiometabolic multimorbidity development in RA vs. matched controls

	RA (N=28,537)		Controls (N=252,602)		
	N	IR (95% CI)*	N	IR (95% CI)*	aHR (95% CI)**
Traditional Cardiometabolic Multimorbidity (CAD, Stroke, DM)

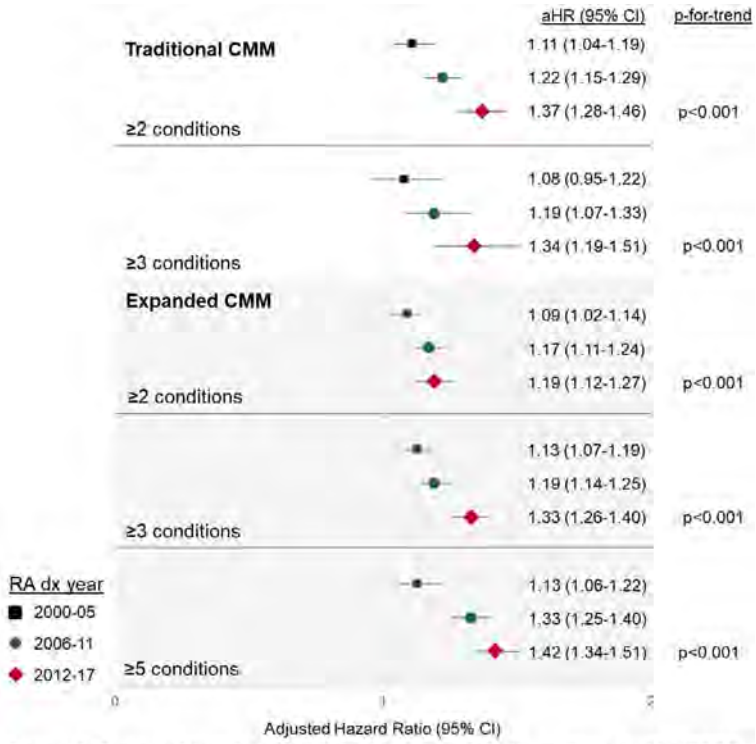

Figure 1. Temporal trends in the risk of cardiometabolic multimorbidity (CMM) in RA vs. matched controls. Adjusted hazard ratios (aHR) and 95% confidence intervals (CI) estimated in Cox regression models, stratified on matched sets and adjusted for age, sex, race, ethnicity, BMI, smoking status, rurality, and healthcare utilization. Models stratified by RA diagnosis year in sequential 5-year time periods, testing the interaction of RA and time-period in a linear manner.

Conclusion: RA-related wrisk of CMM is worsening over the past two decades despite advances in RA disease activity management. The burden of CMM highlighted by these data underscores the need for additional RA-specific strategies paired with disease activity control to reduce cardiometabolic risk and improve CVD-related outcomes in this high-risk population.

Table 2. Risk of cardiometabolic multimorbidity development in RA vs. matched controls, stratified by seropositivity and baseline acute phase reactants

	Seropositive RA	Seronegative RA

Cardiovascular Risk Prediction in Systemic Lupus Erythematosus: Comparing the PREVENT and SLECRISK Models

Youngmin Kim[1], Hongshu Guan[2], Emily Oakes[1], Katherine Zhong[3], Misti Paudel[4], May Choi[5], Katherine Liao[1], Brittany Weber[6] and Karen H. Costenbader[7], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital/Harvard Medical School, Boston, [3]Brigham and Women's Hospital, Short Hills, NJ, [4]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, MA, [5]University of Calgary, Calgary, AB, Canada, [6]Brigham and Women's Hospital, DEDHAM, MA, [7]Harvard Medical School and Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Epidemiology & Public Health II (2567–2572)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have increased risk for atherosclerotic cardiovascular disease (CVD) events, often underrepresented in traditional risk models. We previously developed an SLE-specific 10-year CVD risk model, SLECRISK, incorporating SLE-specific variables (Choi et al., 2024). The American Heart Association (AHA) recently introduced the PREVENT (Predicting Risk of cardiovascular disease EVENT) algorithm to assess CVD risk (Khan et al., 2024). We compared the predictive performance of SLECRISK and PREVENT in our SLE cohort.

Methods: Adult SLE patients meeting ACR 1997 and/or EULAR criteria from our academic center were included. SLECRISK and PREVENT estimated 10-year risk of myocardial infarction, stroke, or cardiac death. Outcomes were adjudicated by two cardiologists. Discrimination was assessed using c-statistics. Model performance was compared by sensitivity, specificity, and AIC. Calibration was evaluated by decile-based observed vs. predicted risk plots. Risk categories were defined as ≤7.5% (low), 7.5–20% (moderate), or ≥20% (high). Demographics and clinical features of patients classified as moderate/high risk by SLECRISK vs. PREVENT were analyzed using t-tests and chi-square tests.

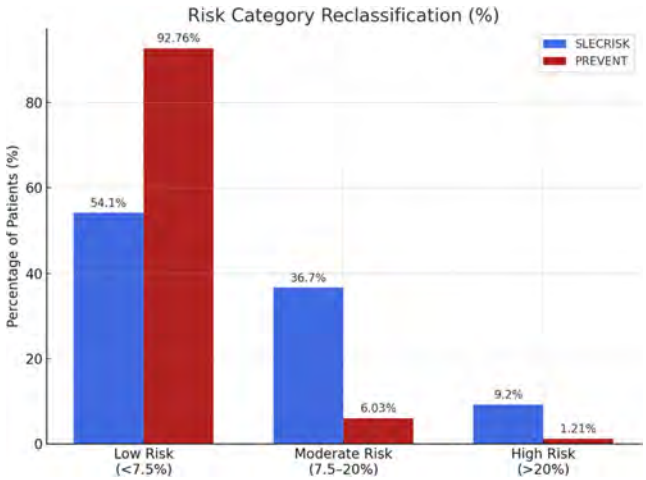

Figure 1. Risk Category Classification of SLECRISK and PREVENT in definite (adjudicated) and probable MACE.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In this cohort of 1,243 patients, PREVENT and SLECRISK yielded similar discrimination (AUC: 0.756 vs. 0.744; p = 0.68), but SLECRISK showed better model fit (AIC: 592.2 vs. 611.1). **Figure 1** shows proportions of patients categorized into low, moderate, and high CVD risk by each model. Using a ≥7.5% cutoff, 581 patients (46.7%) were classified as moderate/high risk by either model: 491 by SLECRISK only, 11 by PREVENT only, and 79 by both. Patients flagged by SLECRISK alone were significantly younger (mean 42.5 vs. 57.5 years, p < 0.0001), had lower systolic BP (122.0 vs. 145.3 mmHg, p < 0.0001), creatinine (0.93 vs. 2.55 mg/dL, p < 0.0001), and LDL (101.9 vs. 110.4 mg/dL, p = 0.02), but higher prevalence of SLE autoantibodies, including anti-dsDNA (78.6% vs. 36.7%) and anti-RNP (55.7% vs. 27.8%), all significant (**Table 1**). Calibration analysis showed better concordance between predicted and observed CVD with SLECRISK (**Fig. 2**).

Conclusion: SLECRISK identified more at-risk SLE patients, effectively capturing younger individuals with greater immunologic activity and lower traditional cardiovascular burden. Despite similar AUCs, SLECRISK showed better calibration and model fit. These findings support integration of SLECRISK into clinical care and guidelines for CVD risk stratification in SLE.

Table 1. Comparison of baseline characteristics between patients classified as moderate/high cardiovascular risk (7.5% and greater) by SLECRISK only versus by PREVENT only or by both models among 1,243 patients

Baseline Characteristics	SLECRISK (n=491)	PREVENT (n=90)	p-value
Age, years	42.5 (12.6)	57.5 (17.2)	<0.0001
Female, %	92.1	92.2	0.96
Total Cholesterol, mg/dL	182.7 (38.2)	204.6 (111.9)	0.001
LDL, mg/dL	101.9 (27.6)	110.4 (42.1)	0.02
SBP, mmHg	122.0 (16.6)	145.3 (24.4)	<0.0001
DBP, mmHg	76.0 (11.1)	82.2 (16.4)	0.001
Smoking, %	9.4	7.8	0.91
Diabetes, %	5.3	32.2	<0.0001
Mean SLE Duration, years	14.9 (10.2)	14.0 (10.7)	0.48
Creatinine, mg/dL	0.93 (0.68)	2.55 (2.83)	<0.0001
Anti-dsDNA, %	78.6	36.7	<0.0001

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Epidemiology & Public Health II (2567–2572)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of heart failure (HF) compared to the general population, and HF with preserved ejection fraction (HFpEF) is the predominant subtype in RA. The 2023 Predicting Risk of Cardiovascular Disease Events (PREVENT) risk equations include estimates of 10-year risk for HF (PREVENT-HF) in the general population. As inflammation is important in HF, particularly HFpEF, the ability to estimate HF risk in the RA population may open opportunities for earlier intervention with anti-inflammatory therapy. We aimed to study the performance of the PREVENT-HF risk equation for incident HF among patients with RA.

Methods: We studied a multi-institution electronic health record (EHR)-based longitudinal RA cohort. The study applied validated definitions for RA diagnosis, and patients were followed for incident HF, and HF subtype [HFpEF (EF≥50%) vs HF with reduced EF (HFrEF, EF< 50%)] using a combination of ICD codes and clinical information extracted using natural language processing. RA diagnosis date was the index date, and subjects with prevalent HF were excluded. Covariates for PREVENT-HF and other known HF risk factors were extracted from the EHR 1 year prior and 3 months after the index date. The PREVENT-HF score was calculated at the index date. Subjects were followed until their 1st HF diagnosis, loss to follow-up, or through 10 years, whichever occurred earlier. Discrimination of PREVENT-HF was evaluated by calculating the area under the curve (AUC), and calibration was tested using a calibration plot and the Hosmer-Lemeshow test.

Results: We studied 2,209 patients with RA, and 150 (6.8%) developed HF within 10 years after the index date. RA patients with HF were older, more likely to be male, with higher BMI, lower eGFR, and a higher burden of cardiovascular risk factors than patients without incident HF (Table 1). Those with incident HF also had higher C-reactive protein (CRP) and were less likely to be on methotrexate or TNF inhibitor than patients without incident HF. Of those with incident HF, 72% had HFpEF (EF≥50%) and 28% HFrEF (EF< 50%). The PREVENT-HF estimated median 10-year HF risk was 8.2% (IQR 4.5-16.1) among those who developed HF and 2.4% (IQR 0.9-5.4) among those who did not. The AUC of PREVENT-HF was 0.78, and the calibration plot showed overall underestimation of HF risk (Hosmer-Lemeshow p-value < 0.001; Figure 1). Underestimation was more prominent in the borderline and intermediate risk categories, which were predominantly HFpEF (Table 2).

***n=6 (4%) HF subjects without EF data

Conclusion: The PREVENT-HF equation is a promising tool to identify RA patients at increased HF risk, however it generally underestimates HF risk particularly among subjects with borderline and intermediate risk. Further work is needed to determine factors that may enhance prediction for HF, particularly HFpEF, in RA.

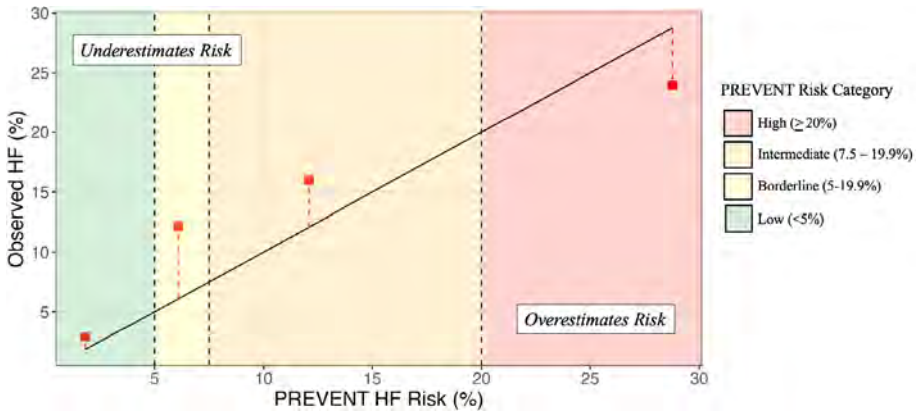

Figure 1. Calibration plot of predicted HF risk by PREVENT-HF compared to observed incident HF events [red squares denote predicted vs observed by PREVENT-HF risk category].

Table 2. Comparison of the predicted HF risk by PREVENT-HF to observed incidence of HF, categorized by risk category.

PREVENT-HF Risk Category	Total (n)	Average predicted incident HF (%)	Observed incident HF, (%)	HF subtypes within each category (%)	
				HFpEF	HFrEF

Accelerometer-derived 'weekend Warrior' Physical Activity, Genetic Susceptibility, and Incident Rheumatoid Arthritis: A Prospective Cohort Study

Zihao Xu[1] and **Zhixiu Li**[2], [1]Southern University of Science and Technology, ShenZhen, China (People's Republic), [2]Southern University of Science and Technology, ShenZhen, Guangdong, China (People's Republic)

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Epidemiology & Public Health II (2567–2572)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Physical activity is associated with a reduced risk of rheumatoid arthritis (RA). However, it is unclear whether the 'weekend warrior' (WW) pattern, characterized by achieving the majority moderate-to-vigorous PA (MVPA) with 1-2 days, offers similar benefits for incident RA to a more evenly distributed pattern. This study aimed to explore the association of accelerometer-deviced WW and other patterns patterns with incident RA, and the modification effect by genetic susceptibility.

Methods: A total of 89,241 participants from the UK Biobank without a prior diagnosis of RA and with a complete week of accelerometer-based physical activity data (collected between 2013 and 2015) were included. Participants were categorized according to guideline-based thresholds: inactive (< 150 min/week), active WW (≥150 min/week with ≥50% of total MVPA accrued in 1–2 days), and regularly active (≥150 min/week but not meeting the active WW criteria). A polygenic risk score for RA was was used for further assessing the interactions and joint effects of genetic risk and activity pattern. The associations between different activity patterns and incident RA were evaluated using multivariable Cox proportional hazards models, adjusting for potential confounders.

Results: During a mean follow-up of 7.8 years, 675 individuals developed RA. Overall, a nonlinear inverse relationship was observed between total MVPA and incident RA (P for nonlinearity = 0.003). Compared to inactive group, both the active WW (HR = 0.60, 95%CI, 0.50-0.71) and regular active (HR = 0.62, 95%CI, 0.50-0.77) group exhibited a similarly reduced risk of RA. When WW and regular activity were compared directly, there were no statistically significant difference. Similar

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

findings were observed when applying the median MVPA threshold of ≥230.4 min/week. No significant interaction between genetic risk of RA and activity pattern was observed. Moreover, participants with an active WW pattern and low genetic risk had the lowest risk of incident RA (HR = 0.33, 95%CI, 0.23-0.46) compared with inactve individuals with low genetic risk.

Conclusion: Both concentrated MVPA accumulated over 1 to 2 days and evenly distributed physical activity were associated with a reduced risk of developing RA, even in the high and middle genetic risk group. These findings suggest that meeting MVPA guidelines—whether through a WW or regular pattern—may mitigate RA risk even in individuals with elevated genetic predisposition.

Rare Clinically Significant Methotrexate Toxicity Despite Frequent Laboratory Abnormalities: A Population-Based Study of Methotrexate Monitoring

Griffin Reed[1], Jeffrey Yang[1], Georges El Hasbani[1], Cynthia Crowson[2], Hannah Langenfeld[1], Jeffrey Sparks[3], Bryant England[4], gabriela Schmajuk[5], Kaleb Michaud[4], John Davis[1] and Vanessa Kronzer[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Stewartvillle, MN, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Nebraska Medical Center, Omaha, NE, [5]University of California, San Francisco, and San Francisco Veterans Affairs Medical Center, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Epidemiology & Public Health II (2567–2572)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Methotrexate laboratory monitoring is highly resource intensive, and recent evidence questions whether the true toxicity of methotrexate has been over-estimated. Therefore, we aimed to determine the incidence of clinically significant methotrexate toxicity.

Methods: We leveraged a population-based cohort in a geographically defined area. We screened these 1.4 million individuals for adults with ≥2 diagnostic codes for systemic rheumatic disease and new initiation of low-dose (≤25 mg/week) methotrexate between January 1, 2012 and December 31, 2024. We manually confirmed incident methotrexate use, recorded covariates including frequency of methotrexate laboratory monitoring as compared to ACR guidelines (≥3 in the first 3 months, ≥3 in the next 3-12 months, and at least every 3 months thereafter), determined whether each potential methotrexate-related abnormality [AST (high), ALT (high), creatinine (high), hemoglobin (low), platelets (low), or white blood cells (low)] was clinically significant (defined as temporary or permanent methotrexate dose reduction and/or discontinuation), and quantified healthcare resources used as a result of any abnormalities. We calculated the incidence of clinically significant methotrexate toxicity per 100 person-years.

Results: Of the 3,558 individuals reviewed, we included all 2,606 who met the above inclusion criteria (mean age 58 years, 65% female, mean 4.3 [SD 3.1] years methotrexate use spanning 11,169 total person-years, 324 [12%] meeting ACR monitoring guidelines across all time points, **Table 1**). Many patients developed laboratory abnormalities (**Table 2**). However, only 97 of 4,847 (2.0%) of these abnormalities were clinically significant (0.9 per 100 person-years). Of those, 31 (32%) resulting in a reduced dose of methotrexate, and 66 (68%) resulting in permanent discontinuation, mostly for elevated AST

Ankylosing spondylitis	1%
Large vessel vasculitis	1%
Polymyalgia rheumatica	6%
Psoriasis/ psoriatic arthritis, or other spondyloarthritis	21%
Rheumatoid arthritis	64%
Sjögren's disease	1%
Systemic sclerosis, limited or diffuse	1%
Other/unknown	6%
Methotrexate use duration during follow-up, (%)	
<3 months	6%
3 to <6 months	6%
6 months to <1 year	7%
1 to <5 years	41%
5+ years	39%
Formulation of the first methotrexate prescription, (%)	
Oral	93%
Subcutaneous	7%
Met ACR methotrexate monitoring guidelines, N (%)	
Months 0-3	1,507 (58%)
Months 3-12	1,566 (63%)
≥12 months	420 (18%)
All time points	324 (12%)

BMI = body mass index, SD = standard deviation

Table 2. Incidence of abnormal methotrexate monitoring labs and their clinical significance

Laboratory measure	Patients ever abnormal N (%)	Abnormal/total monitoring tests N (%)	Clinically significant abnormalities N tests (rate per 100 py)
AST or ALT	871 (33%)	1223/25863 (5%)	59 (0.53)
Creatinine	688 (26%)	1114/25863 (4%)	5 (0.05)
Hemoglobin	1065 (41%)	1697/25863 (7%)	11 (0.10)
Platelets	357 (14%)	514/25863 (2%)	13 (0.12)
White blood cells	226 (9%)	299/25863 (1%)	9 (0.08)
Total	1743 (67%)	4847/129315 (4%)	97 (0.87)

ALT = alanine Aminotransferase, AST = aspartate aminotransferase, py = person years

and/or ALT (**Table 2, Figure 1**). On the other hand, the methotrexate monitoring abnormalities led to an additional 4,546 blood draws, 84 healthcare visits, 104 imaging studies, 16 bone marrow biopsies, and 2 liver biopsies.

Conclusion: This first population-based study of manually-validated methotrexate toxicity events found that the incidence of clinically significant methotrexate toxicity was low, and healthcare resource utilization in response to abnormal labs was high. These results suggest that less frequent methotrexate monitoring may be justified. Future work will elucidate the populations that most benefit from less frequent monitoring and identify the optimal monitoring protocols.

Multi-Modal Machine Learning Prediction and Phenotyping of Systemic Lupus Erythematosus Using Longitudinal EHR and Genomic Data from the *All of Us* Program

Hunter Sporn[1], Roshni Parulekar-Martins[1], Haopeng Wang[1], Xinran Yu[1], Jeong Yee[2], Youngmin Kim[3], Jing Cui[4] and Karen H. Costenbader[5], [1]Massachusetts Institute of Technology, Boston, [2]Sungkyunkwan University, Suwon, MA, South Korea, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital/ Harvard Medical School, Boston, [5]Harvard Medical School and Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Epidemiology & Public Health II (2567–2572)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Timely diagnosis and clinically meaningful stratification of systemic lupus erythematosus (SLE) remain major unmet needs. Existing risk models rely on limited genetic or lifestyle predictors and are often built on non-representative cohorts. Phenotyping studies, meanwhile, typically use curated registries that fail to capture the real-world complexity of SLE presentations. The NIH All of Us program, a US-wide cohort, offers an unprecedented opportunity to integrate genetic risk scores (GRS), structured electronic health record (EHR) data, using unsupervised learning at scale to address both challenges.

Methods: Within All of Us (version 8), we identified SLE cases (≥2 ICD-10 codes on separate days) and matched controls by age, sex, and genetically inferred ancestry. Supervised models (logistic regression, random forest, XGBoost) were trained using 5-year pre-diagnosis features: GRS, medications, symptoms, reproductive, and self-reported lifestyle factors. Performance was assessed across time windows on a held-out test set.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

For phenotyping, we implemented two unsupervised clustering pipelines. Approach A used normalized immune, renal, and metabolic lab data during flare and non-flare periods. Approach B integrated post-diagnosis lab values, medication classes, and grouped conditions (6-18 months post-index). Dimensionality reduction (PCA, UMAP) preceded clustering (k-means, HDBSCAN). Clusters were interpreted based on lab profiles, treatment exposure, and organ-specific manifestations.

Results: 1526 SLE cases were matched to 3942 non-SLE controls. (**Table 1**) Prediction models yielded AUCs 0.61–0.64. GRS, joint pain, depression, and obesity were consistent predictors. Accuracy peaked near diagnosis (AUC 0.71), though at the cost of recall—highlighting the challenge of early signal detection.

Clustering revealed distinct, interpretable phenotypes (**Figures 1-2**). A flare-associated cluster had concurrent dsDNA elevation, proteinuria, and transaminitis (renal/hepatic flare). A non-flare cluster featured persistent hypocomplementemia and hypertriglyceridemia, consistent with systemic inflammation and metabolic dysregulation. A 3rd group had high psychiatric and musculoskeletal burden with minimal serologic activity or immunosuppressant exposure—suggesting a care-intensive, serologically quiescent phenotype. Clusters demonstrated high clinical interpretability and mapped to established organ-domain patterns, with approach-specific silhouette scores from 0.27–0.49.

Conclusion: This is among the 1st studies to apply integrated machine learning across genomic and EHR and self-reported data to model both SLE risk and phenotypic heterogeneity. While predictive performance remains limited, phenotyping revealed actionable, domain-aligned subtypes with potential to inform prognosis, treatment, and clinical trial design. These findings highlight the promise of real-world, multimodal data to advance precision medicine in rheumatology.

Table 1. Selected Demographic and Clinical Characteristics of the SLE Cases and their Matched Controls for 5 year - 1 year Pre-Diagnosis (SLE Diagnosis Index Date) in the All of Us Cohort, version 8

Feature	SLE Cases (n=1526)	Controls (n=3942)
Demographics		
Age (mean, SD)	55.305 (14.677)	56.557 (14.348)

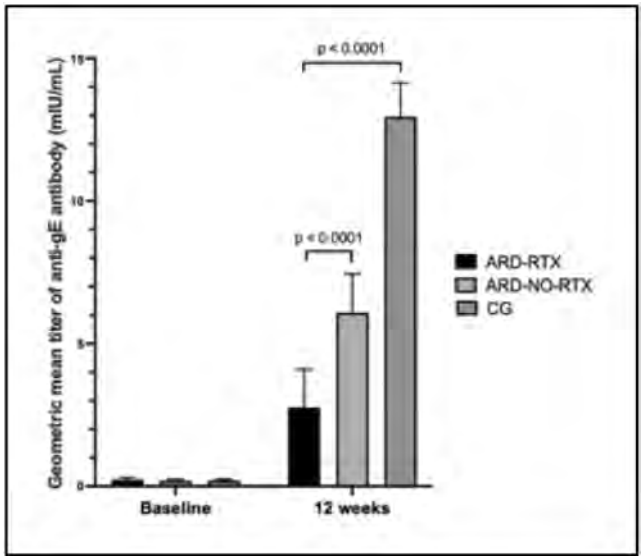
SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Infection-related Rheumatic Disease (2573–2578)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Patients with autoimmune rheumatic diseases (ARDs) are at increased risk for herpes zoster (HZ), especially those treated with B-cell depleting agents. Although the recombinant zoster vaccine (RZV) has demonstrated high efficacy in healthy individuals, its immunogenicity in rituximab (RTX)-treated ARD patients remains poorly defined. This study aims to assess humoral immunogenicity to the RZV in ARD patients treated with RTX (ARD-RTX group), compared to both healthy control group (CG) and immunosuppressed ARD patients not exposed to RTX (ARD-NO RTX). Secondarily, to evaluate the influence of demographic variables, disease, and concomitant immunosuppressive drugs on RZV immune response in RTX-treated ARD patients.

Methods: This prospective controlled phase 4 study included adult ARD patients who had received at least one cycle of RTX 22–28 weeks prior to enrollment (ARD-RTX group). Two comparator groups were included: a CG of non-immunosuppressed individuals (1:3 ratio) and ARD-NO RTX group (1:3 ratio). All participants received two intramuscular doses of RZV six weeks apart. Anti-glycoprotein E (anti-gE) antibody levels were measured before the first dose and six weeks after the second dose. Anti-gE geometric mean titers (GMTs) were calculated and humoral response/seroconversion (SC) was defined as a 4-fold increase in titers. Adverse events were assessed.

Results: 76 patients ARD-RTX and 228 CG subjects were enrolled. The ARD-RTX included rheumatoid arthritis (36%), systemic lupus erythematosus (26%), Sjögren disease (13%), systemic sclerosis (11%), systemic autoimmune myopathy (17%), and ANCA-associated vasculitis (4%). Seventy-two ARD-RTX patients were compared to 216 ARD-NO RTX group with similar mean age, sex distribution and diagnoses ($p > 0.05$). Glucocorticoids use was higher in ARD-RTX (50% vs. 29.2%, p=0.001), whereas ARD-NO RTX used more leflunomide, iTNF, tocilizumab and belimumab ($p < 0.05$). Baseline GMTs were comparable between the three groups (p=0.487). Following full vaccination, ARD-RTX group had lower GMT compared to ARD-NO RTX group and CG [2.77 (95%CI 1.87–4.1) vs. 6.1 (95%CI 5.0–7.44) vs. 12.96 (95%CI 11.87–14.15) mUI/mL, $p < 0.001$] (Figure 1). Similarly, factor increase in GMT was reduced in ARD-RTX compared to ARD-NO RTX and CG [12.3 (95%CI 7.6-19.8) vs. 31.4 (95%CI 24.6-40.0) vs. 64.6 (95%CI 54.3-76.8), $p< 0.001$]. ARD-RTX patients



Comparison of humoral immunogenicity after RZV between autoimmune rheumatic diseases (ARD) patients under rituximab (RTX) with ARD without RTX and healthy control group (CG)

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

also demonstrated a lower SC compared to ARD-NO RTX and CG group (66% vs. 85.6% vs. 99%, p< 0.001). There was no association of SC in ARD-RTX with age, ARD diagnosis, glucocorticoid, or immunosuppressive therapies (p >0.05). Regarding safety, no severe adverse events were reported. Local reactions (60.5% vs. 84.6%, p< 0.0001) and systemic reactions (39.5% vs. 63.2%, p< 0.0001) following first vaccine dose were significantly lower in ARD-RTX group compared to CG.

Conclusion: RTX significantly impairs humoral response to RZV in ARDs, independent of age, diagnosis, or concomitant immunosuppression. These findings highlight a possible vulnerability in vaccine protection and support the consideration of RZV before RTX use to optimize immune response (ClinicalTrials NCT05879419).

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Infection-related Rheumatic Disease (2573–2578)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Individuals with systemic autoimmune rheumatic diseases (SARDs) are at risk for worse acute and post-acute COVID-19 outcomes due to use of immunosuppressive medications and possibly prolonged viral shedding. Whether individuals with SARDs have higher levels of viral antigens and/or longer persistence of viral antigens after COVID-19 has not been studied.

Methods: We evaluated differences between an immunocompromised state and prolonged SARS-CoV-2 antigen (spike, S1 [Spike protein that contains the receptor binding domain], and nucleocapsid) positivity after COVID-19 in two prospective cohorts. We studied immunosuppressed individuals with SARDs in the RheumCARD study at a large US healthcare system and immunocompetent individuals in the RECOVER study. SARS-CoV-2 antigens were measured in collected plasma or

serum samples using previously validated ultra-sensitive single molecule array, a digital enzyme-linked immunosorbent assay that uses antibody-coated magnetic beads to capture antigen molecules, which are then detected and loaded into microwell arrays through the enzymatic cleavage of a fluorescent substrate. We used logistic regression to evaluate unadjusted and adjusted (for age, sex, calendar year of infection, and vaccination status at the time of infection) odds ratios for SARS-CoV-2 antigen positivity comparing RheumCARD vs. RECOVER at 3 and 6-months following COVID-19.

Results: Among 210 immunocompromised individuals with SARDs in RheumCARD and 429 immunocompetent individuals in RECOVER (**Table**), the mean age was 56.3 vs. 45.0 years, respectively, and 81.0% vs. 66.4% were female in each cohort. COVID-19 occurred in pre-Omicron variants (before 12/16/2021) in 37.6% of RheumCARD vs. 33.8% of RECOVER. Most individuals were vaccinated at the time of infection (73.3% in RheumCARD vs. 89.0% in RECOVER). Among those with SARDs, the most common SARD type was inflammatory arthritis (61.0%) and most (53.8%) had low disease activity. Many patients (31.4%) were receiving conventional synthetic DMARDs only, with 25.2% receiving TNF inhibitors and 8.6% receiving CD20 inhibitors. A minority (15.7%) were receiving glucocorticoids at the time of infection.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

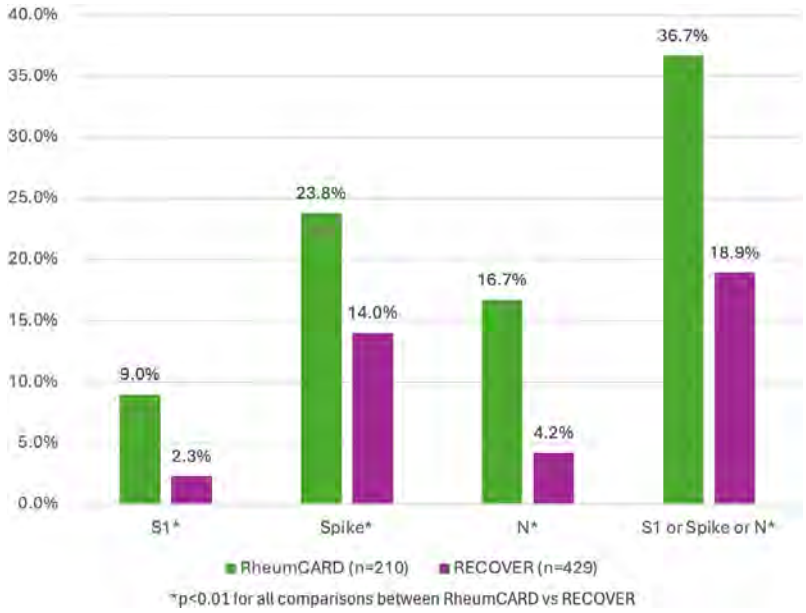

Figure 1. Frequency of positive SARS-CoV-2 antigens (S1 [spike protein that contains the receptor binding domain], spike, or nucleocapsid [N]) after COVID-19 in the RheumCARD vs. RECOVER cohorts at time of blood draw

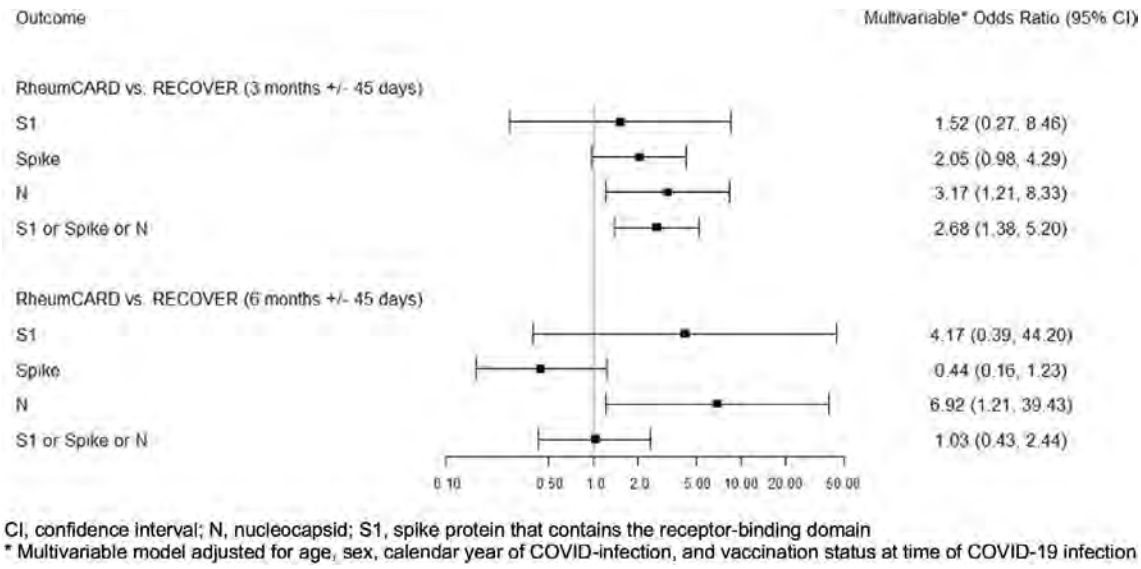

Figure 2. Differences in antigen positivity in the RheumCARD vs. RECOVER cohorts at 3 and 6 months following COVID-19 infection

At the time of blood draw, any SARS-CoV-2 antigen positivity was more common in those with SARDs (36.7% in RheumCARD vs. 18.9% in RECOVER; p< 0.001) (**Figure 1**). Those with SARDs had higher odds of nucleocapsid antigen positivity (adjusted OR 3.17, 95%CI 1.21-8.33) or any antigen positivity (adjusted OR 2.68, 95%CI 1.38-5.20) 3 months after COVID-19 (**Figure 2**). At 6 months following COVID-19 infection, nucleocapsid antigen positivity remained significantly higher among those with SARDs (adjusted OR 6.92, 95%CI 1.21-39.43).

Conclusion: Individuals with SARDs were more likely to have SARS-CoV-2 antigen positivity at 3 and 6 months following COVID-19 infection compared with immunocompetent individuals, not explained by demographics, variant, or vaccination. Persistent nucleocapsid antigen positivity, a marker of viral shedding rather than vaccination, was the greatest driver of differences between groups, suggesting that an immunocompromised state may result in prolonged antigenemia.

Influenza and COVID-19 Vaccination Uptake Among Women with Systemic Rheumatic Diseases in New York City Assessed Between 2022 and 2024

Yongjay Kim[1], Sandhya Kannayiram[2], Amaya Smole[3], Lucy Masto[4], Neha Nagpal[5], Naiva Manuela Piatchou Donfack[5], Deanna Jannat-Khah[5], Lisa Mandl[5], Caroline Siegel[5], Sarah Lieber[5], Michael Lockshin[5], Lisa Sammaritano[5] and Medha Barbhaiya[5], [1]Hospital for Special Surgery, Englewood Cliffs, NJ, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, [3]Hospital for Special Surgery, Brooklyn, NY, [4]Hospital for Special Surgery, San Francisco, CA, [5]Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Infection-related Rheumatic Disease (2573–2578)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Women with systemic rheumatic diseases (SRDs), and particularly those on immunosuppressive medications, are at increased risk for serious infections such as influenza and COVID-19. While current guidelines recommend vaccination with non-live vaccines for patients with SRDs, patient uptake of vaccines in real-world settings remain unclear.

Methods: Women aged 18-65 evaluated at least twice by a rheumatologist at the Hospital for Special Surgery (HSS) who were enrolled in the HSS Rheumatology Women's Reproductive Health and Wellness Cohort between 2022-2024 were included. All subjects had an SRD diagnosis by ICD-10 code-based algorithms and completed demographic, medical history, and vaccination questionnaires. Bivariate analyses compared demographic, socioeconomic, lifestyle, and clinical factors of patients ever versus never vaccinated for influenza or COVID-19. Multivariable models evaluated factors associated with ever versus never vaccination for COVID-19 and influenza vaccination separately.

Results: Of 740 participants (mean age 47.4±12.4 years, 538 [72.7%] White, 98 [13.2%] Hispanic or LatinX, 668 (84.6%) self-reported ever receiving influenza vaccination and 719 (97.2%) reported receiving COVID-19 vaccination. Compared to unvaccinated patients, women vaccinated for influenza more frequently had a Bachelor's degree or higher (88.0% vs 75.0%), were married/partnered (67.1% vs 48.6%), on immunosuppressive medications (60.2% vs 47.9%), saw a primary care physician (PCP) (78.0% vs 56.9%) or gynecologist (75.5% vs 54.2%) at least yearly, and had an inflammatory arthritis (IA) diagnosis (62.2% vs 44.1%), but were less frequently on corticosteroids (12.0% vs 20.8%). Participants ever vs. never vaccinated for COVID-19 were more frequently married/partnered (66.0% vs 42.9%), privately insured (88.4% vs 70.0%), employed (71.1% vs 38.1%), ever used alcohol (83.8% vs 61.9%), and saw a PCP (76.6% vs. 52.4%) or gynecologist (74.0% vs 52.4%) at least yearly, but were less frequently on corticosteroids (12.2% vs 33.3%) [**Table 1, p< 0.05**]. Among patients never vaccinated for influenza, participants with IA versus connective tissue diseases were more likely to cite vaccine side effects as a reason for not getting vaccinated (19.2% vs 0.0%). In multivariable analyses, the odds of never receiving influenza vaccination were greater among individuals with < 1 PCP visit per year (OR 2.78, 95% CI [1.52–5.06]), but lower among those taking immunosuppressive medications (OR 0.45, 95%CI [0.24–0.84]) [**Table 2**]. For COVID-19, the

Rheumatology Diagnosis			
• Inflammatory Arthritis	*Referent*		
• Connective Tissue Disease	1.66	0.56 – 5.21	0.4

A p-value of <0.05 was considered statistically significant. Patients who chose not to respond were excluded from the model.

odds of never receiving vaccination were greater among those who were Black versus White (OR 4.15, 95% CI [1.04-14.3]) [**Table 3**].

Conclusion: Influenza and COVID-19 vaccination uptake was overall high in this cohort of women with SRDs, with notable associations between black race, immunosuppressive medication use, and frequency of PCP visits with vaccination status. Factors associated with COVID-19 vaccination should be interpreted cautiously due to few unvaccinated women in the current study. Addressing concerns about side effects and improving access to routine care may further optimize vaccination uptake.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Infection-related Rheumatic Disease (2573–2578)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: The MARCH study evaluates the efficacy of methotrexate monotherapy in patients with chikungunya-associated arthritis and aims to elucidate its pathologic mechanism via cytokine analysis. As of May 05, 2025, 140 of the targeted 162 participants have been enrolled, with recruitment ongoing.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

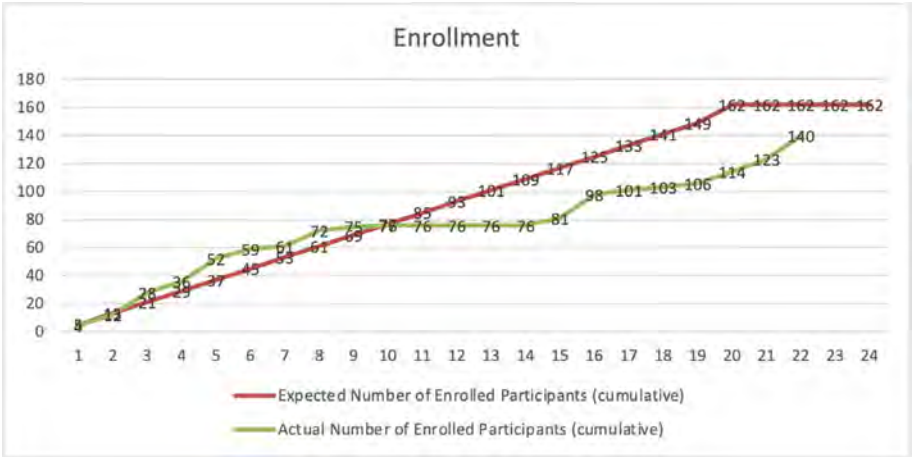

Figure 1. Cumulative enrollment of participants over time in the MARCH trial. The green line represents the actual number of participants enrolled each month, while the red line indicates the expected cumulative enrollment target. As of Month 22, 140 participants have been enrolled out of the planned 162, with final enrollment expected to be completed by June.

Methods: Enrollment began on July 18, 2023, in Barranquilla, Colombia. This randomized, placebo-controlled, double-blind, parallel-design Phase 3 clinical trial investigates six months of methotrexate/placebo randomized 2:1 in adult volunteers with a history of Chikungunya Arthritis. An optional dose escalation from 15 mg/week to 20 mg/week is permitted at six weeks, followed by an optional open-label extension from six to 12 months, with follow-up until 24 months. Immunological profiling was performed using a Meso Scale Discovery (MSD) multiplex immunoassay platform, which enables the simultaneous, high-sensitivity quantification of multiple cytokines and chemokines in serum samples.

Results: Of 245 screened participants, 140 were enrolled (111 females, 29 males), and 132 remain actively in treatment (Figure 1). The mean age of the cohort is 55.54 +/- 12.93 years, with 53% having completed elementary education. Over six months, there was a significant reduction ($p < 0.001$) in disease severity, as measured by arthritis disease activity by the disease activity score-28 (DAS-28), disability by the health assessment questionnaire (HAQ), and arthritis flare activity by the flare score, indicating a shift from moderate/severe to mild disease activity, improved functional capacity, and less flare intensity (Figure 2). Immunological analysis revealed statistically significant increases in wound healing cytokines including Eotaxin, B-NGF, TGFB-2, TGFB-3, and HGF, while inflammatory and pain cytokines such as RANKL/TNFSF11, GM-CSF, IL-10, IL-17, IL-1B, IL-4, IL-6, IL-8, and Substance P showed significant decreases over time. TNF-α, TGFB-1, and IL-2 exhibited slight, non-significant increases, whereas IFN-γ demonstrated a non-significant decrease (Figure 3).

Conclusion: Interim analysis indicates that methotrexate is generally well-tolerated in treating chikungunya-related arthritis. The study's cohort, with a mean arthritis duration post-infection of approximately ten years, provides valuable insights into the chronic impact of the disease. The evolving immunological profile suggests transitioning from an acute

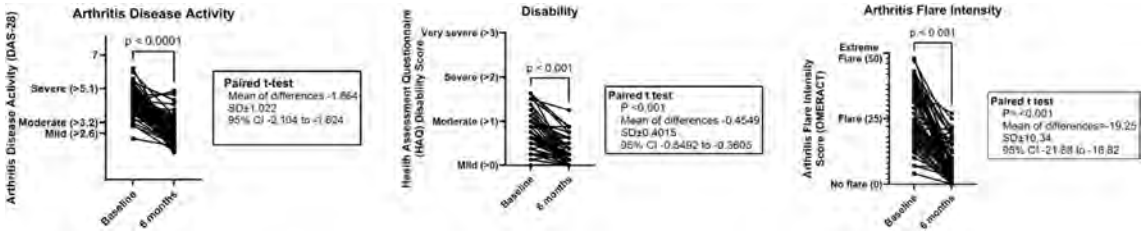

Figure 2. Patient reported outcomes. 2a) Arthritis disease activity measured by the Disease Activity Score-28 2b) Disability measured by the Health Assessment Questionnaire 2c) Arthritis Flare Intensity measured by the Arthritis Flare Intensity Score adapted for use in Chikungunya arthritis.

pro-inflammatory state to a reparative state. These findings underscore the complex interplay between inflammatory and regulatory mechanisms in chronic alphaviral arthritis and are expected to inform future treatment guidelines. The study remains blinded, with most enrolled participants having completed the closed-label phase and currently in the open-label follow-up stage. As the study is still blinded, it remains unclear whether the observed clinical and immunological changes are attributable to the therapeutic effect of methotrexate or reflect the natural course of disease improvement.

Session Title: Abstracts: Infection-related Rheumatic Disease (2573–2578)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: People with rheumatic diseases are at risk for acute and post-acute COVID-19 outcomes in part due to immunosuppressive medications. Those on B-cell depleting therapies (BCD) tend to have worse outcomes, and some uncontrolled retrospective case reports and case series showed prolonged viral shedding. Recent data suggest that tumor necrosis factor inhibitors (TNFi) have less impact on COVID-19 severity. We aimed to prospectively investigate duration of SARS-CoV-2 viral shedding in rheumatic patients using BCD or TNFi

Methods: We conducted a matched cohort study among participants in POSITIVES, a prospective study enrolling outpatients with acute COVID-19 infection within 5 days of diagnosis. Anterior nasal swabs were self-collected three times weekly over 2 weeks and then weekly until two negative PCR results. Viral PCR and culture were performed on each sample. In this analysis, we evaluated people who were on BCD or TNFi at COVID-19 onset. For each case, immunocompetent comparators with acute COVID-19 were matched (1:2) using propensity scores based on age, sex, race, ethnicity, number of prior COVID-19 vaccinations, calendar time, and use of antivirals. We used Cox regression and linear mixed-effects models to compare each immunocompromised group with their immunocompetent comparator for time to negative PCR (primary), time to negative viral culture, and viral load trajectories.

*All participants with B cell depletion were taking rituximab

TNFi, tumor necrosis factor inhibitors; SD, standard deviation

Results: We analyzed 30 TNFi and 16 BCD users, each matched to 53 and 33 immunocompetent comparators, respectively. The most common rheumatic disease was RA (53% among TNFi; 30% among BCD). More than 60% were using an antiviral and the mean number of COVID-19 vaccinations was 4.3 (**Table 1**). The median time to undetectable viral load was similar between TNFi users and comparators (HR 0.77, 95%CI 0.48 to 1.23, p=0.27; **Figure 1**). In contrast, there was a significant difference in the median (IQR) days to undetectable viral load between BCD users 15 (7, 23) vs. their comparators 7 (3, 13; HR 0.43, 95%CI 0.22 to 0.86; p=0.017). Results were similar when examining time to negative viral culture. When analyzing the difference in viral decay trajectories, the BCD group had significantly different trajectory than their immunocompetent comparators (p=0.008), while TNFi and their comparators had similar trajectory (p=0.19, **Figure 2**).

Conclusion: In this prospective study of viral shedding during acute COVID-19, BCD users had longer SARS-CoV-2 viral persistence than immunocompetent comparators. While BCD users had about 8 days longer median duration of viral shedding, nearly all had negative PCR after one month of follow-up. Studies are ongoing to evaluate whether BCD may be associated with in-host viral evolution and the impact of prolonged viral shedding on patient outcomes.

Abstract Number: 2578

Association of Oral Outpatient Antiviral Medications for COVID-19 with the Risk of Post-acute Sequelae of COVID-19 in Individuals with Systemic Autoimmune Rheumatic Diseases

Madison Negron[1], Jiaqi Wang[2], Xiaosong Wang[3], Lauren O'Keeffe[4], Grace Qian[4], Kevin Mueller[4], Alene Saavedra[4], Natalie Davis[5], Liya Sisay Getachew[6], Jeffrey Sparks[6] and **Naomi Patel**[7], [1]Harvard Extension School, Medford, MA, [2]Massachusetts General Hospital, BOston, [3]Brigham and Women's Hospital, Natick, MA, [4]Brigham and Women's Hospital, Boston, [5]Brigham and Women's Hospital, Brookline, MA, [6]Brigham and Women's Hospital, Boston, MA, [7]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Infection-related Rheumatic Disease (2573–2578)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Prior studies have evaluated the efficacy of antiviral medications on acute outcomes of COVID-19 infection as well as the risk of post-acute sequelae of COVID-19 (PASC, i.e., "long COVID") in the general population. However, there are little data regarding the effectiveness of these agents for reducing the risk of PASC in individuals with systemic autoimmune rheumatic diseases (SARDs).

Methods: We consecutively enrolled individuals with SARDs into the prospective RheumCARD study at a large US healthcare system following their COVID-19 infection from December 16, 2021 (following the start of the Omicron era and availability of oral outpatient therapy) until January 30, 2024. Individuals who were hospitalized for acute COVID-19 and/or who received COVID-19 monoclonal antibodies or remdesivir were excluded. Individuals completed surveys at least 28 days following COVID-19 infection regarding the presence vs. absence of persistent symptoms as well as the duration of symptoms. We assessed the odds of PASC at both 28 and 90 days following COVID-19 infection and used multivariable logistic regression to compare those who did versus did not receive oral outpatient antiviral medication (either nirmatrelvir/ritonavir or molnupiravir) for acute COVID-19 infection. The multivariable model was adjusted for age, sex, and race.

Results: Among 430 patients (49% treated with nirmatrelvir/ritonavir or molnupiravir and 51% not treated with antiviral medications), the mean age at COVID-19 onset was 56.2 years, 82% were female, and 91% were White (**Table**). The most common SARD category was inflammatory arthritis (37%), followed by connective tissue disease (11%). Many were using conventional synthetic DMARDs (49%), biologic DMARDs (41%); 7% were using CD20 inhibitors) and 15% were using systemic glucocorticoids at the time of COVID-19 infection. Nearly all (97%) were vaccinated at the time of COVID-19 infection. The prevalence of PASC at 28 days in those who did vs. did not receive antiviral therapy was 33% vs. 31% (p=0.77). However, the prevalence of PASC at 90 days in those who did vs. did not receive antiviral therapy was 5% vs. 11% (p=0.02). Compared to those who did not receive antiviral medications (n=221), those prescribed antiviral therapy (n=209) had

csDMARD, conventional synthetic DMARD; bDMARD, biologic DMARD; tsDMARD, targeted synthetic DMARD

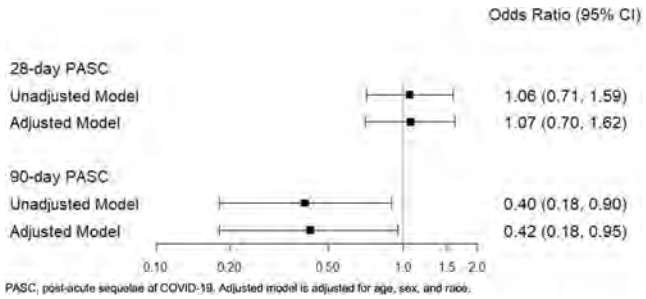

Figure. Odds of PASC at 28 and 90 days in individuals with rheumatic diseases and COVID-19 who did vs. did not receive antiviral therapy for acute COVID-19 infection

significantly lower odds of PASC at 90 days (adjusted OR 0.42, 95% CI: 0.18-0.95), while there was no difference in odds of PASC between groups at 28 days (**Figure**).

Conclusion: In this prospective contemporary cohort, individuals with SARDs who received oral outpatient antiviral therapy had significantly lower odds of PASC lasting at least 90 days following COVID-19 infection than those who did not receive antiviral therapy, while odds of PASC lasting at least 28 days did not differ between groups. These findings support additional potential benefits of oral outpatient antiviral treatment for PASC risk among individuals with SARDs who are eligible and do not have contraindications.

Mutant COPA Permits Aberrant NETosis and Exacerbates Autoimmune Lung Disease

Richard Moore[1], Lihong Huo[1], Colin Koziel[1], Barry Stripp[2], Tiphanie Vogel[3], Daniel Wallace[4] and Caroline Jefferies[5], [1]Cedars-Sinai, Beverly Hills, CA, [2]Women's Guild Lung Institute, Cedars-Sinai Medical Center, Los Angeles, CA, [3]Baylor College of Medicine, Houston, TX, [4]Cedars Sinai Medical Center, Studio City, CA, [5]Cedars-Sinai Medical Center, Beverly Hills, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Innate Immunity (2579–2584)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: COPA syndrome is an autosomal dominant disease caused by missense mutations within the *COPA* gene. Typical onset begins during childhood with patients developing lung disease such as diffuse alveolar hemorrhage (DAH). Despite its severity, the cause of lung involvement in COPA syndrome is unknown. Here, we find that mutant COPA worsens and prolongs disease in a murine model of DAH and permits aberrant NETosis in humans and mice, offering a route by which lung disease may progress in patients with COPA syndrome.

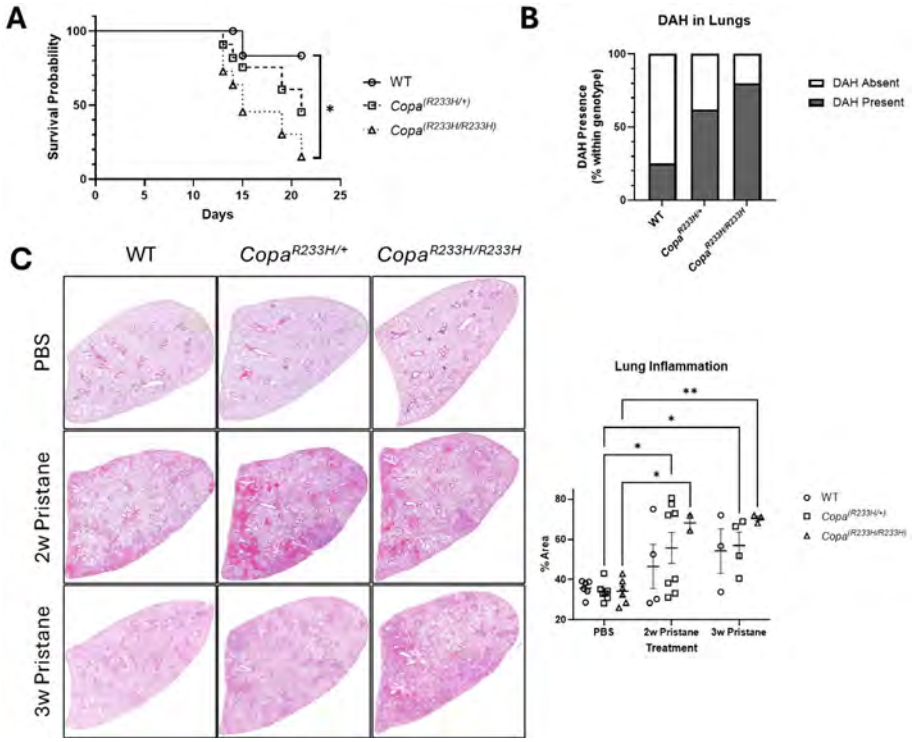

Figure 1: Mice bearing the Copa-R233H allele develop worsened and protracted disease in response to pristane. A) Survival of mice in response to a single intraperitoneal dose of pristane. B) Presence of diffuse alveolar hemorrhage in lungs 2 weeks after pristane injection. C) H&E-stained left lung lobes from PBS- or pristane-treated mice 2 or 3 weeks after i njection (left) as quantified by relative stained area (right). Values are mean +/- SEM. Statistical significance was determined using Log-rank (Mantel-Cox) or Two-Way ANOVA tests. *p<0.05, **p<0.01.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

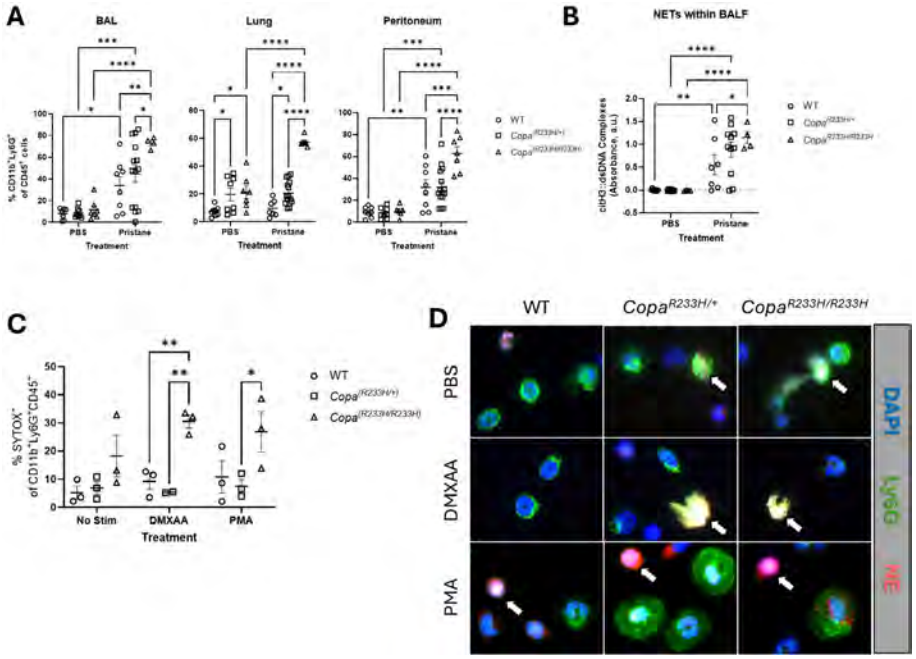

Figure 2: Copa-R233H promotes neutrophil infiltration into inflamed tissue and allows spontaneous and STING-dependent NETosis. A) Neutrophils as a percentage of CD11b+Ly6G+ of CD45+ cells within inflamed tissues 2 weeks after pristane injection. B) Presence of NETs, as measured by citH3::dsDNA complexes, within BAL fluid 2 weeks after pristane injection. C, D) Ability of peritoneal neutrophils to undergo NETosis in response to the STING agonist DMXAA or PMA, as measured by SYTOX+ via flow cytometry (C) and visualized via immunofluorescence (D, arrows). Values are mean +/- SEM. Statistical significance was determined using Two-Way ANOVA. *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

Methods: *Copa*$^{+/+}$ (WT), *Copa*$^{R233H/+}$, and *Copa*$^{R233H/R233H}$ C57BL/6 mice were generated and treated with pristane to induce DAH. Tissues were isolated at 4, 14, or 21 days and analyzed by flow cytometry, ELISA, qPCR, immunofluorescence (IF), and H&E. Circulating whole blood, neutrophils, and plasma were isolated from healthy control (HC) and COPA patients and analyzed by IF, ELISA, and scRNA-seq. Primary lung basal epithelial cells (BECs) isolated from COPA lung explants and immortalized HC BECs were transfected with dsDNA and analyzed via qPCR.

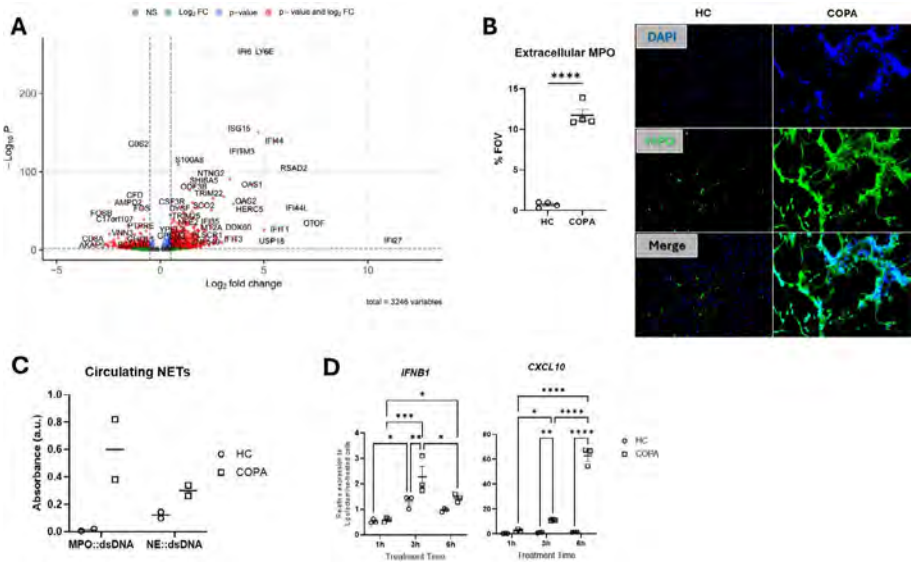

Figure 3: COPA-R233H fails to restrain inflammation in patient neutrophils and epithelial cells. A) Neutrophils from patients with COPA syndrome display a dramatic inflammatory signature as determined via scRNA-seq. B, C) Patient neutrophils undergo spontaneous NETosis after 4 hours in culture (B), and patients have elevated circulating NETs as measured by MPO::dsDNA and NE::dsDNA complexes (C). D) COPA patient-derived basal epithelial cells fail to curb IFNB1 and CXCL10 transcript production in response to dsDNA transfection. Values are mean +/- SEM. Statistical significance was determined using Two-Way ANOVA. *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Results: Unlike WT, mutant mice failed to recover from pristane-induced disease as observed by survival, development of DAH, and lung inflammation (Fig 1A-C). Mutant mice underwent dramatic granulopoiesis reflected in dominant neutrophil infiltrates within the BAL, lung, and peritoneum versus WT (Fig 2A). We found elevated neutrophil extracellular traps (NETs) within mutant BAL, and mutant neutrophils underwent increased NETosis compared to WT (Fig 2B-D). Additionally, scRNA-seq of human neutrophils revealed a highly elevated inflammatory signature in COPA versus HC, corroborated by increased NETosis and circulating NETs in these patients (Fig 3A-C).

To ask how neutrophils may be recruited into the lung during COPA, we exposed human BECs to dsDNA to simulate alveolar NETs. COPA BECs generated a robust and prolonged inflammatory response compared to HC, specifically *IFNB1* and the neutrophil chemoattractant *CXCL10*, suggesting an amplified capacity to recruit neutrophils (Fig 3D).

Conclusion: In summary, we found that COPA^{R233H} exacerbates pristane-induced lung disease, is associated with increased NETosis, and permits excessive *CXCL10* production in epithelial cells. Taken together, our data detail a route by which lung inflammation in COPA syndrome may be promoted in a feed-forward manner via aberrant NETosis and inflamed alveolar epithelium.

Session Title: Abstracts: Innate Immunity (2579–2584)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Neutrophils are essential for inflammation and host defense against infections. Our group has previously highlighted their key roles in the pathogenesis of diseases that are more common in women, such as systemic lupus erythematosus (SLE) and other systemic rheumatic conditions. We have also reported sex-based differences in neutrophil biology that affect key biologic processes and may influence this differential predisposition to systemic autoimmune disease and response to infections. These differences include variations in sensitivity to type I interferons (IFN-I), immunometabolic activity, and maturation status of neutrophils, all with significant functional and pathogenic implications. Our previous work suggests that sex hormones may contribute to these differences, although the exact mechanisms remain unclear. We hypothesize that estrogen influences neutrophil gene expression and chromatin structure during granulopoiesis, ultimately shaping neutrophil function.

Methods: We used single cell transcriptomics (sc-RNAseq), as well as flow cytometry, to analyze neutrophils. In mouse models, we performed oophorectomy (Oop) and sham surgeries, with or without administration of exogenous estradiol, to manipulate levels of gonadal hormones. Neutrophil extracellular trap (NET) formation was assessed by immunofluorescence microscopy. Human biospecimens were collected at the NIH Clinical Center for similar sc-RNAseq and NET assessments.

Results: Single-cell RNAseq, revealed that Oop significantly reduced a neutrophil subset characterized by high expression of by IFN-I stimulated genes (the "IFN-I cluster"). Neutrophils from Oop mice also showed reduced NET formation in response to danger signals. In contrast, treatment with exogenous estradiol restored IFN-I cluster prevalence and enhanced granulopoiesis in bone marrow and spleen. To translate these findings into humans, we studied individuals with androgen insensitivity syndrome (AIS; XY karyotype) who have higher levels of circulating estrogen compared to healthy volunteer (HV) males. Neutrophils from AIS individuals were more mature, had an expanded IFN-I cluster, and expressed higher IFN-I signatures than neutrophils from healthy men. Functionally, AIS neutrophils resembled those from women, showing enhanced NET formation and different bioenergetics.

In SLE, sex differences in neutrophil biology are also observed. Female SLE patients had more IFN-I cluster- neutrophils and a stronger IFN-I-gene signature compared to male patients, though this difference diminished after menopause, further supporting the role for estrogen.

Conclusion: Our findings demonstrate that estrogen modulates neutrophil development and function in both mice and humans. Estrogen promotes granulopoiesis, drives the formation of an IFN-I-responsive neutrophil subset, and enhances neutrophil effector functions such as NET formation. These sex hormone-mediated differences in neutrophil biology may help explain the increased prevalence of autoimmune diseases in women.

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Innate Immunity (2579–2584)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: The majority of SLE patients are sensitive to ultraviolet light (UV), which can lead to local and systemic inflammation, including lupus nephritis (LN) flares. While we previously showed that neutrophils remigrate from UV-exposed skin to the kidney, how these neutrophils impact renal structural cells remains unclear. We hypothesize that neutrophils play a reparative role in healthy kidneys but exert pro-inflammatory effects in lupus-like kidneys.

Methods: ScRNA-seq was performed by 10X Genomics on saline-perfused, digested kidneys and enriched neutrophils from 3-month-old female B6 mice before and 2 days after a single UVB exposure (500 mJ/cm^2). Clustering (Seurat), pathway analysis (clusterProfiler), and ligand-receptor analysis (CellChat) were used. Neutrophils were profiled by flow cytometry 6 days post-UVB in 3-month-old female B6 and MRL-lpr mice. Spatial transcriptomics (Visium) was performed on class III/IV LN kidneys, and urinary immune cells were quantified by DNA methylation deconvolution.

Results: Acute skin exposure to UV in B6 mice resulted in the expansion of renal glomerular endothelial cells, confirmed by increased CD31 staining. Of the most highly upregulated pathways in the expanded glomerular endothelial cluster were *regulation of angiogenesis* and *vascular development*, which were validated by increased angiogenesis transcriptional scores and expression of *Angpt2, Angptl1*, and *Angptl4*. Ligand-receptor analysis of the structural cells and enriched neutrophils showed significant increase in neutrophil-endothelial interactions (Cd177-Pecam-1). Neutrophil scRNAseq and flow cytometry at D2 showed UV skin exposure recruits CD177hi neutrophils that infiltrate the kidney. On day 6 post-UV, neutrophils in B6 kidneys had increased surface expression of CXCR4 and the inhibitory receptor CD371 (Clec12a). In contrast, CD371 levels were significantly decreased on the kidney infiltrating neutrophils of MRL-lpr mice after UV and no change in CXCR4 was seen. Spatial transcriptomics analysis of LN patient kidney biopsies revealed increased intra-glomerular neutrophil signature in patients with active skin disease and increased angiogenesis pathway score. In support of neutrophil-mediated skin-kidney crosstalk in SLE, intrarenal neutrophil levels were higher in lupus nephritis (LN) patients with active skin disease at the time of kidney biopsy than in LN patients without cutaneous involvement. In a subset of SLE patients without clinical signs of LN, high urinary neutrophils were associated with active skin disease, suggesting distal inflammation in the skin could contribute to subclinical renal processes in SLE.

Conclusion: Our findings reveal that UV exposure triggers glomerular endothelial expansion and pro-angiogenic signaling in the kidney, accompanied by increased recruitment of CD177$^+$ neutrophils. The regulatory phenotype of renal neutrophils post-UV in health kidneys is lost in lupus-like kidneys. Spatial and urinary profiling in LN and SLE patients supports a model of neutrophil-mediated skin-to-kidney crosstalk, implicating cutaneous flares in both clinical and subclinical renal involvement.

Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) is a life-threatening systemic disorder characterized by inflammation and increased risk of opportunistic infections. VEXAS results from somatic mutations in the ubiquitin-activating enzyme 1 (*UBA1)* gene that abolish UBA1 function in hematopoietic stem cells and peripheral myeloid cells. Monocytes from VEXAS patients are numerically and functionally impaired and display an inflammatory signature. However, the relationship between the *UBA1* mutation and the clinical manifestations of the disease remains elusive. We investigated the functional consequences of *UBA1* inactivation in VEXAS monocytes/macrophages.

Methods: We generated human monocytic THP-1 cells with a conditional Cas9-mediated knockout of endogenous *UBA1* in parallel with constitutive expression of wild-type ($UBA1^{WT}$) or VEXAS-associated ($UBA1^{M41V}$) *UBA1* gene. We assessed spontaneous and TNFα-induced inflammatory cell death using flow cytometry, Western blotting and live cell imaging. We also analyzed inflammatory cell death pathways in VEXAS skin biopsies. Next, we assessed pathogen-driven immune responses by measuring cytokine production after TLR stimulation of both whole blood from VEXAS patients (TruCulture system) and $UBA1^{WT}$ and $UBA1^{M41V}$ THP-1. THP-1-derived macrophages were assessed for differentiation, polarization, cytokine production by Luminex, transcriptome, and efferocytosis process by flow cytometry, Western blot and immunofluorescence.

Results: The $UBA1^{M41V}$ THP-1 monocytes exhibited poly-ubiquitination defects, an inflammatory transcriptional profile and increased spontaneous cell death. Specifically, $UBA1^{M41V}$ THP-1 cells were more susceptible to TNFα-induced cell death via RIPK1 activation, which was rescued by caspase- and RIPK1-specific inhibitors. These observations were confirmed in $CD14^+$ sorted cells from peripheral blood and in $CD68^+$ cells in skin biopsies from VEXAS patients. TLR-induced cytokine production was defective in $UBA1^{M41V}$ THP-1 cells, which correlated with impaired NF-κB signaling. Similar results were obtained in whole blood from patients after stimulation with TLR agonists.

$UBA1^{M41V}$ THP1-derived macrophages displayed an inflammatory phenotype with increased secretion of pro-inflammatory cytokines (IL-1β, IL-6, IFN-γ, TNF-α) and increased spontaneous cell death. They also exhibited defective efferocytosis, with decreased MERTK expression and impaired lysosomal degradation of engulfed cells. This was associated with decreased expression of LAMP-1 and cathepsins.

Conclusion: Our results show that the $UBA1^{M41V}$ mutation disrupts TLR-induced monocyte cytokine production and increases cell death, which may explain the severe monocytopenia and susceptibility to serious infections in VEXAS. In addition, the $UBA1^{M41V}$ mutation skews macrophages toward an inflammatory phenotype with an impaired efferocytosis, which likely contributes to chronic inflammation and susceptibility to intracellular pathogen infections. Overall, we provide new insights into the pathophysiology of VEXAS.

Session Title: Abstracts: Innate Immunity (2579–2584)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Giant cell arteritis (GCA) is a large-vessel vasculitis affecting individuals over 50 years of age. Current models implicate genetic susceptibility, immune senescence, activation of vascular dendritic cells, and recruitment of CD4+ T cells driving inflammation via IFN-γ and IL-17. These cytokines stimulate vascular resident cells and recruit monocytes that differentiate into macrophages. While macrophages are consistently present in GCA lesions, their phenotypic heterogeneity and molecular drivers remain poorly characterized. Here, we explore macrophages landscape and heterogeneity in human temporal artery biopsies (TAB) from GCA patients to identify key regulators of myeloid cell response in GCA.

Methods: We analyzed blood and TAB from patients with biopsy-proven GCA and age-matched controls. Spatial transcriptomic profiling of TAB was performed using GeoMx and Visium HD plateforms. TREM-1 and TREM-2 protein expression was assessed by multiplex immunofluorescence (IF). Flow cytometry analyzed TREM-1 and TREM-2 expression on circulating monocytes, and serum soluble TREM-1 (sTREM-1) and sTREM-2 were measured by ELISA. *In vitro* functional analyses included THP-1-derived macrophages cultured and a TREM-1 inhibition assay using nangibotide.

Results: Spatial transcriptomics showed TREM-1 signaling among top upregulated pathways in media-infiltrating $CD68^+$ macrophages from GCA lesions, alongside Th1, IL-6, and interferon signaling pathways, and identified IFN-γ and TLR activation as major upstream regulators using Ingenuity Pathway Analysis. The intima showed upregulation of myofibroblast-related genes, with causal network analysis predicted TREM-2 activation. High-resolution spatial transcriptomics (Visium HD) revealed $SPP1^+$ $TREM1^+$ inflammatory macrophages in the media, and $MERTK^+$ $FOLR2^+$ $GPNMB^+$ $TREM2^+$ macrophages in proximity to myofibroblasts. IF confirmed TREM-1 protein expression by most media-infiltrating $CD68^+$ macrophages, while a smaller subset expressed TREM-2.

Circulating monocytes expressed high TREM-1 and low TREM-2 in both GCA and controls. In contrast, serum sTREM-1 and sTREM-2 were significantly elevated in GCA patients (sTREM-1: 419.3 ± 30.5 vs. 224.9 ± 17.1 pg/mL, $p< 0.0001$; sTREM-2: 829.2 ± 106.4 versus 284.7 ± 26.6 pg/mL, $p< 0,0001$, for TREM-2), and sTREM-1 correlated with CRP ($r=0.55$, $p< 0.01$) and IL-6 (**$r=0.58$, $p< 0.01$**).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

In vitro, culture with IFN-γ/LPS increased proinflammatory genes and *TREM1* in THP-1-derived macrophages, while IL-4/IL-13 - associated with an anti-inflammatory and pro-resolving phenotype - induced both TREM1 and TREM2 expression, suggesting a homeostatic role for TREM-2. Finally, nangibotide, a TREM-1 inhibitor, reduced THP-1 monocyte migration and decreased NFkB activation when added to IFN-γ/LPS-polarized THP-1-derived macrophages, suggesting a role for TREM-1 in macrophage recruitment and activation.

Conclusion: TREM-1 and TREM-2 define distinct macrophage subsets in GCA. TREM-1 is associated with inflammation and monocyte recruitment, while TREM-2 may mediate homeostatic functions. These findings position TREM-1 as a promising therapeutic target.

Background/Purpose: Colchicine is recommended for the treatment and prophylaxis of gout flares and approved for secondary prevention of ischemic cardiovascular disease (CVD). While its primary anti-inflammatory mechanism is thought to be tubulin disruption, other biological pathways are likely impacted. This study evaluated the effect of prophylactic colchicine on gene expression among individuals with gout enrolled in the 72-week STOP Gout clinical trial (O'Dell JR et al. NEJM Evid 2022).

Methods: STOP Gout participants (N=940) met classification criteria for gout, were randomized to treat-to-target allopurinol or febuxostat, and received anti-inflammatory prophylaxis (90% colchicine). Prophylaxis was stopped at 24 weeks but could be continued or resumed up to week 48 if desired or clinically indicated. This study limited to those with whole blood RNA PaxGene (BD Biosciences) tube samples at 24 and/or 48 weeks (N = 259). Those identified as in active flare or with 0-10 pain score >3 at the time of lab draw were excluded (N = 45). Sequencing libraries were prepared from extracted RNA using Illumina Stranded Total RNA Prep with Ribo-Zero™ Plus rRNA Depletion + Globin Reduction. Sequence reads were aligned and counted via STAR aligner software. Normalized counts were generated using DESeq2. Differential expression was

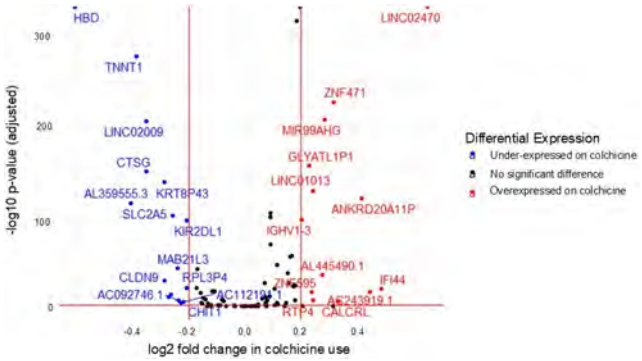

Figure 1. Gene expression differences by colchicine use among STOP Gout participants at 24 and 48 weeks. Cut-offs for significance defined as absolute log2 fold change >0.2 and adjusted p-value <0.1.

evaluated using mixed effects negative binomial regression with subject-specific random intercepts accounting for repeated measures in the GLMMseq package (R 4.4.1). For each gene, hypothesis tests of fixed effects were made for colchicine use status, timepoint, and colchicine:time interaction. Genes were filtered for false discovery rate-adjusted p-value < 0.1, |log2 fold change| >0.2, and absence of time interaction.

Table 1. Description of genes differentially expressed on colchicine with functional classification. Abbreviations: fold change (FC) Negative log2 fold change (grey) is under-expressed on colchicine. Positive log2 fold change (orange) is overexpressed on colchicine. Functional classification of "-" denotes none established.

Results: Of 214 gout participants included, 165 had samples at one timepoint and 49 at both (total 263 samples). At 24 weeks, 98 of 132 samples (74.2%) were on colchicine, whereas 33 of 131 (25.1%) were on colchicine at 48 weeks. There were 29 genes associated with colchicine use (**Figure 1**; 16 under-expressed and 13 overexpressed). Nineteen had a described physiologic function on NIH Gene and literature review and were descriptively classified, most commonly as related to innate immunity (**Table 1**). Delta hemoglobin (HBD) was suppressed on colchicine, consistent with its known potential for anemia. Long non-coding RNA LINC02470, previously described as a correlate of transforming growth factor (TGF)-β-mediated inhibition of the innate immune response, was the most overexpressed gene on colchicine. SLC2A5, a requisite gene in dietary fructose-induced hypertension, and TNNT1, a troponin subunit that regulates myocardial contraction, were under-expressed on colchicine.

Conclusion: This study identifies potential mechanisms underlying the systemic impact of colchicine in individuals with gout. The most overexpressed gene, LINC02470, is a novel finding in gout but has been shown to correlate with innate immune inhibition and is also in close proximity to CLEC12A, which is known to bind monosodium urate crystals and suppress immune response. SLC2A5 is essential for fructose-induced hypertension, and its reduced expression with colchicine suggests one potential link to CVD risk reduction.

Abstract Number: 2586

Estimated Carrier Prevalence of HLA-B*58:01 Across Diverse Populations in the US and Globally

Qiping Xu[1], Joan Bathon[2] and Yiming Luo[2], [1]Mayo Clinic, Mankato, [2]Columbia University, NEW YORK, NY

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (2585–2590)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: The HLA-B*58:01 is strongly associated with allopurinol-induced severe cutaneous adverse reactions. The 2020 American College of Rheumatology (ACR) Guideline for the Management of Gout conditionally recommends HLA-B*58:01 testing prior to initiating allopurinol in patients of certain Asian or African descent, while advising against routine testing in other ethnic groups. These recommendations are based on reported carrier prevalence and cost-effectiveness analyses. However, data remain limited for populations such as Native American, South Asian, and Middle Eastern groups. This study aimed to estimate the prevalence of HLA-B*58:01 carriers across diverse U.S. and global populations.

Methods: We performed a descriptive analysis of HLA-B*58:01 carrier prevalence across diverse populations using two data sources: (1) the National Marrow Donor Program (NMDP) , a large U.S. hematopoietic cell registry of approximately 2.9 million individuals. Allele frequencies, estimated via a modified expectation–maximization algorithm from mixed-resolution HLA typing data, were publicly available (Gragert et al., 2013). Carrier prevalence was inferred assuming Hardy-

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Carrier prevalence of HLA-B*58:01 across U.S. populations from the National Marrow Donor Program registry (NMDP, panel a) and global populations from the 1000 Genomes Project (1KG, panel b). In NMDP data, carrier prevalence was estimated from allele frequencies under the assumption of Hardy-Weinberg equilibrium. In 1KG data, carrier prevalence was directly calculated from individual-level HLA genotyping. Carrier prevalence (%) and carrier counts (carrier number/sample size) are shown for each population. Error bars represent 95% confidence intervals calculated using the Wilson score method. The 1.6% threshold for cost-effective testing is indicated for reference.

Weinberg equilibrium; and (2) the 1000 Genomes Project (1KG) , an international consortium that includes 2,693 individuals with publicly available four-digit HLA typing data. In the NMDP, population categories are based on self-reported race and ethnicity, whereas 1KG populations were sampled by self-identified ancestry and are widely used as genetic ancestry reference groups. We compared carrier prevalence to 1.6%, the threshold for cost-effective testing based on a prior modeling study cited in the ACR guideline (Jutkowitz et al., 2017).

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Results: In the NMDP, estimated HLA-B*58:01 carrier prevalence exceeded the 1.6% threshold for cost-effective testing in individuals self-identifying as Chinese (16.7%, 95%CI 16.5%-16.9%), Vietnamese (13.4%, 95%CI 13.0%-13.7%), Korean (11.7%, 95%CI 11.5%-11.9%), other Southeast Asian (9.3%, 95%CI 9.0%-9.7%), Filipino (7.9%, 95%CI 7.7%-8.1%), South Asian Indian (8.2%, 95%CI 8.1%-8.3%), African American (7.4%, 95%CI 7.3%-7.5%), Middle Eastern or North African (3.4%, 95%CI 3.3%–3.6%), Hawaiian or other Pacific Islander (2.9%, 95%CI 2.6%-3.2%), and Hispanic (2.7%, 95% CI 2.7%-2.8%) (Figure 1a). In contrast, the estimated prevalence was below the 1.6% threshold for cost-effective testing among Japanese (1.5%, 95%CI 1.4%-1.7%), American Indian or Alaska Native (1.5%, 95%CI 1.4%-1.6%), and European American (1.4%, 95%CI 1.4%-1.5%). Carrier frequencies in ancestry-based populations from 1KG were largely consistent with NMDP estimates (Figure 1b).

Conclusion: Estimated HLA-B*58:01 carrier prevalence varies by race and ethnicity, with most groups exceeding the 1.6% threshold for cost-effective testing. Among those below the threshold, prevalence was only marginally lower. These findings raise the possibility that broader HLA-B*58:01 testing than recommended by the 2020 ACR guideline could be considered prior to allopurinol initiation.

Nanoencapsulated Sirolimus Plus Pegadricase Reduced Disease Burden in Patients With Uncontrolled Gout: Results From the Phase 3 DISSOLVE Trials

Puja Khanna[1], Amar Majjhoo[2], Rehan Azeem[3], Ben Peace[4], Bhavisha Desai[5] and Vibeke Strand[6], [1]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [2]Shores Rheumatology, St. Clair Shores, MI, [3]Global MACD, Sobi Inc., Waltham, MA, [4]Statistical Science, Sobi, Stockholm, Sweden, [5]Sobi, Glastonbury, CT, [6]Division of Immunology/ Rheumatology, Stanford University, Palo Alto, CA

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (2585–2590)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Patients (pts) with uncontrolled gout (UG; persistent elevation in serum uric acid [sUA] levels and clinical manifestations despite oral urate-lowering therapy) have poor health-related quality-of-life (HRQOL) outcomes. The global UG disease burden is substantial and increasing. NASP (formerly SEL-212) is an investigational, novel, every 4-wk (Q4W), sequential 2-component infusion therapy consisting of targeted nanoencapsulated sirolimus (NAS, formerly SEL-110), which mitigates the formation of antipegadricase antibodies, and a uricase (pegadricase [P]; formerly SEL-037), which reduces sUA. Here, we report sUA levels, joint exam findings, and HRQOL outcomes in pts with UG who received 6 doses of NASP or placebo (PBO) in the phase 3 DISSOLVE I and II (NCT04513366, NCT04596540) studies.

Methods: Eligible pts had a history of symptomatic gout (≥3 gout flares within 18 mo of screening, ≥1 tophus, or current gouty arthritis), inability to normalize sUA and control symptoms with treatment, and screening sUA ≥7 mg/dL, which aligned with ACR diagnostic criteria for gout (Neogi *et al. Arthritis Rheumatol* 2015). Pts were randomized 1:1:1 to receive high-dose (HD) NASP (0.15 mg/kg NAS; 0.2 mg/kg P), low-dose (LD) NASP (0.10 mg/kg NAS; 0.2 mg/kg P), or PBO Q4W; those who received 6 doses were included in this post hoc analysis. Pt-reported outcomes (PROs) included the 36-Item Short Form

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1: (A) sUA Over Time and (B) Number of Tender/Swollen Joints at Baseline and Week 24. Error bars show standard deviation for both panels. In panel A, n values were 42 at baseline and 37 at week 24 for HD NASP, 35 at both time points for LD NASP, and 67 at both time points for PBO. D, day; HD NASP, high-dose NASP; LD NASP, low-dose NASP; n, number of patients; NASP, nanoencapsulated sirolimus plus pegadricase; PBO, placebo; post, post-dose; pre, pre-dose; sUA, serum uric acid; Wk, week.

Health Survey (SF-36) physical component summary (PCS) score (minimal clinically important difference [MCID], 5) and Health Assessment Questionnaire-Disability Index (HAQ-DI) pain score (MCID, 16).

Results: In pts receiving HD NASP (n=42), LD NASP (n=35), or PBO (n=67), mean sUA changes of –88%, –94%, and –0.3% (median: –97%, –98%, and 1.5%) were observed from baseline (mean [standard deviation (SD)]: 8.5 [1.4], 8.5 [1.3], and 8.7 [1.6] mg/dL) to wk 24 (mean [SD]: 1.1 [2.0], 0.5 [0.8], and 8.5 [2.0] mg/dL), respectively. In the NASP arms, sUA reduction was noted immediately after the first dose, and mean sUA generally remained ≤2.0 mg/dL throughout the study (**Figure 1A**). Pts receiving HD NASP, LD NASP, and PBO had mean reductions in the number of tender (–74%, –92%, and –40%) and swollen (–90%, –91%, and –54%) joints from baseline (mean number of tender/swollen joints:

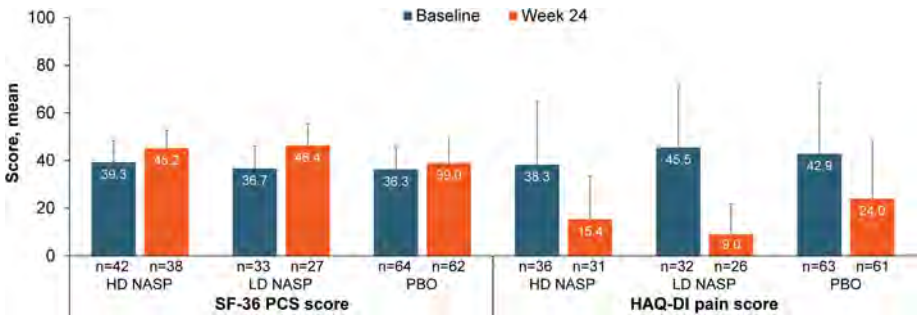

Figure 2: SF-36 PCS Score and HAQ-DI Pain Score at Baseline and Week 24. Error bars show standard deviation. Higher SF-36 scores indicate greater improvement in health-related quality of life; lower HAQ-DI scores indicate greater improvement in functional ability and less disability. HAQ-DI, Health Assessment Questionnaire-Disability Index; HD NASP, high-dose NASP; LD NASP, low-dose NASP; n, number of patients; NASP, nanoencapsulated sirolimus plus pegadricase; PBO, placebo; PCS, physical component summary; SF-36, 36-Item Short Form Health Survey.

23265203, 2025, 59, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

5.8/2.9, 6.1/3.5, and 7.7/5.2) through wk 24 (mean number of tender/swollen joints: 1.5/0.3, 0.5/0.3, and 4.6/2.4). HD and LD NASP generally led to an approximately 2-fold reduction in the mean number of tender and swollen joints vs PBO (**-Figure 1B**). NASP-treated pts showed improvement in mean SF-36 PCS scores (HD NASP: 5.9; LD NASP: 9.7) that exceeded the MCID and was >2-fold higher than the change for PBO-treated pts by wk 24 (2.8); NASP-treated mean SF-36 PCS scores (HD NASP: 45.2; LD NASP: 46.4) were comparable to the US general population (49.2; Maglinte *et al*. *J Clin Epidemiol* 2012). By wk 24, a greater mean HAQ-DI pain score reduction was seen with NASP (HD NASP: –60%; LD NASP: –80%) vs PBO (–44%; **Figure 2**).

Conclusion: NASP-treated pts had meaningful reductions in disease burden and key clinical manifestations, as reflected by improvements in sUA levels and PROs. This therapy has a noteworthy impact on resolving acute gout symptoms over 6 treatments and shows promise for improving HRQOL.

Nanoencapsulated Sirolimus plus Pegadricase (NASP) Demonstrates a Reduction in Gout Flares: Results from the Phase 3 DISSOLVE Studies

Angelo Gaffo[1], Herbert Baraf[2], Anand Patel[3], Tuhina Neogi[4], Rehan Azeem[5], Wesley DeHaan[6], Ben Peace[7], Hugues Santin-Janin[8], Bhavisha Desai[9] and Naomi Schlesinger[10], [1]Division of Rheumatology and Clinical Immunology, University of Alabama, Birmingham, AL, USA; Birmingham VA Medical Center, Birmingham, AL, USA, Birmingham, AL, [2]The Center for Rheumatology and Bone Research, Rheumatology, Wheaton, Maryland, USA; Division of Rheumatology, The George Washington University, Washington, DC, [3]Conquest Research, Winter Park, FL, USA, Winter Park, FL, [4]Boston University School of Medicine, Boston, MA, [5]Global MACD, Sobi Inc., Waltham, MA, [6]Sobi, Inc, Waltham, MA, [7]Statistical Science, Sobi, Stockholm, Sweden, [8]Sobi, BASEL, Switzerland, [9]Sobi, Glastonbury, CT, [10]Spencer Fox Eccles School of Medicine, University of Utah, Salt Lake City, UT, USA, Salt Lake City, UT

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (2585–2590)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Urate-lowering therapy is recommended to lower serum urate (sUA) and for long-term prevention of gout flares (FitzGerald *et al. Arthritis Care Res (Hoboken)* 2020; Dalbeth *et al. Lancet* 2021), though an initial increase in gout flares after ULT initiation has been documented (Feng *et al. Int J Clin Exp Med* 2015; Schlesinger *et al. Nat Rev Rheumatol* 2023). NASP (formerly SEL-212) is an investigational, every 4-week, sequential infusion therapy designed to reduce sUA levels in patients (pts) with uncontrolled gout (UG), consisting of targeted immunomodulating, nanoencapsulated sirolimus (NAS; formerly SEL-110), sequentially administered with pegadricase (a pegylated uricase; formerly SEL-037). Gout flare incidence in pts receiving NASP has been previously reported (Baraf *et al. British Society for Rheumatology (BSR) 2024 Annual Meeting;* Poster P084). Here, we report gout flare outcomes in pts who received 6 doses of NASP or placebo (PBO).

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

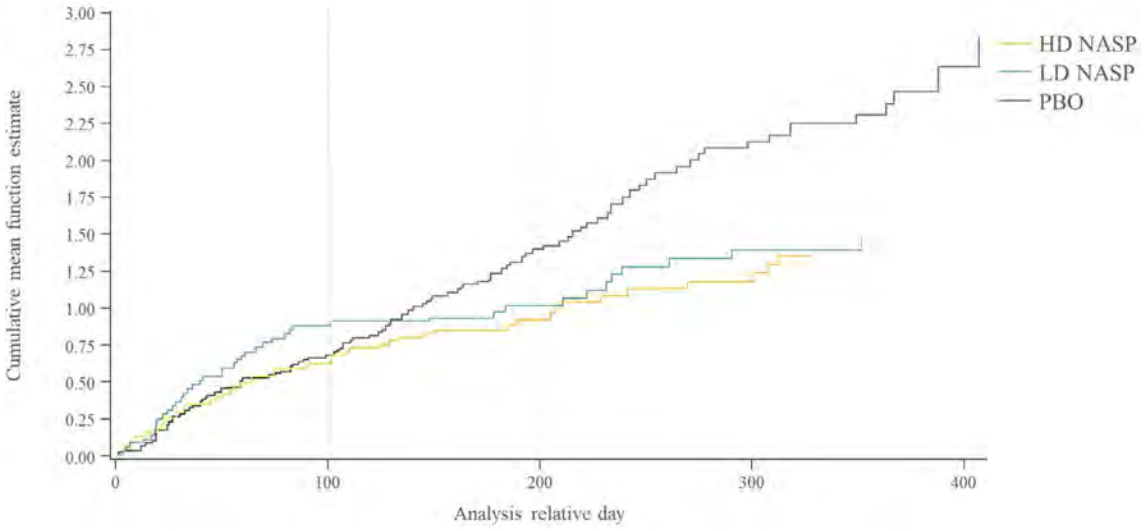

Figure 1. Cumulative mean estimate of gout flares in patients who completed 6 doses of study drug. Cumulative mean function estimate of gout flares per patient is shown for patients receiving 6 doses of HD NASP (yellow), LD NASP (teal) or PBO (dark gray). The event of interest is gout flare, and multiple gout flares are taken into consideration in the cumulative mean function. The analysis relative day is the number of days since the first dose of treatment. HD NASP, sequential infusions of 0.15 mg/kg nanoencapsulated sirolimus and 0.2 mg/kg pegadricase, LD NASP, sequential infusions of 0.10 mg/kg nanoencapsulated sirolimus and 0.2 mg/kg pegadricase; PBO, placebo.

Methods: This *post hoc* analysis of pooled data from DISSOLVE I (NCT04513366) and DISSOLVE II (NCT04596540) focuses on gout flare outcomes in pts who received 6 doses of NASP (high-dose [HD]: sequential infusions, 0.15 mg/kg NAS and 0.2 mg/kg pegadricase; low-dose [LD]: sequential infusions, 0.10 mg/kg NAS and 0.2 mg/kg pegadricase) or PBO every 4 weeks. Flares were assessed using a validated definition in pts with gout (Gaffo *et al. Arthritis Rheumatol* 2018).

Results: Overall, 42, 35 and 67 pts received 6 doses in the HD, LD, and PBO groups, respectively. At treatment initiation (weeks 1–4), the proportion of pts who experienced a gout flare was similar in the three treatment arms: 23.8%, 28.6% and 20.9% in pts treated with HD NASP, LD NASP and PBO, respectively. Over the study period (up to week 24), the proportion of pts experiencing flares decreased for NASP and remained consistent for PBO: 4.8%, 5.7% and 22.4% of pts in the HD, LD, and PBO arms, respectively, experienced a flare during weeks 21-24. During weeks 13–24, the average number of gout flares per patient was 2.3 and 5.7 times fewer on HD and LD, respectively, vs PBO (HD: 12 flares in 42 pts, rate of 0.29 gout flares per patient; LD: 4 in 35 pts, rate of 0.11; PBO: 44 in 67 pts, rate of 0.66). Cumulative gout flare rates over time were similar between NASP- and PBO-treated pts through Day 100. Between days 100–200, cumulative gout flare rates plateaued in NASP-treated pts but continued to increase in PBO-treated pts (**Figure 1**). Across all treatment arms, most flares ranged from mild to moderate intensity.

Conclusion: The proportion of pts with flares and number of flares decreased with NASP compared to PBO over the course of the study, with 95.2% and 94.3% of HD and LD-treated pts being flare-free during weeks 21–24. These results highlight the potential of NASP as an effective therapy for reducing disease burden and improving a key clinical outcome in pts with UG.

Abstract Number: 2589

Multi-omics Integration Reveals Gut Microbiota–Metabolite Dysregulation in Gout with Metabolic Syndrome

Yuanpiao Ni[1], Fanxin Zeng[2], Yufeng Qing[3] and Quanbo Zhang[3], [1]Affiliated Hospital Of North Sichuan Medical College, Nanchong, Sichuan, China (People's Republic), [2]Dazhou Central Hospital, Dazhou, Sichuan, China (People's Republic), [3]The Affiliated Hospital of North Sichuan Medical College, Nanchong, Sichuan, China (People's Republic)

SESSION INFORMATION

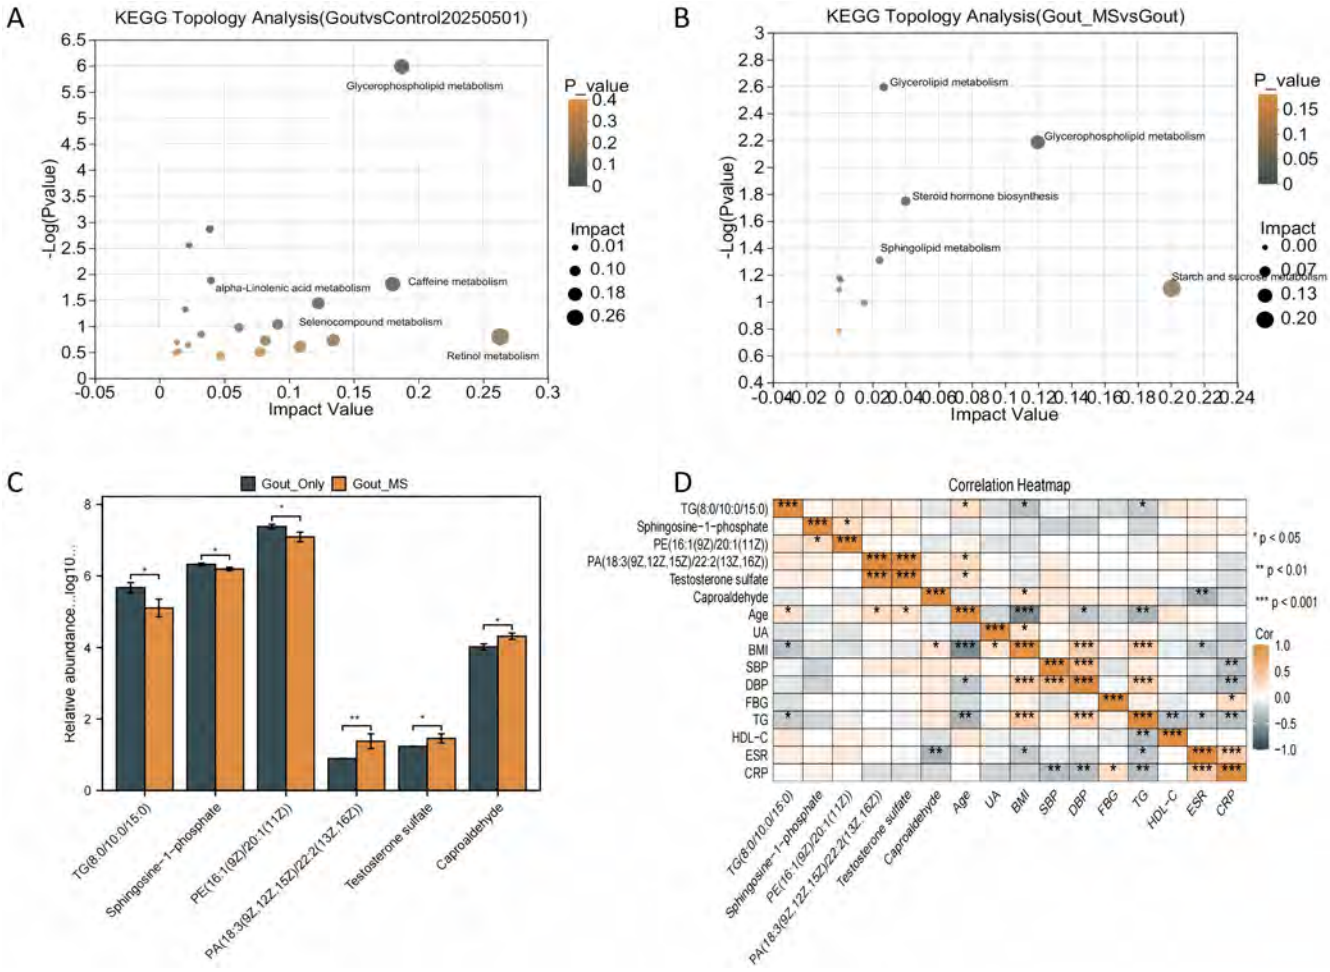
Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (2585–2590)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Gout is a metabolic disorder driven by abnormalities in urate metabolism and chronic inflammation. Recent studies suggest that gout is not limited to joint involvement but is also closely associated with various systemic metabolic disturbances, particularly metabolic syndrome (MS), which comprises central obesity, insulin resistance, hypertension, and dyslipidemia. MS significantly increases the risk of cardiovascular disease, type 2 diabetes, and mortality. The comorbidity between gout and MS suggests that the two conditions may share common pathophysiological mechanisms. As a critical interface between environment, immunity, and metabolism, the gut microbiome may play a key role in the



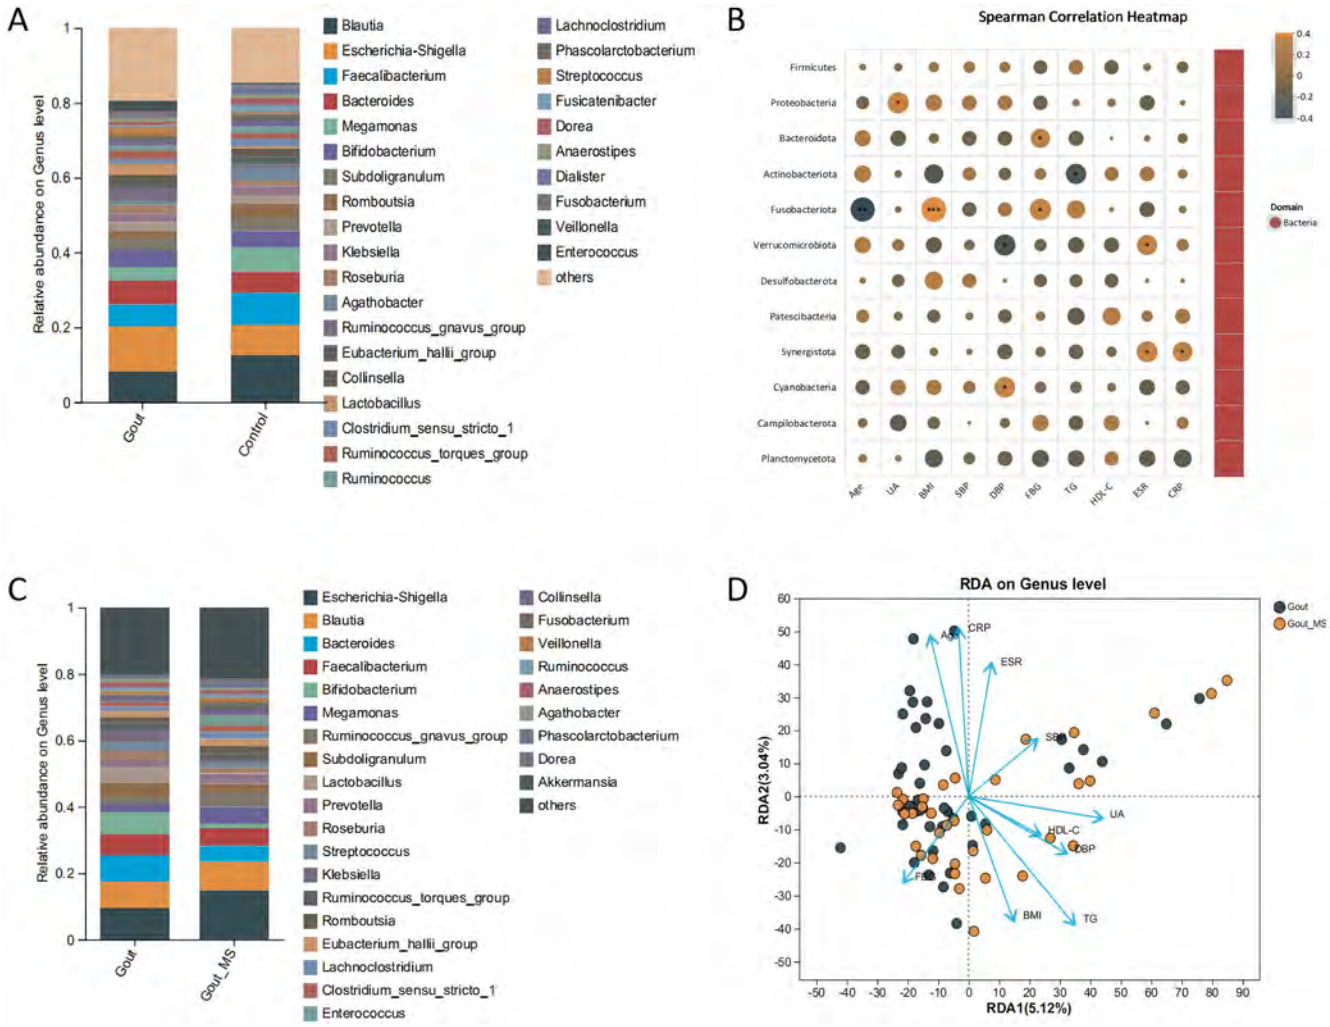
Key Pathways and Metabolites Revealed by Metabolomics and Their Correlation with Clinical Indicators

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

interaction between gout and MS. However, there is currently a lack of systematic multi-omics research elucidating the characteristics of microbiota–metabolite interactions, which hinders the development of personalized prevention and treatment strategies.

Methods: This study included 77 patients with gout, stratified into two subgroups based on the presence of MS: gout + MS group (n = 34) and gout-only group (n = 43). Additionally, healthy controls (n = 73) were recruited for microbiome (n = 73) and metabolomics (n = 50) comparisons. We applied 16S rRNA sequencing, metagenomics, and untargeted metabolomics to characterize gut microbial composition and metabolic profiles. Multi-omics integration was used to construct a microbiota–metabolite interaction network.

Results: Metabolomic analysis revealed significant disturbances in short-chain fatty acid, purine, and bile acid metabolism pathways in gout patients, along with marked alterations in glycerophospholipid levels. The presence of MS further exacerbated abnormalities in glycerolipid, sphingolipid, steroid hormone biosynthesis, and carbohydrate metabolism, leading to the identification of six key differential metabolites. Microbial analysis showed a depletion of beneficial taxa such as Actinobacteria and Firmicutes, along with an enrichment of potentially pathogenic Bacteroidetes, particularly in the gout + MS group. These microbial changes were closely associated with metabolic indices. Multi-omics integration identified microbiota–metabolite modules specific to the gout + MS group. A random forest model based on differential taxa and metabolites demonstrated strong discriminative performance (AUC = 0.81).



Analysis of Gut Microbiota Structure in Gout and Its Correlation with Clinical Indicators

23265203, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Conclusion: This study provides a comprehensive characterization of gut microbiota and metabolic alterations in gout patients with and without MS, offering new insights into the microbiota–metabolite interaction networks underlying these conditions. These findings enhance our understanding of disease heterogeneity and may inform future biomarker-based stratified management strategies.

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025

Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (2585–2590)

Session Type: Abstract Session

Session Time: 1:00PM–2:30PM

Background/Purpose: Approximately 21% of US adults have hyperuricemia, the causal precursor for gout. Human cells do not degrade urate (due to uricase gene inactivation). However, a cluster of 7 bacterial genes in ~15-20% of commensal human gut purine degrading bacteria (PDB) encodes high capacity anaerobic uricolysis [1], distinct from strictly aerobic microbial uricase activity. Moreover, the majority of gut bacteria reside in the deeply anaerobic colonic lumen. By converting urate to xanthine, lactate, and short-chain fatty acids (SCFAs), PDB compensate for murine uricase knockout, thereby maintaining lower serum and cecal urate levels. Here, we seminally tested the association between gut PDB uricolytic genes and urate levels in humans.

Methods: We analyzed available blood and stool metagenomic (Illumina) data collected contemporaneously from men and women enrolled in three independent, prospective, nationwide cohort studies: Framingham Heart Study (FHS; N=1129 men and women), Men's Lifestyle Validation Study (MLVS; N=296 men), and Mind Body Study (MBS; N=207 women). The sequences of previously characterized urate-metabolizing genes (i.e., *ygeX*, *ygeY*, *ygeW*, *ygfK*, and *ssnA*) [1] were mapped to Uniref90 sequences and their corresponding species-level genomic bins, using HUMAnN and diamond [2-4]. We calculated the Spearman correlation between urate levels and each putative urate-metabolizing gene / Uniref90. These were visualized as undirected networks using the igraph and ggraph R packages.

Results: We identified 15 human gut-associated species-level genomic bins containing at least five urate-metabolizing genes in their pangenomes, corresponding to commensal gut species **(Figure 1)**. These included *Flavonifractor plautii*, *Enterocloster bolteae*, and *Ruminococcus torques*. **Figure 1** shows undirected associations between species-level genomic bins and their corresponding urate-metabolizing genes. In all, 12 of 48 identified urate-metabolizing genes significantly correlated with urate (spearman rho $q < 0.1$) in at least two studies, and 31 significantly correlated in at least one study **(Figure 2)**. Additionally, 6 urate-metabolizing genes significantly correlated with urate only among participants in the MBS (i.e., women-only cohort) but not FHS or MLVS **(Figure 2)**.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. Figure 1. Undirected network diagram illustrating the associations between species-level genomic bins and corresponding urate-metabolizing genes.

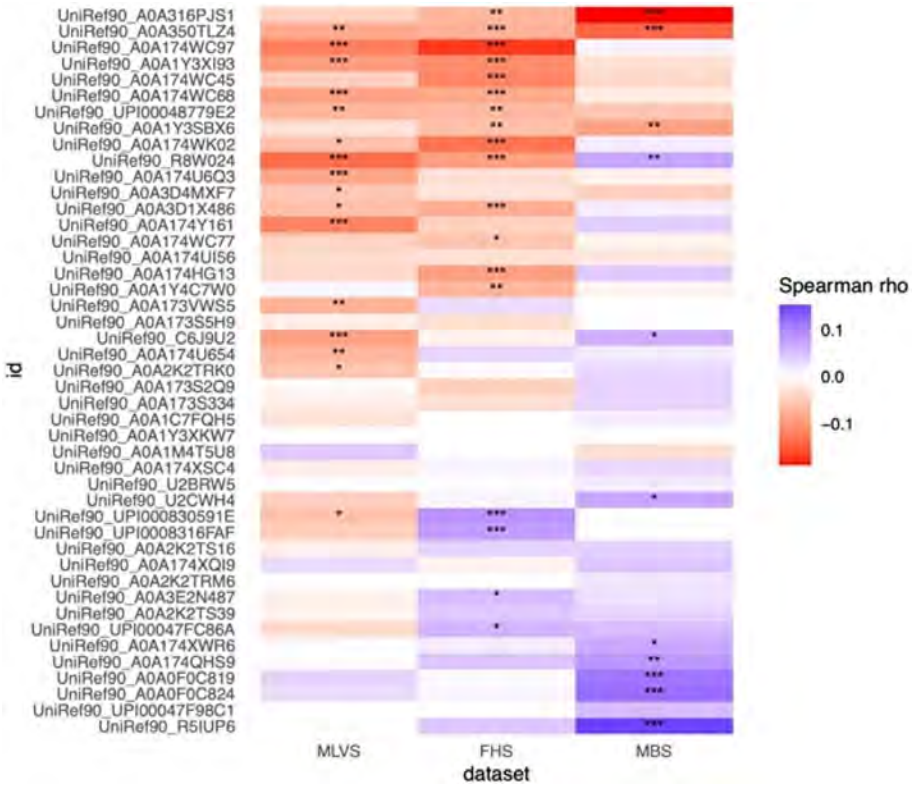

Figure 2. Correlations between network Uniref90 genetic sequences and urate levels in each of the three cohorts. Symbols: *qval < 0.1, **qval < 0.05, ***qval < 0.01.

23265205, 2025, S9, Downloaded from https://acrjournals.onlinelibrary.wiley.com/doi/10.1002/art.43421 by Readcube (Labtiva Inc.), Wiley Online Library on [10/12/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Conclusion: The abundance of putative urate-metabolizing genes is significantly correlated with urate in 3 human cohorts, and some may be sex-influenced. The commensal gut species identified may be particularly relevant to hyperuricemia and gout, including capacity for anti-inflammatory SCFA production (e.g., butyrate) and documented associations with other inflammatory conditions. These results, superimposed on known gut dysbiosis in gout [5], support actual modulation of urate by the gut microbiome in humans, and suggest a novel potential therapeutic target for prevention and treatment of gout.

Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science (2591–2596)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Osteoporosis (OP) is characterized by low bone mass and microarchitectural deterioration, increasing fracture risk. Bone Mineral Density (BMD), T-score, and Trabecular Bone Score (TBS) are key diagnostic and monitoring tools. Systemic inflammatory markers linked to cardiovascular risk such as neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and monocyte-to-lymphocyte ratio (MLR) have been proposed as potential indicators of and other cardiovascular events. Romosozumab (ROMO), a sclerostin inhibitor with dual anabolic and antiresorptive action, is approved for high-risk postmenopausal OP patients. This study evaluated the association between changes in TBS, T-score, BMD, and inflammatory ratios in women treated with ROMO.

Methods: We conducted a retrospective observational study of postmenopausal women with OP treated with ROMO. Pre- and post-treatment measurements of TBS, T-score, BMD, NLR, PLR, and MLR were analyzed. Delta changes (post-treatment minus baseline) were calculated for each parameter. Correlation analyses and linear regression models assessed the predictive value of inflammatory ratios on bone parameter changes.

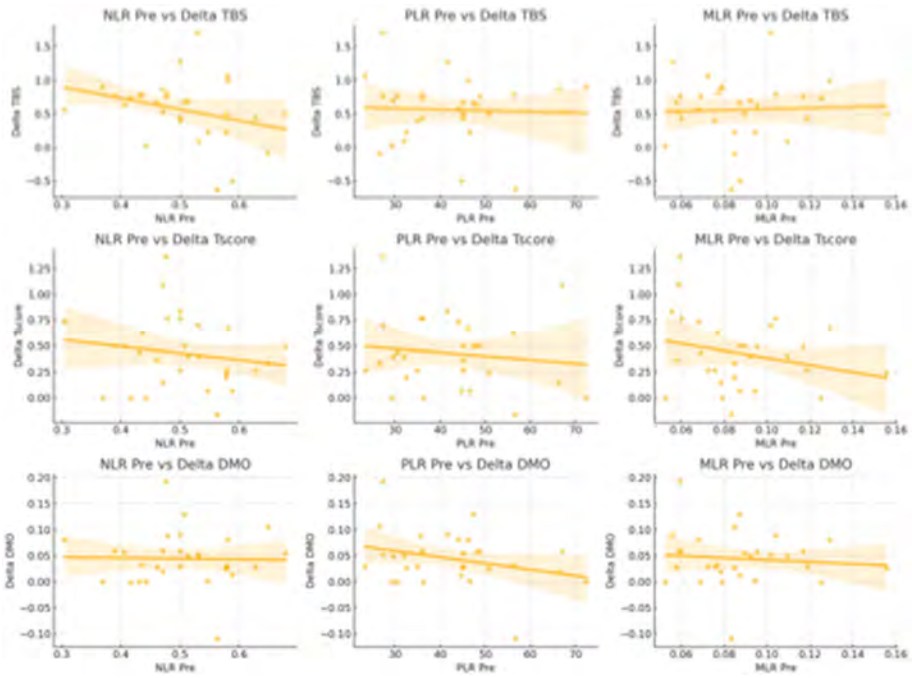

Figure 1. Relationships Between Baseline Inflammatory Ratios (NLR, PLR, MLR) and Changes in Trabecular Bone Score (TBS), T-score, and Bone Mineral Density (BMD) in Postmenopausal Women Treated With Romosozumab. Regression analyses show no significant predictive capacity (R^2 < 0.1) across all models.

Results: Thirty-seven postmenopausal women (mean age 46.0 years) completed ROMO therapy and follow-up. Fracture history included single (62%), multiple (32%), or no fractures (5%). Comorbidities included inflammatory diseases (8%), COPD (14%), dyslipidemia (38%), hypertension (43%), and smoking (14%).

Significant improvements were observed in TBS (mean +0.85 units, p< 0.001), T-score (mean +0.61 units, p< 0.001), and BMD (mean +0.06 g/cm^2, p< 0.001). A moderate positive correlation was found between NLR change and TBS improvement (r=0.45, p< 0.05). No significant associations were found for PLR or MLR. Regression models showed low predictive capacity of NLR, PLR, or MLR on changes in TBS, T-score, or BMD (R^2< 0.1 in all models). Baseline ratios also showed negligible predictive value (R^2 TBS=-0.75, T-score≈0.00, BMD≈0.005).

Conclusion: Romosozumab significantly improves bone quality and density in postmenopausal women with OP. While NLR changes moderately correlate with TBS improvement, inflammatory ratios NLR, PLR, and MLR lack predictive utility for treatment response. Additionally, ROMO treatment did not significantly alter these inflammatory markers of cardiovascular risk in various clinical contexts, supporting a neutral effect on subclinical systemic inflammation linked to cardiovascular risk. These findings may be relevant in the context of cardiovascular safety discussions surrounding ROMO.

Abstract Number: 2592

Romosozumab and Denosumab Combination Therapy in Postmenopausal Osteoporosis

Giovanni Adami[1], Francesco Pollastri[2], Angelo Fassio[2], Camilla Benini[2], Davide Gatti[2], Ombretta Viapiana[2] and Maurizio Rossini[2], [1]University of Verona, Italy, Verona, Italy, [2]University of Verona, Verona, Italy

SESSION INFORMATION
Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science (2591–2596)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: Transition from long-term denosumab to PTH-analogs or romosozumab might expose patients to the risk of the so-called rebound phenomenon. Adding romosozumab to denosumab might represent an option in patients experiencing a fracture while on denosumab. The aim of this study was to investigate the effects of the combination of romosozumab to denosumab in post-menopausal osteoporosis.

Methods: We did a 36-month prospective, quasi-experimental, study. Post-menopausal women were divided into two groups: patients on denosumab who added romosozumab to denosumab (Dmab from M-24 to M0 à Dmab+Romo from M0 to M+12), and matched controls on denosumab continuing denosumab (Dmab from M-24 to M0 à Dmab from M0 to M+12). Patients for this group were selected from the overall pool of post-menopausal women treated with denosumab referring to our outpatient clinic who had available baseline (M-24) and follow-up DXA scans and serum samples collected (n=388). Patients were then matched through propensity score matching to balance baseline characteristics between the treated and control groups. Bone mineral density (BMD) and bone turnover markers (CTX, P1NP) were assessed at follow-up time points.

Results: A total of 50 women were included in the study. Twenty-five patients in the Dmab à Dmab+Romo group and 25 matched controls in the Dmab à Dmab group. Overall, lumbar spine BMD increased more in the Dmab à Dmab+Romo group (11.6% SE 3.0, p 0.010) compared to the Dmab à Dmab group (8.3% SE 3.3, p NS). Adding romosozumab to denosumab increased P1NP significantly between M0 and M+3 (+22.5 ng/mL SE 8.7, p 0.028). **Figure 1** shows the bone markers trends in the two groups, **Figure 2** shows the BMD trends in the two groups.

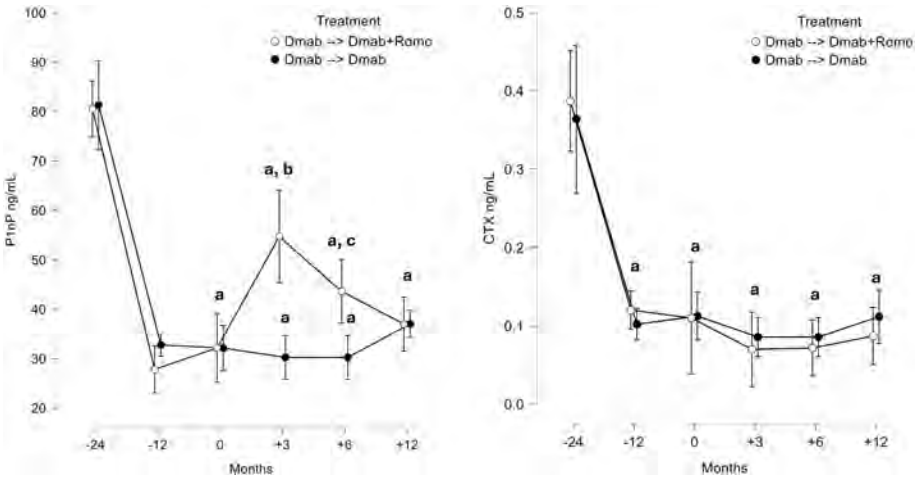

Figure 1. Bone turnover markers (BTMs) changes over the study period

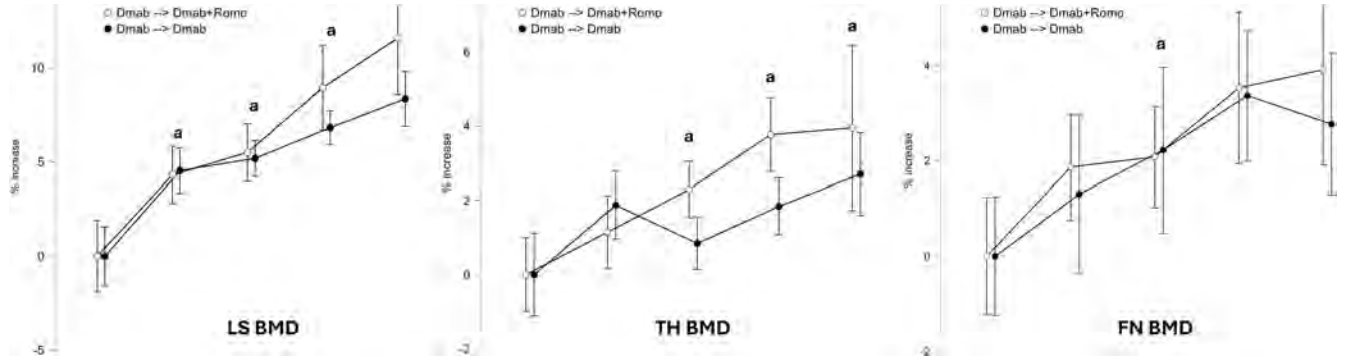

Figure 2. Bone mineral density (BMD) changes over the study period

Conclusion: Ongoing treatment with denosumab did not blunt the anabolic response of romosozumab, indicating sustained modeling-based bone formation activity. Adding romosozumab in patients failing denosumab might be a valuable option.

Single Switch from Reference Denosumab to TVB-009 in Women with Postmenopausal Osteoporosis: Analysis of the Phase 3, Randomized, Double-Blind, Multinational, Multicenter Study

Karel Pavelka[1], Frank Schneider[2], Deepak S[3], Bracha Timan[4], Hadas Barkay[4] and Anton Buchner[2], [1]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic, [2]Teva GmbH, Ulm, Germany, [3]Teva Pharma India Private Limited, Bangalore, India, [4]Teva Pharmaceutical Industries Ltd., Netanya, Israel

SESSION INFORMATION

Session Date: Tuesday, October 28, 2025
Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science (2591–2596)
Session Type: Abstract Session
Session Time: 1:00PM–2:30PM

Background/Purpose: TVB-009 is being developed as a proposed biosimilar candidate to the reference denosumab. Biosimilarity of TVB-009 to US-licensed denosumab (US-denosumab) and EU-approved denosumab was demonstrated in healthy participants in a Phase 1 pharmacokinetic/pharmacodynamic study. No clinically relevant differences in efficacy or safety between TVB-009 and US-denosumab were demonstrated in women with postmenopausal osteoporosis (PMO) in the 52-week main treatment (tx) period of a 78-week Phase 3 study (NCT04729621). The objective of this analysis was to evaluate the impact of a single switch from US-denosumab to TVB-009 on safety, immunogenicity, and efficacy in women with PMO during the subsequent 26-week transition period.

Methods: Eligible participants included postmenopausal women aged 60–90 years with a diagnosis of osteoporosis and a lumbar spine bone mineral density (LS-BMD) measurement T-score of ≥–4.0 to < –2.5 at screening. At baseline, participants were randomized 1:1 to receive 60 mg of TVB-009 or US-denosumab by subcutaneous injection on Day 1 and at Week 26 in the main tx period. In the transition period, participants in the US-denosumab arm were re-randomized 1:1 to

Table 1. TEAEs in the Transition Period of the Phase 3 Study in Women with PMO

TEAE, n (%)	TVB-009/ TVB-009 (n=148)	US-denosumab/ US-denosumab (n=72)	US-denosumab/ TVB-009 (n=71)
Any TEAE	50 (33.8)	20 (27.8)	26 (36.6)
TEAEs related to study drug	2 (1.4)[a]	0	0
Serious TEAEs	5 (3.4)[b]	0	1 (1.4)[c]
TEAEs leading to discontinuation	0	0	0
TEAEs leading to death	0	0	0
Most frequent adverse events (≥ 2%)			
Headache	4 (2.7)	1 (1.4)	3 (4.2)
Hypercalcemia	4 (2.7)	2 (2.8)	2 (2.8)
Dyslipidemia	0	0	2 (2.8)
COVID-19	3 (2.0)	0	1 (1.4)
Upper respiratory tract infection	3 (2.0)	2 (2.8)	1 (1.4)
Nasopharyngitis	4 (2.7)	5 (6.9)	0
Arthralgia	4 (2.7)	4 (5.6)	0
Pain in extremity	3 (2.0)	3 (4.2)	0
Back pain	8 (5.4)	2 (2.8)	0
Spinal pain	3 (2.0)	2 (2.8)	0

PMO, postmenopausal osteoporosis; TEAE, tx-emergent adverse event; tx, treatment.
Safety was analyzed in all participants who received the third dose of the study drug. [a]A total of 3 TEAEs related to the study drug were reported for 2 participants in the TVB-009/TVB-009 group: periorbital hemorrhage, low-density lipoprotein increased, and back pain; all were mild in severity. [b]Serious TEAEs included bone cancer, chronic obstructive pulmonary disease, urinary incontinence, COVID-19 pneumonia, helicobacter infection, and malaise in 1 participant each; none of these serious TEAEs had a reasonable possible relationship to the study drug. [c]Serious TEAEs included cholelithiasis, which was mild in intensity with no reasonable possible relationship to the study drug.

receive a single dose of TVB-009 or a third dose of US-denosumab at Week 52, while participants in the TVB-009 arm received a third dose of TVB-009.
